As technology rapidly improves, classrooms are equipped with lots of technological tools (computers, projectors, tablets, etc.). If implemented properly, technology-supported instruction enhances students' learning and understanding (e.g., Dori & Belcher, 2005; Kim & Hannafin, 2011). However, it has been reported that teachers do not integrate technology frequently and efficiently in their classrooms (Bang & Luft, 2013; Harris, Mishra & Koehler, 2009; Kushner Benson, Ward, & Liang, 2015). Some studies (e.g., Angeli & Valanides, 2009; So & Kim, 2009) revealed that teachers had difficulties in integrating educational technologies (such as technological devices or software programs) into their classrooms, in particular in deciding the most appropriate tools for teaching effectively and enhancing student learning. Additionally, teachers sometimes fail to integrate technology effectively into their teaching because of a lack of pedagogical knowledge (Koh, Chai & Tsai, 2013; Kramarski & Michalsky, 2010).

Science issues, in particular chemistry concepts, generally deal with microscopic levels rather than macroscopic levels of perspective. Students often have difficulty understanding and visualizing microscopic concepts such as atoms, molecules, or chemical reactions. Educational technologies such as animations and simulations are quite helpful in visualizing these concepts; chemistry teachers who integrate those educational technologies into the teaching and learning process may support effective learning (Moore, Herzog, & Perkins, 2013; Ryan, 2013). For effective technology integration in instruction, knowledge about technology is not enough; teachers should have different knowledge types content, pedagogical, and technology as well as the ability to integrate these knowledge types (Mishra & Koehler, 2006; Koehler & Mishra, 2009). A technological pedagogical content knowledge (TPACK) framework that explains these knowledge types has been suggested as a requirement for effective technology integration (Mishra & Koehler, 2006). Similarly, in order to graduate pre-service chemistry teachers who use technology effectively in their future instruction, TPACK is essential. Hence, this study examined an intervention implemented to develop the TPACK of pre-service chemistry teachers in a university. The intention is to provide an answer to the question of whether there was a difference between the pre-service chemistry teachers' TPACK was at the beginning of the semester before the course related to educational and instructional technologies and at the end of the semester in terms of gender.

Therefore, the purpose of this study was to:

- trace the development of pre-service chemistry teachers' technological pedagogical content knowledge,
- examine an intervention implemented to develop the pre-service chemistry teachers' TPACK,
- explore whether gender was significant factor in TPACK development.

METHOD

This section consisted of four parts: participants, design of the study, instrument, and description of the instructional technology and material development course.

Participants

This study included 17 pre-service chemistry teachers from the Faculty of Education of a public university. All of the participants were from the department of chemistry education, in the eighth semester of a 10-semester chemistry education program, and they were all involved in the Instructional Technology and Material Development course. All participants in the current study had taken subject matter courses related to chemistry (e.g., General Chemistry, Analytical Chemistry, Organic Chemistry, and Physical Chemistry), general pedagogical courses (e.g., Introduction to Education, Curriculum, Measurement and Evaluation in Education), and subject-specific pedagogical courses (e.g., Theories and Approaches in Teaching and Learning, Methods of Chemistry Teaching) beforehand. Computers and projectors were available in all classroom environments in the university. These participants did not have any school experience in teaching.

Design of the Study

The one-group pretest-posttest design (Fraenkel & Wallen, 2011, p. 269) is used as an experimental design in this study (see Table 1 for research design details).

Table 1. Research Design.

Participants	Pre-test	Intervention	Post-test
Pre-service chemistry teachers	Pre-TPACK	The course related to educational and instructional technologies	Post-TPACK

Instrument

The pre-service Chemistry Teachers' Knowledge of Teaching and Technology Questionnaire (CTKTTQ) was administered in this study to evaluate the pre-service chemistry teachers' TPACK. This questionnaire was developed by Schmidt, Baran and Thompson (2009). The questionnaire covers seven components, which are technological knowledge (TK), content knowledge (CK), pedagogical knowledge (PK), pedagogical content knowledge (PCK), technological content knowledge (TCK), technological pedagogical knowledge (TPK), and technological pedagogical content knowledge (TPCK). However, in this study the items in the questionnaire were restricted to the chemistry discipline (see Table 2). There were 42 items, rated on a 5-point scale. The reliability of the instrument was calculated using Cronbach's alpha coefficient; the scores were .88 for the pre-TPACK and .92 for the post-TPACK.

Table 2. Sample Items for the Components of the TPACK.

Component	Sample Item
Technology Knowledge	I know how to solve my own technical problems.
Technology Content Knowledge	I know about technologies that I can use for understanding and doing chemistry.
Technology Pedagogical Knowledge	I can choose technologies that enhance students' learning for a lesson.
Technology Pedagogical Content Knowledge	I can teach lessons that appropriately combine chemistry, technologies, and teaching approaches.

Description of the Instructional Technology and Material Development Course

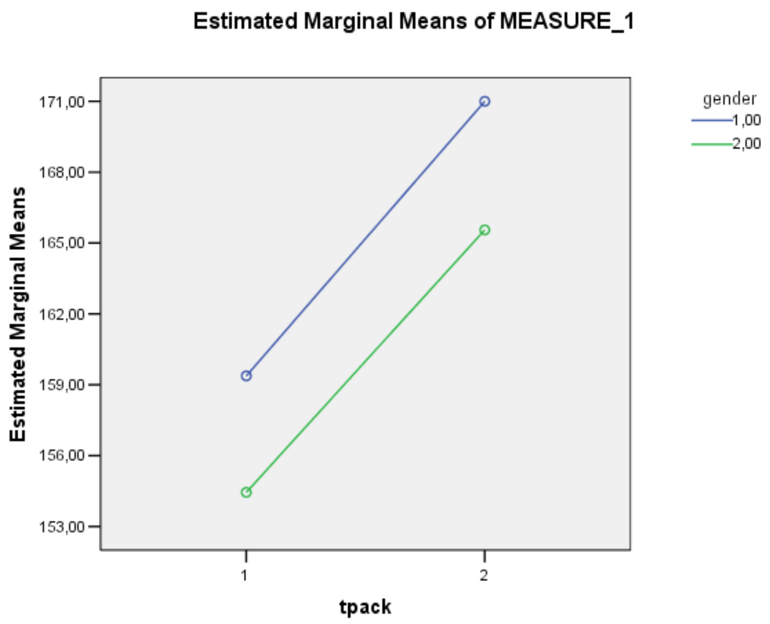
Pre-service chemistry teachers enrolled the Instructional Technology and Material Development (ITMD) course in their fourth year (eighth semester) of the five-year chemistry education program. The purpose of this course was to learn how to integrate simulations, animations, instructional games, data-logging, virtual labs and virtual field trip into chemistry instruction considering factors such as chemistry subjects and their students' possible alternative conceptions or previous chemistry knowledge. This course had two class hour-long theoretical sessions and two class hours-long laboratory sessions each week. While designing the ITMD course, constructivist learning approaches were taken into account in which pre-service chemistry teachers applied their new knowledge of each instructional technology, wrote reflection papers before and after introducing the instructional technology, discussed the importance of alternative conceptions and prerequisite knowledge in chemistry learning, implemented their own materials (such as educational games and posters) to the class, and designed lesson plans considering one of the instructional technologies.

RESULTS

A mixed between-within subjects analysis of variance (Pallant, 2007, p. 236) was conducted to assess the impact of gender on the pre-service chemistry teachers' TPACK across two periods (Table 3). The results indicated that there was no significant interaction between gender and TPACK, Wilks' Lambda= .987, $F(1,13)=.174$, $p=.684$, partial eta squared=.013. There was a substantial main effect for TPACK, Wilks' Lambda= .593, $F(1,13)=8.913$, $p<.05$, partial eta squared=.407; with female and male participants revealed an increase in their overall TPACK scores (see Graph 1).

Table 3. Descriptive Statistics for the TPACK in terms of Gender.

	Gender	Mean	Std. Deviation	N
Pre-total TPACK	1,00	159,3750	13,77303	8
	2,00	154,4444	11,81219	9
	Total	156,7647	12,61710	17
Post-total TPACK	1,00	171,0000	13,36306	8
	2,00	165,5556	6,28711	9
	Total	168,1176	10,28277	17



Graph 1. The change of pre-service teachers' TPACK in terms of gender.

When follow-up analysis was conducted for the components of TK, CK, PK, PCK, TCK, TPK, and TPCK (Table 4), the difference to reach statistical significance for main effects were CK, Wilks' Lambda=.620, F(1,15)=9.191, p=.008, partial eta squared=.380; PK, Wilks' Lambda=.366, F(1,15)=25.991, p=.000, partial eta squared=.634; PCK, Wilks' Lambda=.553, F(1,15)=12.124, p=.003, partial eta squared=.447; and TCK, Wilks' Lambda=.741, F(1,15)=5.251, p=.037, partial eta squared=.259. The largest effect was from PK, indicating approximately 63% of the variance in the pre-service chemistry teachers' TPACK was explained by pedagogical knowledge.

Table 4. Descriptive Statistics of TPACK and Its Components.

	Pre-statistics			Post-statistics		
Variables	Mean	Standard Deviation	Number	Mean	Standard Deviation	Number
TK	23. 94	4.19	17	25.53	3.10	17
CK	46.18	4.99	17	50.18	4.39	17
PK	23.94	3.23	17	28.23	2.19	17
PCK	10.53	1.50	17	11.82	1.24	17
TCK	11. 76	1.30	17	12.77	1.03	17
TPK	20.06	2.01	17	20.12	1.99	17
TPCK	19.77	2.68	17	20.47	1.55	17
Total score (TPACK)	156.81	13.03	17	168.12	10.62	17

DISCUSSION AND CONCLUSIONS

The findings of this study indicated that the pre-service chemistry teachers' TPACK developed and significantly improved during the course. During the semester, the pre-service chemistry teacher participants learned about different educational technologies, discussed how those technologies could be efficiently used during instruction, and applied these technologies during lab sessions. PK is deep knowledge about the processes and practices of teaching and learning, encompassing educational purposes, goals, values, strategies, and more. A teacher with deep PK understands how students construct knowledge and acquire skills in differentiated ways, as well as how they develop habits of mind and dispositions toward learning. PCK covers essential knowledge of teaching and learning content-based curricula, as well as assessment and reporting of that learning. An awareness of students' prior knowledge, alternative teaching strategies in a particular discipline, common content-related alternative conceptions, how to forge links and connections among different content-based ideas, and the flexibility that comes from exploring alternative ways of looking at the same idea or problem, and more, are all expressions of pedagogical content knowledge and are essential to effective teaching.

These discussions were held for each educational technology and they promoted the pre-service chemistry teachers' TPACK, giving them a better understanding of how to teach chemistry using educational technologies for varied chemistry concepts. Therefore, the pre-service chemistry teachers were able to understand the interaction of chemistry, pedagogy, and technology knowledge. These results are consisted with the studies of Koh and Chai (2014) or Li and Tsai (2013). Therefore, the development of pre-service and in-service chemistry teachers' TPACK is essential teachers should realize the potential of technology in the real-world classroom environment.

ASSESSING STUDENT TEACHERS' SKILLS TO PLAN PHYSICS LESSONS

Jan Schröder[1], Christoph Vogelsang[2] and Josef Riese[1]
[1]RWTH Aachen University, Aachen, Germany,
[2]Paderborn University, Paderborn, Germany

A main goal of university teacher education programs is to enable pre-service teachers to provide high quality learning environments. Therefore, theoretical courses focus on imparting professional knowledge, which consists of content knowledge (CK) about the subject to be taught, subject-specific pedagogical content knowledge (PCK) and pedagogical knowledge (PK). In doing so, it is assumed that professional knowledge is used as a resource, especially when planning lessons. In addition, practical courses at the university and a long-term-internship at local schools shall provide practical insights into German teachers' daily routines and enable pre-service teachers to gather first teaching experiences on their own. However, it is not quite clear what makes a teacher good in accomplishing his daily tasks. Especially the effect of professional knowledge (acquired at university courses) on teaching quality in real classroom situations is unclear up to now and could only be shown regarding very specific and narrow aspects of teaching quality. Thus, this study aims to narrow the gap by researching the relationship between pre-service physics teachers' professional knowledge and their performance when planning a certain physics lesson and the development of that performance within a long-term-internship. Therefore, we developed a performance assessment which is used to gather student teachers' skills to plan a physics lesson under standardized conditions. Within the assessment, students have to plan a physics lesson in a hypothetical situation. In addition, we used written tests for CK, PCK and PK to analyse the effect of professional knowledge on the quality of lesson plans. The tests for professional knowledge as well as the performance assessment are administered in a longitudinal study before and after a long-term-internship to student teachers (N=174 individual lesson plans, N=68 longitudinal datasets) at four German universities from three different federal states. Results regarding the test's validity, the effect of the internship and the relation between the skill to plan an lesson and professional knowledge will be presented.

Keywords: Initial Teacher Education (Pre service), Performance Assessment, Professional Development

SUBJECT AND PROBLEM

The creation of highly effective learning environments is a crucial task for every teacher. In doing so, learning environments have to respect students' individual needs as well as prior knowledge and should allow an accessible approach to the content. In order to provide these environments, specific lessons have to be planned and prepared. So skills to plan physics lessons are of vital importance especially for novices, as they cannot fall back on tacit scripts or routines. In science education, teachers' professional knowledge, composed of content knowledge (CK), pedagogical content knowledge (PCK) and pedagogical knowledge (PK; cf. Shulman, 1986; Baumert & Kunter, 2013), has been assumed to be a significant factor affecting teaching quality (e.g. Fischer, Neumann, Labudde, & Viiri, 2014). Nevertheless, it is an open research question whether or not CK, PCK, and PK are the key factors that affect teaching quality - or even if these knowledge areas are relevant at all for teaching (for the domain of physics, see Cauet et al., 2015). Thus, it remains unclear to what extent professional knowledge affects the skill to plan a lesson in particular. The study presented in this paper tries to close the gap by developing a standardized and authentic method that is able to assess skills required to plan physics lessons in a first step. In a second step, the development of skills to plan a physics lesson is examined during a long-term-internship, since this kind of internship appears to be a good opportunity for student teachers to practice and develop those skills. Third, the relationship between those skills and professional knowledge (CK, PCK, PK) is analysed.

THEORETICAL FRAMEWORK AND RESEARCH QUESTIONS

Despite the importance of lesson planning, there is no universal definition of lesson planning. Nevertheless, its importance is stated by many authors, e.g. Rakhkochkine (2011) points out that "*The preparation of instruction is one of the central responsibilities of teachers and can be seen as a focal point of the interaction of theory and practice*" (p.95; cf. also Klafki, 1958). Written lesson plans usually serve two different purposes. On the one hand, teachers shall prepare their actions in order to minimize possible insecurities and to provide action alternatives. One the other hand, especially for student teachers, written lesson plans shall also provide some justifications of the planned lessons, as they are evaluated by teacher trainers (Vogelsang & Riese, 2017). The process of lesson planning itself can be assumed to be a recursive process. Within this process, teachers analyse preconditions, anticipate a certain behavior and reflect their decisions afterwards (Shavelson & Stern, 1981). Even though experienced teachers mostly do not elaborate their lesson plans, as they have scripts and routines to fall back on, student teachers need to plan lessons and reflect on their lessons in order to develop those scripts (Stender, 2014).

When measuring subject-related skills to plan lessons, two different approaches can be found in literature. On the one hand, authentic lesson plans, which were created for teaching real classes, are analysed (e.g. Windt, Hasenkamp, Rau, Lenske & Rumann, 2016; König, Bremerich-Vos, Buchholtz, Fladung & Glutsch, 2019). However, this authenticity comes with the problem of finding a way to compare those lesson plans, since they differ regarding planning schemes, content or learning prerequisites. This is a particular problem if lesson plans are to be analysed holistically. Therefore, often only certain aspects of lesson planning are analysed, for example König et al. (2019) focus on adaptive teaching within the lesson plans, which is the fit between the cognitive preconditions of a learning group and the planned tasks to be worked on in class. On the other hand, more standardized, but less authentic paper-pencil-tests are used. For example, Baer et al. (2011) presented short classroom situations to student teachers, who were asked to apply or reproduce their knowledge about planning. However, a high score within these tests can be achieved without actually planning any lessons, so inferences about the ability to plan lessons should be considered with care.

Our study tries to combine the advantages of both approaches by developing a standardized and authentic *performance assessme*nt in which student teachers need to plan a whole lesson instead of reproducing knowledge about lesson planning. The performance assessment follows Miller's (1990) suggestion, whose domain is medical education. According to him, there is a third kind of assessment between *tests for knowledge*, such as tests used to assess knowledge about planning, and *tests for action*, which are represented by observing professional practice. Miller (1990) proposes a performance assessment to put test persons into real authentic but controlled situations, which represent standard situations test persons will have to face frequently as a professional. This kind of assessment has already been used to assess pre-service teachers' "skill to explain physics", which also represents a standard situation for teachers (cf. Kulgemeyer & Riese, 2018). Since the results showed a positive impact of CK and PCK on the explaining performance, this kind of assessment seems to be a promising way to clarify the relationship between professional knowledge and aspects of teaching quality. As this study aims to develop a performance assessment capable of assessing pre-service teachers' skills to plan a physics lesson, we focused our first research question on criteria for test quality:

RQ1: How far can the developed performance assessment measure the skill to plan a physics lesson validly?

Furthermore, we try to investigate the effect of professional knowledge and the performance shown in the developed assessment within a long-term internship that is part of many MA degree programs in Germany.

RQ2: What development of the skill to plan a physics lesson occurs during a long-term-internship?

RQ3: How does the professional knowledge, especially CK and PCK, affect the skill to plan a physics lesson?

DESIGN

To answer those research questions, a performance assessment has been developed by following Miller's (1990) approach. The paper-pencil instrument puts students in a situation where they have to plan a lesson focusing on Newton's third law. Therefore, a short description of the class and their learning prerequisites are provided and specific learning objectives are determined. The lesson plan has to be documented on a pre-structured planning paper, which suggests some mandatory parts of physics lessons. These parts include an analysis of the physical content, possible student misconceptions, intended experiments and tasks or questions, explanations or justifications, a short conclusion for the blackboard and a lesson draft. By these requirements and the standardized aids, namely copies from three different sources about Newton's third law, these lesson plans allow a higher comparability than completely free lesson plans.

In order to evaluate the quality of lesson plans, we developed a theoretical model, derived from the model of educational reconstruction (Duit, Gropengießer, Kattmann, Komorek & Parchmann, 2012), which revolves around the analysis of the content and the conceptions and affective variables of leaners in order to plan lessons. As a result, the model to evaluate the ability to plan physics lessons contains seven different categories to evaluate:

- Physical content and correctness
- Elementarization

- Presentation and consideration of students‘ perspectives
- Reachability of learning objectives
- Presentation and use of experiments
- Presentation and use of tasks or questions
- Use of examples and contexts

The model was developed by using subject-specific literature and various guidebooks on lesson planning, since theoretical literature seldom goes into detail about planning single lessons. It was also combined with an inductive approach, resulting in a codebook with N=26 two- or three-staged items. However, the rater-agreement was quite low with this stage of the codebook (agreement of 75% for *N*=32 lesson plans), especially for items judging the quality of certain aspects. Consequently, all items were transformed into more detailed and dichotomous item, resulting in a total of *N*=59 items. The codebook contains instruction and examples of whether or not an item is rated one or zero points, an example regarding the presentation of experiments is shown in figure 1.

Experiment - Materials	
Aim: The experiment is described in such a way, that others would be able to prepare the experiment by themselves. Required materials are specified.	
Item solved **(1P)**	Item not solved **(0P)**
Required Materials are specified in description of the experiment or in the lesson draft, e.g.: • *„2 students on separate skateboards, connected with a rope. Both students hold on to one end of the rope. First, only student A pulls in the rope, […]. Can be repeated with force meters attached to the ends of the rope“* • *„Materials: 2 skateboards, 2 students, 1 rope, 2 force meters“* • *“A student is standing on roller skates and has to throw away different balls (tennis ball, basketball, medicine ball) horizontally. The balls and his motion shall be observed”* • …	Important materials are not mentioned, e.g.: • Within the experiment, forces are to be measured, but no force meters are mentioned • Description of experiment not clear • No materials mentioned at all No experiment described

Figure 6. Sample item regarding the presentation of experiments with examples whether the item is solved (1P) or not (0P).

The assessment is administered to students from four German universities both before and after the long-term internship together with tests for professional knowledge, which have been validated in previous projects (for CK: Enkrott, Buschhüter, Borowski & Fischer, 2019; for PCK: Riese, Gramzow & Reinhold, 2017; for PK: Riese, 2009), and questions about the internship. When participating in all assessments, the total testing time amounts 305 minutes per measurement point. In between pre- and post-test are approximately 4.5 months (*M*=139d, *SD*=16d), during which students practice at local schools and have to prepare and hold lessons on their own in physics and their second subject. For that time, they are supervised by experienced teachers with whom they discuss their lesson plans and reflect on their lessons afterwards. In the current state, *N*=174 individual lesson plans have been collected over both measuring points, resulting in *N*=68 sets of pre- and post-tests due to the dropout among students. On average, the 68 students whose longitudinal data is available visited *M*=66 physics lessons (*SD*=34) and held *M*=20 (*SD*=11) physics lessons on their own. At the time of the post-test, they were about M=25.4 years old (SD=4.0) and in their 9th or 10th semester at university.

ANALYSIS AND FINDINGS

In this chapter, we will first discuss some test quality criterial of the developed performance assessment. Following, results regarding the posed research questions will be presented and discussed.

Test quality criteria

After scoring the available *N*=174 lesson plans using the codebook containing 59 test items, all items were analysed. For 14 of these test items the relative probability of solution p was too high (p>0.9), too low (p<0.1) or the item-total correlation r was extremely low (r<0.1). Consequently, those items were discarded for further analysis. The internal consistency for the remaining *N*=45 test items amounts $\alpha_{Cronbach}$=0.81 and the mean total score is *M*=50% (*SD*=15%, min=11%, max=87%). For interrater agreement, *N*=52 lesson plans were double-coded by two independent and trained raters. Their agreement for the *N*=45 items amounted 87.6%, resulting in a Gwet's AC_1 coefficient of 0.83, which indicates substantial agreement (Gwet, 2014). The test items could not be separated empirically into the seven categories, which were used to develop the test items, so there are no sub-scores for the individual categories. Given the mutual dependency of different parts of lesson planning, the lack of separability seems comprehensible, since for example the consideration of leaners' perspectives should affect the selection and use of experiments or tasks to be done, so a strict separation of the seven categories is not necessarily reasonable. However, when using the total test score, the codebook seems to provide an objective and consistent measurement for the ability of lesson planning, which will following be used for further analysis.

Research question 1: Validity of the assessment

To answer RQ1, among others, interviews with three teacher trainers were conducted and their judgements regarding the quality of three selected lesson plans were compared to corresponding results provided by the codebook. The interviewed teacher trainers, who regularly judge student teachers' lesson plans and lessons, have also been practicing as teachers for seven to twelve years at German schools. Prior to the interview, three lesson plans were chosen based on the score provided with the codebook in order to achieve a high variance among the lesson plans. At the start of the interview, the teacher trainers had to judge the lesson plans quality by their own criteria without knowledge of the total score or the codebook, resulting in a school grade. During the interview, the lesson plans were discussed more detailed regarding the seven categories contained in the theoretical model. By the end of the interview, the teacher trainers were asked to judge the lesson plans once again, resulting in a second school grade. To allow a better comparability to the score generated with the codebook, school grades were transformed to percentages, following the German system of grading. As shown in figure 2, the results indicate an agreement among the teacher trainers about the perceived order of quality of those lesson plans as well as an agreement of their mean grades' order to the order of the planning score provided by the codebook.

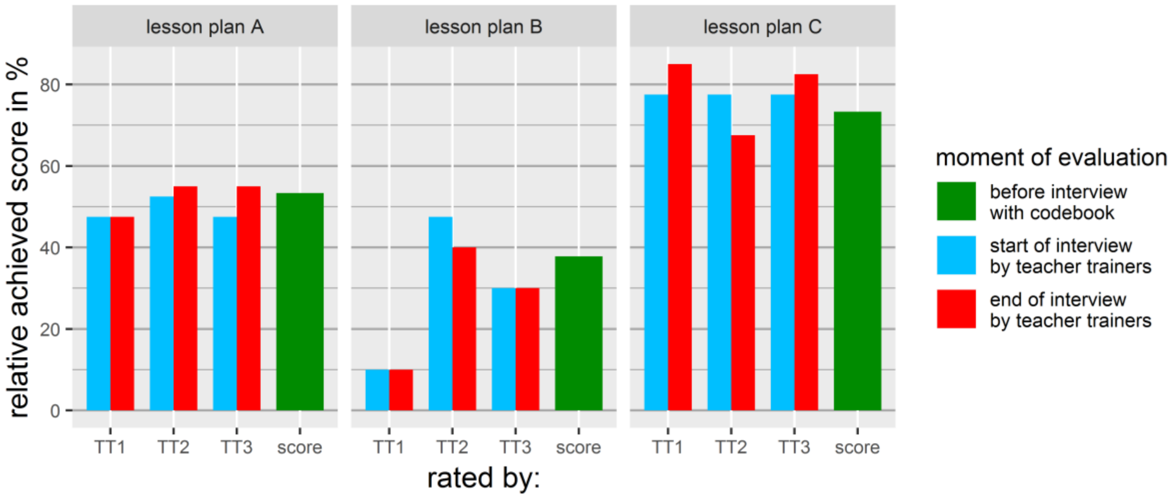

Figure 7. Comparison of three different lesson plans (A, B, C) regarding the plans' quality. Each plan was rated twice by three different teacher trainers (TT) and with the codebook, resulting in the (test-)score. Teacher trainer judgements were transformed to %-values according to the German grading system for higher comparability.

All teacher trainers as well as the codebook evaluate lesson plan C best and plan B worst. Only when looking at the results for lesson plan B, teacher trainer 1 differs considerably from his two colleagues and rates the lesson plan with the worst grade possible. Furthermore, the teacher trainers' judgements shift only slightly during the interview, so knowledge of the seven categories, which were used to score the lesson plans with the codebook, doesn't seem to result in a shift of perceived quality among the teacher trainers. Consequently, we can assume that the perception of lesson plan quality of teacher trainers is similar to that generated with the codebook.

A subset (N=17) of the standardized lesson plans were also compared to real lesson plans, which were created during the internship by the same students. The student teachers taught real classes according to their lesson plans afterwards, so the real plans were prepared for real classes. Due to the diversity among the lesson plans regarding physical content and external conditions, we focused on structural elements and analysed the occurrence and extent of aspects. For this purpose, an independent category system was developed using qualitative content analysis (cf. Mayring, 2015). For example, it was compared if an experiment was described within the lesson plan, how detailed the description was and whether or not the experiment was addressing certain misconceptions. Overall, we found indication of a similar planning behaviour, so the assessment's hypothetical setting does not seem to pose any problems regarding the authenticity.

Research question 2: Development during long-term internship

During the long-term internship, which is mandatory for the teacher education at the participating universities, student teachers visited and held numerous lessons on their own. On average, student teachers held about 20 physics lessons and spent roughly three hours for the preparation of those lessons. As the student teachers are supported by experienced teachers, we can assume that the majority of lesson plans was reviewed by those teachers. After the lesson has been held, student teachers are given the opportunity to reflect on their lessons. On average, student teachers spend about ten minutes talking to their supporting teachers, both before and after holding a lesson. So on the basis of this data, the long-term internships' impact on the ability to plan a physics lesson can be investigated. In table 1 the longitudinal results are summarized, regarding the total score comprised of the N=45 test items.

Table 2. Relative achieved score separated by measurement point and results from a paired t-test.

N=68	Pre-test		Post-test		Paired t-test, t(67)=2.8	
	Mean	SD	Mean	SD	*p*-value	Cohens *d*
Score	48%	14%	53%	15%	0.0075	0.334

When looking at the relative achieved score of those N=68 students in the pre- and post-test, a significant increase of the test score can be observed, but the effect size is small. Still, the long-term internship seems to lead to a slightly higher score in the lesson planning performance assessment among students. These results can be reproduced when using the non-parametric Wilcoxon signed-rank test.

Research question 3: Relation to professional knowledge

As described previously, it remains an open research question to what extent the professional knowledge is related with the ability to plan a lesson respectively the teaching quality in general. Therefore, the professional knowledge was also assessed using written tests for CK, PCK and PK. The correlations (Pearson's r) between the planning score and the total test scores of the three areas of professional knowledge are shown in table 2.

Table 3. Relation between achieved planning score and total score from tests for professional knowledge. Significance levels: Not significant ≙ $p \geq 0.05$ (n.s.), $p < 0.05$ (*), $p < 0.01$ (**).

Bivariate Correlations		CK		PCK		PK	
		r	N	*r*	N	*r*	N
Planning	Pre-tests	0.008 (n.s.)	59	0.318**	74	0.356**	55
	Post-tests	-0.063 (n.s.)	38	0.325**	71	0.247*	71

The case numbers N vary due to the absence of test persons at separate assessments of professional knowledge, especially during the second measurement point. For PCK and PK, small correlations between the test score and achieved lesson planning score can be seen for both pre-test and post-test. However, no correlations between lesson planning score and the test score for CK were found at any measurement point.

DISCUSSION

The results regarding research question 1 seem to provide first evidence that the developed performance assessment is capable of measuring the quality of lesson plans and so the skill to plan a lesson. Interviews with teacher trainers showed exemplary that the perceived quality of lesson plans created within the assessment is similar to the total score generated with the codebook. Furthermore, the hypothetical setting of the assessment doesn't seem to restrict the ecological validity of the test, so the performance assessment appears to be a valid possibility for measuring the skills to plan a physics lesson.

The longitudinal data, which were gathered before and after a long-term internship show a significant increase in the test score along the internship (RQ2), but with a small effect size. It is reasonable to assume that the internship represents an opportunity to increase the ability to plan a lesson, however, given the small effect size, these results should be treated with caution. A possible explanation for the small effect might be that during the internship student teachers are focused on the creation of learning materials and methodological aspects or classroom management, which are not addressed in the performance assessment. Given the demographic data, that was also gathered with the tests for professional knowledge and an additional questionnaire about experiences and the mentoring relationship will allow a more detailed analysis

Regarding research question 3, we can see small correlations between the skill to plan a lesson and the PCK respectively the PK. The correlation between the ability to plan a lesson and the PCK seems more consistent along the internship than the correlation with the PK, which is roughly one third lower after the internship. The correlation with CK could not be shown at all. However, a minimum level of CK appears to be a requirement for a high level of PCK, the connection between lesson planning ability and CK might be included in the correlation with the PCK. It should be noted that we are only considering correlations at this point and not causal aggregations, which we will investigate at a later stage of the project.

DEVELOPMENT OF PROSPECTIVE PHYSICS TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE WHILE PREPARING FOR AN INTERNSHIP

Ann-Kathrin Joswig-Käfer[1], Josef Riese[1]
[1]RWTH Aachen University, I. Institute of Physics (IA), Aachen, Germany

In recent years, several large-scale studies have researched prospective science teachers' pedagogical content knowledge (PCK) to get findings on how to improve academic teacher education. While a general increase of PCK most often can be found, it is widely unclear how university learning opportunities and other influencing factors affect certain areas of PCK in detail. In this project, the development of prospective physics teachers' PCK and reasons for individual changes in the amount and characteristic of their PCK are researched over a number of months while preparing to a long-term internship. In that time, two subject specific university seminars have to be taken with a focus on methods for planning physics' lessons respectively methods for dealing with students' preconceptions in the physical topics electricity and optics. In methodological terms, in a first step, 24 prospective physics teachers were surveyed with a written quantitative PCK-test in a pre-post design to evaluate the development of their PCK when attending the two seminars. The PCK-test comprises four different areas of PCK (instructional strategies, students' conceptions, adequate use of experiments, physics education concepts) and covers three physical topics (mechanics, optics and electricity). In a second step, guided interviews were conducted with all test persons and analysed by using qualitative content analysis. In the interviews, the prospective physics teachers were individually confronted with changes in their test behaviour (pre-post) as measured by single items of the PCK-test and they were begged to reason why responses differ in the pre-post comparison. Furthermore, the development of PCK in specific areas was related to their individual use of learning opportunities. Thereby we also explore how far the acquisition of PCK depends on a physical topic. First results from the longitudinal part and clues derived from the interviews will be presented.

Keywords: Pedagogical content knowledge, Initial Teacher Education (Pre-service), Professional Development

PROBLEM DEFINITION

Teacher education programs in general as well as introduced innovations in detail should be evaluated with respect to the development of teachers' professional knowledge. Therefore, many studies were conducted to assess certain aspects of science teachers' professional knowledge like pedagogical content knowledge (PCK; Ledermann & Abell, 2014; Shulman, 1986). In the German-speaking research on science teacher knowledge, most studies focus on large-scale methods when researching the development of PCK, so several written PCK-tests have been developed and validated in various projects – especially in the domain of physics (FALKO: Schödel & Göhring, 2017; KiL: Kröger, Neumann & Petersen, 2013; ProfiLe-P: Riese et al., 2015 & Vogelsang et al., 2020; ProWiN: Tepner et al., 2012; QuiP: Olszewski, 2010). Some of those studies found, for example, differences in the amount of PCK (regarding a general total score) depending on the type of teacher education program or the study progress. However, beyond quantitative correlations, there is still a lack of findings how far individual learning opportunities taken at university, learning opportunities taken in daily routines or test-specific and person-specific effects affect becoming teachers' PCK in detail. Those findings would be helpful to explain different development processes of science teachers' PCK in science teacher education programs.

THEORETICAL FRAMEWORK

Pedagogical content knowledge as a part of teachers' professional knowledge

In science teacher education, teachers' professional knowledge has been assumed to be a fundamental factor affecting teaching quality (e.g. Fischer, Neumann, Labudde & Viiri, 2014; Vogelsang et al., 2020). So many studies have been conducted to research teachers' professional knowledge (Ledermann & Abell, 2014). In doing so, most studies refer to Shulman's (1986) fundamental considerations about teachers' professional knowledge, who described seven categories of professional knowledge (content knowledge [CK]; general pedagogical knowledge [PK]; curriculum knowledge; pedagogical content knowledge [PCK]; knowledge of learners and their characteristics; knowledge of educational contexts; and knowledge of educational end, purposes, and values; cf. Shulman, 1987). Recent studies highlight CK, PK and PCK having a great impact on teaching quality (e.g. Baumert et al., 2010; Cauet, Liepertz, Kirschner, Borowski, & Fischer, 2015), where these three domains are sometimes described as including the seven categories. Following those approaches, CK can be understood as subject matter knowledge underlying the content selected for teaching, PK can be described as knowledge of how to act in teaching situations in general and PCK can be regarded as domain-specific knowledge of how to teach the selected content.

Measuring pedagogical content knowledge

Following Shulman (1986), pedagogical content knowledge (PCK) represents a key part of teachers' professional knowledge and comprises knowledge about typical difficulties in teaching a specific topic, knowledge about students pre- and misconceptions and knowledge about representing and formulating a subject to make it comprehensible to others (Hume, Cooper & Borowski, 2019; Park & Oliver, 2008; van Driel & Berry, 2010). Based on those suggestions, several large-scale studies have been conducted in the domain of physics to research (student) teachers' PCK. In doing so, studies usually focus on Topic Specific PCK when measuring PCK to ensure that empirically based subscales can be found within a survey with limited test-time. For example, Fischer et al. (2014) assess certain areas of PCK (e.g. students' misconceptions, difficulties of contents, reactions on students' answers, suitable tasks) only in the physical topic electricity while Gramzow, Riese & Reinhold (2014) and Vogelsang et al. (2020) focus on the physical topic mechanics as students' conceptions in mechanics are well known in science education research. So the approaches chosen in these studies follow the idea that PCK comprises of General PCK, Domain Specific PCK and Topic Specific PCK (Mavhunga, 2014; Veal & MaKinster, 1999). But it is unclear if such an approach allows a representative and valid measurement of physics (student) teachers' PCK when evaluating (parts of) academic teacher education programs or evaluating an intervention with mixed topics, since the role of the physical topic when acquiring Domain Specific PCK is unclear.

AIMS AND RESEARCH QUESTIONS

In order to introduce the research questions, a brief introduction into the structure of typical German teacher education programs is given. In a first step, pre-service teachers usually have to graduate an academic part which lasts five years in most cases. First, in those programs, there is a focus on the acquisition of subject related content knowledge (CK) while the last two years often focus on the acquisition of pedagogical content knowledge (PCK) and a long term internship. In a second step, the academic part is followed by a traineeship with a duration of one to two years where the pre-service teachers receive a wide range of teaching practice at school.

As a first aim, our study presented in this paper evaluates a preparation phase to a long term internship (as mentioned above) at the RWTH Aachen University as a specific part of a typical university teacher education program in Germany. In doing so, the development of physics (student) teachers` PCK is researched by a written PCK-test in a pre-post study design while preparing to the long-term internship. During this time, the student teachers have to take two specific preparatory seminars with a focus on methods for planning physics' lessons and dealing with students' preconceptions in the physical topics electricity and optics. This leads to a first research question:

RQ1: To what extend does physics student teachers' PCK develop in the topics mechanics, electricity and optics while attending those two preparatory seminars?

Moreover, when acquiring PCK, the role of the physical topic is researched:

RQ2: Does the acquisition of PCK independently happen within a distinct physical topic (being taught) or does PCK develop as a whole construct (above different topics)?

Furthermore, more general conclusions about the development of PCK should be drawn. Therefore, the impact of various categories of subject-specific, university learning opportunities as well as other types of influencing factors on prospective teachers` PCK are researched in detail. This leads to two research questions:

RQ3: Which categories of individually taken subject-specific, university learning opportunities facilitate the development of PCK?

RQ4: Which categories of further influencing factors and individual specifics lead to changes in PCK?

METHODS

To answer those research questions, first of all, the development of prospective physics teachers' PCK was measured by a written PCK-test, that was mostly developed and validated in previous projects (Gramzow, 2015; Kulgemeyer & Riese, 2018). In addition to those existing items in mechanics, some more items have been developed in the topics electricity and optics. The test was applied in a pre-post design at the beginning and at the end of those above mentioned two university seminars in the winter semesters 2017/2018 (N = 10) and 2018/2019 (N = 14). With regard to curricular validity, the test considers specifics of the German-speaking teacher education programs and comprises four different areas of PCK (instructional strategies, students' conceptions, adequate use of experiments and physics education concepts), that were empirically verified in previous projects with a four-dimensional Rasch-model (Kulgemeyer & Riese, 2018). The test items were created following a three dimensional model for itemdevelopment as shown in figure 1.

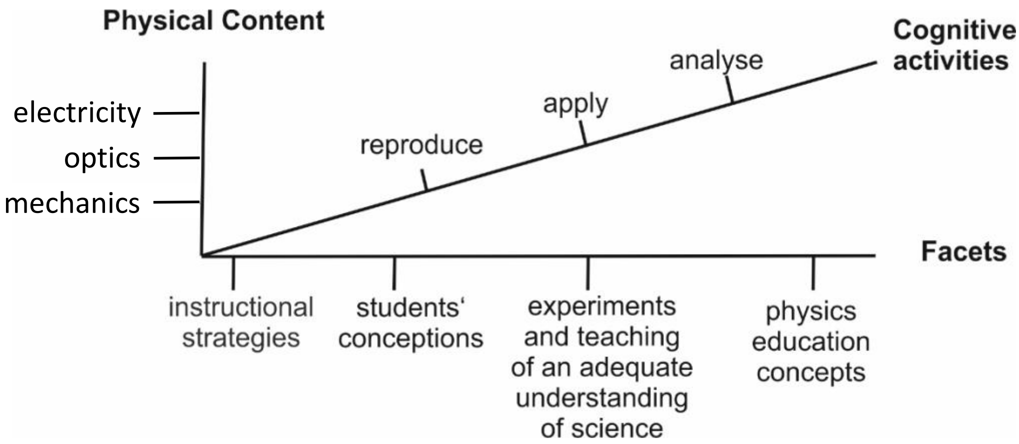

Figure 1. **PCK model for item development modified from Gramzow, Riese & Reinhold (2014, p. 2244).**

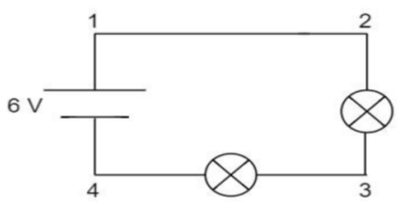
Furthermore, the test covers three physical topics (mechanics, electricity and optics), while the physical topic mechanics was not directly addressed in both university seminars. On the whole, the paper-and-pencil test includes 41 items with open situational judgment items as well as multiple-choice items (multiple select). In figure 2, an example of a test item in the physical topic electricity is presented. This sample item is assigned to *electricity*, *student's conceptions* and *analyse* (see figure 1). The testing time for each participating student was limited to 105 minutes.

A student should consider the following electric circuit with two identical lamps:



The student says the following sentence:

"Between all points the same voltage drops and the same current flows."

What wrong conception does the student have?

Figure 2. Sample item in the physical topic electricity.

With regard to research questions 2 to 4, moreover, guided interviews (90 min) were conducted after the post-test with all participants and they were analysed by using qualitative content analysis (Mayring, 2014). In the interviews, the becoming physics teachers were individually confronted with differences (pre-post) in their responses to single test items and they were begged to reason why responses differ in the pre-post comparison. Furthermore, the development of PCK in specific test-items was related to their individual use of different categories of learning opportunities.

ANALYSIS AND FINDINGS

With respect to the pre-post-survey, first results show a statistically significant increase regarding the mean total score of PCK with a medium effect size (table 1). In more detail, the Topic Specific PCK score in electricity also increases with a medium effect size, whereas no increase regarding the Topic Specific PCK score in mechanics can be found at all. The subscore in optics lies within these poles (table 1). These results may indicate that our sample of prospective physics teachers further develop their PCK while attending those two university seminars that prepare to a long-term internship (RQ1). Furthermore, these results lead to the conclusion that there might be an influence of the physical topic being taught when acquiring PCK (RQ2) as the approach of "Topic Specific PCK" (Mavhunga, 2014; Veal & MaKinster, 1999) suggests.

Table 1. Results from dependent t-tests for the PCK total score and corresponding subscores in mechanics and optics (Wilcoxon-test) as well as electricity (each topic: max. 21,5 points, total score: 64,5 points).

dependent t-tests, Wilcoxon-test (optics)				
	Mean	Sd	Sig (2-tailed)	|d| Cohen's d
PCK total score (N=22)	+ 2.16	4.56	0.04	0.47
PCK mechanics (N=24)	- 0.23	3.06	0.72	0.08
PCK optics (N=23)	+ 0.76	2.76	0.30	0.28
PCK electricity (N=22)	+ 1.43	3.30	0.05	0.43

To gather further evidence with respect to research questions RQ3 and RQ4, a more descriptive look at individual changes of the PCK-scores and scores in the three topics mechanics, optics and electricity has been taken to identify test persons with a conspicuous test behaviour. Table 2 presents individual PCK scores of three exemplarily chosen test persons. Regarding the pre-post comparison, it gets obvious that one and the same test person can achieve opposite progressions concerning different topics (e.g. student 1). This result leads to the conclusion that PCK probably does not develop simultaneously in different topics and that the topic is an important factor when acquiring PCK (RQ2).

Table 2. Selected results of individual PCK total scores and scores in the three topics mechanics, optics and electricity in a pre-post comparison. In each of these topics 21,5 points can be achieved (total score: 64,5 points).

Student	PCK **total score** Pre-test	PCK total score Post-test
1	30,0	30,5
2	22,5	28,0
3	18,0	26,0
Student	PCK **mechanics** Pre-test	PCK mechanics Post-test
1	8,0	11,0
2	11,0	11,0
3	12,0	6,0
Student	PCK **optics** Pre-test	PCK optics Post-test
1	8,5	9,0
2	4,0	9,0
3	6,0	11,0
Student	PCK **electricity** Pre-test	PCK electricity Post-test
1	13,5	10,5
2	7,5	8,0
3	0,0	9,0

Having these findings in mind, guided interviews were conducted with all test persons in which the prospective physics teachers were individually confronted with changes in their test behaviour (pre-post) regarding single items of the PCK-test and they were begged to explain their answers respectively the shifting of their answers. To analyse the interview transcripts with qualitative content analysis (Mayring, 2014), first of all, a multilevel category system had been developed which consists of deductive and inductive categories, e.g. effects caused by the test rerun, successfully use of specific learning opportunities, self-made experiences in the students' everyday life or other personal aspects. The category system was proofed by an external rater ($\kappa_{Brennan/Prediger}$=0.69) and by an intrarating ($\kappa_{Brennan/Prediger}$=0.84) which means a substantial resp. almost perfect agreement (Landis & Koch, 1977). Preliminary results from the interviews indicate that personal particularities as well as specific learning opportunities taken at university might affect changes in test behaviour. Individual characteristics of test persons seem to affect their PCK to a rather great extent. For example, the changes in the PCK-scores of student 3 (table 2) can be referred to a different time management in the pre- and post-test. We are going to analyse all 24 interview transcripts to answer RQ3 and RQ4 in detail.

ACKNOWLEDGEMENT

"This project is part of the "Qualitätsoffensive Lehrerbildung", a joint initiative which aims to improve the quality of teacher training. The programme is funded by the Federal Ministry of Education and Research. The authors are responsible for the content of this publication."

TEACHING CHEMISTRY INCLUSIVELY – ARE WE PREPARED?

Katharina Gross[1]

[1]University of Vienna, Institute of Chemistry Education, Vienna, Austria

Related to the ratification of the Convention on the Rights of People with Disabilities, school teachers are faced with new challenges in chemistry lessons. Due to the increasing students' diversity, appropriate learning environments which are able to support learners according to their individual learning, development and cognitive abilities are needed. Important criteria for an appropriate perception and handling of heterogeneous learning groups in the sense of adapted class design are teachers' competences and attitudes towards inclusive chemistry education. Based on these requirements, the project aims at supporting pre-service chemistry teachers in acquiring central inclusive competences as well as reasonable attitudes towards inclusion during university education. The results of the explorative preliminary study show that teacher students' attitudes as well as their skills and knowledge deviate from the demands desirable for inclusive education. Taking these findings into account, it is necessary to offer appropriate courses at university. Thus, a course was planned, conducted and evaluated in order to detect a possible way to prepare prospective chemistry teachers adequately. The course aims at provoking them to reflect upon their attitudes towards inclusion and discovering how they can be enabled to work with learners' diverse abilities, interests and needs (both perceived and real) in inclusive chemistry lessons. To gain insights into their individual processes, questionnaires and process-portfolios had been used to collect data which were analysed by means of qualitative content analysis. In addition, validated scales were used to evaluate prospective chemistry teachers' inclusive attitudes and competences before and after the intervention. The paper will outline first results of the main study and will illustrate potential shifts of pre-service teachers attitudes and competences before and after attending the course.

Keywords: Inclusion, Initial Teacher Education (Pre-service), Teacher Preparation

INTRODUCTION

There is a general consensus that inclusion and consequently, inclusive chemistry education is a complex issue and its realization requires various changes at different levels (i.a. UNESCO, 2005; Rouse, 2008; Florian & Black-Hawkins, 2011). Aggravating this situation, inclusion is often discussed with regards to ethics and norms and therefore causes uncertainty among (pre-service) teachers, not least, because of a missing practical definition and missing underlying inclusive didactics. However, to successfully implement inclusion at all levels of (chemistry) education, it is necessary that (pre-service) chemistry teachers acquire appropriate competences and accept their responsibility for the learning process and development of all students (Booth & Ainscow, 2002), which has been shown in several research studies (Gross & Reiners, 2012; Abels, 2015). Thus, the role perception of teachers plays a significant role in promoting students' equal participation and individual development in inclusive chemistry education (Saloviita, 2015). Particularly with regard to secondary school teachers it also means that they see their role as chemistry teachers as transformers of knowledge rather than as educators (Rouse, 2008). However, numerous studies show that many teachers feel challenged educating students with and without special educational needs simultaneously for several reasons: either they do not feel safe enough for inclusive teaching, have made negative experiences in dealing either with challenging students and/or the required cooperation partners or they simply do not feel responsible because of their own role perception (i.e. Forlin, 2001; Gavish, 2017).

TEACHERS AS CRUCIAL PREDICTORS FOR SUCCESSFUL INCLUSION

Trying to focus on every student's needs, the educational work of teachers is gradually gaining more and more importance and is no longer limited to the transfer of knowledge anymore. In order to implement inclusive education successfully, students' content and social learning must be combined. Learning has to be based on positive student-teacher-relationships and a respective feedback culture. Therefore, cooperative and activating forms of learning must be employed within a flexible and (goal-) differentiated setting (Booth & Ainscow, 2002). Such learning arrangements require professional competences of teachers based on positive attitudes towards and mind-sets supporting inclusion (Florian & Black-Hawkins, 2011). Relevant literature claims that the attitudes towards heterogeneity and inclusion as well as the teachers' competences are of major importance when dealing with the heterogeneity faced in (chemistry) lessons (i.e. UNESCO, 2005; Lindsay, 2007). Exploring day-to-day lessons, it becomes obvious that although teachers are familiar with particular strategies for adaptive chemistry education, they do not adopt these strategies in their teaching. There might be various different reasons for not doing so, but obviously there are certain decisive factors for teachers whether or not they act according to their theoretical knowledge. According to the Theory of Planned Behaviour, attitudes as well as perceived behavioural control strongly influence behavioural intention and consequently determine the actual performance of a certain behaviour (Fishbein & Ajzen, 1975; Ajzen, 1991). Attitudes can basically be defined as a person's willingness to evaluate a certain set of behavioural beliefs positively or negatively, based on feelings, affections as well as opinions and perceptions (Bierhoff, 2000). Whether intended behaviour leads to actual behaviour, depends on the perceived behavioural control though: the more a person feels capable of carrying out a certain type of behaviour and feels like being able to control this behavioural pattern, the stronger are the intentions to engage in the behaviour in question. The significant influence of behavioural control on a person's actual behaviour is also considered in the concept of self-efficacy, which is based on Bandura's Social-Cognitive Theory. In order to carry out intended behaviour, it is of major importance how confident a person is with their own skills. A person is more likely to perform intended behaviour, if he/she feels certain to successfully master a complex or challenging situation based on competences or qualities like effort and endurance (self-efficacy expectation, (Schwarzer & Jerusalem, 2002)). Besides the person-related self-efficacy and efficacy expectations, the relationship between an action set and the expected result, i.e. the outcome expectancy, plays an important role when engaging in certain behaviour. Consequently, the actual realization of a certain behavioural pattern strongly depends on the person's expectations.

With regard to inclusive chemistry education these theories show, that the teachers' competence is relevant, but not sufficient for actually teaching chemistry in an inclusive and learner-centred way. Moreover, teachers' positive attitudes towards inclusion as well as their confidence in their own competences and self-efficacy, and therefore their perceived capability of satisfying the diverse needs of heterogeneous learner groups, are crucial factors for engaging in certain behaviour.

Based on Dlugosch (2010) the following two aspects are significant for realizing successful inclusive education: ideally teachers have positive attitudes towards inclusion and corresponding role perceptions. They see themselves as responsible for every student and their expectations towards the performances and achievements of every single student are positive. Moreover, they have a high self-efficacy expectation and they are convinced to be able to teach effectively in an inclusive learning environment (Dlugosch, 2010). Jordan et al. (2009) also claim that not only the normative values of a school, but also the attitudes of teachers towards their own roles in the process of inclusive education are fundamental for effective teaching that motivates and fosters students and finally leads to successful learning. Teachers' willingness to take responsibility for all students as well as accepting whatever special educational needs they have („teacher P-I beliefs") and their self-efficacy expectations („teacher efficacy") are crucial for successful inclusive education. (Jordan, Schwartz & McGhie-Richmond, 2009). In summary it can be said that teachers' professional handling of inclusive learning environments requires a high amount of self-regulative skills, such as regulation of emotion and willpower. They are even stronger if a teacher's self-efficacy expectation is high. Furthermore, professional teaching is strongly influenced by teachers' assumptions about and attitudes towards inclusive chemistry education, which sometimes might appear rather contradictory (Baumert & Kunter, 2006).

In order to promote teachers' professional action, it is necessary to provide courses for pre-service chemistry teachers at university, in which they learn how to deal with inclusive classes and reflect upon their opportunities and challenges (i.e. Meijer, 2010). Schlüter & Melle could show that preparing pre-service chemistry teachers for inclusive education in the course of their university education led to a positive change of attitudes, opinions and self-efficacy towards inclusive education (Schlüter & Melle, 2018).

OVERVIEW OF THE PROJECT

Based on the training units from Rouse (2008) ("Apprenticeship of the head, of the hand of the heart") the project aims at exploring how theoretical basic knowledge (head: knowing), practical knowledge (hand: doing) and a positive attitude (heart: believing) can be developed for prospective chemistry teachers in order to reduce individual preconceptions about inclusive chemistry education step by step. Moreover, the question arises whether and to what extend pre-service teachers are able to develop competences and positive attitudes which meet the demands of inclusive education as early as at university.

For this reason, a preliminary study enquiring pre-service teachers' pre-experiences, pre-conditions and pre-conceptions concerning inclusive chemistry education was conducted qualitatively. Based on the results of this study, a course focussing on the particular needs of pre-service teachers regarding inclusive chemistry education, combining theoretical aspects of special (needs) education and practical methodological skills, was designed. The course included and combined elements of promoting theoretical knowledge, practical procedural knowledge and (self-) reflective knowledge (see table 1, and Rouse, 2008).

Table 1. Elements of the course "Inclusive Chemistry Education – Opportunity or Challenge?!".

Knowing	**Develop basic theoretical knowledge** • Particularities of inclusion/ inclusive chemistry lessons; characteristics of chemistry teaching; pragmatic know-how for inclusive chemistry lessons
Doing	**Develop pragmatic and content-related knowledge** • Design and implementation of actual hands-on opportunities for inclusive chemistry education
Believing	**Perceive and reflect upon the different perspectives of inclusion:** • Individual examination of personal experiences and attitudes towards inclusive chemistry education • Experiments in labs with different handicaps, pre-service teachers taking different roles

The main focus of the course was on stimulating active, reflective theoretical discussion and getting practical experience in order to familiarize pre-service teachers with opportunities and limitations of inclusion. Therefore, their attitudes and opinions (self-reflection and self-perception) on the one hand and chemical particularities (reflection upon chemical topics) were discussed. In order to be able to take the individual requirements and pre-requisites of the participating students into account appropriately, the topics were pre-selected and modified according to the needs and aims of the participating pre-service teachers. Additionally, all the topics discussed were dealt with in the context of chemistry education, as only this approach allowed for the pre-service teachers to gain insights into the particular challenges of teaching chemistry in inclusive learning environments and to acquire the respective relevant competences. In this regard the course offered pre-service teachers the opportunity to reduce personal barriers and discover strategies dealing with inclusion. The pre-service chemistry teachers were able to acquire and reflect upon these strategies autonomously and topic-related and could increase their awareness for their newly-acquired skills.

Kopmann & Zeinz (2016) emphasize the importance of being conscious of and reflecting upon existing teacher student beliefs. In combination with the integration of newly acquired knowledge and practicing alternative strategies of action this can lead to effective, sustainable changes in attitude (Kopmann & Zeinz, 2006). In their empirical studies on teacher students' and teachers' attitudes and self-efficacy beliefs Hecht, Niedermaier & Feyerer (2016) found out that university education can provide comprehensive knowledge of and a positive view on inclusion and should therefore create opportunities for gaining experience with inclusion, so teacher students can develop self-efficacy in this respect (Hecht, Niedermaier & Feyerer, 2016). In order to do so, they particularly highlight the necessity of acquiring competences in the fields of diagnosis, differentiation and individualized learning. Additionally, the teacher students should be given opportunities to experience what it means to have special needs as well as time and place to discuss and reflect upon these experiences in order to be able to teach in an innovative and demand-oriented way.

The course has already been conducted three times at two different universities in the course of the master studies programme ($N_{Master\ students}$=57) and has been evaluated with regards to the following superordinate research question: How does a demand- and target-oriented course-setting influence chemistry teacher students' competences with regard to inclusive education? The superordinate research question had to be concretized into the following two research questions:

RQ1 In what way can the course address chemistry teacher students' needs and can consequently lead to the development of key competences?

RQ2 How does the course strengthen chemistry teacher students' confidence to teach chemistry in an inclusive way, work collaboratively when necessary and deal with behavioural disorders?

METHODOLOGY

The long-term aim of the project is to evaluate in what way and to what extent pre-service chemistry teachers are able to develop competences and appropriate attitudes towards inclusive chemistry education at university. Therefore, a mixed-methods research design (Döring, Bortz & Pöschl, 2016) was planned, of which the course is the central element (see fig. 1).

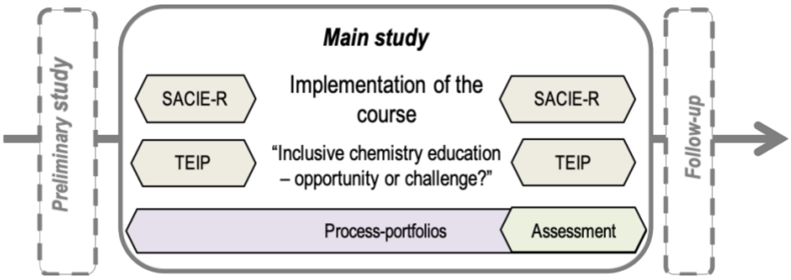

Figure 1. Overview of the research design of the project with research elements and research tools.

In order to develop a demand- and target-oriented course-setting and to be able to answer the research questions, it was necessary to evaluate the needs of pre-service chemistry teachers in advance and to compare those to general research findings (preliminary study). To gain insight into teacher students' needs semi-structured interviews and questionnaires were conducted (*N*=15). Based on these findings a course was developed and conducted (see table 1). The didactic structure of the course took the following aspects into account to the same extent: the aims of teaching chemistry inclusively based on (content-specific) research findings and teacher students' individual preconditions about inclusive chemistry education. The issues that teacher students raised as well as chemical content were considered in each course session in terms of an iterative and reflexive process. The course was qualitatively analysed and evaluated employing process-portfolios which the participants put together during the course. This approach gave teacher students the opportunity to construct, reflect and extend their personal knowledge and attitudes towards inclusion (structuring content analysis, Mayring, 2014). Moreover, before and after the intervention the validated SACIE-R-scale ("The Sentiments, Attitudes and Concerns about Inclusive Education Revised (SACIE-R) scale", 3 subscales with a four-level Likert scale (0-4), Forlin et al., 2011) as well as the validated TEIP-scale ("Teacher Efficacy for Inclusive Practices", three subscales with a six-level Likert scale (0-6), Sharma, Loreman & Forlin, 2012) were used to gain deeper insight into teacher students' shifts of perspectives on inclusive education (see fig. 2). In a follow-up study the acquired competences of the teacher students will be evaluated and analysed with regard to their application in inclusive chemistry lessons.

In the following section the results of the main study shall be presented in more detail. All in all, 57 master students studying at two different universities took part in the main study. 38 participants put together a process portfolio. Concerning the pre-post-questionnaires 42 students filled in the SACIE-R-scale whereas 39 filled in the TEIP-scale. On average the students were 23,5 years old. 52% of them were female. 81% of the participants had no or hardly any experience teaching students with special needs and 60% said that the amount of training they received in teaching students with special needs was limited or very limited.

FINDINGS

The results of the process-portfolios show that pre-service chemistry teachers' knowledge increased in all three dimensions (see table 2): the students gained essential theoretical knowledge about inclusive chemistry education (see K1). Furthermore, the professionalization process was target-oriented as the students had stated that the experiment belonged to every chemistry lesson, no matter how heterogeneous the learning group was. Particularly the pre-service chemistry teachers' self-experience in the lab, taking the role of students with special needs using devices to simulate these demands, allowed them to gain fundamental insights into the design of inclusive chemistry lessons and to improve their teaching (see K3).

Table 2. Excerpt from the categories for the evaluation of the process portfolios (*N*=38).

Categories	Results (anchor statements)
K1 Theoretical basic knowledge *(Knowing)*	"For me, an inclusive chemistry lesson includes four aspects: content learning, social learning, conducting experiments and ensuring safety. [...] Thus, inclusive learning can be ensured by the experiment" [MK, 17;19]
K2 Pragmatic and content-related knowledge *(Doing)*	"The highlight was the practical implementation of the chemistry lesson we designed ourselves. [...] We had difficulties realizing the lesson but this made our insights and impressions even more sustainable." [SE, 08] "For me, particularly the practical examples showed what we had to learn: they showed me which aspects I have to focus on when teaching [students with special needs] […], I am still convinced that experimenting and doing something practically is most important to learn new content." [SK, 40;42]
K3 Self-reflective knowledge *(Believing)*	"Especially the experiences in the lab when I took another role deliberately, gave me safety and new insight into conducting an experiment with different handicaps." [CS, 46] "I feel definitely [...] better prepared now. I also became aware of [...] how important it is to actively reflect and examine the personal role as a chemistry teacher when designing an inclusive chemistry lesson. My focus is on the students' resources and I see myself as a teacher who values and considers heterogeneity and who wants to teach in an unbiased way." [CH, 32]

Based on the newly acquired basic theoretical knowledge, the students were able to build up practical skills (see K2), which in turn changed their views of inclusive education positively and helped them to comprehend their own role as a chemistry teacher in inclusive classes (see K3). This brief insight into the results of the qualitative content analysis of the process portfolios already showed, that the pre-service chemistry teachers could acquire necessary competences for the successful realisation of inclusive chemistry education due to the particular course design. Both, the practical elements and the theoretical discussion of potentials and challenges of inclusive chemistry education positively affected the pre-service chemistry teachers' perception of teaching chemistry inclusively as well as their awareness of their role as teachers. This is also made explicit in the following statement of a participating teacher student: *"[...] The course provided a lot of new experiences, which allowed me to develop new ideas. [...] I learned new approaches towards inclusive chemistry teaching [...]. Experiments are an important part of chemistry lessons and all students, regardless of their limitations, should be encouraged in this field. [...]. The practical experience in the laboratory was helpful as my empathy and my understanding for students with special needs, as well as my self-confidence in differentiating and foster all students in an inclusive environment has grown [...]"* [NM, 23].

The pre-post-test survey about sentiments, attitudes and concerns about inclusive chemistry education (SACIE-R-scale) shows that the pre-service chemistry teachers' attitudes towards inclusion (1st subscale SACIE-R, α=.79) have already been quite positive (M=3,02) and have become even better (M=3,06) after they have taken part in the course. It has to be mentioned though that the visible growth, cannot account for a significant transformation of attitudes (*N*=42, Z=-0.529, *p*=.597). On the other hand, teacher students' sentiments (2nd subscale SACIE-R, α=.62) have already been low (M=1,94) before the course, but have minimally increased (M=1,98) after the course, not significantly though (*N*=42, Z= 0.385, *p*=.700).

In contrast, the subscale "concerns" shows a mediocre effect concerning the reduction of teacher students' concerns (3rd subscale SACIE-R, α=.52) about inclusive chemistry education (*N*=42, M_{pre}=2.87, M_{post}=2,60, Z=-2.816, *p*=.005, r=0.307). Figure 2 shows that particularly those concerns in relation to items 2 and 5 could be reduced (see fig. 2). Before the course, students said they were worried about not being able to give the attention needed to all the learners in an inclusive classroom (item 2) and not having the knowledge and skills required to teach students with disability (item 5). Both concerns could be reduced after attending the course.

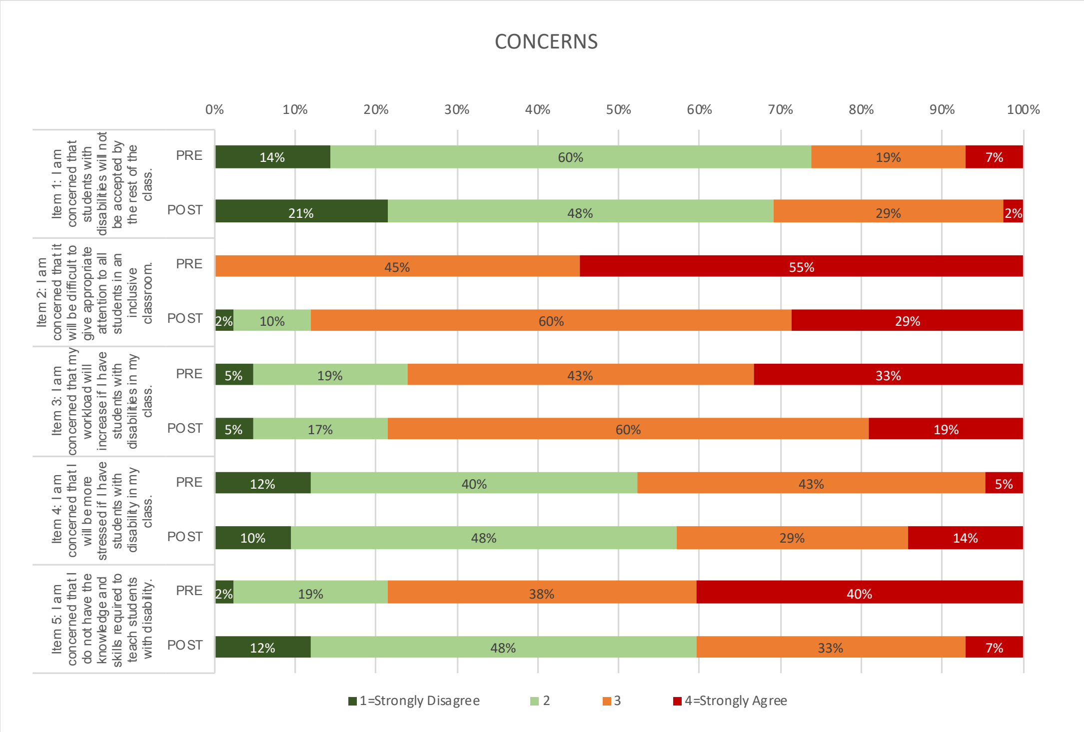

Figure 2. Results of the individual items of the subscale "concerns".

The pre-post-test survey on the pre-service teachers' efficacy for inclusive practice (TEIP-Skala) shows that the teacher students' confidence in their ability to design inclusive chemistry lessons as well as their efficacy to teach chemistry inclusively improved significantly (1st subscale TEIP, α=.71) in the statistics (N=39, M_{pre}=4,44, M_{post}=4,71, t=-3.560, p<.001, d=0.51).

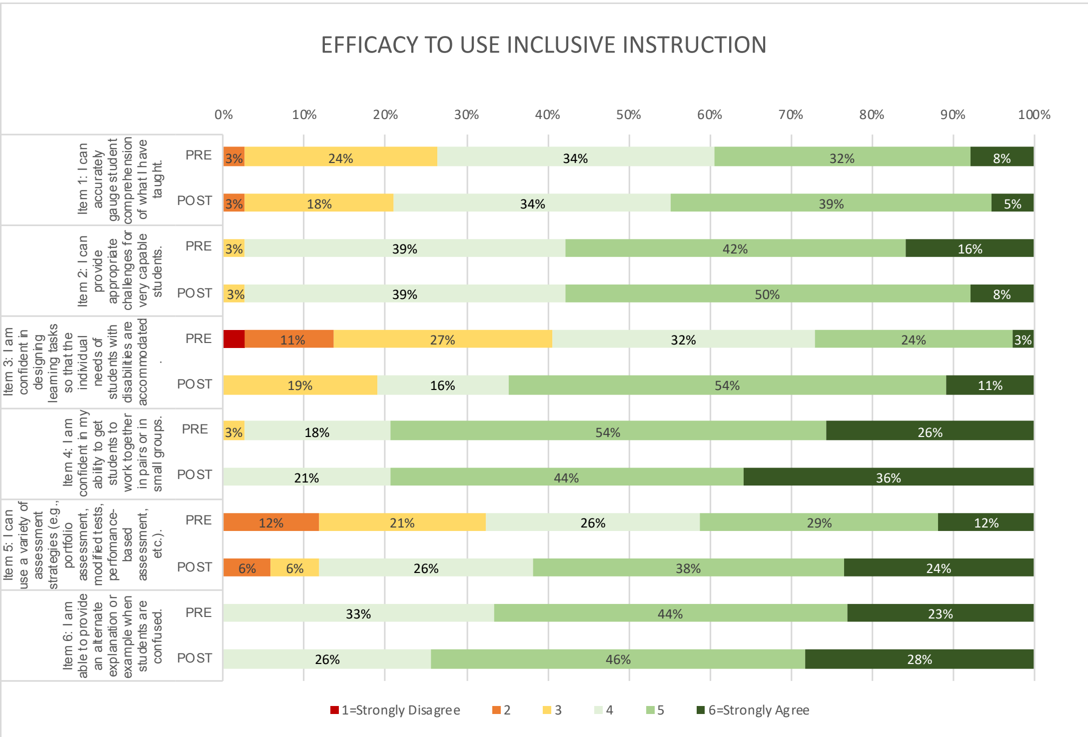

Figure 3. Results of the individual items of the subscale "efficacy to use inclusive instructions".

Breaking down the subscale into individual items shows that the teacher students could particularly gain confidence in designing learning tasks that consider the individual needs of students (item 3) and in using various assessment strategies (item 5, see fig. 3). This increase of self-efficacy when teaching chemistry in an inclusive setting, might be a reason why the pre-service teachers' concerns have decreased significantly (see fig. 2). Additionally, it can be observed that teacher students' efficacy in interdisciplinary collaboration (2nd subscale TEIP, α=.88) has increased significantly (N=39, M_{pre}=4,17, M_{post}=4,58, t=-3.481, p<.001, d=0.56) after attending the course. Furthermore, the analysis of the sample generally shows a rise in pre-service teachers' estimation of their efficacy in managing disruptive behaviour (3rd subscale TEIP, α=.83) after attending the course, to a statistically not relevant degree though (N=39, M_{pre}=4,53, M_{post}=4,64), t=-1.572, p=.124).

CONCLUSION

The results of the study show that through participating in the course pre-service chemistry teachers learned new approaches and gained insights into planning and teaching chemistry in an inclusive way. They were also able to develop a positive attitude towards inclusive chemistry education as well as towards their own roles as instructors in this process (i.e. Schlüter & Melle, 2018). As the sample was rather small, the quantitative data has to be interpreted carefully and it is necessary to link it closely to the results of the qualitative data in order to be able to evaluate the actual effectiveness of the course or parts of the course. Although the students have studied chemistry-related challenges of inclusive chemistry intensively during the course, their practical knowledge and competences are limited to the safe and protected environment of university education. Therefore, further studies must evaluate whether and how students can implement these competences and attitudes they have acquired at university in real, day-to-day situations when teaching chemistry in an inclusive way. Finally, the results and consequences of the whole project must be transferred to other universities in terms of multiplier-trend. Thus, this project may be seen as a relevant step towards inclusive chemistry didactics.

ARE WE PREPARING TEACHERS FOR INTERDISCIPLINARY PRACTICE? A LOOK TO THE PRESERVICE CHEMISTRY TEACHER EDUCATION IN BRAZIL

Fabiana Ocampos[1], *Gildo Girotto Jr.*[2]
[1]State University of Campinas, Campinas, Brazil
[2] State University of Campinas, Campinas, Brazil

The official documents regarding secondary and higher education in Brazil outline the importance of practices related to contextualization and interdisciplinarity in initial teacher education. In this scenario, formative activities have been implemented in the curricular structure of the initial teacher education that aims to approach specific contents, teaching practices, and aspects related to contextualization and interdisciplinarity. One of the primary curricular changes involves the implementation of the so-called Practice as a Curricular Component (PCC), to articulate knowledge and to provide the transposition of the pedagogical knowledge to teaching-learning situations. In this work, a survey was made of how actions related to practices associated with contextualization and interdisciplinarity have been implemented, to recognize in which context these actions are developed. We verified that most of the activities occur in non-curricular practices. Also, the PCC is practically absent about contextualized and interdisciplinary training proposals.

Keywords: Context-based Learning, Preservice Teacher Education, Science Education Policy

INTRODUCTION

There are several ways to approach the concepts of interdisciplinarity and contextualization in teaching, and there is no consensus on its definition. For interdisciplinarity, Lenoir and Hasni (2004) point out the existence of different concepts: francophone, oriented to a work of epistemological reflection; the anglophone American, which has an instrumental perspective ("know-how") and the Brazilian concept with a subjective logic and privileges the human and affective dimensions. The contextualization considers education as one that promotes critical thinking so that students can use the scientific knowledge to understand reality, to transform it, and, in this way, an education that promotes citizen participation in decision-making.

The official documents related to education in Brazil reflect the importance of the theme. About the teachers in training, the profile of the graduate students must be "...based on principles of interdisciplinarity, contextualization, democratization, pertinence and social relevance ..." (Brasil, 2015, p.7).

In this perspective, public policies have been implemented through teaching training programs and curricular changes to favor the development of professional knowledge. These include two proposals: PIBID (Institutional Program for Teaching Initiation Scholarships) and PCC (Practices as a Curricular Component) and these are practices that enable a contextualized and interdisciplinary work.

The first offers teaching initiation scholarships to undergraduate students who, under the guidance of a university teacher and the supervision of a secondary teacher, are dedicated to teaching and teaching-related activities in public schools. Although this program was implemented in 2008, it is intermittent, and each implementation lasts years and a half on average.

The second is part of the curriculum of undergraduate courses, corresponding to a total of 400 hours, and its goal is to articulate different practices to provide the transposition of specific knowledge for teaching-learning situations. The PCC may occur throughout the training course and may be applied from the first semester and distributed into specific subjects or subjects designed for this purpose. As part of the curriculum of all courses, this program includes all undergraduate students.

Considering different practices that exist in teacher training courses and that it is a viable path for the development of contextualized and interdisciplinary activities, the present work seeks to raise data and interpretations of how the contextualization and interdisciplinarity are present in the initial training courses of chemistry teachers of Brazilian Educational Institutions. For this, we analyzed the works on the subject, published in congresses and journals on teaching science in the Brazilian scenario.

METHODOLOGY

This paper presents itself as a qualitative research (Bogdan & Biiklen, 1994) and was carried out from the reading and categorization of papers presented in two Brazilian congresses (National Meeting of Science Education Research and National Meeting of Chemistry Teaching) and six journals whose theme is science or chemistry teaching (Electronic Journal of Science, Science and Education, Journal Essay, Research in Science Teaching, New Chemistry at School and Brazilian Journal of Science Education Research).

The research was implemented using the keywords contextualization, interdisciplinarity, and practice as a curricular component, for works published from 2013 to 2018. After searching for the keywords, we proceeded to read the abstracts, and the articles dealing with contextualized or interdisciplinary practices in the initial training courses of chemistry were read in full. The analytical treatment of the information was the categorization of the texts. Text Categorization consists of classifying texts by thematic categories based on a predefined set, and it is possible to incorporate new classifications throughout the analysis (Sebastiani, 2002).

RESULTS AND DISCUSSION

As noted earlier, a literature review was performed, which resulted in a total of 297 works. As an initial filter, we selected the works related to the initial formation of chemistry teachers. For categorization, we decided for mixed categorization, with a priori and a posteriori categories. The categorization resulted in 55 papers related to interdisciplinary or contextualized practices developed in the initial teacher training course of chemistry.

Table 1 shows the defined categories and the number of related works. It is noteworthy that the categories came from the curricular structure of the training courses, which subdivide the course into specific disciplines (chemistry in this case), pedagogical disciplines, practicum, training programs, or policies – PIBID, and practices developed in the PCC. Throughout the analysis, we noticed a set of works that were developed by research groups in the initial formation in different ambiances, defining this as a posteriori category.

Table 1. Works related to contextualized/interdisciplinary activities developed in the initial formation of chemistry graduates.

ACTIVITY	number of works
PIBID	27
Practicum	13
Research/study groups/workshops	9
Pedagogical disciplines	3
PCC	2
Not informed	1
Chemistry disciplines	0
Total	**55**

The results show that 27 (49%) of the papers presented refer to contextualized/interdisciplinary practices in PIBID, 13 (23.6%) in practicum, 9 (16.3%) in research groups, and 2 (3.6%) in the PCC. Surprisingly, we found no reports of work developed in the specific disciplines of the undergraduate chemistry course.

The largest number of published works refers to the activities developed in the PIBID, which is part of the National Teacher Training Policy of the Ministry of Education and aims to allow the students to experience the pedagogical practice in the school context in the first half of the course.

Among the 27 works that are part of this research, there are examples of using PIBID to develop contextualized practices with undergraduates, such as Maciel et al. (2017), who used the jigsaw cooperative learning technique to study the chocolate. The undergraduates studied various aspects related to the theme, such as cocoa and chocolate composition, its history, and production.

Some works aim to develop professional knowledge necessary for the contextualized work in the undergraduates. Silva et al. (2016) developed with the students a contextualized didactic sequence about oil for the teaching of hydrocarbons. The sequence was applied to the secondary students by the undergraduates. They also wrote a diary with considerations about the development of the work, in which they reflected on the stages of the process, from the planning to the reflection on the teaching practice.

Nogueira and Fernandez (2019) conducted a “state-of-the-art” study of papers presented in journals and dissertation and theses about PIBID, and report that the participation of undergraduates in the program “influenced the professional choice, contact with various teaching methodologies and the perception that the chemical contents should be appropriate to the school context” (p.10). Also have enabled “a critical and reflective training on the teaching practice, besides emphasizing that the studies directed to the structuring of the classes were fundamental for their development as students” (p.10).

From the quantity and content of the works, it is possible to infer that PIBID has been established as an important teacher training program in Brazil since its implementation in 2008, and contributes significantly to the development of the professional knowledge of undergraduates. However, the program does not include all undergraduate students, since the granting of scholarships depends on federal government-sponsored edicts and budget allocation, varying with the country's political and economic situation.

The second category with the largest number of works is the practicum, which constitutes a broad possibility for the development of interdisciplinary and contextualized activities since they are related to the intervention and performance of the future teacher in the real classroom setting. As they are compulsory subjects of the degree course, they include all undergraduates. Thus, the existence of works related to this category is considered positive.

As an example, Pena and Quadros (2016) used the practicum to develop didactic sequences with the undergraduates based on a textbook considered innovative and that uses generating themes, as opposed to traditional textbooks. The students prepared didactic sequences about water and the environment and had the opportunity to teach secondary students. The authors report that the discussions during the elaboration of the sequences generated conflict in the undergraduates due to the different proposals. However, these discussions have somehow influenced the practice of these undergraduates during the immersion to teaching and were important to their development.

Despite being a privileged opportunity for contextualized and interdisciplinary work, practicum depends fundamentally on teacher involvement, both on the part of the teacher educator at the university and the supervising professor at the school where the graduate will work. Thus, not all experiences achieve the expected result, which is the development of the professional knowledge of undergraduates.

Lopes and Falcomer (2015) report that some of the problems pointed out by students refers to the school structure that suppresses the availability of supervising teachers to work with undergraduate students. The secondary curriculum structure, which is fragmented, makes it difficult for teachers from different areas to work together and leads to a lack of willingness on the part of teachers to carry out contextualized or interdisciplinary work.

Regarding the PCCs, there is a low number of contextualized/interdisciplinary works, a fact that can be contradictory, since such practices enable the development of this type of activity, and, as a part of the curriculum, it involves all students. Its development can take place within specific chemistry disciplines or as a discipline that integrates others, such as pedagogical disciplines.

In this sense, the activities of PCC would enable the integration between pedagogical, chemical and other knowledge areas, in addition to knowledge related to teaching chemistry in basic education, thus promoting the reflective process in the undergraduate student, surpassing the model based on the segregation between specific and pedagogical knowledge, whose character was too theoretical (Saviani, 2009). It is observed, however, that although the reformulation was implemented in 2002, there is still a great difficulty for its effectiveness.

When discussing the training of higher education teachers, Pereira and Mohr (2017) observe that the majority of teacher educators feel unprepared for teaching and the development of PCC activities, since their training took place to privilege specific knowledge over the integration of theory and practice, present in the current model.

The PCC involves a clear intersection between specific content and pedagogical content, which means that it must be conducted by professionals who can work in these two spheres of professional knowledge. Thus, for its implementation, the teacher training process must be stimulated, so that they can develop in students the professional knowledge necessary for their performance when they become teachers.

In the Brazilian scenario, in general, the teachers responsible for the pedagogical disciplines have training in pedagogy or similar areas and may not have the theoretical framework of the specific discipline to carry out this articulation. On the other hand, teachers responsible for chemistry subjects often lack pedagogical training and, therefore, are not formally prepared to carry out this articulation (Viveiro & Campos, 2011). On the other hand, some reformulations in the guidelines have been carried out in several undergraduate courses to address this issue, and, in several courses, subjects such as an internship or other subjects of a pedagogical nature have already been taught by teachers with specific training.

Although all articles have highlighted the importance of contextualized work, the scenario chosen for its development is almost always dissociated from the specific subjects of the course, and pedagogical subjects. The task of interdisciplinary and contextualized work is delegated to the practicum or non-curricular proposals such as PIBID and study groups, and not to specific chemistry subjects. As an example, most works with this characteristic occur in activities not related to the course curriculum (65.3%) - PIBID, study groups, and thematic workshops.

Among the few works developed in pedagogical or specific disciplines, Sampaio, Bernardo, and Amaral (2016) bring an interesting proposal to the contextualized work in which the authors used the methodology of the study cases with undergraduate chemistry students in the discipline of pedagogical practices. The topic studied was the implementation of a thermoelectric plant, which was in vogue at the time in the State of Pernambuco, where the university stays. The authors point out that students understood the various scientific concepts related to the theme, such as combustion, energy conversion, physical transformations, environmental issues, among others. Also, they developed argumentative and critical skills when positioning for or against the installation of the plant.

Another example is the work developed by Barros, Bittencourt, and Volpato (2016) in which they discussed why different soils present different colors. They used bond theories as theoretical support. They discussed the limitations of the Valence Bond Theory and the applicability of the Crystal Field Theory to explain soil colors since the colorful minerals have a metallic center in their structure.

The authors noted that there was an increase in students' understanding of the topic and reported students' satisfaction in working with the concept in a contextualized way. One caveat of the authors regarding the work done was the lack of time to accomplish activities such as reading texts and carrying out experiments, which could contribute even more to the learning of the theme.

This approach uses an everyday theme (color of different soils) to work on complex concepts (Valence Bond Theory and Crystal Field Theory), and allows, in addition to theoretical classes, experimental activities. Thus, it could be used in the specific discipline of the course in which these bonding theories are taught; however, it was carried out in a study group with a small number of undergraduate students.

Reading the selected articles shows that none of the works proposed contextualization as a part of the specific subjects of the course (General, Organic, Inorganic, Analytical, Physical Chemistry, or Biochemistry). The closest to this scenario involves collaborative work between different teachers, including technical and pedagogical disciplines. This fact highlights the difficulties of educators themselves about working with contextualized chemistry classes, which is reflected in the reproduction of technical classroom models (Viveiro & Campos, 2011).

CONCLUSIONS

The official documents of basic and higher education in Brazil point out the importance of teacher training with a focus on interdisciplinary and contextualized work. All the works analyzed consider these aspects important. However, the development of activities rarely occurs in the chemistry disciplines, and most of the works delegate the task of interdisciplinary and contextualized work to the disciplines of practicum and extracurricular proposals.

The insertion of the PCC in the initial training courses represents a (theoretical) progress regarding the previous model and a possibility for the promotion of contextualized and interdisciplinary actions. We emphasize, however, that there is a need to better structure this training component, especially about the educators (teachers who work developing the PCC).

In principle, it is necessary to implement the practice as a curricular component within the scope of specific disciplines. Subsequently, proposals related to contextualization and interdisciplinarity in these same disciplines must be incorporated.

The change in the curricula of undergraduate courses represented a major advance in the initial training of teachers. It is now up to the teachers the challenge of overcoming their limitations, promoting meaningful learning for undergraduate students. Also, it is necessary to overcome the model for implementing innovative proposals only in activities different from specific disciplines.

There are already programs, albeit incipient, for the pedagogical training of teacher educators (initial and continuing education) at Brazilian universities. It is necessary to improve these actions, as well as the investigation of their impacts. Also, it is possible to implement joint actions between teachers in the field of education and the field of chemistry, expanding the scope of knowledge of teachers.

The impacts of new regulations and programs on education must be investigated in the long term. Although there are gaps to be addressed, an increase in proposals that involve interdisciplinarity in Brazilian secondary education has been observed in the literature (Lamego & Santos, 2017). Thus, investing in new teacher training actions can further contribute to the expansion of these proposals.

EXAMINATION OF PRE-SERVICE PHYSICS TEACHERS' PROBLEM SCOPING IN ENGINEERING DESIGN PROCESS OF A STEM PROJECT

Fatma Caner[1], *Feral Ogan-Bekiroglu*[2]
[1]Marmara University, Istanbul, Turkey,
[2]Marmara University, Istanbul, Turkey,

STEM is an interdisciplinary field of science, technology, engineering and mathematics. Engineering design process has a crucial role to integrate STEM effectively because it supports many opportunities for the students. It includes a real-world context for learning science and maths by using high-level thinking and problem-solving skills. STEM student competencies are key elements in the engineering design process. One of these STEM student competencies is problem scoping. Problem scoping is a skill that designers need to learn and practice to be effective. The aim of this study was to examine pre-service physics teachers' problem scoping in Roller Coaster STEM activity. For this purpose, STEM approach was conducted with a total of 16 pre-service physics teachers in a state university during one semester. Multiple case study design was carried out for this research. Activity papers and project presentation video records of the pre-service physics teachers were analyzed. Findings showed that they highly focused on the materials to be used in the activity. Most of the pre-service physics teachers did not focus on energy conservation equations on problem scoping and they jumped to the solution of the problem or prototyping.

Keywords: Engineering design process, STEM, pre-service teachers.

INTRODUCTION

Nowadays, STEM education is one of the most intriguing educational movements (Sanders, 2009). It is an interdisciplinary field of science, technology, engineering and mathematics (Bybee, 2013). "STEM education" has become a commonly-used term in K-12 education and there are some definitions of STEM based on the content. Bybee (2013) points out that STEM education integrates all the four disciplines and engineering design process to promote problem solving and innovation. Another definition of STEM education belongs to Moore and his colleagues (2014). In their opinion, integrated STEM education is a curriculum design that combines all or some of the STEM disciplines into the lesson by using real-world problems. On the other hand, Kelley and Knowles (2016) argue that integrated STEM education is an approach to teaching STEM from two or more STEM disciplines through an authentic context.

Engineering is a challenging situation for integration for many science teachers. A lack of knowledge about engineering confines teachers' and pre-service teachers' efforts to integrate engineering in to their science teaching (Guzey et al., 2014). Guzey and colleagues (2019) suggest that more research is required to identify effective examples of integrated engineering design process. According to Purzer and Shelley (2018), STEM competencies are key elements in the engineering design process. These competencies are problem scoping, evidence-based decision making, idea fluency, engineering ethics, process awareness, and technical communication and teamwork.

The current study presents findings from pre-service physics teachers' problem scoping in engineering design process. The research question guiding this study was as follows: How do pre-service physics teachers refine a problem as a problem scoping competency in engineering design process?

Problem scoping means developing a problem statement from the perspectives of stakeholders and refining the problem statement as additional information found through the process of design (Purzer and Shelley, 2018). Because engineering design problems are complex and problem scoping can be a key factor for a better understanding of the engineering design process. Atman and colleagues (2009) created a model in their work to better understand the design process. In this model, as shown in Table 1, there are definitions for design activities and stages. According to this model, the problem scoping includes the process of defining the problem and gathering the information necessary for the solution of the problem.

Table 1. Definitions for design activities and stages. (Atman, Deibel and Parnell, 2009)

Stage	**Activities Involved**
Problem Scoping (SC)	Problem Definition, Gathering Information
Designing Alternative Solutions (DAS)	Generating Ideas, Modeling, Feasibility Analysis, Evaluation
Project Realization (PR)	Decision, Communication
Design Activities	
Activity	**Definition**
Problem Definition (PD)	Defining the details of the problem
Gathering Information (GATH)	Collecting information needed to solve the problem
Generating Ideas (GEN)	Thinking up potential solutions (or partial solutions)
Modeling (MOD)	Detailing how to build a solution or parts of a solution
Feasibility Analysis (FEAS)	Assessing possible or planned solutions
Evaluation (EVAL)	Comparing two or more solutions within constraints
Decision (DEC)	Selecting one idea or solution
Communication (COM)	Revealing and explaining design elements to others

In detail, problem scoping occurs both at the beginning of the design process, when designers do not have specific solutions in their minds and when they redefine the problem while developing the solution. According to Watkins and her colleagues (2014), problem scoping includes more than listing criteria and information, it includes prioritizing and integrating different aspects of the problem so they argue for the importance of attending to the following features in students' problem scoping:

1. Naming: Identifiying the different constraints, criteria and pieces of information in a problem
2. Setting the context: Considering interactions among problem requirements and prioritizing different components in a problem
3. Reflecting: Acknowledging and evaluating the problem in detail.

Although research in the literature explains what needs to be done to determine the problem scoping in the design process, there is still a comprehensive question that needs to be addressed:

In what ways do pre-service physics teachers evaluate the problem scoping? How do they make this evaluation individually and in groups?

METHODOLOGY

Document analysis, a qualitative research method, was used in the process of examining the problem scoping of physics teacher candidates. Bowen (2009) defines this research method as the researchers interpreting and making sense of the documents related to the study systematically. According to Bowen (2009), this method includes thematic coding of the content of the document as in the analysis of the interview copies. In this study, STEM activity papers were used as data collection tool. Activity papers include the daily life problem as well as what should be known to solve this problem and what resources should be used to solve the problem. The answers given by pre-service teachers to the questions on the activity sheet were coded by open coding method and thematic frames were created. Frequencies and percentages of the categories were calculated based on the responses of the participants. The answers of all participants were coded and compared by another researcher. The researchers agreed about 90%, and the agreed results were shared after the differences of opinion were clarified by the method of mutual discussion. In Table 2, all categories of problem scoping of physics teacher candidates are presented. In Table 3, the problem scoping processes of physics teacher candidates in individual and group are presented in more detail. The participants were 16 pre-service physics teachers enrolling in a state university and all of them were female. The participants experienced engineering design based challenges and STEM design challenges by doing the following activities: making the highest tower with spaghettis, my soup does not get cold, my egg does not break, cars that are made with balloons. For the last activity, pre-service physics teachers were asked to design a safe and fast roller coaster with at least two loops with using one-meter long foam insulation track, two different marbles, masking tapes, timer, and metric ruler. In the activity, the problem was to design a roller coaster section that would allow a coaster car (marble) to travel at a high speed without going off the track. The pre- service physics teachers were expected to investigate the roles of both kinetic and potential energy in determining the speed that the roller coaster cars could travel and experiment to determine the effect of the starting hill height and loop diameter on the performance of the roller coaster. When viewed in the all process, the participants identified the problem, defined what was given in the problem, produced possible solutions, developed a prototype to show their solutions, and received feedback from their classmates.

To examine their problem scoping process, K-W-S (What I **K**now- What I **W**ant to Know- What **S**ource I Need) chart was used for each participant from their documents. Findings are composed by comparing these K-W-S charts in individual or in group. Firstly, the pre-service teachers filled K-W-S charts individually after explained the daily life problem situation. They stated what they knew about the problem, what they wanted to know and the method of research for problem solving. They repeated the same procedure after discussing with their group peers. They presented their processes as a group.

RESULTS

In this study, which aimed to determine the problem scoping in the engineering design process of the physics teacher candidates and to reveal the differences of individual and group work in creating a problem scoping, the K-W-S charts were examined. By comparing all K-W-S charts, 175 codes were determined and linked to the related frames. The results of coding were shown in Table 2 with their frequencies and percentages in response to the first research question. A coding scheme of six frames was developed to characterize the extent of the design problem scoping. The definition of each frame was made as shown in Table 2. For example, the design frame included engineering and design related words and decisions about having design. Considering the determined the frames and their percentage, design was the second lowest value among other values for the pre-service teachers. This issue may show us that teacher candidates needed to gain a designer perspective. On the other hand, the participants ignored the limitations, although one of the most important points for solving the given problem was to consider limitations. They solved the problem by trying over and over again.

Materials frame was related to prototype materials that could be used to solve the problem. The pre-service teachers focused on what the materials of the problem were, but not on the properties of the materials or the differences of the materials. Because prospective teachers examined sample STEM projects on the internet, they focused on whether the materials in that project existed. For example, marbles with two different surfaces were used in the STEM activity. One of them had a rougher surface and the other one had a more slippery surface. They noticed that these marbles had different surfaces in the testing section of the engineering design process. This issue was also one of the limitations in the solution of the problem. Teacher candidates were expected to create at least two loops and to travel safely with two different marbles in STEM activity. For this reason, teacher candidates should be enabled to focus on their own materials and problems.

In the process of problem scoping of teacher candidates, physics concepts were the most mentioned 43.29% in K-W-S charts of activity. These concepts were energy (kinetic and potential), velocity, acceleration, friction and centripetal force respectively. But unfortunately, most of the pre-service physics teachers did not focus on energy conservation equations on problem scoping and they jumped to the solution of the problem or prototyping.

Although safety was part of the design, it was considered as a separate frame. The pre-service physics teachers made many attempts to reach a solid or strong structure. Finally, resource of their research frame was formed by utilizing the section I in the K-W-S chart. In order to solve the problem, the pre-service physics teachers identified the use of resources as searching the internet, collaborating with friends, looking at exemplary STEM studies, reasoning, applying mathematical modeling and applying trial and error method. However, attention should be paid on resource use. Doing internet research limited creativity and it brought limited use of the material. Because teacher candidates focused on the materials of exemplary projects they saw on the internet.

Table 2. Definitions of frames, descriptions, frequency and percentage used during the coding process.

Frame	Description	Frequency	Percentage %
Design	Engineering vocabulary, design issues, decisions about having design.	14	8
Materials	Prototype materials to be used to solve the problem	15	8.57
Physical Concepts	Emphasizing the concepts of physics such as velocity, friction, centripetal force and acceleration etc.	74	43.29
Safety	Durability of the structure or track.	24	13.71
Awareness of Limitation	Be aware of restrictions such as number of loops, velocity of the marble etc.	6	3.43
Resource of their research	Determination of resources of the research to find the solution of the problem.	42	23

Table 3 provides more detail about pre-service physics teachers' problem scoping. This table was prepared for the answer to the second research question. With this table, it is tried to reveal the way of the pre-service teachers' creating problem scoping as individual and in a group.

For instance; P-1 (Pre-service physics teacher-1) stated that she needed to minimize the friction force in relation to the daily life problem and she had to ensure the safety of the ball. She wanted to know how to guide the balls. She emphasized that she would conduct relevant research on the Internet. After talking with her group friends, she stated that she would solve the problem by taking into account the friction force. The P-1 and her group mates did not solve the problem for the two different marbles because they thought that the friction force should be low in their problem scoping process. They noticed this situation in the testing process and they made corrections in the evaluation process. Furthermore, P-1 and her group peers did not have any calculation for the roller coaster by using energy conservation equations. They used only trial and error method. If we evaluate the process over the codes, it is seen that P-1 first focused on the concepts of physics and then safety issues. In setting the context, the same participant only considered the design. However, at the end of the group study after the individual study, this participant took into consideration physics concepts, design and safety issues in reflecting period and turned the focus of design as well as the material to solve this problem. The processes of the other participants were presented in the table as in the logic of coding.

There are two issues that are appropriate to address. When we look at the participants of P-3 and P-10, while taking AL (awareness of limitations) individually into consideration, it was not included in the problem scoping in group work. In addition, the participants of P-10, P-11 and P-14 ignored the design in the group work while individually adding the design to the problem scoping. In other words, when it came to group work, some individually conceivable points can be bypassed. The teacher candidates may not have been able to defend what they thought individually.

Table 3. Pre-service Physics Teachers' Frames for Problem Scoping in K-W-S Charts.

Participant	Individual (What I Know)- Naming	Individual (What I Want to Know)- Setting the Context	Individual (What Source I Need)- Setting the Context	Group (What I Know)- Reflecting	Group (What I Want to Know)- Reflecting	Group (What Source I Need)- Reflecting
P-1	PC-S	D	RM-RM	PC-D-S	M-D	RM
P-2	S-D	M	RM	PC- D-S	M-D	RM

Abbreviations in the table are as follows; PC= Physical Concepts, S= Safety, D= Design, M= Materials, AL= Awareness of Limitations, RM= Resource of Research

CONCLUSION AND IMPLICATION

It is thought that providing students with engineering design problems involving multiple disciplines and integrating different disciplines is one of the most critical points of STEM education (Wang, Moore, Roehrig & Park, 2011). Engineering design problems are tools for learning science and mathematics knowledge in STEM education and require an in-depth analysis of these problems (Kolodner, 2002). As stated by Guzey et al. (2014), design process is a challenging situation for integrated STEM for many science teachers. A lack of knowledge about engineering confines teachers' and pre-service teachers' efforts to integrate engineering into their science teaching. In STEM, we need such studies to understand the problem solving in the design process. For this reason, this study was carried out to examine the problem scoping of the prospective physics teachers in the STEM project and to determine their problem scoping in the individual and group work. As a result of these inferences, teachers can effectively integrate STEM into their lessons. Besides, students can use physics concepts to encourage different problem solving methods.

More than half of the pre-service teachers did not use physics concepts when describing the problem and they focused more on the engineering design process. However, it is recommended that engineering should be integrated with science, not as a separate design (Wang et al., 2011). However, this focus is mostly on the prototyping part of the engineering design process. This finding is not compatible with Capobianco and Rupp (2014)'s study. Because they argue that teachers devote most of their time to problem definition, linking with daily life, and solution suggestions, which are the first steps of the engineering design process.

On the other hand, collaboration is important in problem-based learning environments. Because each group member contributes to the process by generating different ideas for understanding and solving the problem (Hung, 2009). In this process, it may be appropriate to consider the different ideas of each of the students. As the existing steps in the individual studies of the students disappeared after the group work, individual activities can be done in addition to group work in STEM activities. Dayton (Ohio) Regional STEM Center (2011) published a framework for quality of STEM education and this framework includes ten components. One of the components of this framework is individual accountability in a collaborative culture. This component explains that quality STEM learning experiences often require students to work and learn independently and in collaboration with others using effective interpersonal skills. Individual accountability is a belief that each member of group is responsible for his/her performance (Laal et al., 2013). As Johnson et al. (1991) suggests, individual accountability is one of the five key elements of collaborative learning. Therefore, students can develop their belief that they are responsible for their work by working individually in STEM activities. In addition, pre-service teachers and in-service teachers can be given argument training to defend their own thoughts.

WHAT IT TAKES TO BE A GOOD SCIENCE TEACHER? PROJECT-BASED LEARNING AS AN IMPETUS FOR STUDENT-TEACHERS' PROFESSIONAL GROWTH

Dina Tsybulsky[1] *and Yulia Muchnik-Rozanov*[1]
[1]Technion – Israel Institute of Technology, Haifa, Israel

This study examines the way in which PBL contributes to the professional-identity development of novice science teachers, and the role of emotional experiences in this process. More specifically, we examine the science student teachers' expectations and emotionally intense experiences as well as the connection between the former and the latter. The data were obtained from the student-teachers' reflective reports (n=32) and were analysed utilising linguistic and non-parametric statistical analyses. The study points out that introducing the PBL approach in a pedagogical course may expose student-teachers to positive emotional experiences and leads to optimistic expectations, which tend to nurture the students' growing confidence as teaching professionals, and, consequently, enhances the development of students' professional identity creating a sense of professional self-efficacy.

Keywords: Teacher education, project-based learning, reflection

INTRODUCTION

The constant search for the best teaching methods by which to promote the development of science student- teachers' professional identity has always been a central issue when discussing teacher-education programs (Caires, Almeida, & Vieira, 2012). One of the most promising approaches is the integration of Project-Based Learning (PBL) into pedagogy and disciplinary courses (Marshall, Petrosino, & Martin 2010; Kokotsaki, Menzies, & Wiggins 2016).

The PBL approach has the potential to positively influence the development of student teachers' professional identity (Tsybulsky & Oz, 2019; Tsybulsky & Muchnik-Rozanov, 2019; Tsybulsky, Gateneo-Kalush, Abuganem, & Grobgeld, 2020). Positive and negative emotionally intense experiences during PBL process play an important role in student-teachers' development of professional identity (Tsybulsky & Muchnik-Rozanov, 2019; Timoštšuk & Ugaste 2012). Another significant yet largely neglected aspect of teacher identity development involves a future dimension of reflective discourse–student teacher expectations. Ursua and Vasquez (2008) view future-projected talk as an essential part of the identity-shaping process that student-teachers undergo. Such projective reflections tend to describe their personal perceptions of how the future events will possibly unfold, based on their current emotions and their professional knowledge and beliefs (Debreli, 2011).

The current study investigats student teachers' perceptions regarding their experiences accumulated while learning about the PBL approach and how these perceptions influenced the development of their professional identity. We focused on the following research question: is there a connection between emotionally intense experiences and student teachers' expectations.

We hypothesized that the greater the number of instances of positively perceived emotionally intense experiences, the greater would be the number of positive expectations and the fewer the number of negative expectations reported by the student teachers. Should our hypothesis be confirmed, we interpret the correlation as an indication that student teachers gained confidence and a sense of professional empowerment, as they began to perceive themselves as more professional and knowledgeable teachers, compared to heir self-perception at the beginning of the PBL. Hence, confirmation of this hypothesis would also provide an indication of the significant role that the PBL process has in stimulating the development of student teachers' professional identity.

METHODOLOGY

Context of the study

The participants of the study were 16 Jewish and Bedouin student teachers in their first year of studies towards the B.Ed. degree with a specialization in teaching sciences at the elementary school level. The sample consisted of men and women between the ages of 20 and 24 years, who resided in the country's southern region and came from a low-to-mid-level socioeconomic background.

The student teachers participated in a yearlong (two semesters) PBL process, which was experienced in the framework of a first-year pedagogical course, consisting of four weekly hours (a total of 121 hours over the course of the year). In addition, during the second semester, student teachers were enrolled in a practicum module, which took place in schools, for a total of six weekly hours (a total of 84 hours for the entire semester). The practicum presented them with the opportunity to implement what they had studied.

Research tools and data collection

The data were obtained from the student teachers' reflective reports submitted at the end of both the first and the second semesters, Overall, a total of 32 reports were analyzed. Participants were instructed to write their reflections in a completely free manner, without any guidance or structure, and to describe, their learning and teaching experiences, as they saw fit, while noting what they found significant, what they felt and thought during the learning process, the difficulties encountered, what they learned from the process, and what they would implement in their professional lives.

Data analysis

Data were analyzed utilizing a multi-level approach integrating linguistic analysis and quantitative non-parametric statistical analyses. Student-teachers' perceived experiences were grouped according to the following categories: (1) positive or negative emotional experiences; (2) prospective reflections conveying expectations.

(1) Experiences Perceived as Positive or Negative

The instances of positively perceived experiences were coded when the student-teachers' descriptions --of either their experiences teaching science classes using a PBL approach or their expectations regarding their professional future-- contained expressions (mainly clauses) using words with a clearly positive connotation. In the context of the present study, a positive connotation refers to positive associations and subjective feelings evoked by a particular word (i.e. an associative, subjective, or affective meaning attributed to a word). A negative connotation refers to an undoubtedly negative feeling evoked through the associative, subjective, or affective meaning attributed to a word. Instances of positively perceived experiences were observed when the student-teachers wrote. “I liked learning”, “I learned a lot about myself”, “I was able to cope well with the study materials”, “I'm feeling very optimistic”, “That's extremely encouraging”, “I'm already able to work much more independently”, etc. Instances of negatively perceived experiences were observed when the student-teachers wrote: “I feel like I'm trying but still not succeeding”, “I found it difficult to answer the question”, “I felt like there were instances in which I began to feel stressed and sometimes I lost my sense of direction”, “Sometimes I felt a bit frustrated', etc.”.

Based on the systemic functional linguistic theory, certain adverbs indicate higher or lower intensity and may convey intensification by emphasising quality of experience. Such intensifiers may be “interpersonally” neutral (e.g., very, much, quite, really, completely, utterly, almost, etc.) or “ derive from some interpersonally significant scale (amazingly, awfully, unbelievably, perfectly, etc.)” (Halliday and Matthiessen 2004, p. 356). The effect of intensification can also be achieved through lexical reiteration, i.e. repetition of a particular lexical item in order to emphasise a given point (Halliday and Matthiessen 2004). We viewed the use of intensifiers as a means of expressing the student teaches’ emotions in reflective narrative as well as the markers of more emotional experiences than those described without the intensifiers. Descriptions were coded as conveying more emotional experiences (both positive and negative) when any intensifier was used regardless of its interpersonal quality, or when certain lexical items were repeated within a span of five adjacent clauses. When the description of perceived experiences did not include intensifiers or lexical reiterations, these instances were coded as unmarked emotional experiences. For example, instances of experiences perceived as more emotional were identified when the students wrote words such as *terribly*, *very, most, much, really, even more, indeed, a lot, so much, amazingly, plenty*, *more (than anticipated*), and *I can*. The following phrases demonstrate various types of intensifiers: “Each day I was happy to be a part of the school… In other words, my confidence and desire to be a teacher grew stronger from one day to the next” (the underlined phrase exemplifies the use of lexical reiteration to emphasize a point); “I am certain that I can stand in front of the class and I am absolutely certain that I chose the right profession” (the intensification via lexical reiteration as well as the use of the intensifier *absolutely*).

(2) Prospective reflections that convey expectations

Following Ursua and Vasquez (2008) we drew a distinction between retrospective reflection (a teacher’s reflection on a certain past action) and prospective reflection, which is seen as reflecting on an intended action. From Throughout the reflective reports, students' descriptions were coded as expectations of future experiences either when the future form of the verb was used (in Hebrew, these forms are characterised by inflectional morphology) or the present tense was used to convey a sense of something to come. The following are examples of phrases coded as expectations of future experiences: “My positive feelings will increase”, “I will continue to face challenges”, “I have no intention of being easy on myself”, “Pedagogy lessons will continue to provide me with tools", "I will be able to conduct a lesson in the classroom", "I will enjoy myself as much as possible", etc.

The frequency of the variables examined was calculated using Spearman's one-tailed correlation test. In particular, correlations were tested between the number of positive/negative emotionally intense perceived experiences (i.e., Working on this project was a *very significant* part of the deep understanding gained of this fascinating profession and therefore ,it opened up a very broad perspective for me'), and the number of positive/negative expectations (i.e.,'I'll continue to face challenges successfully, I'm not going to give up, the pedagogy lessons are going to provide me with various tools').

RESULTS AND DISCUSSION

Reports and descriptions of emotional experiences included both positively and negatively perceived experiences. It was found that emotional experiences (both with and without the intensification) were mostly viewed as positive (88% in the middle of the year, and 92% in the year's end). Table 1 contains a summary of the types of perceived experiences and examples excerpted from the collected data.

Table 1. Examples of Positive and Negative Emotional Experiences.

Emotional Experiences	**Examples with Intensification via Adverbs**	**Examples with Intensification via Lexical Repetitions (reiterations)**
Perceived as Positive. Midyear: 88%. End of the year: 92%	Working on this project was a *very significant* part of the deep understanding gained of this fascinating profession and therefore ,it opened up a very broad perspective for me. (Natalie) There's no doubt that as the year continued, this course contributed *a great deal* to my pedagogical knowledge and was enriching .But more than anything, I found an answer to the question: what does it mean to be an excellent teacher? (Valerie)	*I felt* that the atmosphere in the classroom had changed and *it felt* much better! *I feel* that my confidence is higher after the course: despite having come to realize just how complicated this profession is, *I feel* that I have received numerous tools for coping. (Shira)
Perceived as Negative Midyear: 12%	Before I began studying, I had *lots of* fear, for example: how would I manage to stand in front of the class? (Hanina)	I *was terribly afraid* that I would fail; I *was afraid* that I would not manage to cope in front of an entire class of

End of the year: 8%	students and managed to convey the lesson properly. (Eden)

Findings indicated that student-teachers described mostly positive expectations regarding their professional future, both at the midyear point (72%) and at the end of the year (85%). Their positive expectations, conveyed both through the content of the narrative and by means of linguistic markers, concerned their desire to continue studying and developing on their way to becoming educators in the meaningful sense. Negative expectations were related mostly to anxiety regarding the challenges they would encounter in the classroom and how they would manage the students. Table 2 includes descriptions of positive and negative expectations.

Table 2. Examples of positive and negative expectations.

Prospective Reflections that Convey Expectations	**Examples**
Positive	I want to continue to study and develop, so I can *become* an excellent teacher. (Eden)
Midyear: 72%.	The course's helped me acquire skills that I will continue to *apply* in the. (Iman)
End-of-the-year: 85%	I expect to *continue* learning new things, to acquire additional tools for coping with issues that are important to emphasize in teaching and in forming my professional persona. (Inna)
	I am certain that everything I have learned in this course *will provide* numerous advantages in the following years and in the future. (Natalie)
Negative	I'm afraid that I *won't be able to handle* the students in terms of discipline. (Ya'ara)
Midyear: 28 %.	I am anxious because --what if I *don't succeed* in becoming a significant teacher? (Valerie)
End-of-the-year: 15 %	I worry that I *won't find the time* to prepare the lessons and about how I will perform in classroom. So far only a student of education who still doesn't have all of the tools. (Jabri)

Our findings revealed a significant correlation ($p < .01$) between described emotionally intense experiences and positive expectations. In particular, the high frequency (88% and 92%) of the positively perceived emotionally intense experiences correlated with a higher frequency (72% and 85%) of positive expectations. Thus, also the third hypothesis was confirmed. Moreover, a significant negative correlation ($p < .01$) was found between positively perceived emotionally intense experiences and negative pessimistic expectations. In other words, the high frequency (88% and 92%) of the positively perceived emotionally intense experiences correlated with a lower frequency (28% and 15%) of pessimistic expectations. These correlations were found at the midyear point, as well as at the end of the academic year.

A major implication of this finding is that the high number of emotionally intense experiences that student teachers garnered throughout the process of PBL learning contributed to more optimistic and positive feelings regarding their own future as teachers and reflected a better understanding of just how meaningful PBL process may be for the learners. This way, feeling more hopeful towards the completion of the PBL process points to student teachers' gains in confidence and a sense of professional empowerment, as they start perceiving themselves as professional and knowledgeable teachers. Moreover, relying on the existing literature, positive emotions tend to be associated with implementing more effective pedagogical methods (Ruthig et al., 2007; Trigwell, Ellis & Han, 2012). As our findings revealed, implementing PBL pedagogy, one of the most promising methods in teacher education, resulted in student teachers' positive perceptions of the learning process they underwent.

It should be mentioned that only recently has professional research begun to focus on student teachers' emotional experiences (Anttila et al. 2016) and only a few studies have examined this aspect in the context of shaping professional identity through project-based learning of pedagogical courses (Tsybulsky & Oz, 2019; Tsybulsky & Muchnik-Rozanov, 2019). The current study sheds light on the emotional aspect of the perceptions of the PBL-related experiences and its impact on the student teachers' professional identity. Our findings can contribute to current and future studies on the process of preparing preservice teachers through student-centered, inquiry-based learning approaches such as the PBL. We suggest that this process has the potential to expose student teachers to positive emotional experiences, which are linked to the kind of optimistic expectations that tend to underlie the students' growing confidence as teaching professionals. In turn, these gains in self-confidence reflect the shaping of the student teachers' professional identity, as they learn to view themselves as increasingly confident and knowledgeable teachers. It appears that investigating student teachers' emotional experiences is worthwhile, particularly in the context of understanding student teachers' identity construction and, hence, it is recommended as a direction for further research.

BECOMING A CHEMISTRY TEACHER – EXPECTATIONS FOR CHEMISTRY EDUCATION COURSES

Sabine Streller[1], *Claus Bolte*[1]
[1]Division of Chemistry Education, Freie Universitaet Berlin, Germany

The development of professional competence is of major importance for each education student and ultimately, for the entire education system. Therefore, optimising the learning processes of these students is a goal of professional development at the university level. Learning processes are influenced by the prior knowledge, beliefs and expectations individuals hold. Gaining insights into student beliefs and expectations should provide an opportunity to optimise their university courses. To acquire insights in these beliefs and expectations, we used a questionnaire with open questions. We developed a category system based on the COACTIV model of professional competence, with which we categorised all statements given on the questionnaire by the 168 students (BA/MA). The students assume the most important influence on their future profession is whether they have self-related ability cognitions, but they do not expect to develop such cognitions in their university courses. As a consequence of the results, the Division of Chemistry Education is now offering students authentic learning situations with real pupils. This approach provides the chance for the students to try out the teacher role and reflect upon their first teaching experiences. They can revise their image of this role and obtain a realistic view concerning their future profession.

Keywords: professional competence, chemistry education at university

INTRODUCTION

When young, in-service teachers retrospectively reflect on their university studies, a majority expresses a lack of adequate preparation through their courses for the job of teaching chemistry. Education students often experience chemistry (content knowledge, CK), science education (pedagogical content knowledge, PCK) and pedagogy (pedagogical knowledge, PK) as distinct areas in their studies – but the interaction of these areas is of major importance in supporting and enhancing their professionalism as future teachers (Shulman, 1986). The Division of Chemistry Education at FU Berlin tries to work against such student estimations: Firstly, by acquiring insights into the expectations and beliefs students have regarding their future profession and their science education courses. Secondly, by considering these expectations and beliefs in the science education courses to come and – if necessary – fostering a more realistic view of the future profession. Thirdly, by optimising the chemistry education courses to find a balance between subject, education, and the needs of the students (Streller & Bolte, 2018). In this contribution, we focus specifically on these student expectations.

Theoretical Background

In Germany, school education and teacher training is based on standards (KMK, 2004), which are important for study regulations at university. The standards define requirements to be met by teachers, the most important of which being: “Teachers are experts of teaching and learning. Their core task is the specific and scientifically reasoned design and reflection of teaching and learning processes. They should perform their educational role properly, undertake advisory and assessment tasks, and develop their skills continuously” (KMK, 2004, 6). In addition to these general tasks, more specific requirements for each subject in teacher education are described; in chemistry: basic knowledge in organic chemistry, inorganic chemistry, physical chemistry and biochemistry, as well as knowledge in chemistry education and practical teaching skills (KMK, 2008, 12). Finally, the standards describe an enormous catalogue of knowledge, skills, and motivational orientations teacher need to possess.

Beside the normative requirements teachers must meet, educational research about professional development investigates different factors trying to find effective ways to improve (science) education courses. Empirical educational research has investigated various aspects of the teaching profession to improve teacher recruitment and training (EC, 2013; Baumert & Kunter, 2013, 25). In the project COACTIV a model combining findings from various research perspectives was developed and empirically tested.

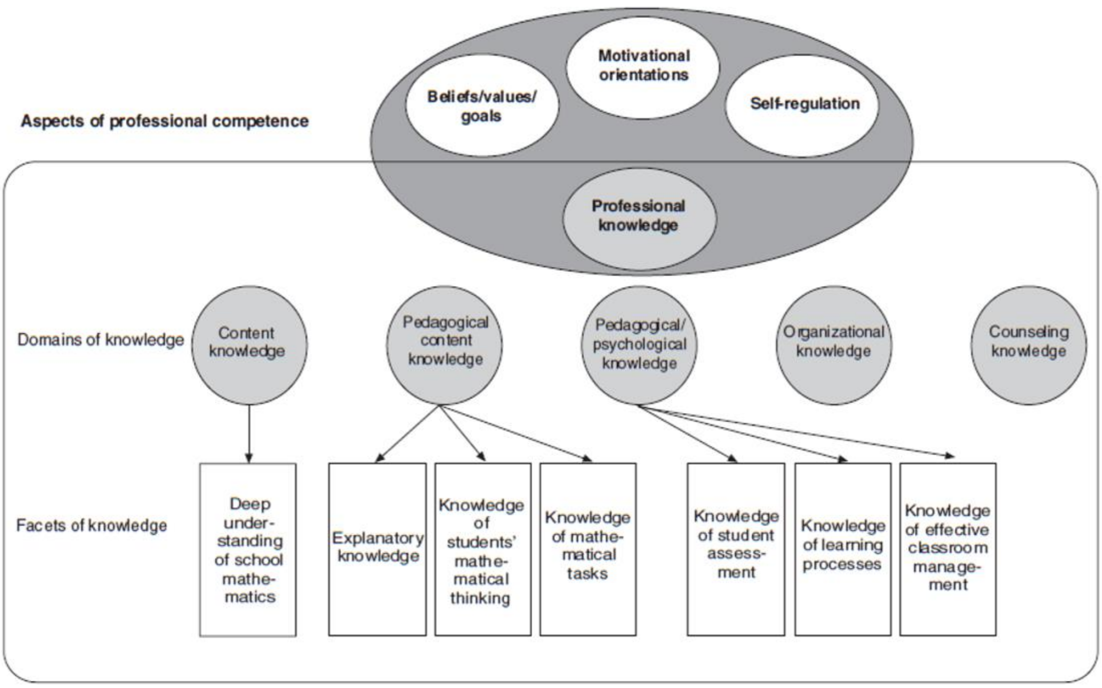

Figure 1. COACTIV model of professional competence in the context of teaching (Baumert & Kunter, 2013, 29)

This non-hierarchical model contains aspects, domains and facets of professional competence (such as knowledge and skills) in the context of teaching; the different facets (Figure 1) are operationalised by concrete indicators (Baumert & Kunter, 2013, 28). For example, an indicator in the domain of pedagogical content knowledge (PCK) and the facet of knowledge of tasks is knowledge of the cognitive demands and the prior knowledge that they implicitly require (Baumert & Kunter, 2013, 33).

Focusing on effective professional development research there are aspects like prior knowledge, beliefs and expectations of learners which have to be known as a starting point and basis for developmental processes because these influence each learning process. Professional development is no exception, but, *"too often the cognitive research on learning is forgotten when it comes to designing teacher's training"* (Loucks-Horsley et al. 2010, 53).

Research Goal

In our study, we wanted to find out what expectations and beliefs our students express regarding their future profession as teacher and what expectation they have for their chemistry education courses. Since learning processes are influenced by beliefs and expectations, we pursue the long goal, to optimise our chemistry education courses by taking into account the results of this study.

METHOD

To get an insight into the aforementioned beliefs and expectations, the university students were asked two questions in an open questionnaire:

1. What do you think is expected of you as a teacher?
2. What do you expect from your studies, especially from your chemistry education courses?

Since winter term 2012/13 168 students of the BA and MA programme took part in this study (table 1).

Table 1. Sample (number of students).

	Students				
	2012/13	2013/14	2014/15	2015/16	2016/17
Bachelor	37	26	18	29	-
Master	-	16	-	23	19

To categorize the answers we developed a category system based on the COACTIV model (Figure 1). The category system contains all aspects, domains and facets as well as the concrete indicators to operationalize the facets. The domains and facet form superordinate categories and for the sub-categories we mainly recourse to the indicators which specify the facets (table 3). We added sub-categories coming from the list of teachers' competence compiled by the European Commission (EC, 2013, 45f.) to differentiate the 1. facet of *knowledge of tasks* (practical skills), 2. aspect of *beliefs/values/goal* (disposition to team-working, commitment to promoting the learning of all students, critical reflection to one's own teaching), 3. aspect of *motivational orientation* (disposition to ongoing professional improvement). Furthermore, we added knowledge of experiments as a sub-category to knowledge of tasks. Experiments represent a special type of tasks in science lessons and should reflected in a separate categorie. Finally, our system contains 50 categories for question one and 53 for question two. The categorization proceeds with the program MaxQDA by at least two people to ascertain the inter-rater reliability (Cohens κ).

RESULTS

Both questions were answered usually detailed by the 168 students; 821 statements could be used for analysis of question 1 and 550 statements are the data source to investigate question 2 (Table 2). We will consider the results for both questions separately below.

Table 2. Number of statements (differentiated by question 1 and 2)

	Number of statements (question 1 and *2*)									
	2012/13		2013/14		2014/15		2015/16		2016/17	
Bachelor	182	*110*	123	*80*	72	*48*	153	*114*		
Master			79	*55*			123	*81*	89	*62*

Results regarding question 1 – expectations: teachers' role

530 statements of BA and 291 statements of MA students could be used for analysis (Table 2). Two people coded the statements to ascertain the inter-rater reliability; the value of Cohen's kappa is .79.

Table 3. Summarised overview of BA and MA students' statements reg. question 1: What do you think is expected of you as a teacher?

Aspect	**domain**	**facet**	**BA N_{St}=530**		**MA N_{St}=291**	
			Σ St	**%**	**Σ St**	**%**
knowledge	content knowledge (CK)		**48**	9.06	**24**	8.25
	pedagogical/psychological knowledge (PPK)		**8**	1.51	**5**	1.72
		general pedagogical knowledge of instructional planning	**26**	4.91	**18**	6.18
		knowledge of effective classroom management and orchestration	**56**	10.56	**27**	9.28
		knowledge of learning processes	**96**	18.11	**61**	20.96
		knowledge of student assessment	**22**	4.15	**14**	4.81
		prof. behavior in school context	**2**	0.38	**4**	1.37
	pedagogical content knowledge (PCK)		**7**	1.32	**4**	1.37
		explanatory knowledge	**80**	15.09	**27**	9.28
		knowledge of students thinking	**3**	0.57	**1**	0.34
		knowledge of tasks	**40**	7.55	**25**	8.59
		knowledge of experiments	**0**		**0**	
	organisational knowledge		**1**	0.19	**4**	1.37
	counseling knowledge		**9**	1.70	**10**	3.34
beliefs/values/goals			**99**	18.68	**47**	16.15
motivational orientation			**21**	3.96	**16**	5.50
self-regulation			**3**	0.57	**1**	0.34
global statements			**9**	1.70	**3**	1.03

Table 3 shows the distribution of the statements. Most statements of the BA students were assigned to the categories *beliefs/values/goals*, *knowledge of learning processes*, and *explanatory knowledge*. Most of the statements of the MA students were assigned to *knowledge of learning processes* and *beliefs/values/goals*. The greatest difference between both groups of students we find in the category *explanatory knowledge* (Δ = 5.81%).

Because so many statements were coded in the category *beliefs/values/goals* we provide a closer insight into this category (Figure 2).

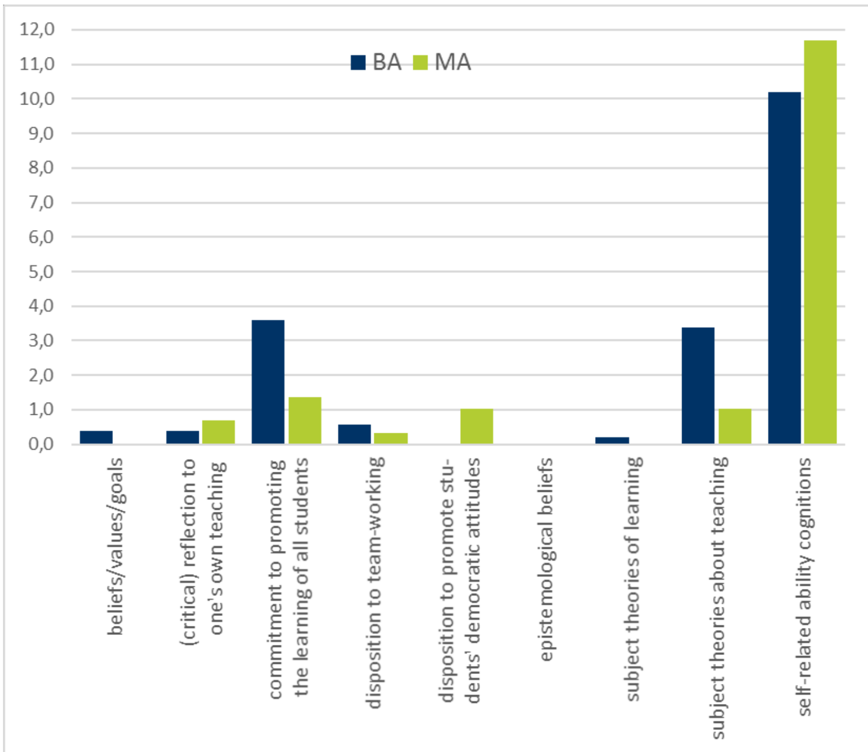

Figure 2. Aspect beliefs/values/goals – differentiated description in percent (N_{BA}=99, N_{MA}=47).

More than 10% of the statements (Table 3) belonging to the category *beliefs/values/goals* are coded in the sub-category self-related ability cognitions. Students express many attributions, such as: as a teacher I have to be patient, punctual, polite, a role model, industrious, always fair, likeable.

Results regarding question 2 – expectations: chemistry education

In light of the data, the category system for question 2 was adjusted accordingly by three categories (last three rows in Table 4). 352 statements of BA and 198 statements of MA students could be used for analysis (Table 2). Regarding question 2 the number of statements is less than for question 1 (550 < 821). Once more, the inter-rater reliability for this classification system was calculated, κ .68.

Most statements of the BA students were assigned to the categories *general pedagogical knowledge of instructional planning*, *explanatory knowledge,* and *knowledge of effective classroom management and orchestration*. Most statements of the MA students were assigned to the categories *requests on design/methods of seminars* and *general pedagogical knowledge* *of instructional planning.* Primarily MA students express particular wishes on the design of seminars. Regarding this aspect, we find the maximum difference between both groups of students (see Table 4). Altogether, the answers of MA students are more balanced over all categories (see Table 4). Both BA and MA students express their expectation to become familiar with a selection of feasible experiments and safety regulations although they do not mention experiments at all regarding question 1 (Table 3 and 4)

Table 4. Summarised overview of BA and MA students' statements reg. question 2: What do you expect from your studies, especially from your chemistry education courses?

DISCUSSION AND CONCLUSIONS

The category system is suitable to analyse the students' answers; Cohens kappa is satisfactory ($\kappa 1$ .79; $\kappa 2$ .68). Surprising for us is that students of both groups assume the most important influence on their future profession are self-related ability cognitions. In contrast, they do not expect to develop such cognitions in the university courses.

Both groups of students expect to learn from their science education courses primarily how to plan a lesson and to acquire explanatory knowledge. BA students want to be able to equip pupils with this knowledge of chemistry in an effective, creative, and fascinating way using various methods and teaching styles. A traditional view of learning arises out of these assumptions, the constructivist perspective on learning seems to be unknown to them. This view is also expressed in the expectations students have on their training courses in chemistry education. Here, they wish to be equipped with a catalogue of practical examples of how to acquire the tools and techniques for lesson planning, which help them to facilitate knowledge and instruct them on how to plan a lesson. This traditional view on teaching seems to shift during the study. For example, the MA students also want to know more about learning processes, but in their statements we find changes in perspectives from a teacher-centred view towards a more pupils-centred view: 'How can I promote a pupil' instead of 'how can I transfer knowledge.'

A central aspect of chemistry education courses was nearly totally left out by all of the participating students: The aspect of research into science education and its importance for teachers was not even mentioned once in the sample of the BA students. These results introduce a task for us as science education researchers and educators. We have to introduce students to science education research and to present this discipline as a practically-based and research-intensive counterargument to the simplified traditional beliefs of students. The answers of the students show how important it is to stress the impact of science education research in the university courses.

MA students express detailed requests regarding the organisation and designing of the university courses. They want to have contact to schools and pupils during their studies and want to discuss authentic examples and situations they may have to face in school. As expected, MA students have a more differentiated view on their studies (balanced answers). They are experienced and have a broader view on diverse aspects of (chemistry) education courses. Nevertheless, even for MA students educational research seems to play a minor part.

In our opinion, it is incredibly important to consider these results as we move forward. Firstly, we are now able to consider their wishes in the courses and secondly we can avoid misunderstanding and disappointment regarding the university courses. In our chemistry education courses we have started to focus explicitly on the areas of chemistry, chemistry education and pedagogy with students in authentic learning situations. This means, in an early stage of the bachelor programme, the students get the opportunity to teach pupils in class to attain a more realistic view on their future profession. Furthermore, we already introduce students in the bachelor programme to science education research and present this discipline as an important part of professional knowledge and in this way as a sturdy foundation for their future as science teachers.

ACKNOWLEDGEMENT

We thank all the participating students and in particular Michelle Kube for her support in the evaluation of the questionnaires.

SELF-REFLECTION OF A CHEMISTRY TEACHER

Jarmila Kmetova[1], *Marek Skorsepa*[1]
[1]Matej Bel University, Banská Bystrica, Slovakia

The methods of self-reflection are e.g. a self-monitoring, audio and video recording, a feedback from students, knowing the learning success of students (students' grades), inspection in classes and using the pedagogical diary. This contribution deals with the importance of self-reflection in a teacher's work. An integration of self-reflection program into the pregradual training of chemistry teachers is presented, especially in relation to Didactics of Chemistry (a university subject for future teachers) and the pedagogical practice. The main aim is to demonstrate a specific tool that can be used by a university student – future teacher (pre-service teacher), during his/her pedagogical practice to reflect and develop his/her self-reflection abilities.

Keywords: Evaluation, Reflection, Self-Regulation, Education, Chemistry teacher

THEORETICAL BACKGROUND

The efficacy and quality of process of education is not accidental. It mainly depends on teacher, his/her approach to work and students. The self-reflection of a teacher can be considered the basic determinant to affect this efficacy and quality. It leads teacher to his/her internal dialog with himself/herself (Hupková & Petlák, 2004). Only a teacher who performs its own self-reflection can improve himself/herself. No successful teacher can get along without self-reflection of his/her own educational activities, it is not possible to develop his/her teaching profession without it.

Self-reflection is not only about evaluating the abilities and opportunities of a person. The main point of self-reflection is to conclude findings for further personality development. It is one of indicators of person's responsibility to see and assess himself from outside, in broader cultural and social context. It moves on individual activities and broadens horizons in which one is able to discover the sense of his performances and also to understand the actions of the other people. However, the self-reflection is performed only in case of teacher's personal need (Körkkö, Kyrö-Ämmälä & Turunen, 2016). Self-reflection can be perceived as an act in which the thinking is returning back to itself in order to deepen its analysis. It can also be perceived as a mental process based on a tendency of reshaping and restructuring our experiences, views and knowledge.

The need for existence of reflection has come in two kinds of rationality that can only be linked through reflection. These are the rationalities:

Cognition as epistéme – PLATON – conceptual knowledge:

- theoretical, general, timeless, relatively constant,
- is ruled by principles, rules, laws,
- cognitive insight, intellectual forms, description.

Cognition as phronesis – ARISTOTELES – perceptual knowledge, practical wisdom

- understanding of particular cases and ambiguous situations;
- flexible, responsive to situations, ready for unexpected surprises, unclarity of practical, inventive in improvisation,
- long-term experience, assessments, choices, confrontation with consequences.

One of the functions of self-reflection is to help teachers realize their mental structures, to revise them and reshape them if needed. Well-known functions are: cognitive, feed-back, preventive, developing and relaxing.

In addition to the concept of *competency* also the other concept - *professional knowledge in education* - is important for self-regulation and self-reflection. *Knowledge* is a final integrated information with an indication of its practical usage. The professional knowledge in education can be classified as follows:

- *theoretical knowledge* – scientific knowledge transformed didactically (planning of the education),
- *acting knowledge* – knowledge enriched by experience obtained in practice (realization of education),
- *context knowledge* – the relations between theory and practice through reflection, confronting the practical experience with the theoretical schemes (evaluation and improving the education).

In fact, a teacher can use only a specific part of the theory that is directly connected to its practical usage. A self-reflection become a mirror of his practice (Hatton & Smith, 1995).

The most frequently used methods for teacher's self-reflection in educational practice are: (i) *self-monitoring*, (ii) *audio and video recording*, (iii) *feedback from students*, (iv) *students' grades*, (v) *observing (inspections) by the other teachers* and (vi) *pedagogical diary*. However, in order to provide teachers to be able to realize and interpret their own self-reflection, they have to be taught how to do that (Beatty, 2000).

The issue of self-reflection, its importance in the existence of man, in the context not only of his professional growth but of his general existence, is part of many studies in the field of pedagogy, psychology and social sciences. However, the fact is that self-reflection, the need to get feedback and reflect on it, is not part of many relevant documents, statements or scientific studies. The OECD states in its report that 21st-century employees need to have information-processing skills, including reading literacy, mathematical literacy and problem-solving skills. Besides, they must also have 'generic' skills, such as interpersonal communication, autonomy and ability to learn. (OECD, 2013). According to economists Hanushek and Woesmann (2008), skills related to thinking and learning, such as critical thinking and problem solving, play a significant role in the economic growth of countries. Nor is self-reflection included in the content of defined skills by the European Commission (2011). The term "competence" has become a phenomenon over the last 20 years, which was considered by many researchers as an element in education that provides an alternative to traditional education. Competences, competency models have become a means of obtaining a quality, a means of measuring and evaluating performance. Based on an analysis of the 21st-century competence framework review by Voogt and Roblin (2012) based on documents from organizations supporting the development and assessment of skills for the current century or by recommendations from international organizations supporting the development of education, economic growth and technology, perceived as skill or competence. The critical competencies recommended by the European Parliament and the Council of Europe are intended for all individuals for their well-being and development, active citizenship, social inclusion and employment (European Commission, 2007). There are 8 of these competencies, but neither describes in its description the need for self-reflection, for its implementation and its reflection.

METHODOLOGY

The nature of self-reflection mentioned above and acquisition of knowledge and competencies in the work of future teachers declares that a pre-service teacher can reflect his/her potential to become a successful teacher by performing a pedagogical practice. Moreover, the study of university subjects in which so-called *reflexive program* is included, can be another field for training self-reflection skills. In our university, such program for pre-service teachers is arranged even before their real pedagogical practice at secondary and high schools. This training is realized within the didactical subjects like (i) *Didactics of Chemistry*, (ii) *Technique and Didactics of School Experiments,* (iii) *Computer in Learning Chemistry*, (iv) *Computer based experiments* and another optional subjects according to students' choice. The pre-service teachers have also opportunity to teach Chemistry in simulated classes (at university classrooms) within an obligatory subject called a *Special Didactics of Chemistry* where their classmates represent the simulated secondary or high school students. The duration of such simulated classes covers a standard class-time as well. The pre-service teachers endeavor to lead the simulated lessons as if they acted at real classes with the real students. The university teacher supervising the class and the classmates (simulated students at the same time) take notes about the process of simulated education in order to subsequent analysis in more detail. Such a reflexive training program provides pre-service teachers a real insight into their work as future teachers of Chemistry. The emphasis is placed on the development of competencies related to professional growth which are then validated and developed even before entering to the real conditions of a genuine school. Performing the simulated classes, the pre-service teachers go through the following single phases of a reflection cycle: (i) *action*, (ii) *feedback on action*, (iii) *realizing the fundamental aspects*, (iv) *creating alternatives* and (v) *examining*. Within these phases, the cognitive characteristics (e.g. pre-concept, describing, self-dialogue, viewpoints, finding links, experience in the specific situations) and emotional connections (e.g. feelings, attitudes, motivation, personal interest, relation to change or resistance) are applied.

As stated before, performing self-reflection and self-evaluation is an important element of the pedagogical practice of a pre-service teacher. At the end of the pedagogical practice training, a pre-service teacher is evaluated by a hosting in-service teacher and a supervising university teacher. However, they also take into account the self-evaluation of a pre-service teacher provided in writing in a specific evaluation sheet (Table 1-4). The evaluation sheet consists of a set of professional competencies and qualities of a pre-service teacher, where the ranking itself is aligned on a 5-point scale, from 1 – insufficient to 5 – excellent. There is a special field in the sheet for self-evaluation to be filled in by a pre-service teacher according to his/her self-reflection. Among other things, the pre-service teacher is expected to provide reasoning and the ways of his/her farther professional development. The knowledge presented in the sheet is categorized according to the following teacher's activities:

1. Planning and preparing of the teaching process (Table 1); *2. Implementation of teaching* (Table 2) (Verbal and non-verbal communication, Educational climate, Social climate, Discipline, Management of the teaching process, Evaluation of a student); *3. Post part of teaching* (Table 3) (Reflection of education, Evaluation and professional development); *4. Context of education* (Table 4).

The planning and preparation of the teaching process section focuses on the student's ability to conceptually and systematically plan and optimize teaching. This part (Table 1) of the evaluation sheet also includes the specifics of the chemistry subject, such as the preparation and implementation of a chemical experiment.

Table 1. Part 1 of the evaluation sheet (Planning and preparing of the teaching process).

Pre-Service Teacher's Knowledge	**Scoring** 1 – insufficient 5 – excellent
1 Planning and preparing of the teaching process	
University Student (Pre-service teacher): • He/she plans the teaching process conceptually and systematically concerning the objectives set out in the state and school education program and the individual possibilities and needs of students. The preparation for teaching includes outputs following the content and performance educational standards of chemistry for the respective level and year of education.	
• In the context of the educational objectives, the nature of the curriculum, the needs and possibilities of students and the educational climate, the optimizes the scope and content of chemical terms.	
• In the context of the educational objectives, the nature of the curriculum, the needs and possibilities of students and the educational climate, he/she chooses the appropriate concept and approaches to education, especially those based on constructivism and developing students' research abilities (problem-based learning, concept based on research).	
• In the context of the educational objectives, the nature of the curriculum, the needs and possibilities of students and the educational climate, he chooses appropriate methods and organizational forms of teaching, appropriate content and reflects logical continuity, complexity and interconnection of curriculum, including in-subject and inter-subject relations and connection to the practice itself. He/she plans to work with unique texts, textbooks, by which he develops reading literacy, especially the level of readability and readability of particular professional text.	
• In the context of educational objectives, the nature of the curriculum, the needs and possibilities of students and the educational climate, he/she chooses the appropriate material means - teaching aids (including models), technical equipment, etc. He/she chooses the optimal inclusion of digital technologies in the classroom, taking into account the digital content used.	
• In the context of the educational objectives, the nature of the curriculum, the needs and possibilities of students and the educational climate, he/she chooses the	

appropriate selection and integration of the school chemistry experiment concerning the curriculum content also focusing on the safety when working. He/she correctly integrates the school experiment into the teaching unit in terms of its classification according to the form of teaching, from the gnoseological point of view, as well as from work accuracy (e.g., quantitative school experiments in connection with using a computer).	
• In the context of the educational objectives, the nature of the curriculum, the needs and possibilities of the students and the educational climate, he plans the students to work with quantitative and qualitative information; graphs, dependencies, diagrams, tables, diagrams, schemes.	
• He/she plans ways of getting feedback for both the student and the teacher. Concerning the student, he/she has a well-thought-out system of questions and tasks, their integration into individual phases of teaching. He/she has elaborated models of problem-solving, through which it leads the student to the right solution and reveals the "mistakes" that the student can make in understanding the curriculum and thus the level of his understanding of the curriculum and ability to solve tasks.	
Self-evaluation, arguments, ways of further development	

The second part of the evaluation sheet (Table 2) is focused on the actual implementation of teaching. It consists of three sublevels containing teaching indicators, namely: verbal and non-verbal communication, educational and social climate, discipline, teaching process management and diagnostics and assessment of the student. In this part of the sheet, it is clear that the teacher needs to evaluate the student only after the student has given his self-assessment. For example, an indicator of the level of control and correct interpretation of scientific discipline knowledge is evaluated here. It is an indicator that is not directly related to the preparation and implementation of teaching by the student; therefore, the student has no direct influence on this level. Therefore, an interesting finding is the mutual consistency of the testimony of the evaluation of this indicator to students and teacher in training.

Table 2. Part 2 of the evaluation sheet (Implementation of teaching, Performing education).

Pre-Service Teacher's Knowledge	**Scoring** 1 – insufficient 5 – excellent
2 Implementation of teaching (Performing education)	
2.1 Communication and conditions in the classroom	
University Student (Pre-service teacher): • He/she uses standard Slovak language during the class. He/she expresses himself in a language that is comprehensible to the student.	
• He/she appropriately uses nonverbal communication means (smile, eye contact, friendly and helpful gestures, movement around the classroom, respect for the personal space zone). He/she uses the correct demonstration techniques and procedures to conduct non-verbal education while doing the experiments.	
• He/she creates sufficient communication space for all students, strives for balanced communication interaction. He/she creates opportunities for thinking, confronting different opinions and ideas of students, leading them to reason. He/she creates	

opportunities for mutual communication among students. He/she leads students to express their understanding of the topic and reflect on the learning process.	
• He/she handles discipline well in the classroom, adherence to the agreed system and rules of coexistence and behavior in the classroom. He responds adequately to the behaviors of disturbing and annoying behavior and ensures that they are minimized. He creates an environment of mutual respect and honesty.	
• He/she includes in the classroom the activities, concepts and approaches that help to develop collaboration, positive classroom relationships and better integration with students that are isolated, rejected by other classmates, and so on.	
• He/she plans ways of getting feedback for both the student and the teacher. Concerning the student, he/she has a well-thought-out system of questions and tasks, their integration into individual phases of teaching. He/she has elaborated models of problem-solving, through which it leads the student to the right solution and reveals the "mistakes" that the student can make in understanding the curriculum and thus the level of his understanding of the curriculum and ability to solve tasks.	
Self-evaluation, arguments, ways of further development	
2.2 Management of the teaching process (management of education)	
• He/she carries out the training according to the preparation, at the same time he reacts to the development of the situation and the needs and possibilities of the students, but does not lose the connection to the set goals; he uses time effectively.	
• He/she knows and interprets the knowledge of the scientific discipline of chemistry, understands the technical terms, events and relations between them. He/she interprets the symbolic and formal language of chemistry correctly and appropriately.	
• He/she individualizes the support of students' learning process concerning their possibilities (e.g., differentiates curriculum and demands, respects individual pace of learning, takes into account integrated students in the classroom and their content and degree of integration, modifies working methods, criteria and assessment methods).	
• He/she supports activity and inner motivation of students to learn - he raises curiosity, interest in learning and knowledge of new things. He asks open questions that activate higher levels of thought and require a more coherent student's speech (Why? What would happen if... What do you predict? Try to formulate the assumption of the upcoming trend and the result of the experiment. How would you explain that .... . What is your opinion .....?). He encourages students to ask questions and appreciates their interest and willingness to ask questions.	
• He/she creates learning situations requiring the cooperation of students, using self-learning practices and frontal forms of learning as needed. He/she teaches students to use effective self-learning strategies (metacognitive strategies).	
• He/she detects students' preconceptions, analyzes them mutually with them, and directs them to learn and interpret it correctly. He/she uses students' acquired knowledge, ideas and experience in their learning. He/she identifies misconceptions associated primarily with misconceptions about chemical concepts and chemical reactions.	
• Through the teaching of chemistry, he/she develops natural science literacy and abstract thinking of students. He/she develops abstract thinking, ability to predict, observe, analyze, draw conclusions and interpret.	
Self-evaluation, arguments, ways of further development	

2.3 Evaluation of a student	
• He/she provides students with assessment criteria (students know what is being evaluated and what weight each criterion weighs in the overall assessment) or allows them to participate in the development of these criteria.	
• He/she evaluates learning processes - provides continuous feedback on learning activities and student behavior in descriptive languages, assesses progress, effort, interest, level of cooperation, suggests strategies for improvement (what and how to change, improve), works with mistakes of students as an opportunity to further improvement.	
• In addition to the level of acquired knowledge, he/she also evaluates the level of acquired skills in the implementation of school experiments, the ability to predict, observe, analyze, draw conclusions, argue and interpret.	
• He/she assesses students' performance in terms of individual possibilities and prerequisites and appreciates individual progress of students.	
Self-evaluation, arguments, ways of further development	

The post-teaching part (Table 3) is a space for introducing a comprehensive reflection of the students, as well as evaluating the ability of self-evaluation and planning the further professional development of the student.

Table 3. Part 3 of the evaluation sheet (Post part of teaching - Reflection of education, Evaluation and professional development).

Pre-Service Teacher's Knowledge	**Scoring** 1 – insufficient 5 – excellent
3 Post part of teaching	
University Student (Pre-service teacher): • After each taught unit, he/she evaluates the selected strategies, methods and organization of teaching concerning the teaching plan, the set goals but also to their achievement.	
• On the basis of self-reflection, he/she plans to further increase his professional qualities.	
Self-evaluation, arguments, ways of further development	

The above-mentioned reflective program tool is designed for the evaluation of a student in the context of the implementation of continuous teaching practice (Table 4), which lasts 2 months at primary or secondary school. The student works in the school environment, whose determinants are not only the student and the teacher but also the parent. Therefore, the last part of the evaluation sheet is the part named Context of Teaching, which focuses on the ability of the student to adapt in the school environment, on the degree of his flexibility towards school activities and his cooperation with parents.

Table 4. Part 4 of the evaluation sheet (Context of education).

Pre-Service Teacher's Knowledge	**Scoring** 1 – insufficient 5 – excellent
4 Context of education	
University Student (Pre-service teacher): • participates in the school life, participates in school activities and projects, attends school meetings, attends meetings of a subject commission, attends the meetings with parents etc.	
• comprehends the school curricula and is aware of its fundamental parts, is able to describe the school philosophy.	
• is interested in the ways of cooperation between teachers and parents.	
• develops skills of communication with parents.	
Self-evaluation, arguments, ways of further development	

CONCLUSION

Since 1990s, the trends of professional training and performance of teachers in the Central European context have identified several dominating tendencies which determine the structure and priorities related to teacher's competencies. The acquisition and validating of these competencies is realized during pregradual education for the first time (Nezvalová, 2000). Therefore, it is necessary to pay attention to the conceptual framework and implementation of reflexive program to the university training of future chemistry teachers.

PART 14: STRAND 14

In-service Science Teacher Education, Continued Professional Development

Co-editors: *Claudio Fazio & Manuela Welzel-Breuer*

CONTENTS

STRAND 14: INTRODUCTION

IN-SERVICE SCIENCE TEACHER EDUCATION, CONTINUED PROFESSIONAL DEVELOPMENT

Strand 14 of ESERA addresses an internationally increasingly recognized complex field of science education research: in-service teacher education and continued professional development of science teachers. It is obvious that the value and success of any educational system strongly corresponds with the quality of its teachers' competences and practices. In this sense, it is not surprising that the strand on in-service science teacher education is always one of the most active strands of ESERA. Compared to the last ESERA conference proceedings, the number of papers presented in this strand was growing from 10 to 32 pieces.

Again, this edition of the ESERA conference proceedings portrays a singular, interesting array of research pieces addressing actual problems of science teacher education and continued professional development from sometimes similar, but quite often very different theoretical and methodological frameworks. Compared to previous editions of Strand 14 of the ESERA proceedings, we probably find here the most diverse representation in terms of internationalization. The 32 papers included in this section, come from all over the world. There is, on the one hand, a strong European presence with papers coming from research institutions in Austria, Germany, Greece, Ireland, Israel, Italy, Portugal, Sweden, Switzerland and UK. On the other hand, non-European, international presence and collaboration becomes visible by papers from South Africa, South-America (Brazil and Chile), Asia (Japan), Oceania (New Zealand). This collection forms a truly international character and confirms the fact that including research pieces from all over the world is a trend that is gaining momentum in each ESERA edition. We think, the ESERA community will strongly benefit from this global exchange of ideas. The visible internationality and number of papers underlines the increased worldwide relevance of this field of science education research and the need of common work on often similar problems.

Looking at the contents and approaches of studies we can find an interesting spectrum. There are theoretical studies as well as empirical ones, but also studies connected to innovations concerning specific course developments and applications including the investigation of its effects and the possibilities of evaluation of science teaching. That variety demonstrates very well, how the complexity of in-service science teacher education and continued professional development is scientifically approached by the ESERA community.

The theoretical studies at the beginning of this chapter, for instance, investigate and discuss the actual situation of science teaching and teacher education in the mirror of already existing studies and results by examining theoretical standards, focusing the linkage of PCK and practical teaching experiences in STEM teacher education. They investigate competencies required by teachers to ensure progression and continuity in students' learning.

Empirical studies to be found in this chapter deal with the professionalization processes of teachers in all phases of their careers. They look at needs, challenges and possibilities for individual support, in order to ensure progression and continuity including the potential of professional learning communities. In addition, structural challenges in the field of science teacher education are tackled. A number of empirical papers investigate effects of innovative teacher training courses for instance concerning the integration of ICT, and the development of teacher knowledge, beliefs and attitudes toward teaching science.

A larger number of papers communicates developmental activities. In the focus of interest are innovative courses and the investigation of specific variables and effects while applying these courses, mainly looking at teachers' competences and learning communities. The innovations presented comprise for example the initiation and investigation of collaboration between teachers and scientists or the implementation of learning communities.
Another group of studies deals with the transformation of pedagogical practices from didactic to dialogic teaching. There are training ideas addressing the use of experiments and the teaching argumentation.

The last (but not least) part of the chapter presents papers dealing with the development and application of methods and tools of evaluation.

Looking at the selection of papers one will find that the ESERA community within strand 14 tackles important issues in order to support improvement of in-service teacher education and continued professional development of science teachers all over the world.

LINKING PEDAGICAL CONTENT KNWOLEDGE AND PRACTICAL TEACHING EXPERIENCES IN STEM TEACHER EDUCATION: A SYSTEMATIC REVIEW OF THE LITERATURE

Peter Wulff[1], Lukas Mientus[1], Anne Hume[2], Antoinette Meiners[1], and Andreas Borowski[1]
[1]University of Potsdam, Potsdam, Germany
[2]University of Waikato, Hamilton, New Zeeland

Teachers' professional knowledge is considered central to improving students' learning outcomes in science, technology, engineering, and mathematics (STEM) subjects (Abell, 2007; Magnusson, Krajcik, & Borko, 1999). Pedagogical content knowledge (PCK), introduced by Shulman (1986) as a very specific dimension of teachers' professional knowledge, is now a well-established construct in STEM education research. Findings in this research field suggest that teachers with well-developed PCK for teaching STEM subjects are more able to provide effective instruction, and professional development to enhance teachers' PCK in STEM education is now advocated (van Driel & Berry, 2012). Research also shows that teachers' PCK development hinges on professional practical experiences, e.g., classroom teaching (Carlson et al., 2019), inferring that provision of practical experiences in teacher education, which are linked to teachers' PCK can help prospective teachers to expand their professional knowledge (Carlson et al., 2019). However, while PCK features in many studies in STEM education research, empirical evidence that establishes a link between PCK and teaching practice in STEM is ambiguous because these studies conceptualise PCK and practical experiences inconsistently (Wilson, Borowski, & van Driel, 2019). To begin addressing this ambiguity and advance understanding of the link between PCK and teaching experiences, this study seeks to analyse how empirical studies link PCK and practical experiences of (preservice) STEM teachers. The analysis is done via a systematic literature review that focuses on N=97 empirical studies. Results suggest that most studies favour Magnusson's (1999) PCK model as a conceptual framework and almost always include the components 'knowledge of student understanding' and 'knowledge of instructional strategies and representations' in their analyses. The implications of these findings for further empirical research regarding links between PCK and practical teaching experiences are discussed.

Keywords: Pedagogical Content Knowledge, Teacher Professional Development, Teaching Practices

INTRODUCTION

Teachers' professional knowledge for teaching in science, technology, engineering, and mathematics (STEM) subjects has been identified as an important attribute for improving teaching and students' learning outcomes (Abell, 2007; Hume, Cooper, & Borowski, 2019; Magnusson et al., 1999). As a category of STEM teachers' professional knowledge (Shulman, 1986), pedagogical content knowledge (PCK) has been considered a key knowledge form for improving teaching (Hume et al., 2019; Loughran, Berry, & Mulhall, 2012), since it facilitates a transformation of subject matter knowledge into a more comprehensible form that is accessible to students (Shulman, 1986). Authors like Grossman et al. (2009), Magnusson et al. (1999) and Park and Oliver (2008) added refinements to Shulman's PCK construct including, amongst others, components of PCK for effective STEM teaching, i.e., orientations to teaching science (OTS), knowledge of student understanding (KSU/KS), knowledge of instructional strategies and representations (KISR), knowledge of curriculum (KC/CuK), knowledge of instructional strategies (KI), and knowledge of assessment (KA). Other knowledge categories should also be given due consideration for effective STEM teaching, including content knowledge (CK), and pedagogical knowledge (PK) (Shulman, 1986), and more recently knowledge of teaching context (CxK) (Fernandez-Balboa & Stiehl, 1995; Grossman, 1990) as a knowledge of the specific classroom circumstances and the students (e.g., ethnic background and gender composition). It is argued developing applicable PCK in professional development is presupposed upon effectively applying PCK in authentic practical teaching situations (Grossman et al., 2009; Shulman, 1986). Accordingly, some research studies began investigating effective ways for implementing practical teaching experiences in (preservice) STEM teacher professional development that promote development of applicable PCK. For example, the use of Content Representations (CoRes) by Loughran, Mulhall and Berry, (2004) and reflective writing after practical teaching experiences by Hume (2009) were found to be successful ways to make PCK explicit and promote professional development. Unfortunately, to date studies have employed a varied plethora of methods, research designs, and PCK conceptualisations for analyzing links between PCK and practical teaching experiences, resulting in findings that are difficult to integrate and reach consensus.

This paper reports partial findings from a systematic literature review we undertook in an attempt to compare and integrate methods and findings from studies that examine links between PCK and practical teaching experiences in STEM teacher education. In this paper, we address one of the research questions (RQ) from this study: How do STEM studies that link teachers' PCK and their teaching practice conceptualise PCK?

METHOD

The systematic literature review began by explicating the research interest (i.e., what links exist between PCK and practical experiences in STEM teacher education) and browsing through relevant electronic literature databases (peDocs, ERIC, WoS and PsycINFO) using the key terms "(knowledge AND practice) AND (teacher OR teaching OR "teacher education") AND (physics OR chemistry OR biology OR mathematics OR science OR STEM) AND ("Pedagogical Content Knowledge" OR PCK)". Peer reviewed articles from 1986 to 2018 that used a PCK conceptual framework and investigated a link between teachers' PCK and their practical experiences were included. Overall, N=97 studies were retained for analysis. For the data related to the RQ reported in this paper, content analysis was used, such that established PCK models (e.g., Magnusson et al., 1999, Park & Oliver, 2008, and others) formed the initial coding units and formerly unidentified PCK models were added in the process. Interrater reliability, as measured through Cohen's κ, was substantial: $\kappa = 0.93$.

RESULTS

Each of the reviewed studies adhered to one of two broad categories of PCK models as described by Park and Oliver (2008) and Kind (2009): either to more integrative models (N=9; 9.3%) or to more transformative models (*N*=88; 90.7%). The integrative model holds that PCK is comprised of different knowledge categories (and is therefore not in itself a unique knowledge form), while the transformative model considers PCK to be an independent knowledge category (Kind, 2009). In the first group, all studies examined PCK in combination with CK and PK, while KS, CuK, and AK were interspersed at times in these analyses (see Table 1). In the larger second group, almost a third of the studies used the PCK model by Magnusson et al. (1999) (*N*=30, see Table 2). The majority of these studies included all five PCK components, however OTS was most often left out in the minority that used fewer components. Another *N*=36 studies were identified that did not specify a particular PCK model but rather eclectically used different components of PCK, most often KSU and KISR.

DISCUSSION

The review revealed that studies examining PCK and teaching practice together employ a variety of PCK conceptualisations. Differentiation of studies into those with either an integrative or a transformative perspective of PCK was considered reasonable, where the former applies to a group of studies that view PCK as an integration of different knowledge categories rather than a separate entity, and the latter applies to studies that conceptualise PCK as an independent knowledge category. The group with the integrative perspective of PCK proved to be quite small, while the majority of studies adopted transformative models of PCK, most notably the model by Magnusson et al. (1999). Of particular interest with respect to links between PCK and practical teaching experiences was the finding that KSU and KISR are almost always included in the analyses, which is not surprising given these two components resonate most closely with those aspects of teachers' knowledge that Shulman (1986) originally identified as PCK. In our estimation, these choices for analysis are reasonable when considering the complexity of student thinking and the benefits gained from teachers learning to diagnose students understanding for effective teaching (Sadler, Sonnert, Coyle, Cook-Smith, & Miller, 2013). In contrast, it was surprising that only a tiny minority of studies included CxK into their analyses. This was surprising because the context-dependency of PCK was emphasized from early on (Grossman, 1990; Magnusson et al., 1999).

Recently, a conceptual framework known as the Refined Consensus Model (RCM) has been proposed that integrates different PCK models (Carlson et al., 2019). We consider the RCM a useful advancement on existing PCK models, because not only does it comprise the most salient features identified in our reviewed studies that link PCK and practical teaching experience, it also recognises and is sensitive to the context-dependency of PCK. As such, the RCM differentiates three realms of PCK to acknowledge that PCK research shared amongst educational scholars is different to the PCK that a teacher holds, and in turn to the PCK that a teacher enacts in the moment of teaching. This differentiation also acknowledges that potentially teachers implicitly know much about teaching (Carpenter, Fennema, Peterson, & Carey, 1988), but may be unable to access this knowledge explicitly when reflecting on and enacting their teaching.

When studying links between PCK and practical teaching experiences, we suggest the following: 1) Since KSU and KISR are widely established focii in PCK analysis and teaching practice it might be opportune to hone in on particular mechanisms in the teaching context that trigger teachers' use of certain KSU- and KISR-related knowledge. Also, developmental trajectories (e.g., from more transmissive to more constructivist instructional beliefs) can be hypothesised and tested. Such investigations were not revealed in our literature review so a possible gap in the research exists, 2) Adopting the RCM in studies investigating links between PCK and practical teaching experiences seems fruitful, in order to determine what the field knows, what teachers in a certain developmental stage know, and how contextual factors might account for episodes where certain PCK is/is not utilised. Linking suitable research methodologies to the different realms of PCK would be beneficial as a next research task.

A more comprehensive summary of the present study is expected to appear in a peer reviewed publication. In that review, we will address further research questions regarding, employed methods, conceptualisations of PCK, the teaching cycle and other aspects. We will also discuss the limitations of such a literature review when investigating relationships between PCK and teaching practice.

PROFESSIONALISING TEACHERS FOR INQUIRY-BASED SCIENCE EDUCATION - CHALLENGES AND LIMITS

Elisabeth Hofer and Anja Lembens
University of Vienna, Austrian Educational Competence Centre Chemistry, Vienna, Austria

Even though inquiry-based science education (IBSE) has been considered as an indispensable element of contemporary science education, science teachers still refrain from implementing it in their own classes. One of the reasons teachers name for that is that they themselves would not feel confident enough to implement IBSE on their own – even after having participated in a respective professional development (PD) programme. An empirical review has shown that most of the offered PD programmes especially lack elements like authentic inquiry experiences or practicing lesson development. In this study, we present a PD programme, which focuses on lesson development linked with in-depth reflection and, in this way, strives for bridging the gap between theory and practice. Collaborating with three chemistry teachers, we examined what challenges we – as teacher educators – faced when planning and conducting this especially designed PD programme. Moreover, we investigated how far an "ideal" PD programme is realisable under the prevailing conditions and what boundaries teacher educators encounter in this context.

Keywords: Continuing professional development, Inquiry-based teaching, Instructional design

INTRODUCTION

For more than 10 years, elements of IBSE have been incorporated in the Austrian science education standards for grade 8 (BIFIE, 2011) as well as in the curricula for chemistry at lower (BMUK, 2000) and upper secondary schools (BMB, 2016; bm:bwk, 2004). Nevertheless – similarly to many other countries (Capps, Shemwell & Young, 2016; Crawford, 2014; DiBiase & McDonald, 2015; Engeln, Euler & Maass, 2013) – IBSE has found its way into Austrian science classrooms only rarely until now (Hofer, Lembens & Abels, 2016). Reasons teachers name for this are that schools would lack of sufficient resources (time, equipment, spatial resources etc.), the appropriate organisational framework (flexible schedules, project-based approaches etc.) and that IBSE would not be compatible with the requirements of final exams. Moreover, Austrian teachers argue to not be appropriately prepared to apply IBSE to their own science classes without further support (Hofer, Abels & Lembens, 2018; Hofer et al., 2016; cf. Anderson, 2002; DiBiase & McDonald, 2015; Wallace & Kang, 2004).

An analysis of the PISA 2015 results, however, revealed the consequences of this insufficient implementation practice. Austrian students are lacking inquiry skills, especially of those belonging to the procedural and the epistemic domain (Suchan & Breit, 2016). Furthermore, students' statements indicate that science education in Austria still focuses on transferring knowledge rather than on working on problems and developing inquiry skills.

To prepare teachers for implementing IBSE in their own science classes, Capps, Crawford and Constas (2012) suggest developing PD programmes according to the following nine 'critical features of effective PD': *Total Time*, *Extended Support*, *Authentic Experience*, *Coherency*, *Develop Lessons*, *Modeled Inquiry*[1], *Reflection*, *Transference* and *Content Knowledge* (see Table 1). Capps et al. (2012) gained these features from examining literature with regard to PD in both the fields of general education research (Darling-Hammond & McLaughlin, 1995; Desimone, 2009) and of science education research (Garet, Porter, Desimone, Birman & Yoon, 2001; Loucks-Horsley, Love, Stiles, Mundry & Hewson, 2003; Penuel, Fishman, Yamaguchi & Gallagher, 2007). Besides findings from empirical studies, they also included the suggestions given in the teaching standards, one part of the National Science Education standards (National Research Council, 1996, 2000), when creating their list of 'critical features'.

Table 1. Critical features of effective PD programmes for IBSE (Capps et al., 2012, p. 298).

Feature	Description of feature
Total Time	Amount of time allotted for the programme
Extended Support	Programmes providing sustained support for teachers over an extended period of time
Authentic Experience	Programmes in which teachers conduct their own inquiry study
Coherency	Programmes that align with standard documents
Develop Lessons	Programmes in which teachers design inquiry-based lessons for use in their own classrooms
Modeled Inquiry	Programmes offering teachers the opportunity to engage in classroom inquiry
Reflection	Programmes in which teachers are given the explicit opportunity to reflect on their experiences
Transference	Programmes in which teachers explicitly discuss about enacting the curriculum in the classroom
Content Knowledge	Programmes that focus on science subject matter and content learning for teachers

Referring to these nine features, Capps et al. (2012) analysed 17 empirical studies dealing with PD programmes for IBSE and found that none of them addressed all of the nine features. Especially the features *Authentic Experience* (5/17) and *Develop Lessons* (7/17) were considered only rarely. The authors therefore assume these two features being the "missing link in helping teachers enact inquiry-based instruction in their own classrooms" (p. 306). Based on this assumption, they recommend modifying or extending already existing PD programmes in such a way that they particularly emphasise these two features.

In the following, we present a PD programme, which emphasises the feature *Develop Lessons* (one of the two underrepresented features) and links it with in-depth reflection (*Reflection*). After having briefly outlined the design of the PD programme, we discuss the difficulties we encountered when developing and conducting this programme. Moreover, we examine how far it is possible to realise an "ideal" PD programme for IBSE – according to the nine features suggested by Capps et al. (2012) – under the conditions prevailing in Austria.

[1] original spelling

THE PROFESSIONAL DEVELOPMENT PROGRAMME

Based on the data and experience gained in the course of the EU FP7-project TEMI (Hofer et al., 2016), we developed a PD programme that aimed at supporting teachers in implementing IBSE in their own science classes. For this purpose, the programme focused on the feature *Develop Lessons*. This includes designing and planning IBSE units and developing and preparing the material required for implementing them. As illustrated in Figure 1, the PD programme encompassed three IBSE units lasting 100 minutes (equivalent of two chemistry lessons) each. In cooperation with three Viennese secondary chemistry teachers, we collaboratively designed and planned the three units. In the following, these units were implemented individually by each teacher in their own chemistry classes (classes in grade 11 for the Units 1 and 2 and classes in grade 12 for Unit 3). Subsequently, a joint meeting was arranged in which the participating teachers exchanged the experiences they made during the implementation in their own classes and reflected on the findings they gained from this unit. Finally, the teachers discussed the implications and started with the planning of the following unit.

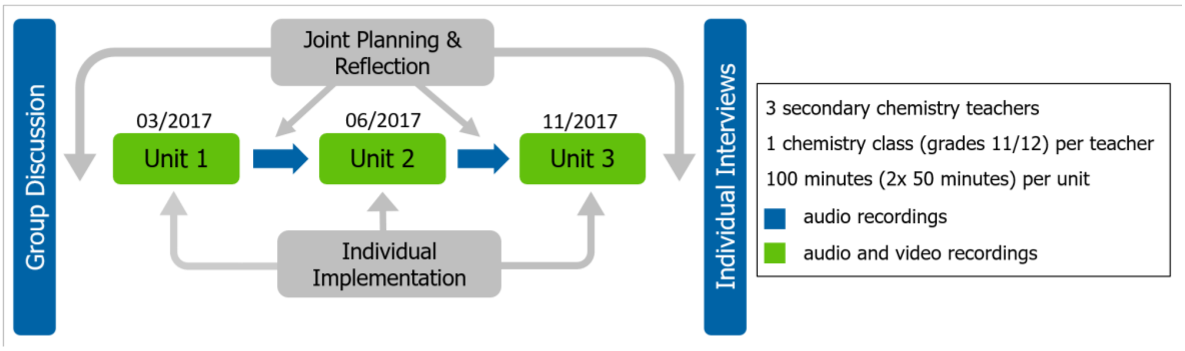

Figure 1. Design of the professional development programme.

In order to identify the emerging challenges and limits, the entire PD programme was accompanied by a continuous collection of data. The statements during the joint meetings (planning and reflection) were audio-recorded and during the individual implementation in the respective classrooms, both audio and video recordings were conducted (see Figure 1). Additionally, field notes were taken and observation protocols were filled in. For the purpose of data triangulation, audio recordings of both a preliminary group discussion and final interviews with the participating teachers were available.

INSIGHT INTO FIRST RESULTS

To discuss the challenges we were confronted with when developing and conducting the PD programme described above, we exemplarily refer to three of the nine 'critical features' proposed by Capps et al. (2012): (1) *Develop Lessons* and (2) *Reflection* (the features this PD programme focused on) as well as (3) *Authentic Experience* (that feature Capps et al. (2012) found to be underrepresented in most PD programmes for IBSE as well). Moreover, we examine how far it is possible to realise an "ideal" PD programme for IBSE – according to the nine features suggested by Capps et al., (2012) – under the conditions prevailing in Austria.

Feature 1: ***Develop Lessons***

In the course of the PD programme, it became apparent that the participating teachers required a systematic support. Especially at the beginning, teachers needed to be accompanied step by step when designing and planning units for IBSE. For us as teacher educators, it constituted one of the most challenging tasks to develop (further) teachers' knowledge and/or skills in several areas (subject matter, scientific inquiry, Nature of Science (NOS) / Nature of Scientific Inquiry (NOSI)) simultaneously. Additionally, knowledge about and skills in these areas had to be linked to the general steps of lesson planning (defining goals, planning lessons from "back to front", considering the process of gaining knowledge from investigations etc.). Due to the participating teachers' beliefs regarding IBSE, NOS/NOSI and science education in general (e.g. investigations are not preceded by a question to be answered; hypotheses can be proved by one experiment; after students have conducted an investigation, the teacher explains the results), it took a great amount of effort and persuasion to align the developed units with the 'Essential Features of Classroom Inquiry' (National Research Council, 2000) at some points.

Feature 2: ***Reflection***

To allow the teachers to reflect systematically on the experiences when implementing IBSE units in their own science classes, relevant knowledge and skill as well as sufficient time are required. In the course of the PD programme, it turned out that the participating teachers were lacking in both. On the one hand, lacking knowledge and skill regarding planning, conducting, observing and reflecting lessons led to subjective and superficial impressions instead of evidence-based observation and reflection. And on the other hand, teachers had such a tight schedule that reflecting on the implemented unit was only possible at the end of a day – six to eight hours after the respective lessons took place. As a result, teachers just wrote down their first impressions in note form instead of reflecting on their experiences in a profound and systematic way. These incomplete records, in turn, made it difficult for the teachers to introduce detailed information and differentiated descriptions of specific issues in the joint sessions. At this point, it was indispensable having available the field notes taken by the researcher. Referring to these records, teachers had the ability to reconstruct selected situations of the unit.

Feature 3: ***Authentic Experience***

Capps, Crawford and Constas (2012) identified – in addition to the feature *Develop Lessons* – especially the feature *Authentic Experience* to be underrepresented in most of the PD programmes they analysed. When attempting to enable teachers to engage in *Authentic Experience*, we primarily faced organisational obstacles. In addition to a lack of time on the part of the teachers, it was challenging to find institutions that were willing to cooperate in this setting. The reasons for this are multifarious. One the one hand, there are legal issues (insurance, disclaimer of liability, non-disclosure agreement etc.) that refrain many institutions from cooperating with teachers in these settings. On the other hand, institutions would need to spend resources in order to accompany and support the teachers; however, they receive no (financial) compensation in exchange for their participation. Beyond this, teachers would need support in order to be able to transfer the experiences they made to their own working environment. Only if they get the opportunity to apply aspects of their experiences to their own teaching strategies, there will be sustained impact to their classroom practice.

Obstacles to realise an "ideal" PD programme

It became apparent already during the design and planning of the PD programme that it is hard to create several of the prerequisites considered being especially beneficial for teacher PD at once. At this point, we are going to discuss two aspects, which result in a situation in which several of the 'critical features of effective PD' are realisable only with difficulty, great effort, or limited scope.

A considerable number of teachers in Austria are allowed to participate only in PD programmes, which are arranged as one-day workshops and/or take place outside teaching time. For this reason, PD programmes that are scheduled to extend over a longer period of time (*Total Time*) and include several full-day and/or multi-day modules are met with little response. Thus, the educational institutions responsible for teacher PD in Austria do not offer long lasting PD programmes already from the outset, reasoning that these programmes would not attract wide interest anyway. Consequently, it is considerably more challenging to conduct programmes that are more comprehensive regarding time (*Total Time*) and overall content (*Content, Knowledge, Authentic Experience*) and thus, support effective and sustainable PD.

Despite the limited duration of most PD programmes, many headmasters allow only one teacher to participate in the same PD offer. For this reason, teachers need to stay in contact with colleagues from other schools in order to make it possible to continue developing their own knowledge and skills in the framework of professional learning communities (cf. Darling-Hammond & McLaughlin, 1995; Garet et al., 2001; Loucks-Horsley et al., 2003). In such communities, teachers would have the opportunity to concentrate on transferring the contents of the PD programme to their own science lessons (*Transference*) and reflect on the experiences (*Reflection*) they gain in the course of application. Depending on professional learning communities outside of a teacher's own school implies a substantially higher effort in terms of both time and organisation.

CONCLUSION

To summarise, conducting the presented study revealed challenges in two main areas: firstly, teachers' prior knowledge, skills and beliefs regarding IBSE and secondly, the framework conditions for teacher PD in Austria. As many Austrian teachers have only little or no experience with IBSE, designing and planning units for IBSE (*Develop Lessons*) constitutes an enormous challenge not only for the teachers participating in the PD programme, but also for the teacher educators who need to support them according to their individual needs. Referring to Capps et al. (2012), the findings from this study would strengthen the hypothesis that the feature *Develop Lessons* could be one "missing link in helping teachers enact inquiry-based instruction in their own classrooms" (p. 306).

Finally, it can be stated that teacher PD in Austria must no longer be regarded as necessary evil, but as an essential element of teachers' professional responsibilities. Only then can we create appropriate framework conditions to realise long-term PD programmes, which build upon one another and, thus, ensure the effective, purposeful and sustainable professionalisation of teachers for IBSE.

ACKNOWLEDGEMENT

We are very thankful for the teachers cooperating in this research project.

This research project arose from TEMI (Teaching Enquiry with Mysteries Incorporated), a project under the Seventh Framework Programme (FP7, Science in Society) of the European Commission, Grant Agreement ID: 321403.

This study aimed to evaluate the development of a continuous education course structured through the 3 Pedagogical Moments (PMs) with Science Teachers from Uruguaiana - RS, Brazil. The production of data occurred through numerous instruments. We noticed some limitations in relation to the teachers in following the proposal presented in the formative process, as well as in carrying out the implementation of the teaching plans in classroom.

Keywords: In-service Teacher Training, Teaching Practices, Science Education.

INTRODUCTION

It is increasingly essential for teachers to participate in spaces that foster their continuous education, because from these it is possible to promote reflections about their pedagogical practice, with an exchange of knowledge between professionals working in the same modality and educational levels, to reframe their teaching practice.

Researchers from different areas of education and teaching are investigating new ways of conceiving and organizing spaces for continuous education. In this sense, one of the studied proposals for this purpose are the 3 Pedagogical Moments (PM) that were proposed by the Brazilian researchers Delizoicov and Angotti (1994) as a transposition of Paulo Freire's dialogical-problematizing concept of education and that emerged from a dynamic planned to develop themes previously chosen in a science teaching project in Guinea-Bissau.

The 3 PM can be described the following way: the first PM is called "Initial Problematization" where real questions and / or situations that the students know and experience and that are linked to the content to be developed are presented. At this moment, the teacher will encourage discussions about the subject, allowing the exposition of alternative conceptions of students or instigating the understanding of other knowledge. The second PM is known as the "Knowledge Organization" where students will study the contents necessary to understand the theme and the first PM. The third PM is called "Application of knowledge", designed to perform the synthesis of the knowledge incorporated by the student, analysing and interpreting both the initial situations of the first PM and other situations that can be explained through the same scientific knowledge (Delizoicov & Angotti, 1994).

According to Fagundes (2013), the 3 PMs can be used to organize the lesson planning, contemplating current reality themes, allowing the contextualization of science teaching. On the other hand Muenchen (2010) and Giacomini and Muenchen (2015) mention that the 3 PM, beyond being used as didactic-pedagogical dynamics in the classroom, to build programs and curricula, can also be used to structure training processes, as long as changes are made to meet this proposal.

To work with the 3 PMs, it is necessary be present a theme in focus that is relevant to the social context in which it will be developed. In this sense, medicinal and toxic plants can be a possible topic to be used in science education, since according to data from the World Health Organization (WHO) 85% of people worldwide use these vegetables to treat diseases (Teixeira et al, 2014). Regarding Brazil, according data from the Ministry of Health, in the period from 2013 to 2015, the demand for treatments using medicinal plants and herbal medicines by the Sistema Único de Saúde (SUS) has more than doubled: a 161% growth was recorded (Portal Brasil, 2016). Besides that, the Sistema Nacional de Informações Tóxico-Farmacológicas (SINITOX, 2016) registered 363 cases of poisoning by plants in Brazil in 2016, and that 350 of them occurred in urban areas. It may seem like a small quantity of poisoning cases, taking in consideration the size of the Brazilian population, the problem is that many cases of plant poisoning are not even known.

If an analysis by Brazilian states is made, it will also be possible to check the presence of these vegetables in daily life, such as in the State of Rio Grande do Sul (RS), in which the population uses a variety of medicinal plants, for the most distinct therapeutic purposes (Dávila, 2011). One of the municipalities in which the use of numerous medicinal plants is verified is the city of Uruguaiana, in the border between Brazil and Argentina, according to the ethnobotanical study by Galvani and Barreneche (1994). In this same municipality, there were also several cases of intoxication by vegetables, as shown in the work of Dávila et al (2008) from their ethnobotanical study regarding toxic plants in the city of Uruguaiana - RS.

According to Silva and Santos (2017), the school represents an important space for the dialogue between popular knowledge and the concepts addressed in class, in addition to exercising the role of valuing students' personal experiences. Through the students popular knowledge, the teacher can (re) discover and (re) build knowledge necessary for scientific and technological literacy (Chassot, 2006).

However, has been seen throughout Brazilian academic productions in the Science Education area, that teachers encounter difficulties and / or feel insecure about the use of other teaching strategies. One way of solving this problem can be through the use of continuous education of teachers, since from these spaces you can promote reflections about pedagogical practice, with exchange of knowledge between professionals working in the same modality and educational level, reframing their teaching practice.

This study proposes to evaluate the development of a continuous education course structured though the 3 PMs, where the Toxic and Medicinal Plants theme in association with the 3 PMs was addressed, verifying the potentialities and challenges of a formative process in this format.

MATERIAL AND METHODS

The subjects involved in this investigation were 30 science teachers from the municipal education network of the city of Uruguaiana - RS, Brazil (Image 1). The choice of the study subjects was intentional, since it were the teachers at this location that asked the first author to develop a continuous education course with them. From this interest, an initial analysis of the conceptions of these teachers about science teaching was made in order to structure the course (Dávila, Folmer & Puntel, 2017).

Image 1 – Location of Uruguaiana - RS.

Source: G1 (2011).

The initial idea was to carry out a training process within the monthly meetings of pedagogical training offered by the Secretaria Municipal de Educação (SEMED), to be developed throughout the year, with periodic meetings. However, due to the annual planning of the pedagogical training of this institution, two meetings were authorized and granted. For this reason, the course consisted of two meetings, each lasting four hours, with an interval of two months between them so that the teachers had time to apply the teaching plans in a school context.

We developed a continuous education course, structured though Delizoicov and Angotti's (1994) 3 PMs, as described in the table below.

Table 01 - Continuous training course organized methodologically through the 3 PMs developing the contextualization theme "Medicinal and Toxic Plants" in association to the 3 PMs.

3 Pedagogical Moments	Description
First PM: Initial Problematization	Presentation of the course structure to situate the teachers. Application of initial questionnaire. Questionings regarding the subjects of the course to problematize it.
Second PM: Knowledge Organization	Expositive and dialogic Presentation of the current reality of science teaching; presentation of data from the dissertation in relation to the academic production in the area of science education; explanation of the results obtained with the participating students in the "Medicinal and Toxic Plants" workshop , showing the evolution of the students' answers and drawings regarding Botany and the theme. Explanation of the 3 PMs theoretical references (who they are and how they are organized), using as reference the books "Metodologia do ensino de Ciências" (Delizoicov & Angotti, 1994) and "Ensino de Ciências: Fundamentos e Métodos" (Delizoicov, Angotti & Pernambuco, 2011). Explanation and discussion about the use of themes in classroom, using for that purpose the official Brazilian documents that govern the Elementary School Final Grades (Parâmetros Curriculares Nacionais (PCN, 1998) and the Diretrizes Curriculares Nacionais (DCN, 2013)).
Third PM: Application of knowledge	Elaboration of structured teaching plans in the 3 PMs to develop the "Medicinal and Toxic Plants" theme in a class of their school (realized in the first meeting). In the second meeting, two months after the formative process, the results of the application of the teaching plan were presented in the form of a "Pedagogical Experiences Sharing Seminar".

Source: the author

The final activity (Pedagogical Experiences Sharing Seminar) was recorded and teachers were invited to participate in a semi-structured interview to present their testimony about this pedagogical experience faced in the course of continuous education.

As for the data analysis methodology, we adopted Content Analysis by (Bardin, 2011). For this analysis a triangulation of the data obtained by the different instruments (field diary, questionnaires, teaching plans and semi-structured interviews) was performed.

RESULTS AND DISCUSSION

From the 30 teachers invited, 14 female teachers took part. All with initial formation in their work area, three of them with specialization, with length of professional experience varying from 1 to 20 years.

We noticed that the first PM of the course provoked concerns, a lot of discussion of the topics selected for the continuous education, with reports of situations that occurred in the classroom during their teaching time. It was interesting, because it provided dialogue between the researcher and the teachers with different time amounts of experience in teaching. This dialogue between the subjects involved in the process was also verified by Giacomini and Muenchen (2015) when working with a group of teachers from different areas of knowledge in a formative process also organized through the 3 PMs, considering that the dialogue was mobilized by the teachers' reflection and action.

In the second PM when addressing the scientific knowledge needed to understand the use of the theme and the 3 PMs in the classroom, there was interest in the subject, questionings being conducted when some point of the theoric referential had not been well elucidated.

In the execution of the third PM, some challenges and limitations for the present study appeared. The first challenge was due to the concern of teachers in continuing the curriculum of the school year of the class where the teaching plan of this course that would be developed, because for them, to subordinate the content to the theme, would mean developing a work in parallel and they did not agree with that. A similar occurrence was seen in the reports of Muenchen (2010) interviews with the trainers of the continuous education courses in the municipality of Santa Maria - RS, Brazil, being one of the reasons that some course planning had a more conceptual than thematic focus. This demand was tried to be met, even knowing that this fact could increase the chances of use of the subject only as an example, illustration or a pretext to continue the programmatic contents of that school year, as pointed out by Wartha, Silva and Bejarno (2013).

The second challenge concerns the difficulty of the teachers to relate the theme of the course to any area other than Botany, showing again that they were trying to associate it to school content and not to explain the theme with the necessary scientific knowledge.

The third challenge of the third PM refers to the few teachers who finished the course, of the 14 participants; only seven teachers implemented their teaching plans.

The fourth challenge is linked to the previous one, because it was found that no teacher was able to develop the proposal of the continous education course, classifying the teaching plans (presented at the Experience Sharing Seminar), into three categories:

1st) Subtheme associated with the 3 MPs: within this category were included the works that approached the proposal of the continuous education.

2nd) Subtheme only: activities that used a sub-theme of the theme presented on the course.

3rd) Did not perform as instructed in the course: works that explored neither the theme nor the 3 PMs, but used the theme as an additional classroom task.

In the first category, two teaching plans were contemplated, from a teacher (called P1) who worked in a rural school and the other from a teacher (represented by P2) acting in a school located in a socially fragile area of the city.

Both plans have in common the approach of subthemes, chosen by the teachers, related to the theme presented in the formative process. The teachers understood that they could do it this way because they needed to adapt it to work with the content envisaged for that school year, in which hey had chosen to implement the activity of the training course. It is noticed that the use of themes was subordinated to the syllabus of that year and not the opposite, as is recommended by Delizoicov, Angotti and Pernambuco (2011).

The teachers addressed subthemes that were part of the students' reality, that besides contemplating the specific programatic contents of that year, had cultural issues, social problems and that had the potential to motivate further study by the students.

When comparing these data with the classification used by Silva and Mortimer (2010) when developing the conceptual, contextual, phenomenological and epistemological aspects of chemical content in the classroom, it is suggested that the teachers of this investigation, to chose subthemes from a contextual dimension, because they aimed to approach scientific content with a social, technological, environmental or historical context.

Next, the teaching plans of teachers P1 and P2 are described.

Teacher P1's teaching plan – Subtheme: Drugs derived from toxic plants and their effects on the nervous system

1st PM – Awareness: Videos about drugs, their effects on the nervous system, the risks to the body, and withdrawal crises were used and after that there was a talk to discuss.

Establish relationships between drugs and their effects on the nervous system: class discussion, and notes on the subject.

2nd PM – Explanation and notes on the nervous system, its anatomy and physiology; visualization in models and boards of the main organs and functions.

Group research on the main plant-derived drugs, their effects on the nervous system and the effects of withdrawal.

3rd PM – Organization of data and construction of information panels on the main plants that give origin to legal and illegal drugs and their main effects on the body.

Presentation of the work carried out to classmates in the form of seminars.

Resumptiom of the videos of the 1st PM.

Discussion of some questions.

Explaining though the use of scientific knowledge.

Teacher P2's teaching plan – Subtheme: Mate Herb

1st PM – Questions and discussion about where the Mate Herb they buy from the market comes from.

2nd PM – Historical, cultural and geographical approach to Mate Herb.

Before introducing scientific knowledge of sciences, students had to answer a questionnaire that contained the following questions: "Do you have the habit of drinking mate?; How many times a day do you take mate ? Do you know any benefits of mate? Do you know any harm of mate?".

Students had to apply this questionnaire to 15 people in their neighborhood and bring the data in the next class.

Creation of graphics with the data collected from the questionnaires.

Discussion of results.

Approach of the questions and answers of the questionnaire with the contents of the human body.

3rd PM – Application of recreational activities (crosswords, question-and-answer game related to the theme, memory game) to students as a way of evaluating the subject.

Regarding the second category "Subtheme only", was composed by only one teaching proposal. The teacher (represented by P3) launched the theme in the classroom to reflect on it, because according to her, already worked with themes in the classroom, but the students chose them. By developing in this way with the theme "Medicinal and Toxic Plants", students ended up leading the approach to "Energy", because they were interested in the process of photosynthesis.

In the last category, four teaching proposals were included, that used the theme "Medicinal and Toxic Plants" as a complementary task to the content that had been addressed by the teachers, in which students should conduct a group research on the subject and after that, present it to the class in a seminar format. All teachers in this category have claimed that the time was a limiting factor to implementing their planned activities.

The activities carried out by each teacher are identified below:

Teacher P4 – from the theme proposed in the training course, she extracted a subtheme of it to carry out a work complementary to the content of human physiology. The chosen subtopic "Substances extracted from vegetables: Caffeine and THC (extracted from marijuana)" was due to an association with the History teacher who wanted to deal with the subject of Coffee. The activity developed by the students corresponded to the elaboration of a folder and a parody, both about caffeine and THC. Four questions were given to guide the work: "what were the drugs Caffeine and THC?"; "where they were found?"; "what are the effects of these drugs on the human body, both beneficial and harmful?" and "a curiosity about these drugs". The history teacher asked for the history of coffee. Students had to present these activities in the classroom.

Teacher P5 - Had the understanding that she should approach the concept of a plant and its structures before the theme, therefore, the demonstration activity was developed before, but even so, she did not finish her planning, went no further than the proposal that will be described. She took a plant and asked the students to observe it and compare what was there of similarities and differences with the human body. Soon after, she placed a plant in water with dye and another plant in a container with water without dye and asked them to observe and write what would happen to the plant that was in the dye. The students made graphs of the hypotheses of what would happen to the plant that was in the dye. After a few days, they looked again at the plant that was in the dye and wrote down the reasons for the vegetable to be showing colored petals, which were initially white. The students made assumptions regarding photosynthesis, that the plants had a "small pipe". After this practical activity, she made a comment in in the classroom about what medicinal plants were and which could become toxic and from this moment on she was unable to carry on working with medicinal and toxic plants.

Teacher P6 – She covered with the students the content of plant morphology to later address the theme, as she believed that students needed prior knowledge to later study the theme. She developed a research activity related to medicinal and toxic plants, that she had found in the textbook, with the students. After researching it in pairs, they had to present it in the classroom.

Teacher P7 – Divided the class into groups and each had a topic about plants (terrarium assembly; plant experiment in the dark; conducting vessels; plant reproduction; root development; germination) and a group with medicinal and toxic plants. The teacher, as well as the others in this category, believed that the students should first have a theoretical background in botany, because she considered her students immature, in the sense that they had no idea what a plant is.

When interviewing teachers about the elaboration and execution of teaching plans, it was found that the teachers had difficulties during the time allotted for this activity. The first one was related to the time to execute the teaching strategy in the classroom. It was found that two months had been a short time to implement their teaching proposal with the students. This hindered the development of plans as discussed in the continuous education course, leading all teachers not to implement the theme “Medicinal and Toxic Plants”, but to unfold it in subthemes and depending on the teacher, to approach it from the 3 PMs or not. This difficulty of lack of time to organize, plan and implement the teaching plan may be linked to the current conditions of teaching work, as evidenced in the study by Donatelli and Oliveira (2010) with basic education teachers in RS.

Another factor present in the teachers' statements that may have limited the execution of the teaching strategy in a satisfactory way: the current curricular organization in schools, which developed a feeling of imprisonment to school content among teachers, becoming a challenge for the implementation of the theme from the perspective of the 3 PMs, limiting the investigation of the potentialities of the proposed theme.

It may be that in this study, the short duration of the training process has failed to change teaching practice. Sauerwein (2008) emphasizes that courses with this characteristic may not allow the increment of this in the permanent education of the teacher, perhaps using it for a short time in their pedagogical practices. However, Neto (2014, p. 13) points out that although this training format “does not seem to offer enough time for the processes of understanding and acceptance to materialize, they are important as they present alternatives, they motivate, they show ways of how, why, where and when to use a particular activity”.

It can also be seen through the interviews, that even teachers did not use the theme as initially proposed in the training process; positive results were obtained regarding the implementation of teaching plans. Although the theme was unfolded in different sub-themes or developed as a complementary activity to the sequence of contents that the teachers were addressing, if it succeeded in instigating the students' curiosity, giving subsidies to promote a dialogue between teacher - student, student - student and between popular knowledge and scientific knowledge. Moreover, through these plans, it can be ascertained that contents and developments can emerge from the theme “Medicinal and Toxic Plants” and serve as a subsidy for future planning, where the theme can be seen as the object of study that disciplinary contents are organized from, opening possibility for an articulation of the different areas of knowledge to work around a common objective.

FINAL CONSIDERATIONS

It was found that the formative process presented did not allow teachers in the 3rd PM to elaborate and execute teaching plans in which the school content was subordinated to the theme, requiring a continous education course like this, which is structured in 3 PM, to be developed with a longer duration and longer meetings, giving a greater support to teachers. However, it provided, as far as possible, the discussion of the pedagogical praxis of teachers as well as a greater interaction between university and school, offering a space for sharing knowledge and getting closer to the academic material.

Another aspect that may have interfered with the success of the 3rd PM was the teaching conception and curriculum of the teachers in this study, as they were shown to be “imprisoned” to the school contents of the current curricular organization of school..

Even with the challenges faced in this continuous education, teachers were active subjects in this training process, in which their concerns, teaching knowledge and doubts were heard and discussed, through the promoted dialogue, in addition to bringing the subjects involved to reflect on their pedagogical practices, studying a different teaching methodology and trying to develop a teaching plan different from their usual.

The theme "Medicinal and Toxic Plants" allowed immersion in different social contexts, as seen in the work implemented by the teachers, but it is believed to have a much greater potential if we have public policies giving subsidies to have greater curricular flexibility in school institutions.

THE TRANSITION FROM PRIMARY TO SECONDARY SCHOOL IN SCIENCE EDUCATION

Julia Brüggerhoff[1], Sarah Rau-Patschke[1], Stefan Rumann[1]
[1]University of Duisburg-Essen, Essen, Germany

In science education, there are serious concerns about continuity and progression in students' learning at key points of transition especially during the transition from primary to secondary school. National and international studies show a lack of progress in students' learning as well as their loss of interest. One of the key issues seems to be a lack of teachers' competencies. Therefore, the aim of this study is to identify competencies required by teachers to ensure progression and continuity in students' learning. For this purpose, a Delphi survey is conducted which includes different experts related to the transition process in science education. In addition, guideline-based interviews with 5th grade students, who recently experienced the transition, will be used to capture the students' perspective. In a preparatory study, transition-related activities were derived deductively from the literature and summarised within a category system. The six main categories Knowledge of Curricula in Science Education*,* School Environment & Organisation*,* Assessment, Teaching Styles & Approaches*,* Cooperation *and* Empathy for Students' Transition Process *were used to structure and analyse the first round of the Delphi survey. First results show that experts demanded competencies in all these six categories.*

Keywords: Primary School, Secondary School, Teacher Professionalism

INTRODUCTION

In Germany, the education system is characterised by a number of transitions. The transition from primary to secondary school represents the first change that all students usually have to pass after the fourth grade at the age of 10. In particular, this transition is associated with changes within social, instructional as well as organisational aspects that might have an impact on students' learning (Ophuysen, 2009). With regard to science education, there are serious concerns about continuity and progression in students' learning related to the transition process.

Science Education in the Transition from Primary and Secondary School- Status Quo

In Germany, the transition from primary to secondary school is accompanied by differences in subjects' structure, teachers' education, as well as teaching styles. In primary school there is an integrative subject combining both natural and social sciences (called "Sachunterricht"; GDSU, 2003). That is why teachers at primary school need a broad (pedagogical) content knowledge in natural and social sciences. Therefore, they are known to be generalist teacher (Möller, 2014), often teaching subjects they did not formerly study themselves. In contrast, in secondary school, there are different science subjects (e.g. physics, biology, chemistry, geography and technology). Teachers of secondary schools are known to be specialist teacher (ibid.), due to their focus on one or two of those subjects. Furthermore, primary school's science education seems to be more student-centred including practical science, whereas secondary school's science education appears to be more teacher-centred (ibid.).

Difficulties associated with the transition process are investigated not only in Germany. International and national studies prove that there are key issues related to the transition from primary to secondary school, which affect students' learning (e.g. Galton, Gray, Rudduck, 1999, 2003; Ophuysen, 2009). In science education, studies across several countries indicated that students fail to manage the transition from primary to secondary school (Braund, 2008a; HMIe, 2005; Möller, 2014). In addition, there is also evidence that students' interest decline in the early years of secondary school. Especially in science education, various studies show the decline in subjects like physics (Walper, 2014). Moreover, the loss of interest when compared with students' interest at the end of primary school is worse in science than in math (Heine, Willeke, Best & Pospiech, 2013).

One of the key issues seems to be the lack of teachers' competencies. As a "co-constructive process" (Griebel & Hiebl, 2010, p. 18), primary and secondary school teachers must be capable of supporting a transition that ensures students' cumulative learning. Hempel and Maltzahn (2012) state, that primary and secondary school science teachers often are unfamiliar with each other's curricula. Moreover, secondary school science teachers are insecure of what to expect from their new students recently graduated from primary school. They even rate the primary school students' prior knowledge in the natural sciences to be quite low (ibid.) although there is no evidence. Instead, Dalehefte and Rieck (2014) indicate that primary school students learned scientific methods and possess a basic knowledge in sciences that are in line with the curriculum at secondary schools. Moreover, Hempel and Maltzahn (2012) point out that secondary school teacher often fail to refer to students' prior knowledge and learning experience. Racherbäumer and Kohnen (2014) declare that the diagnosis of prior knowledge at the beginning of the fifth grade is a rare exception, especially in natural science subjects. Galton, Gray and Ruddock (1999) as well as Braund and Driver (2002) state that teacher of secondary school distrust the students' levels of attainment that they have been assessed in the primary school. Moreover, it is their justification to "still cling to the principle of the 'fresh start'" (Galton, Gray, & Ruddock, 1999, p. 6). Therefore, basic skills and procedure as well as topics are often full repeated in secondary school (Braund, Crompton, Driver, & Parvin, 2003). Various models explaining the importance of teachers' competencies due to their influence on the quality of the transition process (Griebel and Hiebl, 2010; Ophuysen, 2005; Ophuysen & Harazd, 2014). However, the teachers' required competencies are still unkown.

Current Practice in Tackling Transition in Science Education– Review of Literature

The continuity and progression of students' learning at key points of transition have been considered at terms of curricula, administration and teacher training (Möller, 2016). Studies on the development and implementation of a spiral curriculum, so-called bridging units or materials show that a continuous curriculum is possible (e.g. Braund, 2008b; Burr & Simpson, 2006, 2007; McCormack, 2016). At the administrative level, the introduction of subjects which combining natural sciences at the beginning of secondary school was recommended, e.g. by Wodzinski (2006), but not implemented compulsory. Furthermore, joint activities or projects in primary and secondary schools are supported by regional projects (e.g. Demuth, Walther & Prenzel, 2011) and the development of regional school networks (e.g. Järvinen, Otto, Satory, & Sendzik, 2012). In addition, there are recommendations for pedagogic transitional-related activities, which are used in various ways already (Braund, Crompton, Driver, & Parvin, 2003; Galton, Gray, & Ruddock, 1999, 2013; Ophuysen, 2005). However, the transition in science education is rarely supported by teachers' transition-related activities (Hempel & Maltzahn, 2012; Rau-Patschke & Brüggerhoff, 2019).

RESEARCH QUESTIONS

The research aim of this study is to determine teachers' required competencies in order to ensure a continuous development of knowledge, interest and motivation during the transition in science education. Therefore, the central research questions of this study are:

Research Question 1: Which competencies do teachers require in order to ensure continuity in the student's learning process and in the development of knowledge, interest and motivation during the transition in science education?

Research Question 2: What recommendations can be derived from students' own experience during the transition in science education and which issues still need to be addressed to ensure the well-being of the students?

The following information relate to Research Question 1.

METHODS & DESIGN

To answer these questions, a three-stage Delphi survey was designed. The characteristics of the Delphi technique are the anonymous group interaction and responses, the iterative process and the feedback (Linstone & Turoff, 1975). Linstone and Turoff (1975) define the Delphi technique "[…] as a method for structuring a group communication process so that the process is effective in allowing a group of individuals, as a whole, to deal with a complex problem" (p. 3). The complex problem of the present study is the identification of previously unknown competencies required by teachers to ensure the continuity and progression in students' learning in science education. Since the variety of experts determines the quality of the results of the Delphi survey, members of the present Delphi expert panel were selected to represent a community who possess a wide range of expertise in the field of transition, science education as well as teacher training. Individuals from four areas within this community were involved in the study (hereafter called 'expert panel'):

- Science teacher of primary and secondary school
- Researchers in natural science education
- Teacher trainers of primary and secondary school in natural science education
- Headmasters of primary and secondary school

In a preparatory study, transition-related activities were deductively derived from the literature. These activities are used to formulate a first set of teacher's required competencies. They are summarised within a category system. The six main categories *Knowledge of Curricula in Science Education*, *School Environment & Organisation*, *Assessment*, *Teaching Styles & Approaches*, *Cooperation* and *Empathy for Students' Transition Process* are used to structure and analyse the first round of the Delphi survey (Rau-Patschke & Brüggerhoff, 2019).

In Round I, the experts were asked to answer open-ended questions related to these six categories. The main question was:

What are the characteristics of teachers who are capable of supporting a transition that ensures a continuous development of knowledge, interest and motivation during the transition in science education?

The responses are collected and analysed using qualitative content analysis (Mayring, 2015). The analysed skills, abilities and attitudes complete the category system.

In Round II, based upon these qualitative results, a questionnaire with closed questions will be developed and sent to a bigger expert panel (*N*=300). The experts are asked to rate the items on a 5-Point Likert Scale according to their relevance.

In Round III, the same expert panel is given the opportunity to reconsider and, if necessary, change their own opinion based on the group response. Finally, the results are analysed with regard to the consensus between the expert subgroups. Figure 1 illustrates the procedure of the present Delphi survey.

In the pilot phase *N*=16 experts took part of the open-ended questionnaire, equally divided in all four subgroups. For the first round of the Delphi survey a sample size of *N*= 140 experts is addressed. For the second and third round, a sample size of *N*=190 experts is aimed, in which the experts participate in both, the second and third, survey round.

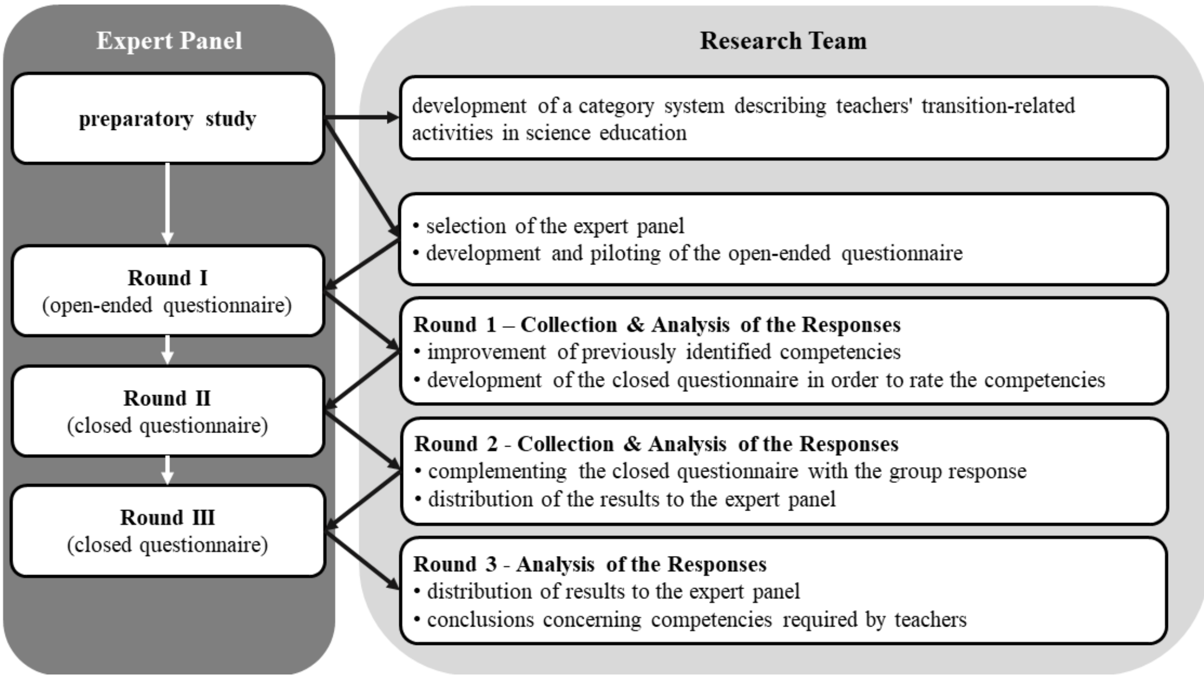

Figure 1. Flow chart of the Delphi study (based on Carabias et al., 2015)

RESULTS

The results show that experts demand skills, abilities and attitudes in all six categories (Figure 2). Especially in the categories *Knowledge of Curricula in Science Education*, *Assessment* and *Teaching Styles & Approaches* the experts require different skills and abilities that deal with knowledge about school policies, prior knowledge, core ideas, contents, methods and subject structures. So far, the demand skills and abilities in the categories *School Environment & Organisation* and *Cooperation* have remained nonspecific related to transition in science education so far. In particular, in the category of *Empathy for Students' Transition Process*, the experts demand specific attitudes and positions from teachers at primary and secondary school, which focus on the empathy of the teachers.

Knowledge of Curricula in Science Education	Primary and secondary school science teachers are familiar with each other's science subject structures.
School Environment & Organisation	Secondary school science teachers make the work in subject rooms a topic of discussion.
Assessment	Primary and secondary school science teachers advise students regarding their performance at key points of transition in science education.
Teaching Styles & Approaches	Secondary school science teachers use well-known methods of science education of primary schools.
Cooperation	Primary and secondary school science teachers are aware of the benefits of cooperation between primary and secondary schools in science education.
Empathy for Students' Transition Process	Primary and secondary school science teachers give attention to the differences between primary and secondary schools in science education.

Figure 2. Skills, abilities and attitudes demanded by the expert-panel

CONCLUSION

As the discussion about continuity and progression in students' learning at key points of transition the aim the study is to determine teachers' required competencies in order to ensure a continuous development of knowledge, interest and motivation during the transition in science education. Related to the categories *Knowledge of Curricula in Science Education*, *School Environment & Organisation*, *Assessment*, *Teaching Styles & Approaches*, *Cooperation* and *Empathy for Students' Transition Process*, the experts require abilities, skills and attitudes. However, they do not only seem to be of high relevance for the continuity and progression in students' learning at key points of transition, but also in everyday teaching. Therefore, the question arises if there are competencies already mentioned in models of teachers' profession which are important especially for transition. In order to answer this question, the main study will involve a larger sample size. In addition, by answering the second research question, the perspective of 5th grade students will also be captured. In guideline-based interviews, they will be asked about their requirements regarding transition-related activities.

THE STRUCTURAL CHALLENGE IN BRAZILIAN TEACHER EDUCATION: THE PHYSICS TEACHER SHORTAGE

André Rodrigues[1], Cristiano Mattos[1]

1 Institute of Physics, University of São paulo, São paulo, Brazil

Studies have indicated the pivotal role that qualified and experienced teachers play in students outcomes as well as in curriculum reforms. Nevertheless, it is reasonable to say that the critical aspects of teacher education such as recruiting and retaining good teachers are commonly overlooked. The main goal of our broader study is to provide an accurate empirical picture about the Physics teacher education in Brazil, which might help to enrich a more international discussion on processes of teacher recruiting, retention and attrition in Science Education. Findings indicate that the distribution of qualified teachers across Brazilian states is uneven with a couple of them with less than 10% of the teachers with adequate qualification in Physics teaching. Moreover, roughly 5% of those who entered in the teacher education programs end up teaching Physics in high schools. It is a massive leak which has its major challenge in filling the gap between higher education institutions and the high school classrooms. To sum up, the study makes possible to empirically ground the debate over Physics teacher shortages and evaluate the extent to which there is, or is not, sufficient supply of teachers in this field. Besides the Physics teacher shortage is huge compared with developed countries, the numbers seem relatively stable throughout the years. It is, on the one hand, a relevant confirmation that the problem is not getting any worse, on the other hand, it is evident that all the effort to improve Physics teacher retention have been achieving little effective results. Today, there is a growing consensus coming from quantitative and qualitative studies that improvements in salary and working conditions are key to change the whole scenario. From an accurate picture of Physics teachers situation, it is possible to understand and work with the concrete educational scenario.

Keywords: Teacher education, teacher shortage, Physics teacher

INTRODUCTION

There is a growing consensus among researchers, policymakers, and practitioners that initial teacher education is a key factor in changing the current state of affairs in Science Education (Bauer & Prenzel, 2012). Even though curricular design, integration between teacher education programs and schools, teachers' knowledge are indisputably at the core of teacher education concerns, it is important to address the nature as well as the current state of Science teacher attrition and retention (Buchanan et al., 2013).

The lack of qualified teachers is especially critical in implementing any substantial change in Brazilian Science Education. Studies have indicated the pivotal role that qualified and experienced teachers play in students outcomes as well as in curriculum reforms (Borko et al., 2002; Delandshere & Arens, 2001). Although, the relevance of well trained teachers in the educational processes has become common sense in research and educational practice, it is reasonable to say that the critical aspects of teacher education as well as attrition, recruiting, and retaining teachers are commonly overlooked (Borko et al., 2002; Buchanan et al., 2013).

The scenario of shortage and to some extent inadequacy of initial teacher education, commonly referred as out-of-field teachers, is not restricted to Brazil. This issue has been the subject of several studies around the world, including in economically developed countries (du Plessis et al., 2014; Ingersoll, 2003). According to Du Plessis; Gillies and Carrol (2014), in Australia 16% of Science and 24% of Mathematics teachers are not qualified, whereas in England 31.4% of Physics teachers are framed in the same problem. As we will see in this study, the Brazilian scenario, with regard to the physics teacher, it is much more worrying and the numbers are not encouraging.

Moreover, since educational data started to be collected covering a variety of aspects, it is possible to identify struggles in Brazilian educational system to improve its general quality (Avalos, 2011), from general indicators like graduation rates to specific ones like the students' achievement in the Programme for International Student Assessment (PISA). We expect that by addressing the shortage of Physics teachers in Brazil might help to shield light in the general issue of teacher retention around the world. To better understand the concrete and structural challenges that developing countries are facing today regarding improving Science education indicators, it is important to build an accurate picture of what are the situation of Brazilian Physics teachers' formation and practical experience (Villani et al., 2009).

STUDY GOALS

The main goal of our broader study is to provide an accurate empirical picture about the Physics teacher education in Brazil. Although the data presented is mostly on national level, the study as might help to enrich a more international discussion on processes of teacher recruiting, retention and attrition in Science Education.

In this study we acknowledge that teachers' education and experience play a pivotal role in different aspects of Science education from pupils learning to curriculum reforms. Therefore, there is an underlying need to substantiate the Science Education research with data and evidence of the challenges that professional development faces today. We focused on two dimensions of teachers situation in Brazil: (i) teachers' undergraduate degree; and (ii) the number of incoming and concluding students in Physics teacher undergraduate programs, and in-service qualified teachers. We looked for relations between this two dimensions in order to understand how the professional choice is maintained or not when they initiate their professional life.

SOME REMARKS ON INITIAL TEACHER EDUCATION IN BRAZIL

Before addressing the Physics teacher situation, it is important to have an overview of how teacher education is structured in Brazil which might have some contrast with European programs, mainly after Bologna (Flores, 2011). Physics teaching is basically concentrated in the high school level and the qualification to teach is a higher education degree -- university level. There are little alternative paths to becoming a high school teacher and even though the design in the teacher education programs might vary, in the general outline al future teachers have to entry the university level of initial teacher education program.

The main implication is that future teachers must have a career decision early on in their academic lives, which might be too early for many. This characteristic of decision making has implications for the process of recruiting new students for teacher education programs and the ways students and institutions find to avoid dropouts. Most of the students take the decision to become a teacher while in the teacher education program and most of them do not go to work as teachers, even if they have completed the four years program (Gatti, 2013).

METHODS AND DATA GATHERING

The study is grounded on the governmental education data at national level in Brazil which stems from the datasets of basic schools and higher education census both publicly available by the Ministry of Education. The study is centered on the descriptive statistic adequate to build the empirical picture of teacher education (Agresti & Finlay, 2009). Most of the effort consists in assembly the data set from the last decade and inquiry about the concrete situation of Physics teachers in schools regarding their qualification.

This empirical picture created with a descriptive statistic might work as a starting point for investigating the concrete situation and public policies as well as provide the bases for models in broader studies.

FINDINGS

It is not uncommon that policymakers, curriculum designers and researchers set their actions and propositions based on an idealized teachers that may not find support in the concrete life of schools. One of the central issues is: who is actually conducting the Physics lessons?

In Brazil, since 2007 is known that Physics is the subject matter that lives the most critical scenario with 26% of its teachers with proper qualification -- i.e. higher education degrees in Physics teacher education (Pestana, 2009).

Table 1 - Percentage of the Physics teachers by each higher education degree | Source: 2018 Brazilian School Census

Teacher education in Math	Teacher education in any other field	Teacher education in Physics	Any other higher education degree	Higher education student	Teacher education in Sciences	Pedagogy
18,801	13070	12,597	5,358	3,238	2,829	3,048
31.9%	22.2%	21.4%	9.1%	5.5%	4.8%	5.2%

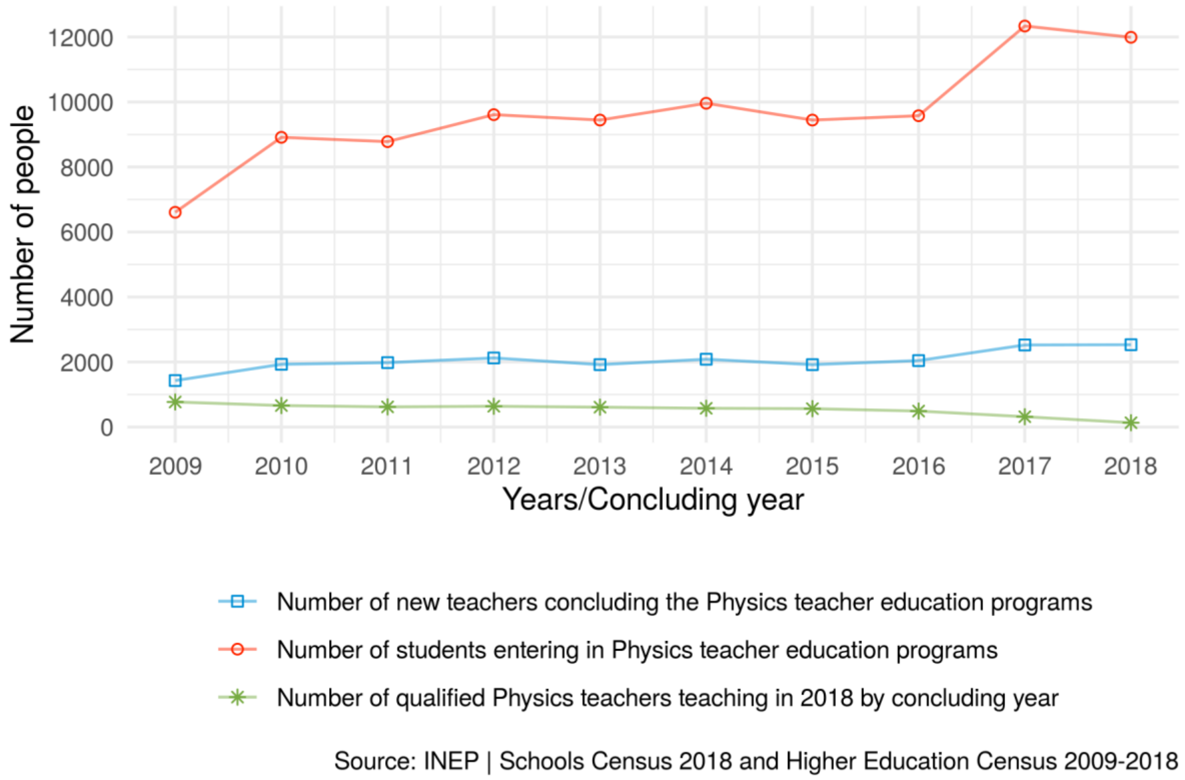

Figure1 - Graphic of the number of students entering in Physics teacher education programs by year, number of new teachers concluding the Physics teacher education programs by year, and number of qualified Physics teachers teaching in 2018 by concluding year.

Table 1 shows the percentage of the Physics teachers by each higher education degree. The largest group is formed by teachers has a background in Mathematics. In the national level, they correspond to 32% of the total number of Physics teachers. The qualified teachers correspond only to the third largest group and it is possible to estimate that 79.5% (more than 46,000) Physics teachers are non-qualified.

The distribution of qualified teachers across states is uneven with a couple of states with less than 10% of the teachers with adequate qualification. For instance the federal district has the best mark with 61% of qualified teachers while São Paulo, the most populous state, has 16.3 %.

The number of students entering into Physics teacher education programs roughly doubled from 2009 to 2017. What is mainly explained by the expansion of the higher education system and the growing number of teacher education programs in almost all subject matters. Although it is possible to observe a tendency of growing in the last year for students entering and new teachers leaving from teacher education programs, only one-quarter eventually concludes. Additionally, only one-fifth of new teacher go to classrooms in public and private schools. It means that roughly 5% of the those who entered in the teacher education programs end up teaching Physics in high schools. It is a massive leak which entails challenges in filling the gap between higher education institutions and the school classrooms as well as improving the ratio between the entering and the concluding in Physics teacher education programs.

Table 2 - Percentage of the Physics teachers by each higher education degree per region | Source: 2018 Brazilian School Census

Region	Teacher education in Math	Teacher education in any other field	Teacher education in Physics	Any other higher education degree	Higher education student	Teacher education in Sciences	Pedagogy
Center-West	1,179 26.3 %	741 16.5 %	803 17.9 %	737 16.4 %	272 6.1 %	492 11.0 %	260 5.8 %
Northest	4,956 31.2 %	4438 27.9 %	2,751 17.3 %	1,209 7.6 %	1388 8.7 %	474 3.0 %	685 4.3 %
North	1,913 33.1 %	1,399 24.2 %	1,093 18.9 %	257 4.4 %	301 5.2 %	325 5.6 %	497 8.6 %
Southeast	2,464 26.6 %	1,596 17.2 %	2,891 31.2 %	1,302 14.1 %	469 5.1 %	380 4.1 %	153 1.7 %
South	1,968 26.4 %	1,323 17.7 %	2,095 28.1 %	374 5.0 %	374 5.0 %	232 3.1 %	1,094 14.7 %

Some regional differences are shown in table 2. It may indicate that the demands and their solutions might be regional driven. regions like South which has historically better education indicators along with Southeast which is known for been a highly industrialized region has the higher rates of qualified teachers with 28.1 % and 31.2 % respectively.

FINAL CONSIDERATIONS

As data shows there is a shortage of Physics teachers in general and it is particularly aggravated for qualified teachers (Araujo & Vianna, 2011). Although such a shortage magnitude is known since 2006 with studies on the 2003 school census (INEP, 2006), there are few studies address the most particular characteristics and issues related to the physics teacher specially in recruiting and retaining in the initial teacher education program. Based on the 2009 school census, Gatti (2014) highlights that among all school subjects, Physics is the one with the lowest percentage of qualified teachers.

Besides the Physics teacher shortage is more acute compared with developed countries, the numbers seem relatively stable throughout the years. It is, on the one hand, a relevant confirmation that the problem is not getting any worse. On the other hand, it is evident that all the effort to improve Physics teacher retention have been achieving little effective results. There is a growing consensus coming from quantitative and qualitative studies that improvements in salary and working conditions are key to change the whole scenario (Richardson & Watt, 2005).

Furthermore, the dominant presence of teachers with Math background may help to explain the strong identification or reduction of Physics teaching to mathematical problems solving. This problem added by the uneven distribution of qualified Physics teachers across regions, allows to hypothesize that Physics teaching could have different characteristics in different regions. Another commonly neglected consequence of the critical Physics teacher shortage is that teachers can not create teachers study groups becoming isolate in his work at school, what may undermine professional development programs grounded on pair exchange and networking within the disciplinary field.

Finally, with a more accurate picture of Physics teachers situation, it is possible to understand and work with the concrete educational scenario and at the same time to propose ways to change it.

SUPPORTING PROFESSIONAL LEARNING COMMUNITIES TO DEVELOP CONTENT KNOWLEDGE FOR TEACHING AND LEARNING PHYSICS AT LOWER SECONDARY LEVEL

Deirdre O'Neill and Eilish McLoughlin
CASTeL, School of Physical Sciences, Dublin City University, Dublin 9, Ireland

Participation of physics at upper secondary level in Ireland, particularly among girls, is a matter of national concern. However, the situation in Ireland is not unique, with many countries seeking to address the low numbers of students continuing in physics at upper secondary level or at University level. In addition, many countries suffer from insufficient numbers of teachers qualified to teach physics at lower secondary level and this directly impacts on the retention rates at upper secondary level. This study reports on findings from a two-year collaboration, between physics education researchers and eleven science teachers, focused on enhancing the teaching and learning of physics at lower secondary level. Two professional learning community case studies are presented in this paper that examine the impact of a school-based professional development programme with all science teachers in two Irish second level schools. In the first year, a series of workshops with teachers were facilitated with three core objectives; namely, increasing teacher's confidence and specific content knowledge for teaching physics; raising their awareness of unconscious biases and career opportunities in Physics. In the second year, teachers and researchers collaborated to co-design a sequence of lessons in physics that embedded these three objectives. Using the Ambitious Science Teaching framework, we have measured the impact of this collaborative approach on teacher's planning of sequences of lessons to enhance the teaching and learning physics at lower secondary level.

Keywords: Teacher Professional Development, Inquiry-based teaching, Physics.

INTRODUCTION

The effect of fostering student and teacher identity in physics in increasing student engagement and participation in science, technology, engineering and mathematics (STEM) has been discussed in recent literature, e.g. Hazari reports that secondary level physics teachers can positively impact on physics identity development among their students (Hazari et al., 2010). Understanding the factors that influence students' interest in STEM, highlights processes that may selectively dissuade females from pursuing STEM career paths (Ito & McPherson, 2018). In particular, female experience of conceptual understanding and real-world/contextual relevance is reported lower than their male counterparts (Hazari et al., 2010). Therefore, increasing teacher awareness around the influence of stereotypes and biases on students' engagement is pivotal in enhancing the teaching and learning of physics at lower secondary level.

In Ireland, the 2019 statistics reported by the State Examinations Commissions show that 14% (7942) of the Irish Leaving Certificate student cohort choose to study and complete the physics examination at upper secondary level. Of the total student cohort (56,008) taking physics for the Leaving Certificate Examination only 4% (2116) of were girls (State Examinations Commission, 2019). The STEM Education Review group reported that 22% of the 723 Irish secondary level schools do not offer Physics as a separate subject at upper secondary level (STEM Education Review Group, 2016). This data highlights the need to encourage more students, particularly girls, to continue in physics at upper secondary level and the urgent need to promote physics teaching as a future career for young people nationwide.

Sustaining the pipeline of physics students in upper secondary school (ages 15-18 years) must begin with improving the student experience with physics at lower secondary level. Currently, in Ireland, teachers registered with the Teaching Council (Regulatory body for professional standards in teaching) with any one science subject in their final degree e.g. Physics, Chemistry, Biology to upper secondary level are also recognized to teach science at lower secondary level, to students aged 12-15 years. As there are only 1259 teachers who are recognised with qualifications to teach Physics, often the teaching of lower secondary level physics (as an integrated strand of science), is facilitated by teachers who have a Biology (3878 teachers) or Chemistry (2376 teachers) science specialism (STEM Education Review Group, 2016). Supporting these teachers so as to improve the quality of the teaching and learning of physics at lower secondary level and to respond to increasing diversities in classrooms is the core aim of this research.

In schools, hours dedicated for science department planning hours are commonly focussed on the upper secondary level science specialisms. However, a lack of collaboration among teachers who teach the same common lower secondary level curriculum and an absence of teacher professional learning communities (PLCs) in schools is widely reported. McLaughlin identifies strong professional communities as those teachers who share a sense of common mission and negotiate principles, policies and resources for their practice. She attributes, a community of teachers who work together and explore ways of improving practice in order to advance learning, to generating knowledge of practice (McLaughlin & Talbert, 2001). Dana & Yendol-Hoppey specify that PLC's unlike department meetings have a central focus on student learning and teacher professional learning. With the power to change school culture, teacher impact and student achievement, PLCs engage in deliberate and purposeful professional dialogue to learn from practice (Dana & Yendol-Hoppey, 2015). The aim of this study addresses this need to foster professional learning communities with teachers from the same science departments and enhance the teaching and learning of physics at lower secondary level.

THEORETICAL BASIS

Implementing teacher professional development programmes that are effective in increasing science teachers' confidence and content knowledge for teaching specific physics concepts at lower secondary level is challenging. The Ambitious Science Teacher (AST) framework outlines pedagogical approaches for engaging science through supporting intellectual engagement and promoting attention to equity (Windschitl et al., 2012). This framework supports teachers professional learning using four key practices: planning for engagement with important science ideas, eliciting students' ideas, supporting on-going changes in thinking and pressing for evidence-based explanations. The first practice, planning for engagement with important science ideas, outlines a design instruction for planning to engage students in big science ideas (Windschitl et al., 2012). Facilitating teachers to construct plans and deepen teachers' understanding of physics content is difficult to balance within teacher professional development programme (Banilower et al., 2006). The Ambitious Science Teaching framework supports teachers to design learning experiences focused on anchoring/big science ideas. Using conceptual tools for exploring big ideas through inquiry-based learning, teachers can frame activities for students in science classrooms (Thompson et al., 2013). Guidelines for teaching science, technology and society from the upper secondary Irish physics curriculum were adapted into the dimensions of planning framework to promote equity by highlighting the need to raise awareness of careers in STEM (National Council for Curriculum and Assessment, 2002).

In the context of the AST framework, this study will address the following research questions:

i) How can teachers be supported to develop their content knowledge for teaching physics at lower secondary level through planning sequences of lessons?
ii) How is teachers' awareness of unconscious bias, gender stereotypes and careers in STEM addressed in their planning of physics at lower secondary level?

METHODOLOGY

This study reports on a collaboration with two Irish second level schools, that are part of a wider research programme aimed at implementing a whole-school approach to addressing gender imbalance in upper second level physics and is further described in recent publications (O'Neill, McLoughlin & Gilheany, 2018). The three key objectives of this research programme are to;

i) Deepen science teacher's confidence and content knowledge for teaching physics,
ii) Increase awareness of STEM and careers in STEM;
iii) Adopt a whole school approach to addressing unconscious bias and gender stereotyping and build confidence and resilience for students, particularly girls, to continue with Physics.

The focus of this collaboration with science teachers was to facilitate workshops with science teachers that model inquiry-based teaching, learning and assessment practices that are appropriate for teachers to adopt in their own classroom practices. The participants in this study were eleven science teachers from two Irish secondary schools identified as PLC1 and PLC2. PLC1 consisted of three teachers qualified to teach Biology, one qualified to teach Chemistry and one qualified to teach physics. PLC2 consisted of three teachers qualified to teach Biology, two qualified to teach Chemistry and one qualified to teach Physics.

During the first year, science teachers participated in both guided and open inquiry-based workshops (Bevins & Price, 2016), that address specific concepts in Physics as identified by the collaborating teachers; Energy, Electricity, Light, Speed, Earth & Space, Forces, Density.

Teachers were facilitated to work in small groups (typically 3-4) to co-design these concept-based workshops alongside the researcher as part of a professional learning community. It is suggested that professional development models facilitate teachers becoming part of professional learning communities for fostering sustained collaborative practices among teachers in schools (Dana & Yendol-Hoppey, 2015).

During the second year, the teachers and researchers collaborated to co-design a sequence of lessons in physics that embedded all of the objectives of the programme; deepen teacher's confidence and content knowledge for teaching physics, increase awareness of careers in STEM and address unconscious bias and gender stereotyping. The co-designing of sequences of lessons consisted of one two-hour planning session with both PLC1 and PLC2 cohorts. The Ambitious Science Teaching (AST) protocols were adapted as a scaffolding tool to support collaborative planning through dimensions of planning (Windschitl et al., 2012). The dimensions of planning; causal explanation, essential question, scientific concepts, lesson activities, links to curriculum and how is the learning assessed were adapted from the Ambitious Science Teaching - Unit Planning Tool to fit the context and language used in the Irish education system (Table 1). Inclusive practices were also included in the approach adopted in this study and included a focus on fostering physics identity, raising awareness of unconscious biases and gender stereotyping (Hazari et al., 2010) and promoting STEM careers (National Council for Curriculum and Assessment, 2002), see Table 1. Teachers used a wind-up toy car, that moved non-linearly and gave off sparks, to anchor the planning of their sequence of lessons. Each sequence of lessons were evaluated using the AST framework to determine if the three key objectives of this research were achieved. The intellectual requirement for teachers in terms of planning questions and tasks in the classroom were classified as low-cognitive demand (focus on memorization, procedural tasks, recall understanding only) and high-cognitive demand (sense-making, no discrete answers, using evidence to support claims etc.) as defined by the cognitive demand in questions and tasks in Ambitious Science Teaching (A Discourse Primer for Science Teachers, 2015). Teachers' sequence of lessons were evaluated according to these criteria to establish patterns in teacher planning for engaging physics.

Table 1. Mapping Dimensions of Planning according to Ambitious Science Teaching and inclusive practices

	Dimensions of Planning	Description
Ambitious Science Teaching	Causal Explanation	• What's happening (description)? • Why is it happening (explanation)? • Detailed (researched) description of the phenomenon
	Essential Question(s)	• Record all questions relating to a phenomenon • Identify essential / investigable questions • Turn questions into investigative questions
	Scientific concepts	• Identify a range of physics/science concepts – related to causal explanation • Student conceptual difficulties
	Lesson activities	• Design experiments to support student learning • Sequence activities/experiments to construct • Consider effective instructional strategies
	Links to curriculum (cross strand)	• Identify learning outcomes on curriculum (in any of the strands) • Create links across the strands of curriculum
	How is learning assessed?	• Outline how the learning will be assessed

		• Develop/adapt rubrics/questions etc/
Inclusive Practices	Career/Societal Awareness	• Suggest similar phenomenon in everyday life that can be explained using this phenomenon • Identify careers in which this information could be helpful • Research/name someone you know who works in this area
	Unconscious Bias Awareness	• Creating awareness of stereotypes that surround different career types • Being aware of how one's own perceptions might influence the teaching process • Identifying any gendered language that may be connected to the topic (difficult, "maths-heavy" etc.)

FINDINGS

Table 2 and 3, present evidence on the dimensions of planning present in the sequences of lessons of two teacher professional learning communities, PLC1 and PLC2. For the specific examples included, the level of cognitive demand was determined and is expressed in each sequence of lessons within the dimensions of planning. Although both groups of professional learning communities received the same resources (access to ambitious science teaching resources, sample sequences of lessons, planning time with department) to work with, very different sequences of plans emerged from their work.

Different elements of the framework were absent on both sets of PLC plans. PLC1 had no evidence of a causal explanation or essential question and focused solely on scientific concepts to build their sequence of lessons. Lesson activities showed a high level of cognitive demand, in PLC1s plan, with activities focused on student inquiry learning and designing learning experiences around learning goals. Key experiments and investigations that were relevant to the development of ideas and practices were included. Assessment practices were clearly described within each activity along with specific questions outlined as appropriate. Curriculum links and reference to careers were specified within activities, however these links were not well described and their connection to success criteria or measurable outcomes were lacking.

Table 2: Evidence of Dimensions of Planning in PLC 1 Sequences of Lessons

Dimensions of Planning	Specific Examples in Plans	Cognitive Demands Questions and Tasks
Causal Explanation	Not Present in plan	
Essential Question(s)	Not present in plan	
Scientific concepts	Forces, Combustion, Light, Torques, Heat, Energy Transfer	
Lesson activities	• E.g. Students design their own lever and explain	Higher Cognitive Demand

	in their own words how it works. • E.g. Light: Design an instrument that will allow you to see objects on the other side of the desk from a variety of different materials.	• Processing Ideas: tasks required students to use ideas and information in ways that expanded understanding. • Connected activities with Ideas; Selected tasks that required some thought and the task solution was not self-evident from the solution.
Links to curriculum (cross strand)	• E.g. Investigate patterns of physical observables – but patterns are not outlined	• Specific cross strand curriculum links highlighted but not linked to success criteria of activities.
How is the learning assessed	• E.g. Questioning: How many mirrors will you use and why? What does this [experiment] tell you about the way light behaves?	Higher Cognitive Demand • Approach outlined with specific questions/connections to activity described
Career/Societal Awareness	• E.g.	• Specific careers linked with each individual activity. No links made with the content specifically.
Unconscious Bias Awareness	• E.g. Fireman/woman	• Bias in gender specific careers mentioned - misconceptions and differentiation included in bias (may be a misunderstanding)

In the sequence of lessons produced by PLC2, most of the dimensions of planning were evident. A causal explanation was described with a strong focus on what was happening rather than a scientific explanation of why it happened. There was some indication that teachers attempted to expand their description to include more in-depth explanation e.g. “When there is an odd number of gears, the last gear will always turn in the same direction as the first one”, but this led to new ideas which caused more confusion among PLC1 members and was the explanation remained without further commentary or clarification.

Table 3: Evidence of Dimensions of Planning in PLC 2 Sequences of Lessons

Dimensions of Planning	Specific Examples in Plans	Cognitive Demands Questions and Tasks
Causal Explanation	• E.g. Adjacent gears are connected to either a chain or belt that is connected to a spring which moves in opposite directions. • E.g. When there is an odd number of gears the last gear will always turn in the same direction as the first one…but why?	Lower Cognitive demand • Seeking only a "what" explanation. • Some consideration of "why" explanation for one specific aspect of the phenomenon but with little detail.
Essential Question(s)	• E.g. How long will the toy work? Does friction stop the toy from working?	Lower Cognitive demand • Does not lend to developing an explanatory model to answer the question.
Scientific concepts	Heat transfer, Graphs and Slopes, Friction, Potential Energy, Kinetic Energy, Speed, Metals/Non-metals	
Lesson activities	• E.g. Write a plan indicating how long it takes to walk 15 metres……Consider why some people walk faster than others.	Medium Cognitive Demand • Connected activity with ideas. Selecting tasks that require some thought, however, approach does not suggest that the task solutions are not self-evident to student.
Links to curriculum (cross strand)	• E.g. for Heat transfer activity link to conductivity in the curriculum is not specified in the activity.	• Specific cross strand curriculum links highlighted but not linked to success criteria of activities.
How is the learning assessed	• E.g. Grouping, Peer assessment and Self-assessment	Lower Cognitive Demand • Assessment methods listed but not connected to activities
Career/Societal Awareness	• Six broad careers listed with no link to context of phenomenon.	
Unconscious Bias Awareness	• Not present	

It was evident from the plans and collaborating with the PLCs on developing these plans, that the two PLCs had very different priorities when planning their sequences of lessons. PLC1 focused their planning on student learning and student outcomes, e.g. “Students design their own lever and explain in their own words how it works”. There was clear evidence to suggest that PLC1 had concerns around how students process ideas. This PLC also engaged fully with the need to raise career awareness in their classroom practice. PLC2 were more focused on the teachers’ content knowledge for teaching physics and approached the planning as if the teachers themselves were the learners e.g. When there is an odd number of gears the last gear will always turn in the same direction as the first one…but why?”. This resulted in a much more disjointed written plan, however, the discussions and sharing among PLC members provided an opportunity for teachers to identify the gaps in their own knowledge and learning.

DISCUSSION

From our analyses of teacher’s plans for sequences of physics lessons, it was evident that teacher written plans lacked detail. All eight aspects of the dimensions of planning, six from Ambitious Science Teaching and two from inclusive practices, were evident to some degree, however all aspects of the dimensions of planning were not evidenced in any single plan. These findings highlight the need for further PLC activities to co-design, implement and reflect on lessons and to consider what refinement is necessary to engage students in physics concepts at lower secondary level.

Our findings indicate that these teachers lack specific content knowledge for teaching physics, and this impacted on their ability to propose complete causal explanations and investigative essential questions. Probing specific content knowledge for the purpose of deepening non-physics science teachers content knowledge for teaching is required to promote teacher confidence and competence in teaching physics at lower secondary level (Etkina et al., 2018).

Finally, enhancing teachers’ reflective and collaborative skills in order to support groups of teachers in planning for engaging science needs to at the goal of a professional learning community. Adopting a research practice partnership model, as proposed by Penuel, that encourages mutualistic relationships between the researchers and teachers through shared learning goals could see an evolution in the support needed to facilitate groups of teachers in designing, planning, implementing, reflecting and refining sequences of lessons for lower secondary level physics (Penuel & Gallagher, 2017).

ACKNOWLEDGEMENTS

This programme has received funding from Science Foundation Ireland Discover Programme (2017-2019) in a strategic partnership with CASTeL at Dublin City University and Institute of Physics.

LEARNING ACTIVITIES TO FOSTER SCIENTIFIC COMPETENCES: A COLLABORATION BETWEEN HIGH SCHOOL TEACHERS AND PHYSICS RESEARCHERS

Filippo Pallotta[1], Alberto Parola[1] and Maria Bondani[2]

[1]Department of Science and High Technology University of Insubria, Como, Italy

[2]CNR Institute for Photonics and Nanotechnologies, Como, Italy

Our group has carried out a collaboration project with a group of high school physics teachers engaged in a PLS (Progetto Lauree Scientifiche) professional development course promoted by the Department of Science and High Technology (DiSAT) of Insubria in Como, Italy. The aim of the course was to enable teachers to create balanced and effective learning activities to be used in class to reinforce the scientific competencies and skills required in the Final Exam of the Italian Secondary School (Esame di Stato). The aim of this paper is to present the result of this collaboration to understand how to better support the collaboration between physics researchers and high school teachers in order to design teaching and learning materials that could be effectively integrated in the daily classroom activities. We focused our attention to problem solving and data interpretation skills and the relationship between theoretical models and measurements process as requested in the last education reform for Italian secondary school final exam.

Keywords: Teachers, Experiments, Competences

INTRODUCTION

The last EU recommendations on key competences for lifelong learning encourage educational institutions to strengthen the collaboration between physics researchers and secondary school teachers in order to implement competence-oriented education, training and learning. The PLS project (Progetto Lauree Scientifiche) promotes teachers training programmes for the educational staff in Como and Varese school district: faculty members and physics researchers in different fields of theoretical and experimental physics have been actively involved in the professional development programme. One of the aims of the PLS project is to support teachers in improving the way physics is taught in Secondary School.

The last education reform in Italy is promoting new curriculum design practices that should help teachers change their role in student's learning process: from operating as mere reviewers of knowledge acquisition to becoming facilitators of scientific competencies development processes. This change of perspective have raised many concerns among teachers, mostly related to the gap between the way physics curriculum is developed in classroom and the framework of the Final Exam Paper (Seconda Prova dell'Esame di Stato per il Liceo Scientifico). Since the last twenty years the Final Exam Paper was mathematics only, structrued as a list of exercises and problems related to a precise syllabus that need to be covered by the school year. Physics was only part of the oral examination: students are supposed to answer a couple of questions about the last year topics (electromagentism, special relativity and quantum mechanics). However "exam simulation papers" published in the last three years focused the attention on scientific competencies and skills such as hypothesizing, interpretation of experimental data and making conclusions more than on content knowledge. In addition to that, in 2018 a new school legislation introduced the possibility of having an exam paper only about physics or with problems that integrates mathematics and physics topics.

To support teachers in this transition between "knowledge – oriented" and "competences - oriented" educational practices, at the beginning of 2018/19 school year the PLS project at DiSAT promoted a collaboration with a group of about 40 mathematics and physics teachers of the Como school district in order to support them in defining appropriate teaching activities to prepare students for the Final Exam Paper. In this way the analysis of learning needs and goals will be easily extended to all the entire physics curriculum and be used to design and plan learning activities since the first year of high school. This PLS project focused its attention to the scientific competencies related to the analysis and interpretation of experimental data and the relationship between physical models and experimental results. The purpose of this paper is to present the results of this collaborative project and to give suggestions on how to foster the process of scientific competencies acquisition and to orient teacher training programs.

Theoretical framework

Long terms experiences and recent researches in physics education in Italy show how high school teachers can be productively engaged in renewing instructional methods if they feel the need of enlarging their own view and understanding of the topic (Besson et al., 2010). Nevertheless the past collaborations between DiSAT and local schools have shown that the transfer process of learning and teaching material from physics researchers to teachers has not been effective in terms of implementing the use of new teaching strategies. A relevant element that has been pointed out by physics researchers at DiSAT, during internal evaluation meetings about their long experience in teachers training in the Como area, is that teachers are often simply delegating to researchers the role of explaining complex topics or running experimental activities in extra-curricular workshops. On the other hand teachers are often concerned about a feasible educational transposition at schools of what they learn in the training courses especially regarding the intrinsic difficulty of the topics, generally labeled as "to difficult for the students", or pointing out the lack of time and resources to perform the laboratory activities presented in the training courses.

In the theoretical framework of active learning (Fraser et al., 2014) the training courses promoted by physics researchers in this project aim to improve conceptual understanding and promote a meta-reflection about the role of scientific competences. In order to renew instructional methods, the training course also include "hands-on/minds-on" workshops using a guided inquiry methodology (Rönnebeck et al., 2016) so teachers can immediately have the perception of the didactic applicability of what they have experienced in the workshop.

Project actions

Between December 2018 and February 2019, our group organized a series of 5 meetings (2 hours each) for a group of 40 high school teachers. On average, 20 teachers attended each meeting. In the first three seminars physics researchers and teachers solved together the problems of the exam paper simulations that were published in December 2018. This activity allowed the participants to define which parts of the test were particularly challenging for the students, pointing out the main skills and competences (problem solving, data analysis and interpretation) needed to tackle the problems. Teachers also shared teaching experiences and materials they used to prepare last year students for the final exam paper.

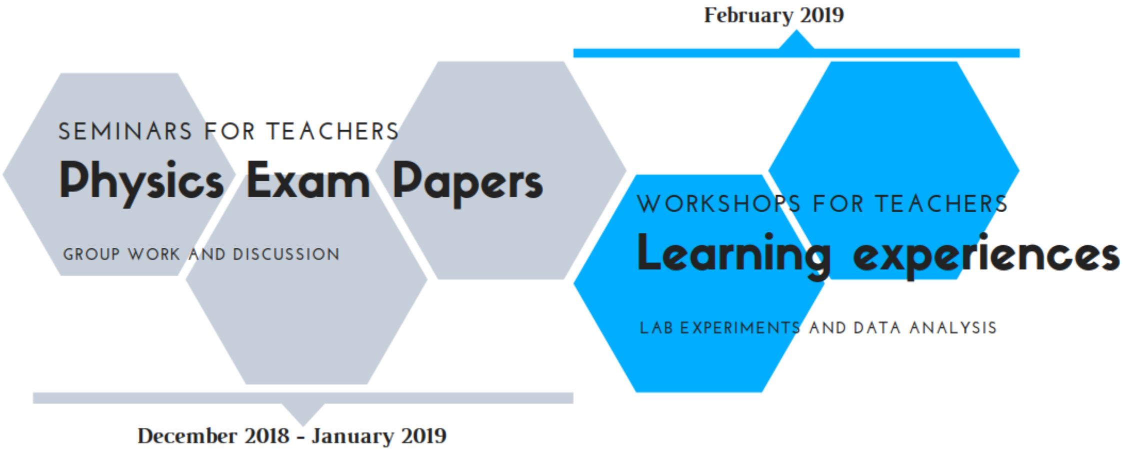

Figure 1. Project structure

In this first three meetings, teachers had the opportunity to discuss and share their view about the problems solving skills needed to solve the exam questions. In the last two sessions, teachers took part in two different physics workshops performing two experiments using simple materials and smartphone sensors. The first learning experience was about the measurement of the magnetic field of a little magnet. The second learning experience was about the measurement of the time collision of a ping pong ball with a table. Both those experiences were selected because the topics are part of the physics curriculum (mechanics and electromagnetism) and give the possibility to easily gather real data that can be analyzed and then discussed with students with different methodologies.

DATA ANALYSIS IN EXAM PAPER PROBLEMS

As mentioned before the first three meetings of the teachers training was dedicated to the analysis of the three exam paper published by the *Ministero dell'Istruzione dell'Università e della Ricerca* to help teachers understand the characteristics of the new exam format. What was relevant in the discussion with teachers was the reflection about the assessment criteria indicators attached to the Exam Paper (table 1) and their relation with specific scientific competences.

Criteria	Description
Analyze	Examine the problem identifying the significant aspects of the phenomenon and formulating the explanatory hypotheses through models, analogies or laws.

Resolution process application	Problem formalization and application of the concepts, mathematical methods and appropriate disciplinary problem solving strategies, performing the calculations needed.
Interpret, represent and elaborate data	Process the data, proposed or derived from experiments, checking the relevance to a chosen model. Representing and connect the data using the necessary graphic-symbolic codes.
Argue	Describe the resolution process adopted, the solution strategy e the fundamental steps. Communicate the achieved results evaluating the consistency with the problems and using disciplinary specific languages

Table 1. Assessment Criteria for the Physics Exam Paper

The criteria are not only related to the ability to solve the problem numerically, but also to the skills and competencies needed to analyze the problem, modelling and interpreting data.

Discussion about the quality of a fit

During one of the seminars the discussion between teachers and researchers was focused on how to fulfil the assessment criteria related to one problem that ask students to show that a give data set could be fit using a linear model. This kind of question allows students to explore the connection between experimental data and the theoretical model used to fit the data. This is worth to be done in a didactical context to foster a more general reflection about nature of science, in particular on how physics researchers' experimental results contribute to the development of interpretative models of physical phenomena.

Unfortunately, as reported by teachers, experimental activities that involve data analysis and interpretation are not part of usual curriculum activities. The lack of materials and resources in school to adequately incorporate performing experiments into curricular activities planning has also been taken into account. Statistic literacy is generally part of mathematics curriculum: as a result, the basic techniques of data analysis, such as the linear regression, are not fully covered during the instruction programme. In addition to that, most of the teachers admitted that they had never been properly trained to run experiments and do not feel competent enough to perform experiments with students.

What makes a measurement a "good one" was the first point of discussion. The conclusion was that a scientifically reliable estimation of a physical variable could be obtained only with a correct measurement procedure that estimates uncertainty from multiple measurements. Than what to do in when the experiment "is not working" and the data are not in accordance with the theoretical model? In that case students should be able to use their measurement device correctly in order to reduce the effect of systematic uncertainties. Following the result of this discussion, the group of teachers took part in two workshops about low cost physics experiments that could be used to recreate the condition presented in the exam paper question and to reflect on the scientific experimental inquiry process.

To promote a more active approach, teachers follow the same learning activity path designed for secondary school students, but they are guided to reflect not only on the content but also on the difficulties that can arise in performing the activity in the class with the students. The two learning experiences have been structured as a guided inquiry learning activity so the participants (divided in small groups of three) have to use a proper theoretical model to describe the physical phenomena to guide the measurement process during experimental activities.

LEARNING EXPERIENCE 1: DATA ANALYSIS

The first workshop was about the measurement of small magnet magnetic field using smartphone sensors (Arribas et al., 2015). The experimetal activity worksheet are also available at https://ls-osa.uniroma3.it/ This experience have been chosen because of its connection with the previous teachers work groups where the necessity of a reflection about the relationship between theoretical physical models and experimental data have been repeatedly pointed out. The inquiry question in this case was abouthow is it possible to fit a set of data using a specific theoretical model?

A specific attention have been payed to the data acquisition process using smartphone app and to the data analysis techniques. The aim of the learning activity is to support students' reflection on the relation between the theoretical model of a physical phenomenon and the experiments related to it.

Activity description

The purpose of the practice is to determine the dependence on the distance of the component x of the magnetic field produced by a small cylindrical magnet. The measurements are taken using the magnetic sensor of a smartphone and an app for the data acquisition: we used Phyphox and Physics Toolbox. The activity also requires a pencil, a sheet of paper and a ruler. The activity took two hours and involved about 15 teachers. The activity structure is intended to mimic the sequence of an experimental scientific inquiry: starting from the elaboration of a theoretical model, moving to the preparation and calibration of experimental set-up and data collection and finally to data analysis and interpretation. During the workshop we focused on the different aspectes of experimental activities.

Development of a physical model

Following teachers' request of being properly introduced to the physics of the small cylindrical magnets magnetic fields, the experimental activity have been preceded by a short lecture by a faculty member of DiSAT. This part of the activity made it possible to analyze in detail the theoretical model underneath the relation between the physics variables used to describe the phenomena. As reported by the teachers during the discussion, this introduction is consider a useful and essential tool to engage the student into the laboratory activity: in their experience, students seem to prefer to infer the interpretation of a single phenomenon from a general model instead of inductively built a scientific model from observations.

The modeling of the magnetic field gives also some elements about the type of magnets that could be used. The field generated by a permanent magnet of cylindrical shape is calculated on the axis of symmetry x-direction at distance much larger than its radius a (but not necessarily larger than its length l). The permanent magnet is schematized as a collection of circular loops crossed by a current of intensity I that can be identified with the superficial magnetization currents. Under this conditions the magnetic field in the x-direction is given by

$$B_x(x) = \frac{\mu_0}{2\pi} m \frac{x}{\left(x^2 - \frac{l^2}{4}\right)^2} \quad (3)$$

where m is the magnetic moment of the magnet and μ_0 is the magnetic permeability of free space. If then $l << x$ the x-component of the magnetic field becomes:

$$B_x(x) = \frac{\mu_0 m}{2\pi} \frac{1}{x^3} \quad (4)$$

Becoming familiar with experimental devices

An important part of the experience was about learning how to properly use the data acquisition device. Teachers spent time to learn how to use the smartphone app, focusing the attention on how the device collects data. The first problem is to determine the position of the sensor inside the device. Secondly, the smartphone sensors need to be properly calibrated, taking into count that the measurements are strongly dependent on the device orientation and distance between the smartphone and the magnet. The possibility to verify the consistency of a theoretical model is bounded by the possibilities given by the characteristics of the experimental devices: this is something students need to understand to properly evaluate the results of their experimental activities. Teachers reported that they could not collect data when the smartphone was too close (less than 5 cm) to the magnet, due to the sensor saturation (when $x < 5$ cm the value of B did not change): that implies that the model could be verified only in a specific interval of distances from the device.

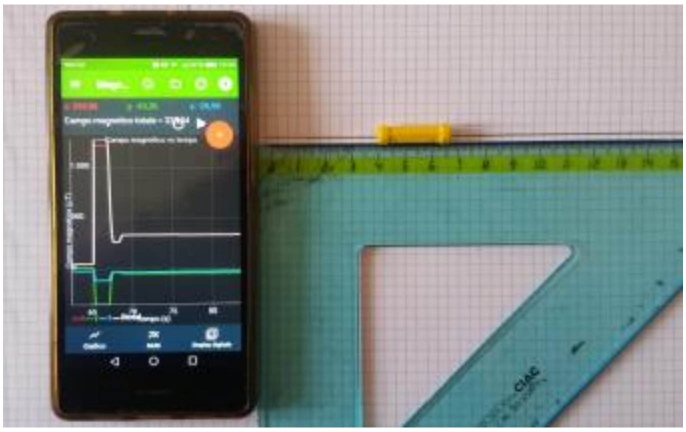

Figure 2. Experimental setup

For the same reason the evaluation of the experimental uncertainty is part of the data acquisition process: every device, even digital ones, collect data with a specific uncertainty. This aspect was reported by the teachers during the practice: the value of the magnetic field measured by the smartphone fluctuates rapidly and this required an adjustment of the acquisition procedure. The values of the field for each measurement could be only obtained by averaging the values recorded in a specific period of time. In this way, an error corresponding to the uncertainty of the mean was associated with each value of B_i.

Data elaboration process

The discussion generated around the problem of data elaboration was about how to fit the function that corresponds to the theoretical model (equation (4)). The spreadsheet used in schools (i.e. MS Excel, LibreOfficeCalc, GspreadSheet) give the opportunity to fit power functions, but some teachers noticed that it would be useful to have the possibility to fit the data using a function using multiple parameters like the following

$$\boldsymbol{B(x) = \frac{k}{x^b}} \quad \text{or} \quad \boldsymbol{B(x) = \frac{k}{x^b} + c} \tag{5}$$

where the parameter could be related to specific physics constant (k) or instrumental offset error (c). As suggested by some teachers during the group discussion, a possible way to tackle this problem is to use a "logarithmic version" of the function in equation (5): in this way the fit function becomes linear and data could be analyzed using familiar the least square method.

$$\boldsymbol{ln(B) = ln(a) - bln(x)} \tag{6}$$

In this case the gradient of the line represents the specific power dependence of the field intensity on distance. As suggested by physics researchers who participated in the meetings, a parametric function fit could be easily done using Matlab or Mathematica. Unfortunately the licences for those softwares are out of the public school budget. A more affordable alternative could be the use of Phyton and its data analysis libraries like NumPy and SciPy or the Python module Pandas. As suggested by teachers, the Python programming language could be also an opportunity to interact with computer science teachers and ICT experts in school. In figures 4 and 5 there are two examples of data elaboration made by the teachers with the data collected during the laboratory activities.

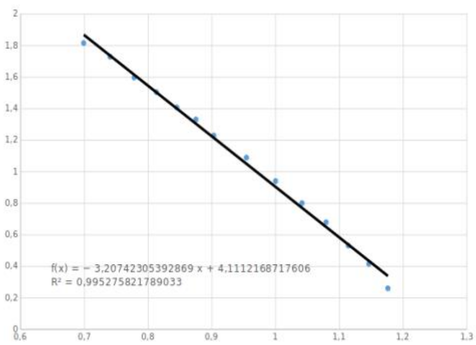

Figure 3. Graph from the data using *ln*(*B*) vs *ln*(*x*) with MSExcel

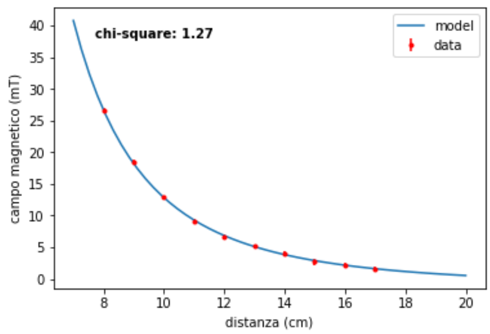

Figure 4. Graph of parametric function from data with Phyton

LEARNING EXPERIENCES 2: MODELS AND MEASURES

The second learning activity had been proposed by one of the teachers and was about the measurement of the time collision of a ping pong ball with a table (Oladyshkin & Oladyshkina, 2016). The same experiment as also been part of the project "Olimpiadi italiane della Fisica – Gara Nzionale, Prova Sperimentale 2018"(https://www.olifis.it/). This experience have been structured as a guided inquiry learning activity so the participants (divided in small groups of three) have to built a proper theoretical model to describe the physical phenomena in order to guide the measurement process during experimental activities. The inquiry question was about how to estimate the time of collision of a freely falling ping-pong ball and a table. During the activity a model of the collision process have been developed, identifying the physical variables that determine the system dynamics during the collision so the measurements have been taken in accordance with the theoretical model.

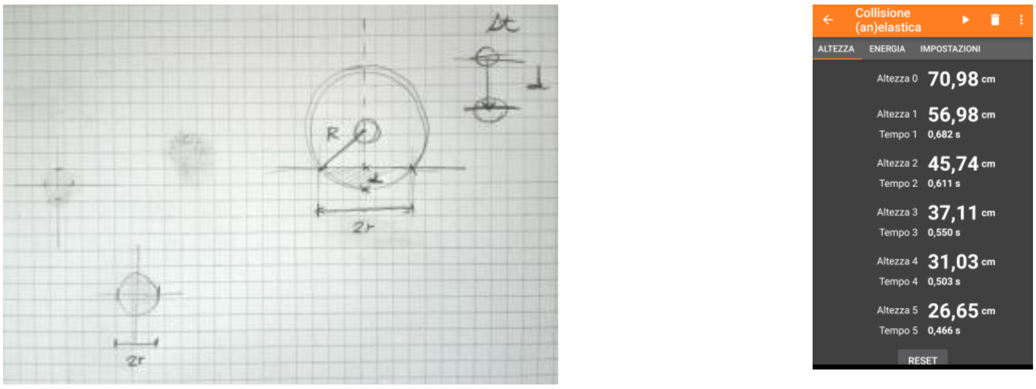

Figure 5. Teachers' notes during group activity and Phyphox App – (in)elastic collision

In the first part each group should explicit the hypotheses used to model the collision between the ball and the plane. The collision is not completely elastic so it is necessary to first determine the coefficient of restitution e_V . Due to the fact that the able is not moving, in this case e_V is the ratio of the velocity of the ball after and before the collision. Also assuming the mechanical energy conservation before and after the collision it possible to determine e using the following formula:

$$e_V = \sqrt{\frac{h\prime}{h}} \qquad (7)$$

where *h'* and *h* are the vertical position of the ball before and after the collision. Using Phyphox "(in)elastic collision" app it is possible to perform multiple measurements of *h'* and *h* and get an estimation of e_V and its uncertainty. In the second part each group painted the ball using a pencil and directly estimate the diameter *2a* of the round shape imprint of the ball on a blank paper.

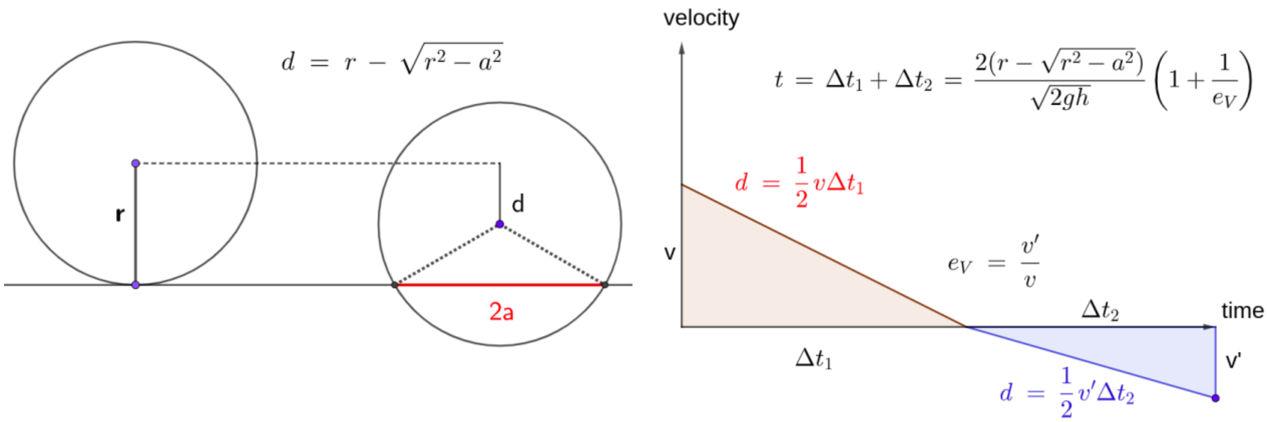

Figure 6: Collision process geometrical analysis and kinematics

In the last part the groups have discussed their conclusions comparing their results, in particular what kind of systematic uncertainty can affect the measurements.

In this activity the connection between the physical model and the measurement process is explicit in the way different theoretical hypothesis (i.e. uniform acceleration, neglecting energy dissipation, during the collision) have been used in order to have measurements sufficiently accurate to get a reasonable estimation of collision time. During the activity teachers have discussed on how to help students to understand the role of those hypotheses in determine systematic errors, generating an overestimation of the duration of the collision.

CONCLUSION

The collaboration between researchers and teachers is crucial to promote the development of science competencies. The activities presented in this paper have showed how school teachers are determined to improve the level of their teaching through collaboration. The meetings have been good opportunities to share teaching experiences and materials. The teachers agreed that high quality, scientifically-based learning activities need to be implemented into the curricular classroom activities and then become part of daily teachers' practices in order to be effective: in this sense teachers need to be more committed to the design of their curricular instructional laboratory activities and processes. On the other hand physics researchers need to foster that design process, promoting collaboration activities with teachers and supporting the creation of an active educational ecosystem.

SCIENCE TEACHERS' PEDAGOGICAL DEVELOPMENT: FOCUSING ON LESSON STUDY

Tetsuo Isozaki[1], Susumu Nozoe[2], and Takako Isozaki[3]
[1]Hiroshima University, Higashi-Hiroshima, Japan,
[2]The University of Miyazaki, Miyazaki, Japan,
[3]The University of Toyama, Toyama, Japan

This study examines how Japanese science teachers pursue pedagogical development. The research questions investigated were (1) what is 'traditional science teaching in Japan'?; and (2) how do Japanese science teachers acquire orthodox teaching values and intentions within their professional learning communities? We focused on 'lesson study', which is a comprehensive and well-articulated approach to examining teaching practices within professional learning communities. A literature review and three empirical research studies were conducted to answer these questions. Quantitative data from questionnaires comparing teachers in Japan and England were summarised in tabular form and statistical tests were applied. The results demonstrated that science teachers' pedagogical development reflects the culture in which they teach. Data sources included life story interviews with five experienced teachers and questionnaires completed by 177 science teachers, focusing on the topic of lesson study for professional development. Furthermore, the results demonstrated that science teachers acquired norms of the teaching profession and orthodox teaching values and intentions through lesson study. We suggest that, to challenge orthodox beliefs, it is important for teachers to recognise that lesson study is one of many effective vehicles for pedagogical development.

Keywords: Pedagogical development, teaching values, lesson study

BACKGROUND, THEORETICAL FRAMEWORK, AND RESEARCH QUESTIONS

Background

Dillon and Manning (2010) argue that science teachers' pedagogical development relates to their challenge of orthodox 'teaching values and intentions' (p. 14), which can be described as 'traditional science teaching' (p. 14). This means that teachers' pedagogical development is a sociocultural activity situated within a professional learning community, and is thus affected by professional norms.

What is traditional science teaching in Japan? As an example, let us consider the National Center for Education Statistics (NCES; 2006), which stated that Japanese science lessons at the eighth-grade level perform the following tasks: (1) focus on developing scientific ideas by making connections between ideas and evidence through an inquiry-oriented, inductive approach, in which data are collected and interpreted to formulate a main idea or conclusion; and (2) be conceptually coherent, with an emphasis on identifying patterns in data and making connections between ideas and evidence, and conducting practical work as a central role in developing main ideas. This is one typical way of teaching Japanese science lessons. Science teaching practices in laboratories and classrooms are partly based on the knowledge base and expertise of teachers. Japanese science teachers have engaged in 'Lesson Study or lesson study', a professional practice that has become deeply embedded in teachers' professional culture (Isozaki, 2015; Isozaki & Isozaki, 2011). Japanese teachers experience the system of lesson study since their pre-service teacher education (see Figure 1), recognising that their knowledge base and teaching competencies are enhanced through lesson study as a part of continuing professional development (CPD).

Theoretical Framework

This study focuses on two theoretical frameworks: first, the socio-cultural perspective of science teaching and science lessons, and second, lesson study (or Lesson Study) in the professional learning community. The NCES (2006) examined the science teaching of five countries through a video study and demonstrated that each country had a different approach to science teaching. This means that science teaching is a socio-cultural activity. Davis, Janssen and Van Driel (2016) reviewed the literature on science teachers and science curriculum materials and pointed out that much of the teacher-curriculum research adopts, either implicitly or explicitly, a sociocultural perspective.

Stigler and Hiebert's (1999) book introduced one reason why lesson study was an important key approach to obtaining a higher score in international comparisons, such as the Trends in International Mathematics and Science Study (TIMSS), which had a strong impact on Japanese educators. We focused on lesson study, which is a comprehensive and well-articulated approach to examining one's teaching practice that Japanese teachers engage in as an essential part of their CPD within their professional learning community. Of course, there are other vehicles for teachers' CPD, such as workshops, action research, and self-study. Isozaki (2015) highlighted the differences amng lesson study, workshops, and action research as follows. First, lesson study should be considered a process that begins with a research question driven by the participants, whereas workshops often begin with answers while being motivated by outside school experts. Second, lesson study emphasizes the process involving collaboration with colleagues (sometimes including outside advisors, such as professors and consultant teachers of local boards of education) and a common focus. In contrast, action research examines teachers' own teaching and students' learning by engaging in research projects in their classrooms, although working with colleagues is usually optional. They, therefore, can learn professional norms through lesson study as well as in schools. This is the reason why we focus on lesson study as the way in which Japanese science teachers challenge orthodox 'teaching values and intentions'.

Research Questions

This study investigated Japanese science teachers' pedagogical development from a sociocultural perspective. The following research questions were investigated: (1) what is 'traditional science teaching' in Japan; and (2) where and how do Japanese science teachers challenge orthodox 'teaching values and intentions' within their professional learning communities? Resolving these research questions will, therefore, contribute to the support of teachers' pedagogical development.

METHODS AND DATA

To address the research questions delineated above, we conducted a literature review on science teaching and lesson study from different sociocultural perspectives. First, we reviewed the literature on science lessons/teaching from international and sociocultural perspectives; for example, The Third International Mathematics and Science 1999 Study Video Study (NCES, 2016), Trends in International Mathematics and Science Survey (TIMSS) 2015 (Mullis, Martin, Foy, & Hooper, 2016), and Stigler and Hiebert (1999). Second, we reviewed the literature on lesson study from international and sociocultural perspectives; for example, Doig, Groves and Fujii (2011), Isozaki (2015), Isozaki and Isozaki (2011), and Lewis and Hurd (2011), Teaching and Learning International Survey (TALIS; OECD, 2014).

We then conducted the following three empirical research studies. First, we conducted comparative research on three dimensions of science teaching–science teachers' beliefs, approaches used in designing lessons, and methods used in teaching science–with 84 science teachers in lower secondary schools in Japan and 24 science teachers at comprehensive schools in England in 2013. The quantitative data from the questionnaires were summarized in tabular form, and statistical tests were applied (Nozoe & Isozaki, 2018). Next, we collected qualitative life-history data through semi-structured interviews with five experienced Japanese secondary school science teachers in 2015, whose teaching careers included more than 30 years of experience to investigate changes in their beliefs about the goals and purposes of science teaching over time. The life history interview data were analysed in terms of the Steps for Coding and Theorization (SCAT; Ueda & Isozaki, 2016). Third, we collected quantitative data in lesson study for Japanese secondary science teachers of all ages (N = 177) in Hiroshima by using a questionnaire survey with multiple choice and short essay questions conducted ion 2016 (Isozaki and Department of Science Education, and the Research Project Centre for the Next Generation Science Education, 2016; Ochi, Ueda, & Isozaki, 2018). We obtained permission from all teachers who contributed to any of these empirical studies.

RESULTS OF EMPIRICAL RESEARCH

Table 1 supports the findings by NCES (2006), Mullis, Martin, Foy and Hooper (2016), and Stigler and Hiebert (1999) that science teaching is a socio-cultural activity. By comparing the data from Japan with data from England, the results indicated that a science teacher's pedagogical perspective depends significantly on the country in which they teach. This demonstrates evidence that the educational culture of that country regulates science teachers' pedagogical development.

The results of the SCAT analysis of the interview data from the five experienced teachers demonstrated that 'the development of beliefs about the goals and purposes of science teaching throughout a teacher's professional career can be perceived as part of the science teacher's consecutive learning both inside and outside of school' (Ueda & Isozaki, 2016, p. 44). This means that experienced teaches initially participated enthusiastically in lesson study both formally and informally, aiming for self-improvement in their teaching, and to acquire the norms of the teaching profession.

Table 1: The most important learning objective in school science

Country	1. Skills of laboratory work and observation	2. Knowledge and understanding about science	3. 'Decision making' ability based on scientific evidence	4. Scientific thinking	5. Interest in science	6. Ability to explain scientifically	7. Investigation and inquiry	8. Relationship between science and daily life	9. Others
Japan (N=74)	3 (4.1)	9 (12.2)	11 (14.9)	10 (13.5)	16 (21.6)	1 (1.4)	4 (5.4)	19 (25.7)	1 (1.4)

(Source: Nozoe & Isozaki, 2018)

The questionnaire data demonstrated that 72.3% (N = 177) of the Japanese science teachers surveyed responded that they participated in lesson study for professional development in teaching and learning science. This trend was observed in the results of the TALIS, in which Japanese teachers reported higher-than-average participation rates (51%) for professional development in terms of observation visits to other schools (as compared to the TALIS average of 19%) (OECD, 2014). Through lesson study, teachers in their 20s to 40s indicated that they intended to learn how to conduct the 'research and development of new teaching materials' (*kyouzai-kenkyuu* in Japanese), and apply new teaching materials produced by others, while those in their 50s intended to learn new pedagogical methods in science. The data from the short essays on the preparation phase of lesson study demonstrated that teachers primarily concentrated on: (1) reflection on previous teaching materials, (2) development of new materials, and (3) development of a lesson plan according to students' understanding and skill levels.

DISCUSSION

What is traditional science teaching in Japan?

Generally, Japanese science lessons from elementary (the first to the sixth grade) to upper secondary school (the tenth to the twelfth grade) consist of three phases: introduction, development, and conclusion (Isozaki, 2015). As Stigler and Hiebert (1999) have observed, one of the main activities in the introduction phase is to review the previous lesson to grasp student understanding. The other important activity is to motivate students regarding today's lesson topic. The introduction phase generally takes up between five and ten minutes of the lesson time.

Japanese science teachers tend to consider the following questions during the preparation phase of lesson study and regular lessons: (1) Why is this unit's topic valuable to students?; (2) What do I want students to gain from this unit?; and (3) How can I provide a successful learning experience to students? To answer these questions, science teachers review their previous teaching and the resources gained through participating in the lesson study and other activities. They interpret the course of study, which is similar to the national curriculum and textbooks, as well as contemplate the scientific and educational values of the unit and teaching materials (Isozaki, et al., 2016).

At the beginning of the development phase, Japanese science teachers usually provide *one* question (*toi* or *hatsumon* in Japanese) extracted from today's topic; sometimes this question shares the same meaning as today's task, directly connecting students to the task before they engage in practical work. After providing this question, and before students embark on practical work, teachers often require students to work in a group or as individuals in forming a hypothesis or making a prediction. Indeed, the TIMSS 1999 video study (NCES, 2006) demonstrates that a higher percentage of Japanese students make a prediction as compared to students in Australia, the Czech Republic, the Netherlands, and the United States. According to the results of Isozaki et. al., (2016), and Ochi et. al. (2018), lower secondary school (the seventh to ninth grade) science teachers emphasize a set of objectives that should be achieved by learners in one lesson to formulate a question that is appropriate for the ability of learners. In designing a science lesson, they carefully consider the coherence between the objectives of the lesson, its *one* question, and the single conclusion to be drawn. Science teachers have to use various types of teacher knowledge, especially pedagogical content knowledge (PCK; Shulman, 1987) when formulating this question. It is noteworthy that Japanese science teachers recognise that formulating an adequate and appropriate question is one of the most important parts of designing a lesson.

After forming a hypothesis, students engage in practical work in conducting and resolving the task. Science teachers require students to collect and record data from practical work carefully. During practical work, science teachers must instruct each group, inspect their notebooks or worksheets to grasp their level of understanding and practical work data, as well as hear their 'thinking aloud' or 'muttering' (*tsubuyaki* in Japanese) as they walk around the classroom or between students' experimental desks. Doing this is considered as an important activity for teachers and called *kikan-shidou* or *kikan-jyunshi* in Japanese. If they discover that students (individuals or groups) are engaging in practical work incorrectly during walking around the classroom or between students' experimental desks, they must correct them accordingly. Of course, walking around the classroom or between students' experimental desks involves other important roles, including, for example, identifying students' degree of understanding, providing guidance to slower groups or students, and carefully observing that students are working safely. Science teachers can also grasp students' latent ideas by careful listening to their thinking aloud.

When engaging in practical work, students follow the worksheet created by the teacher. Some worksheets describe the practical work's objectives, procedures, and the point of discussion. After practical work, students are required to manipulate the data. According to the results of the TIMSS 1999 video study (NCES, 2006), Japanese and Australian students were guided by the teacher or textbook in manipulating data. Such practical work has been criticized as guided inquiry. Discussion after practical work leads to the development of a main conclusion or scientific idea as an answer to a question. Therefore, science teachers carefully consider the objectives of the lesson, leading question, and conclusion drawn, ensuring that they cohere appropriately. In other words, when 'making and revising a lesson plan' (*gakushuushidouan-sakusei* in Japanese), teachers create a narrative story or scenario for the lesson. The development phase generally takes up approximately thirty-five or forty minutes of the lesson.

In the conclusion phase, based on the results of practical activities, small group and whole-class discussions are conducted to pursue the development of one main conclusion; finally, the science teacher summarises the lesson. This conclusion phase takes up the final five to ten minutes of the lesson.

As a result of the analysis of the literature on science teaching in Japan, these processes can be identified as a typical Japanese science lesson from elementary to secondary school level.

Where and how do Japanese science teachers challenge orthodox 'teaching values and intentions'?

Where and how do Japanese science teachers learn this process of a typical science lesson? Prospective teachers experience the nuance of lesson study including the above-mentioned typical Japanese science lessons under their mentors during their short-term teaching practice in schools. After becoming a teacher, science teachers intended to participate in lesson study, which is deeply embedded in Japanese teachers' culture (see Figure 1).

Isozaki (2015) argued that lesson study should be divided into three phases, as illustrated in Figure 1: preparation, research lesson, and reflective meeting. The main activities at the preparation phase of lesson study include the research and development of teaching materials and making and revising a lesson plan. Research and development of teaching materials encapsulate these processes of internal didactic transposition, involving the important process of examining both teaching materials and the students' main activity task. Japanese lesson plans represent a teacher knowledge base, such as pedagogical knowledge, content knowledge, and pedagogical content knowledge, as proposed by Shulman (1987). Teachers believe that to design a good lesson, a teacher must create a question/task that will engage and motivate students (Isozaki et.al., 2016; Ochi et.al., 2018).

In the preparation phase of lesson study, science teachers consider scientific and educational values, reflect on their individual values as science teachers, and consider their students' learning perspectives, such as their needs and interests. If science teachers do not deeply engage in research and development of teaching materials that integrate both scientific and educational values and students' perspectives, there is no meaning for students in conducting the task, which would then be of no value to them (Isozaki, in press). As demonstrated by the results of our empirical research and the results of TALIS (OECD, 2014), Japanese teachers spend significant time on lesson preparation and learn from colleagues through lesson study. Lesson study helps to form a teacher/professional culture that provides opportunities to share the dominant values (Isozaki, 2015). The consideration of various educational values included in a lesson plan is key to a science teacher's role in designing lessons in Japan.

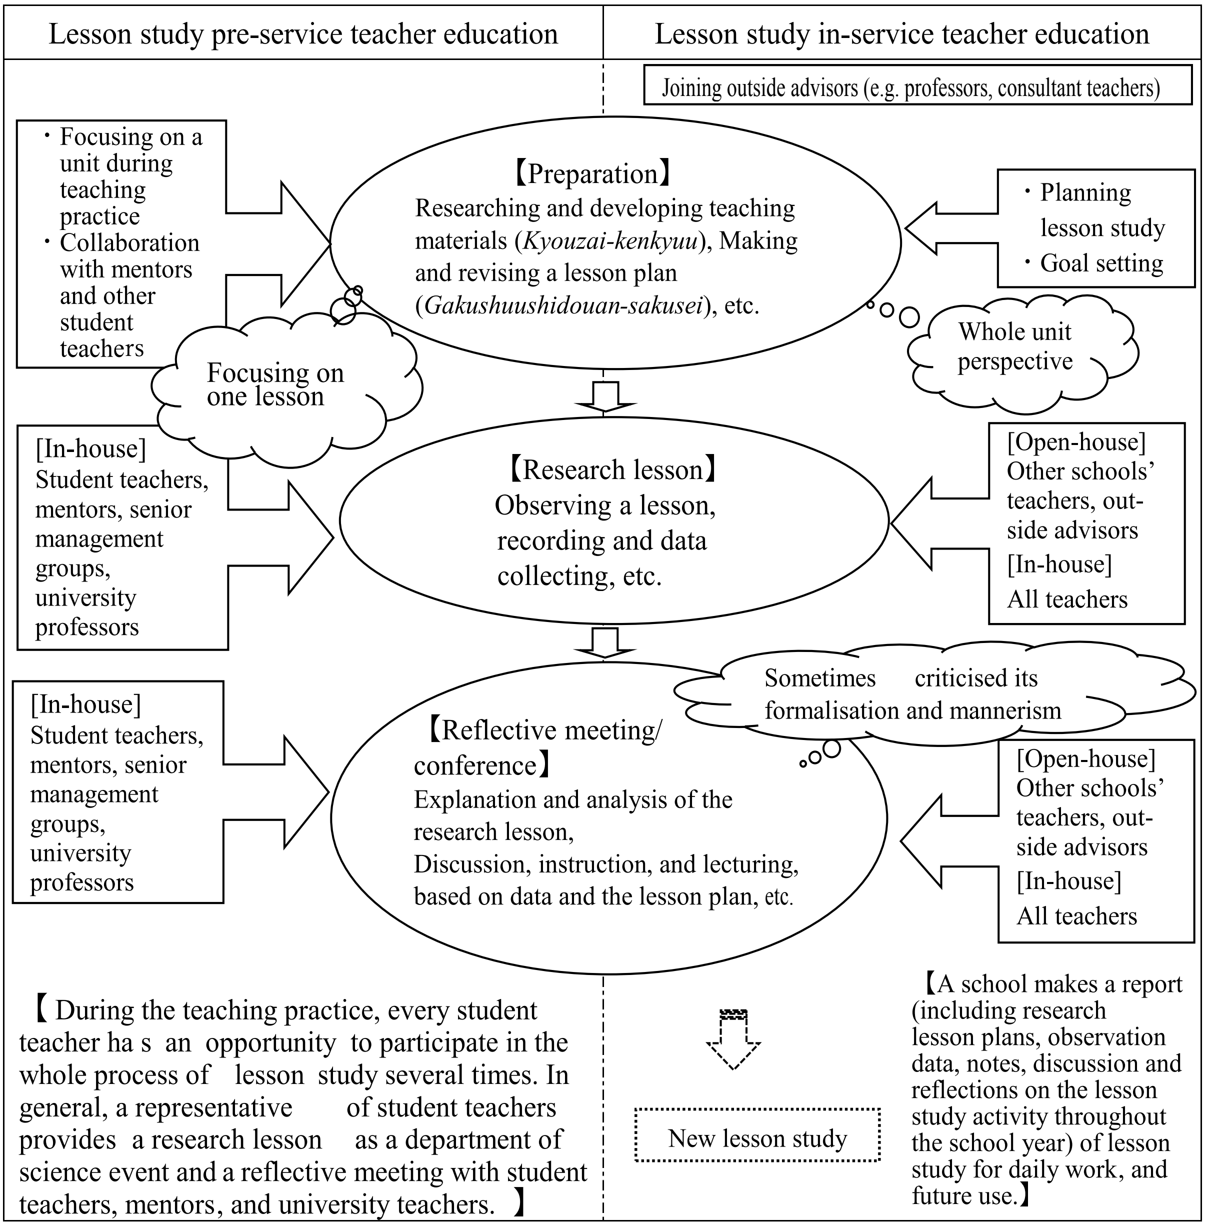

Figure 1: A typical process of lesson study in pre-and in-service teacher education

A research lesson in lesson study has similar processes to a regular lesson, with many science teachers employing an inquiry-based approach (Isozaki, 2015). However, while a science teacher will make and revise their lesson plans, as well as research and develop the teaching material for a regular lesson by themselves, collaboration with colleagues is a fundamental aspect of lesson study. Therefore, a science teacher conducting a research lesson will often consult with their colleagues–including senior school management and outside advisors, such as a professor–in the preparation phase of lesson study (Isozaki & Isozaki, 2011). Participants of lesson study carefully observe the research lesson with the revised lesson plan. While a reflective meeting is held with observers from within and outside the school after a research lesson, a reflective meeting is not held after every regular lesson. Therefore, science teachers need to reflect by themselves or through analysing students' achievements and performances, via notebooks, worksheets, and tests.

Consequently, Japanese science teachers can develop their teacher knowledge and skills within their professional learning community. By participating in lesson study, formally and informally, even experienced science teachers can learn from others and improve their teacher knowledge and teaching competencies.

Subsequently, traditionally, science teachers of Japanese secondary schools have the opportunities to share and learn professional norms and values within their professional learning communities, and to be able to challenge orthodox 'teaching values and intentions'.

CONCLUSION

Through lesson study within the professional learning community, Japanese science teachers can acquire the norms of the teaching profession and values in science teaching. As a result, they can challenge orthodox 'teaching values and intentions'. However, the standardisation of lesson study results in its stylisation (Isozaki, 2015). Therefore, to challenge such orthodoxy, it is essential that science teachers recognise that lesson study is one of the vehicles for science teachers' pedagogical development, and the values shared by science teachers sometimes are not up to date with the latest research trends. Using a comparative study, we need to consider other potential vehicles, such as self-study, to improve science teachers' pedagogical development from socio-cultural perspectives.

Isozaki, Isozaki, Kawakami, and Sawai (2015) demonstrated the qualitative and quantitative differences of PCK between novice and experienced science teachers and concluded that lesson study is potentially effective for developing teachers' professional knowledge base, and it must be an important vehicle for teachers' CPD. Despite its application history, neither teachers nor researchers seemed interested in investigating lesson study in Japan until Stigler and Hiebert's *The Teaching Gap: Best Ideas from the World's Teachers for Improving Education in the Classroom* was published in 1999. Clivaz and Takahashi (2017) argued that theorizing lesson study could help researchers and teachers outside of Japan understand its specific cultural norms. As lesson study is embedded in Japanese teachers' culture (Isozaki, 2015), there is space for non-Japanese science researchers to identify social and cultural norms in the Japanese school context. This means that Japanese researchers and teachers have to provide sufficient information to educators outside of Japan who wish to design similar lesson study projects for professional-pedagogical development to challenge Japan's success rate.

TRANSFORMING THE PEDAGOGICAL PRACTICES OF ETHIOPIAN PHYSICS TEACHERS FROM DIDACTIC TO DIALOGIC TEACHING

Taha Rajab[1], Vanessa Kind[1] and Per Kind[1]
[1]Durham University, Durham, UK

This paper reports on the Transforming the Pedagogical Practices of STEM Subjects project (TPSS) which trialled and implemented a national intervention to change the prevailing lecture-dominated teaching practices of physics teachers in Ethiopia. 60 teachers in fifty upper-cycle primary schools (Grades 5-8) received training on the principles of scientific reasoning, argumentation and dialogic teaching. 80 video-recorded physics lessons from a sub-sample of 40 teachers were analysed quantitatively and qualitatively to examine the impact on pedagogical practice and physics learning of students, including a control group. In-depth interviews with participants were also conducted to glean teachers' views on the training provided, the contextual constraints and the impact on student learning. Findings show that the teachers who received the project combined training (pre-service and in-service) implemented the most significant pedagogical changes. This includes the adoption of a wider repertoire of talk and affording students with opportunities to engage in classroom activities. The contextual challenges facing Ethiopian teachers continue to have an impact on their abilities to deliver the intended aims of the learner-centered curriculum. Implications arise for the introduction of pedagogical practice interventions in low income nations

Keywords: Dialogic Teacher education, physics

INTRODUCTION

Within science classrooms, effective teacher talk plays a central role in maximizing students' abilities to learn scientific concepts and reasoning processes. Verbal classroom discourse and its importance in student cognitive, communicative, social, and cultural development have received much attention from researchers (e.g. Alexander, 2018; Kind, 2017). Teacher talk in science classrooms gains particular significance in contexts that are under-resourced, over-populated, and linguistically-diverse, representative of the Ethiopian context. Several studies concluded that a typical traditional classroom in East Africa (and beyond) is marked by the pervasiveness of 'triadic dialogue' or recitation recipe (Frost & Little, 2014; Lemke, 1990). This creates a closed circuit of communication referred to as Initiation-Response-Feedback or IRF structure and the ensuing teaching practices are dubbed 'didactic teaching' which often comprises one-way lecturing and closed teacher questions as brief evaluations. This is regarded as problematic because active student contributions are discouraged, contradicting socio-cultural learning theory, which suggests knowledge and mental functions are internalized through language and social interaction (Wertsch, 1991).

Over-reliance on didactic teaching may apply to any nation or school subject, but is particularly dominant in STEM subjects (science, technology engineering and mathematics) as these typically teach "facts" given to students. In the UK, for example, Driver and Newton (1999) found that on average more than 75% of teaching time in science classrooms involved passive listening, copying and performing set exercises. Teacher-student dialogue comprised only 13% of teaching time, and mainly involved teacher-led questions. In developing nations, such as Ethiopia, didactic teaching is even more dominant because class sizes are larger, resources are scarce, and cultural traditions set expectations for this style. This restricts and constrains students' learning, and impacts negatively on recruitment and retention in STEM subjects beyond compulsory schooling (Osborne, Simon and Collins, 2003). Developing nations rely on STEM subjects as means to build economic success, and transforming the pedagogy to become 'dialogic' is therefore important to ensure a better future.

The current study draws on disciplinary dialogic teaching, which has additional elements to dialogical teaching, rooted in the socio-cultural theory of learning (Vygotsky, 1978). The additional elements in disciplinary dialogical teaching draw on reasoning and argumentation typical to the science community. Scientific knowledge is the outcome of debate in the 'science community of inquirers' (Peirce, 1934). Science educators have adopted this (philosophical) perspective and merged it with socio-cultural learning to form a strand of research and teaching known as scientific argumentation. In scientific argumentation, focus is on accountable talk, which follows norms and criteria established in the science community (e.g. Driver, Newton, & Osborne, 2000; Duschl & Grandy 2008; Michaels, O'Connor, & Resnick, 2008). Disciplinary dialogical teaching, accordingly, combines Alexander's theory of dialogic teaching and the concept of scientific argumentation: dialogical teaching in science should reflect the cultural ways of arguing/debating that is typical to science. Intervention studies gathering empirical evidence about the influence of dialogical teaching on students' learning of STEM subjects demonstrate significant gains (e.g. Mercer, Dawes, Wegerif, & Sams, 2004; Osborne, Simon, Chistodouluo, Howell-Richardson and Richardson, 2013; Venville & Dawson, 2010). A key aim for dialogical teaching is establishing exploratory talk, which makes students' ideas explicit as a stepping stone towards further conceptual change and development (Mercer, 2008).

The rationale for introducing argumentation-based dialogical teaching in science education rests on claims that informal reasoning is crucial to science inquiry (Latour, 1987). Barmby, Kind & Jones (2008) indicate that students' attitudes to science declines as they progress through secondary education, suggesting that positive experiences in the upper primary/ lower secondary (as used in this project) stage are critical for retaining interest. Dialogue and argumentation permit resolution of misunderstandings, tests students' reasoning, and ultimately prompts satisfaction from learning correct concepts, particularly when directed by a pedagogically skilled teacher. Another theoretical rationale underpinning the study explains conditions for professional development of teachers. It is well respected that many approaches to teacher development has had little sustained impact and that in-service training do not automatically transfer to classroom practice (Opfer & Pedder, 2011; Cazden, 2001). Success depends to a large extent on establishing a practice of collaborative reflection within a supportive community focused on professional learning (Horban, 2002).

CONTEXT

The study was carried out in Ethiopia, which is a low-income nation with many economic, cultural and pedagogical challenges. Traditional educational reforms in Ethiopia focused on enrolment and capacity building i.e. "mass" rather than "elite" education (Woldehanna & Gebremedhin, 2016). In response to that and since 1994, the Ethiopian Ministry of Education (MOE) has designed and implemented a series of Education Sector Development Programmes, in which classroom pedagogy has been the main focus. Compulsory education in Ethiopia is comprised of 8 years of primary education from grades 1 to 8 (7-14 in years) followed by 4 years of secondary school education from grades 9 to 12 (15-18 in years) with both numeracy and language literacy forming its focus (MoE, 2011). Based on the results of their obtained marks in the national Grade 10 Exam, students can either continue to higher education or join vocational training including teacher education. A significant number of primary school teachers come from students scoring lower marks in Grade 10 exams (Joshi & Verspoor, 2013). In addition, secondary school students who fail their 12 Grade National Exam enrol in one of the Colleges of Teacher Education where both groups (graduates of Grade 10 and Grade 12) study the same curriculum for 3 years (Alemu et al, 2019). Since 1994, the Ethiopian MoE introduced and implemented four major teacher education reform initiatives with the aim of expanding, standardizing and improving the quality of teacher education provision across the country. Mixed results were reported on the success of these initiatives in transforming traditional lecture-based teaching to student-centered and active teaching and learning.

Starting from this context, the research study looked towards a teacher education programme for the upper cycle of primary education (Grade 5-8) and sought to answer the following questions:

- To what extent and in what ways does a programme for transforming pedagogy introduced in CTE and as CPD in primary schools, or a combination of these in Ethiopia improve pupils' ability to reason scientifically?
- To what extent and in what ways does a programme for transforming the pedagogy introduced in Ethiopian CTEs and later in schools improve the teaching in primary schools towards disciplinary dialogical teaching? (Will pre-service teachers who have experienced and been trained in using dialogical teaching in ITE transfer this to their own teaching in schools?)

These research questions are related to the strategies of implementing disciplinary dialogical teaching into physics classroom, and if/how these works. We find it important to focus on changes in classroom practice and teachers' orientation/thinking and not just students' attainment. Improving attainment may have to go through many stages of development before we know more exactly which strategy is best, and to understand these intermediate stages we then have to learn from the changes that happens to practice and orientation. We also have to look at the wider perspective and take into consideration contextual factors.

RESEARCH METHODS AND DESIGN

Based on the study context, the study developed three models of training: the first was an initial training programme (pre-service) to implement argumentation-based dialogical teaching into physics courses in a three-year teacher education programme offered by Colleges of Teacher Education (CTEs) in Ethiopia. This was followed by the second training that introduced dialogic pedagogy through a programme of continuous professional development (in-service) to groups of teachers in schools. A third model arises from a combination of pre-service and in-service. This model provides pre-service and in-service to a cohort of teachers over two years, enabling impact on practice to be carried through from pre- to in-service.

The study used the same design repeated in two phases (CTE phase and school phase). It can be characterised as a quasi-intervention study, i.e. an intervention study, but without random allocation to the experimental and control groups. The present paper presents data from video-recordings of whole lessons in the school phase. These were captured simultaneously using two cameras, one recording the teacher with a fly-microphone, and the other recording the whole class. Each teacher in the treatment group was recorded twice, early and late in the academic year. Several sets of data are collected over two phases to investigate the extent to which the intervention enhanced teachers' pedagogic practice. Following candidates from Phase 1 to Phase 2, and dividing teachers in phase 2 into four groups (i.e. Pre-service, In-service, Combined and Control), allowed us to test the project strategies.

80 video-recorded physics lessons from a sub-sample of 40 teachers were collected and analysed quantitatively and qualitatively to examine the impact on pedagogical practice and physics learning of about 1200 students, including a control group. Data was analysed using NVivo 11 and SPSS. Another set of data came from interviews of each teacher after the lesson to ask about their rationales for and experiences of the teaching. Teachers in the experimental group also kept diaries of their lessons. Table 1 gives an overview of used methods, study samples and analysis.

Table 1. Overview of data collection and analysis in the school phase

Phase	Method	Sample	Analysis Procedure
Schools	Video-recording of whole lesson	N= 40 teachers 80 cross-sectional lessons	Recordings translated, transcribed and coded in NVivo with synchronised text and pictures. Quantitative data analysed using SPSS
	Teacher interviews	40 interviews	Narrative analysis used to identify and explore themes

Analysing the video recordings started with translating and transcribing dialogues into English using NVivo 11. Translation was needed because teaching was carried out in a mixture of English and Amharic. Next, transcripts were coded in the same software for time duration using a framework to identify different types of teaching (e.g. lecturing, working in groups, whole class discussions, teacher introducing lessons, teacher summarising lessons, etc.). The data was used to capture volume, i.e. percentage of lesson time spent within each category. We used NVivo for analysing the distribution and duration of teaching and learning activities based on self-developed framework e.g. how long time on lecturing (Rajab et al, 2018). The framework was designed to capture eight main categories based on a thematic analysis for a sample of 40 lessons. This was later statistically analysed using SPSS. During analysis, examples were extracted to illustrate answers to the research questions. Data was collected from a representative cross-sectional sample from many provinces across Ethiopia.

ANALYSIS AND DISCUSSION

Observational data from phase 2 of the study were analysed quantitatively and qualitatively. More often, treatment lessons show teachers demonstrating the intervention teaching, but teacher might exhibit more traditional teaching when not being observed i.e. the Observer's Paradox (Labov, 1994). Teachers, however, presented teaching material and their plans from all lessons and we did find the observed lessons representative of what most teachers did throughout the academic year. In the observed lessons, the average lesson time in the observed school lessons was 34 minutes. The longest lesson lasted around 50 minutes while the shortest recorded was 15 minutes (Figure 1).

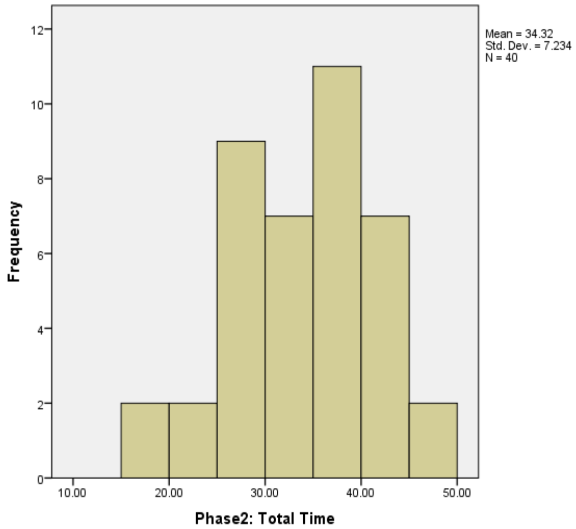

Figure 1. Phase 2: Average lesson time in observed schools

As shown in Table 2, treatment teachers significantly used more whole class dialogue than the control group. Intervention teachers spent more time in whole class discussion, demonstration and summarising student work. They demonstrated higher levels of engagement with the material, the available resources and students. In the control group, however, students spent on average 26% of class time carrying out individual seat-work such as copying the board silently or solving in-class homework. This was reduced to less than 10% in the intervention group. In the intervention group, student-led group work showed a significant increase up to 20% of the lesson time while this took less than 10% in the control group. Students in the intervention group were given more time to talk individually 13% while students' contribution in the control group did not exceed 5%. Lecturing at high levels, however, remains a persistent feature of the observed lessons across the two groups.

Table 2. % Lesson Time Spent on Different Teaching Activities at Schools (Ss: students; S: Student; T: Teacher, Intro: Introduce)

Group		Whole Class Dialogue	Group Work	Ss Seatwork	S Talk Individually	T Revise	T Summarize	T Lecture	T Intro
Control	N	10	10	10	10	10	10	10	10
	Mean	6.9	7.6	18.3	5.3	10.4	35.3	6.3	6.3
	Std. Deviation	6.6	15.6	20.9	8.8	5.5	21.3	3.1	3.1
Treatment	N	30	30	30	30	30	30	30	30
	Mean	13.6	18.7	8.7	5.2	9.3	35.6	5.4	5.4
	Std. Deviation	9.2	19.7	12.1	9.7	7.8	28.02	7.4	7.4
Total	N	40	40	40	40	40	40	40	40
	Mean	11.9	15.9	11.1	5.2	9.6	35.5	5.7	5.7
	Std. Deviation	9.04	19.2	15.1	9.4	7.2	26.2	6.6	6.6

Across the different teaching moves, the intervention group tended to engage students actively in whole class dialogue where scientific reasoning language was increasingly used e,g. how did you get to this answer? Intervention teachers allocated more time for both teacher-led and student-led group work. Students in the intervention group were noticeably afforded more time to express their views/responses while students in the control group spent more time either copying the board silently or solving problems alone. Within the intervention group, teachers showed improvements in balancing the different teaching moves where group work happened at a rate twice of the control teachers. In particular, the majority of intervention teachers managed to keep students engaged, thus avoiding the creation of 'silence pockets' during the course of the lessons. Silence pockets, where teachers chalk the board silently while students copy it, continued to be a major feature in the control group. Also, dialogic teaching, where teachers engage in a true whole class dialogue, was almost none-existing in the control group, but occurred in 11.45% of the time the treatment group as seen in Figure 2. Compared to control teachers, teachers in the treatment group spent more time on summarising tasks and lessons.

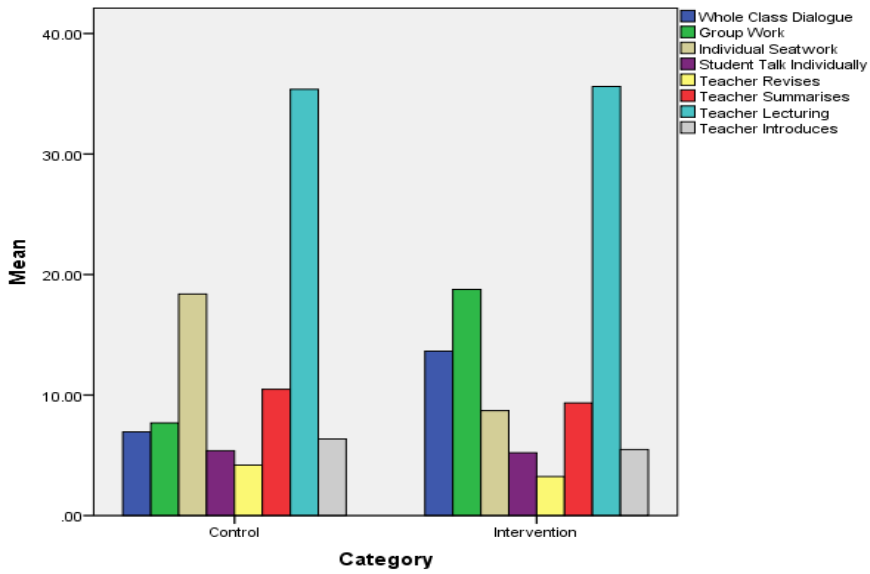

Figure 2. Percent of lesson time spent on different teaching activities at schools

For us, it became apparent that there are considerable changes in the pedagogical practices of intervention teachers as they noticeably reduced lecturing while giving students more space to talk and voice their opinions in the classroom. On the other hand, control teachers continued to use individual seatwork, marked by lengthy chunks of time where teachers were chalking the board silently or assigning tasks for individual problem solving in the classroom. Intervention teachers varied their teaching practices more and had a better balance across the class time.

While intervention teachers' practices changed to become more interactive, lecturing was still dominant across the whole sample as shown in Figures 2 and 3. With the exception of the combined group, lecturing continued to be the highest feature of pre-service and in-service groups. In the combined group, this was replaced with an even balance of teacher and student-led group-work. Even though lecturing (17%) was the third most recurring move in the combined group after group work (35%) and whole class discussion (21%), the control group was dominated by the lecturing at (35%) and individual seatwork (19%). Overall the three intervention groups managed to reduce individual seatwork in favour of diversifying the teaching activities to include granting students more time to express their views (student talk individually) or present their findings in front of the class, or summarising the main points.

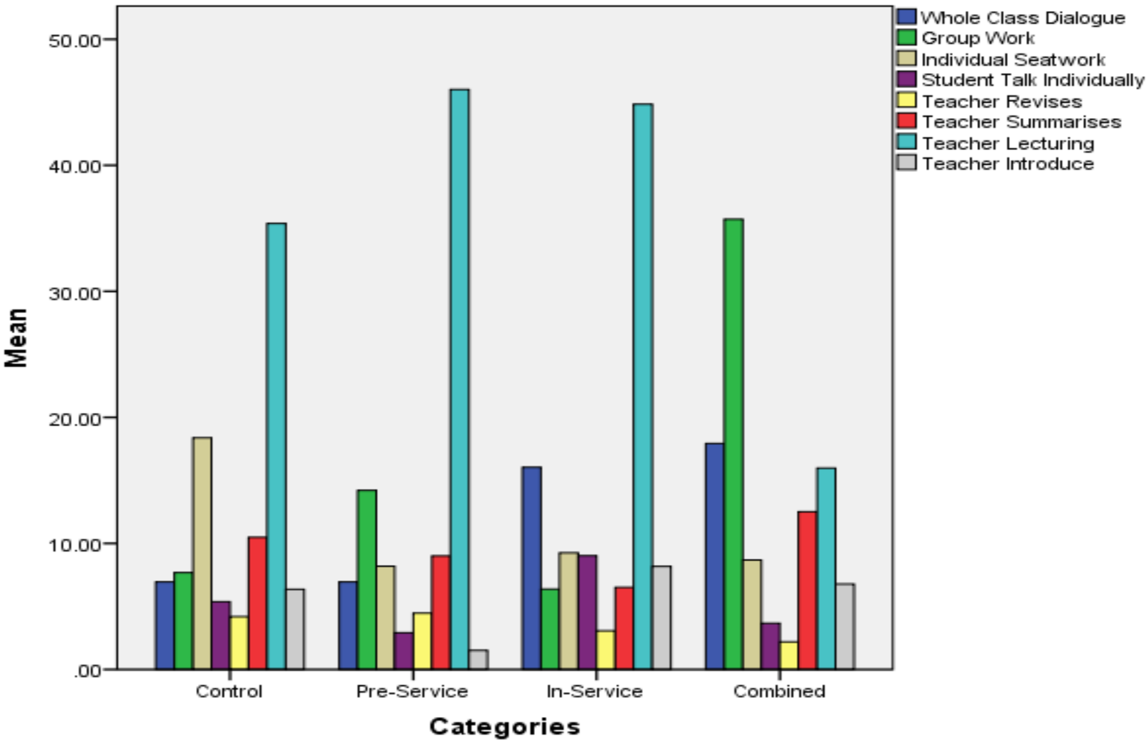

Figure 3. Teaching moves across categories in Phase 2

In discussing the results from Figure 3, it seems that the pedagogical practices of both the combined and in-service teachers were the most dialogic across the group while pre-service and control teachers were close in their use of whole class discussion practices. Individual seatwork was higher in the control group while in-service teachers exceeded other teachers across the whole round in giving individual students to talk more in the form of student presentation.

The video analysis showed a significant contrast between intervention and control teachers. While individual interventions teachers showed significant progress and pedagogical transformative features, the majority of teachers showed little signs of progress. Within the sample, teachers who received pre- and in-service (combined) and teachers who received in-service training were the most interactive and dialogic. In these two groups, teachers used high order reasoning and argumentation questions to probe the student learning process. Students were given the floor to voice out their opinions either individually or in small groups presenting in front of the class.

However, traditional pedagogical practices marked by unbalanced lengthy group work that in some cases occupied more than 65% of the class time prevailed in the control and intervention pre-service teachers. Within these two groups, teachers were not able to move away from the habit of silent chalking on board while students were passively copying the board.

Teachers from the combined group used open and reasoning-seeking questions (e.g. how, agree/disagree). They encouraged students to justify their responses by using why-questions or asking ‘what is your reason?’ In other cases, they asked students to think together by inviting other students to join the discussions. The majority of teacher questions from other groups (pre-service and in-service) continued to be mostly low-level re-call questions, aiming to check student basic understanding and test memorisation skills. The following example (Extract 1) illustrates a combined teacher’s use of good questioning techniques:

Extract 1. Excerpt from Teacher A's using some high-order questioning techniques

1	**T**	Discuss in your 1 to 5 groups. For example if a magnet is cut in two [Teacher is drawing on the board.] Now assume this magnet is cut into 2 parts. Then what will happen? Eve.
2	**T**	**What would you say happen if** a magnet is cut into 2?
3	**S**	[inaudible]
4	**T**	If it is cut north and south are cut, Yulia, do you agree with his assessment?
5	**T**	Do you agree? Badr, Rosa what do you think. Now this is a magnet. And if we cut it into 2 does it attract nails and other materials as it used to before. David what about you guys. Debate on this matter in your groups.

In the extract above, the teacher used a variety of high-order questions such as hypothesis-testing questions 'what would happen if'. He also uses agree/disagree questions encouraging other students to join the discussion. We also found that female teachers showed the most systematic progress with the deepest noticeable pedagogical transformation. The majority of teachers who were interviewed believed that more training would be good to enhance his understanding of dialogic teaching as they acknowledged the importance integrating such discourse in their practices. They believed that dialogic teaching enabled them come up with better questions and encouraged student critical thinking. In order to build on and internalise the pedagogical orientation introduced to intervention teachers, a top-up or refresher training between the two rounds of observation could have showed deeper and more consistent changes.

CONCLUSION

The analysis of the school data raised the main question about which educational strategy was most effective for changing the pedagogy and improving students' learning: training students in CTEs (Pre-Service), doing in-service training (In-Service) or doing both of these combined (Combined). The intervention comprised activities relating to physics concepts taught to 11 – 14-year olds. Data showed that teachers in the combined group presented the most significant changes to practice. Some teachers changed to use more scientific argumentation. Others changed a little and some not at all. There remains a gap between intended and attained curriculum in Ethiopian teacher education. This in turn leads to teachers' poor understanding of the subject matter. Education policy makers need to attend to bridging this gap in order to transform teaching within science subjects within Ethiopian schools.

ACKNOWLEDGEMENT

The TPSS project was kindly funded by an ESRC/ DfID grant from the UK Government.

Professor Per Kind, the original Principal Investigator, passed away on 1 October 2017. His inspiration for and work on the TPSS project is remembered through this publication and in Ethiopia.

ADOPTING KNOWLDEGE BUILDING PEDAGOGY TO SUPPORT EPISTEMIC AGENCY AND COLLABORATVE CONTRIBUTION IN SCIENCE CLASSES: A CASE STUDY IN NEW ZEALAND SCHOOLS

Simon Taylor
University of Waikato, Tauranga, New Zealand

This paper draws on how secondary science teachers from three schools have helped to develop a Knowledge Building community with their junior classes. The following themes will be discussed:

Theoretical frameworks of Knowledge Building; adopting Knowledge Building as a pedagogy to support epistemic agency and collaborative contribution in science learning; initial findings of the research.

The aim of a Knowledge Building community (KBC) is to produce new ideas and knowledge, which is useful to, and useable by the community (Scardamalia, 2002). There is an emerging prospect for science teachers where teaching programmes could be developed for students to improve knowledge, even to create knowledge not just reproduce it. Knowledge Building has been described as a community process where students are empowered in knowledge creation as legitimate contributors (Lai, 2014). This phase of idea creation and improvement is at the heart of the Knowledge Building pedagogy.

Rather than teaching programmes demonstrating science content and verification, there was opportunity to participate in an inter-school collaborative project, gain critical insight into theoretical understanding about knowledge synthesis, and contribute to the approaches and innovations which have been the key in realising the objectives of the pilot study. A design-based research methodology was employed in the multi-site case of Year 9 (13-14-year-old students) studying science in their first year at secondary school. Qualitative data was collected from teacher interviews and professional learning meetings. Audio taped student recordings in class interactions were integrated into the analysis.

Integrating a Knowledge Building community into a science programme was both challenging and complex, however through the exploration on classroom pedagogy using the 12 KBC principles (Scardamalia & Bereiter, 2010), notable shifts were revealed in the quality of student discourse, informed sense making across curricular links and greater epistemic agency.

Keywords: Collaboration, knowledge building, epistemic agency

Introduction

Knowledge Building is a model developed by Scardamalia and Berieter (2003) to support students to be knowledge creators. Knowledge Building may be defined simply as the creating, testing and improvement of conceptual artefact, it is not confined to education but applies to creative knowledge work of all kinds (Scardamalia, 2002). Educators have long been advocating that young people will not be prepared to face the social, political, economic, health and environmental challenges in today's society and indeed the future (Collins & Halverson, 2010; Facer, 2011; Gilbert, 2005). It is argued that there should be opportunities for students to be able to not only share knowledge but invent new knowledge (Lai, 2014). Moje (2008) contends that students' understanding of how knowledge is created is perhaps as important as knowledge itself. Pellegrino and Hilton (2012) view 21st century skills as knowledge that can be transferred or applied in new situations. This transferable knowledge includes both conceptual knowledge within the explanatory domain of a discipline and also epistemic knowledge of how to apply knowledge in order to construct new knowledge. Where emphasis is placed on creating new solutions, new methods to solve problems rather than applying previously learned actions to solve new problems. Conventional teaching and learning centring on transmissive, routine, and reception of existing knowledge, will no longer be adequate in preparing our students to tackle multifarious and interconnected problems. Future-focussed pedagogies in science education should focus on supporting students to be innovative, explorative, and capable of building knowledge collaboratively as a class community or even further, as a community of classes. Consequently, future science education is charged with the responsibility to devise and develop pedagogies to increase young people's innovative capacity in order to meet the challenges of current times.

The Knowledge Building model

The Knowledge Building model stands out from inquiry learning and problem-based learning practices sometimes seen in science or modern learning environment programmes. On the surface, some of the features are similar to inquiry learning, and teachers can have difficulty in distinguishing between these two approaches. The Knowledge Building model goes further, to support students to go beyond sharing and reproducing knowledge. Lai (2014) maintains that the goal of Knowledge Building is to create new ideas and public knowledge communally. It builds a suite of student perspectives, gathering ideas and questions from all. There is an intentional phase of idea improvement, where students have opportunity to develop and create ideas. In this specific pedagogy, the students are supported to contribute their ideas as a community. A digital space is implemented into the learning and teaching programme to support the developing inquiry, where students post their ideas. Knowledge Forum, Moodle or Padlet web-based software have been designed and modified to support Knowledge Building using a set of scaffolding tools. Students can show their classmates their science inquiry over the entire course of lessons and to disclose new ideas created as they proceed in the topic. There is also opportunity for Knowledge Building classes from different schools to work on the same science inquiry, and potentially, whole school involvement to be developed across curriculum areas.

Young people as knowledge creators

Knowledge Building is a pedagogical model described by 12 principles (see appendix) developed by Scardamalia and Bereiter (2010). One of those clearly illustrates that ideas are improvable, able to be improved, and the setting is for young people to have the opportunity to perform this improvement practise as a community, rather than as individuals. Students take control of the inquiry, they are given autonomy to set, plan, have goals, engage in creating further questions and responses. It allows students to take over a significant portion of the responsibility for their own learning including planning, execution and evaluation. Another hallmark of the Knowledge Building model is that it makes an important distinction between learning and knowledge creation. For Bereiter and Scardamalia (2010), Knowledge Building is a means for students to create and develop communal ideas, however, it will also deepen individual understanding of content knowledge and help students become self-directed learners. Learning is seen as a personal, internal, cognitive process of knowledge representation for individuals, whereas Knowledge Building is an external progression of producing ideas, and where students collectively create and improve ideas, ideas are being treated as external, public artefacts (Lai, 2014). Gilbert (2017) reinforces the case that young people can be knowledge creators. She signals Knowledge Building does not focus on how disciplinary knowledge is constructed by experts, nor is it personal construction of content knowledge. Conversely, it provides a sense of autonomy for students to operate in a space between those concepts of personal construction and disciplinary knowledge.

Future-oriented capacities

An intention of future-oriented science education is developing knowledge with learners which considers implications for a human and potentially non-human society (Kurzweil, 2005). Scientific and future technologies come packaged with a variety of moral, political, ethical and indeed practical decisions. Future oriented examples could include: artificial intelligence, natural disaster relief, space travel, human genetic modification, synthetic life, nuclear fusion and renewable energies. Hodson (2010) urges the value of explicitly featuring socio-political contexts in science teaching programmes. Consecutively if current social and environmental problems are to be solved, there is necessity of future generations of scientifically and ethically literate citizens. As science teachers we can place prominence on using topics of personal and societal issues. This takes a much more future-oriented direction to help foster learner capabilities of personal construction using these topics of interest. My viewpoint, is that personal knowledge of socio-political contexts is an active, participatory practice, where learners construct ideas together, where they can make sense of different viewpoints, grapple with conflicting arguments and justify them. The Knowledge Building model develops these specific learner capacities of manipulating knowledge, and working collectively to create and improve ideas. The other important aspect of a future oriented capacity is for students to be encouraged to be responsible for other student's science learning. The Knowledge Building model does this specifically in terms of all student viewpoints are considered through community. Students can take roles in the inquiries, working in teams in the class with specific duties such as technician, researcher and director. They can support each other in the way they learn, using these roles.

Knowledge Building supports epistemic agency

A purpose of studying science defended in the New Zealand Curriculum (Ministry of Education, 2007), is for students "to use their current scientific knowledge and skills for problem solving and developing further knowledge" (MOE, 2007, p.28). Students determining what information is valid and reliable is a necessary part of becoming informed. Authentic scientific inquiry depends on making decisions about whether information is justifiable and posing questions to establish its validity (Barker, 2011). Students could use questions such as: How could we critique this evidence? How could we redesign this investigation to ensure we have not overlooked any issues that may compromise our findings? Scardamalia and Bereiter (2014) argue that Knowledge Building actively supports learners to have agency or the capacity to act and make decisions about knowledge. The concept of epistemic agency is where students have responsibility for the knowledge that they are investigating. This learner capacity to have awareness of and to have insight into the development of knowledge appears to be critical in both Nature of Science (Lederman & Lederman, 2004) and Building Knowledge ideologies.

What did Knowledge Building look like in the science classes?

Knowledge Building involves students using an inquiry progression of scaffolding and building ideas together as a class community (Scardamalia & Bereiter, 2010). This particular Knowledge Building community model developed by Lai (2014) required specific pedagogy that supported movement between analogue and digital experiences. In the early phase of the project students were encouraged to take on the role of knowledge creators, this was carefully discussed and integrated into the lessons by the teachers. Following this, students had experiences of real face to face practical inquiries, integrated with a set of digital affordances or possibilities offered by digital tools such as software programmes: Padlet, Moodle and Knowledge Forum. Prominence was placed on sharing questions and ideas collectively, using digital software. They drew on their experiences and were given opportunity through the digital mechanism to be able to communicate these. Initially the preliminary investigation inquiry involved a start-up question and associated background information, posed by the teacher or student, to evoke interest in a topic. The virtual discussion space was called a "view", and "notes" were posted by the students in the class, to develop a collective noticeboard which displayed the posted notes to all classmates. With support from the teacher students arranged the posted notes into themes, they refuted claims and acknowledged ideas from their peers. The view page simultaneously captured the questions and these were displayed from all members of the class. There was opportunity for small teams of students to collaborate together and consider specific sub-topics, developing side investigations to enable to respond to questions which they have been identified as significant. Other stages of the Knowledge Forum/Padlet/Moodle process were where students posed their own theories, they made notes, identified what they needed to understand, and had the opportunity using the digital medium to improve on the knowledge. Stages were communicated and viewed on specific pages of the software used. At these stages, students read literature; constructed real models with cardboard and paper; searched the internet for information; consulted their teacher/s; discussed their ideas with community experts; and conducted practical tasks. Students used the thinking prompts available or developed their own to support theory building or progressive problem solving.

Initial findings

The participating teachers in this pilot study identified six enablers that supported integration of a Knowledge Building community in their science class. These were signalled through a series of teacher interviews after the Knowledge Building programme was implemented, and from a final discourse where an agreed summary took place. First, teachers must have a good understanding of the Knowledge Building principles and know how to communicate these principles to their students. Without a good ***understanding*** of the Knowledge Building principles, teachers may use this approach just as a form of inquiry learning. Following discussions with the teachers-all commented that it was challenging process and it cannot be accomplished in a short time. The second was to encourage regular focussed episodes of ***evaluation*** where the students (working in small teams) would present to the class in a more formal manner what their current findings were. This was duration of a 30-45-minute progress meeting, usually each week, depending on class and teacher. Teachers noted that the students used this regular event to convey current ideas and questions; to discuss their digital view page; to develop their confidence in speaking to the class using the digital view page; to reflect on how they worked as a group; to use scientific language in the forum; and to hear alternative views on a topic. The students justified their opinions and discussed new questions that had arisen in their study. Students also noted the evaluation meetings as an important opportunity to talk about group dynamics, to call for any changes to the makeup of the teams. Third was ensuring that students had a clear understanding of topic purpose, that there was ***clarity*** around the learning context. Topic examples are as follows: How good is New Zealand's recycling program? Future space travel; and Keeping ourselves safe in a tsunami. Students had viewed for example, the introductory You-Tube clips and read the associated resources such as an introductory information pack that described the context and/or scenario. Teachers said it was important that students were acutely aware of the quality of posting onto the digital platform, and this meant time in class to develop the posts. Occasionally some students could be absent for a lesson or two, hence on return to class, they required an update from their working group. Fourth, that even though the classes had been divided up into small teams of two-three students, each team contributed to the class (see Appendix points 1 and 2) and there was responsibility to ensure all ideas were aired. Hence there was teacher expectation of a ***community of learners*** working together. Examples of this emphasis include: posters up in the room which stated expectations; PowerPoint slides discussing group roles; information packs which had guidelines about working as a team and as a class. Fourthly, each team had the responsibility of generating new questions, taking photos of their investigations, collecting ideas from each team member and writing up new ideas to show evidence that Knowledge Building progress was being made. This was logged into a ***knowledge portfolio***, one class used clear files for this purpose and the other two used digital software: Google classroom and Padlet. The knowledge portfolio showed evidence of ideas being shared. This resource had notes, reflections and the "digital views" from each group. Responsibility of regular updates was shared amongst the group members and this was a resource that the teacher took into consideration in terms of overall group progress. Finally, the teachers spoke fervently about the need to design a topic that had an ***open-ended*** context to it, this took time to prepare and plan for but the effort was rewarded by overall positive student engagement. It meant that some knowledge and investigations were highlighted as essential but teachers stressed the importance of encouraging diverging inquiries from the main context of the topic, where autonomy was apparent and that there was opportunity for students to pursue their own personal questions.

Conclusion

This pilot project confirmed that Knowledge Building communities could be developed in junior science classes through improved teacher understanding of the 12 principles. Integrating a Knowledge Building community into a science programme was a challenging shift in practice, however through the teacher's own exploration on classroom pedagogy using the 12 principles, this could develop and be a very practicable model to support future science learning at Year 9. Six enablers were identified by the teachers, and valid points have been made about the differences between inquiry learning and Knowledge Building; epistemic agency and collaborative contribution. The realisation this research has seen, means placing more faith and confidence in learners to help create knowledge within their class communities using carefully constructed classroom strategies and the use of a digital forum. This research also signals how classes integrating Knowledge Building can influence pedagogical teacher change. It is an area of science education that has opportunity for further investigation.

ACKNOWLEDGEMENT

The study acknowledges the support of the teachers and students who have made this project possible. It has been a partnership between the University of Waikato and three secondary schools in the Bay of Plenty region in New Zealand. Dr Simon Taylor is a lecturer and secondary graduate programme co-ordinator, Te Hononga School of Curriculum and Pedagogy, Faculty of Education, University of Waikato. E-mail: simont@waikato.ac.nz

Appendix

Scardamalia (2002) identifies twelve principles of Knowledge Building as follows:

1. Real ideas and authentic problems. In the classroom as a Knowledge Building community, learners are concerned with understanding, based on their real problems and observations in the real world.
2. Community knowledge, collective responsibility. Students' contribution to improving their collective knowledge in the classroom is the primary purpose of the Knowledge Building classroom.
3. Improvable ideas. Students' ideas are regarded as improvable objects.
4. Idea diversity. In the classroom, the diversity of ideas raised by students is necessary.
5. Rise above. Through a sustained improvement of ideas and understanding, students create higher level concepts.
6. Epistemic agency. Students themselves find their way in order to advance.
7. Democratizing knowledge. All individuals are invited to contribute to the knowledge advancement in the classroom.
8. Symmetric knowledge advancement. A goal for Knowledge building communities is to have individuals and organizations actively working to provide a reciprocal advance of their knowledge.
9. Pervasive Knowledge Building. Students contribute to collective Knowledge Building.
10. Constructive uses of authoritative sources. All members, including the teacher, sustain inquiry as a natural approach to support their understanding.
11. Knowledge Building discourse. Students are engaged in discourse to share with each other, and to improve the knowledge advancement in the classroom.
12. Concurrent, embedded, and transformative assessment. Students take a global view of their understanding, then decide how to approach their assessments. They create and engage in assessments in a variety of ways.

GREEK SCIENCE TEACHERS' TPACK EXPRESSION FOLLOWING PROFESSIONAL DEVELOPMENT

Angeliki Samanta[1], Dimitrios Psillos[2]
[1]27th Primary School of Acharnes, Acharnes, Greece
[2] School of Primary Education, Aristotle University of Thessaloniki, Thessaloniki, Greece

In the present study it was attempted to inquire science teachers' practices after being trained by Greek B' level professional development program concerning ICT integration. Class observations and respective interviews were used as research tools and were set in correspondence with TPACK model. Our goal is to present the outcomes of B' level and inquire the implementation of virtual labs and applets by trained science teachers and the context where this implementation occurs. The data analysis showed that science teachers have understood the use of these tools and actually implement them while recognizing their advantages. Moreover, they prefer that this implementation takes place in inquiry based teaching, following a teaching scenario.

Keywords: Professional development, TPACK

INTRODUCTION

Contemporary professional development programs (PDP) in ICT integration focus in the pedagogical exploitation and integration of ICT in classroom teaching since several studies have shown that effective teacher preparation is an important factor for successful ICT integration in education. (e.g. Giovannini et al 2010).

In Greece, since 2006, science teachers (among other teachers) are being trained by a multi-year and nation-wide professional development program (PDP) called B' level, concerning ICT integration in class provided by face to face or hybrid forms (B' level, 2010, Psillos & Paraskevas, 2017). Similarly to other PD programs (Voogt, Tilva & van den Akker, 2009, Shin et al, 2009, Hong & Stonier, 2014), the content and structure of B' level for science teachers is based on the well known TPACK model which provides for an integrated framework of professional knowledge which teachers have or should develop for effective ICT classroom integration. According to this model the interaction of Technology, Pedagogy and Content factors is a complex process related to synthetic forms of professional knowledge. TPACK is a powerful model used not only as a heuristic for course development but also for research aiming at investigating teachers' practices and implications of PD programs (Chai, Koh & Tsai, 2010).

Voogt, Tilya and Van den Accer (2009) in their research, intended to determine –with class observations- the extent to which trained science teachers were able to practice what they learned during their PDP about the integration of Microcomputer Based Laboratories (MBL) in inquiry based teaching. They, actually, concluded that trained teachers were able to create a classroom environment based on guided inquiry integrating MBL (ICT) which was appreciated by their students as more investigative. In another research, Shin et al (2009) aimed at examining –with class observations too- how teachers (trained by a PDP where they had to work on a range of assignments that required them to learn and use ICT in multiple pedagogical contexts) understood and showed in practice the interaction between technology, content and pedagogy. They find out that teachers gained a deeper understanding of how technology related to other aspects of teaching and they observed changes in teachers' knowledge, noting that this knowledge can have an effect on their practices. Similarly, Hong and Stonier (2014) in their study on whether TPACK understanding helps teachers –trained by a PDP which had as a goal to educate teachers on how to effectively integrate GIS technologies in their teaching by providing technological, pedagogical and content knowledge- integrate ICT, came to the conclusion that teachers integrated GIS in their teaching and this TPACK- based PDP was largely successful at helping them proceed.

In Greece, the content and structure of B' level program for science teachers which is based on TPACK, include: knowledge and applications of pedagogic approaches (mainly inquiry), familiarization and use of contemporary software (such as simulations, virtual labs and web based tools) and their added value (Psillos & Paraskevas, 2014), knowledge and skills about designing activities, worksheets and teaching scenarios integrating ICT.

This research is part of a multi level research program aiming at studying secondary science teachers' perceptions and expression in practice of their TPACK following their attention of B' Level PDP. The present study focuses on the "face to face" form which includes 96 hours of courses (for the General Pedagogical part and for the Specialization in Teaching Science ICT part), 24 hours of preparation and reflection practice and 24 hours of actual teaching (Samanta & Psillos 2015).

In our previous studies detailed elsewhere we used large scale questionnaires and in-depth interviews (Samanta & Psillos, 2015). In the present study, we report results of classroom observations and of the respective interviews, aiming at revealing the expression of teachers' TPACK in science teaching after attending the B level PDP.

METHOD

18 science teachers who had participated in B' level PDP agreed to have their teaching using ICT observed. Class observations were held in different schools during one didactic hour. Class observations were carried out using a special record tool- rubric that was designed according to TPACK model and after analyzing other similar rubrics. We decided to proceed to the linking of parameters observed to TPACK model according to Joyce, Weil & Calhoun (2011). The rubric was piloted and the feedback was taken into account. It was sent to a panel of TPACK experts (3 phd teachers and 2 school consultants) who evaluated the linking between the parameters and TPACK model. A special rubric was developed as well in order to be used during the respective semi-structured interviews. The interview questions were linked to TPACK, similarly to Jimoyiannis (2010) linking. For example, when asking if a science teacher was familiarized to virtual lab interface, the research aimed at revealing science teachers' TK but when asking why this virtual lab was used in this context in class, the research aimed at revealing the interaction between all TPACK's components. It is important to note that, following B' level's policy, the term TPACK wasn't mentioned to the participants so as not to

cause any agitation. After the completion of the observations and the interviews, the two rubrics filled for each participant were merged into one so as to gain an overall image of every teacher's practices. The 2 researchers discussed about the data, analyzed them and the linking between what teachers did (observation data) and what they think they did (interview data) and TPACK model emerged.

In order to better understand the research data and results, we must note that B' level focuses on promoting ICT integration to teachers who were taught and keep teaching in traditional way, who have limited access to equipment (usually 1 pc and projector per class and occasionally laboratories) and who have to follow a very stipulated curriculum. It is important to check and discuss the outcomes of B; level professional development program in such context and under specific limitations.

RESULTS

The observation and interview results were categorized according to TPACK's components which were merged for the sake of brevity (PK with PCK and TK with TCK).

Participants' technological and technological content knowledge (TK & TCK)

It was observed that the majority of science teachers employed virtual labs, simulations and applets which were taught to them during B' level and exist in national data bases. Few of them, in their interviews, mentioned that had searched the web for different applets and simulations suitable for their teaching and this was confirmed in our observation. They were familiar with virtual lab's and simulations' interface and certain affordances showing evidence of Technological Knowledge (TK). However, they did not fully exploit the affordances of these tools and this was confirmed in their interviews. They also admitted not being fully informed about all virtual labs potentialities and that every time they were occupied with them, they were finding new potentialities. So, they expressed the need to dedicate a lot of time, in order to get more familiarized showing evidence of evolving Technological Content Knowledge (TCK) based on B' level instruction. A trainee noted: *"I often use the virtual lab in class but for this, I spend a lot of my spare time searching for its features. I think I'm in the middle of the road and need to keep working and working…"*.

Participants' pedagogical and pedagogical content knowledge (PK & PCK)

Regarding the teaching approaches (pedagogical component- PK), almost all science teachers promoted group work to their students. We must note that teaching took place in science labs where there was only one pc and one projector. It is worth mentioning that the students participated in interactive presentations and manipulated software alternately due to equipment limitation. In their interviews, teachers expressed their preference to less traditional teaching, although they admitted keeping traditional elements. A trainee characteristically mentioned: *"It needs a lot of effort to change something so deep. I was taught traditionally and keep teaching this way but I try to reduce it. I think someday I will manage to do so."*

Most teachers, while interviewed, considered that their teaching is characterised by a high degree of freedom. Observations showed that they mainly applied guided inquiry teaching. Moreover, they stood up for inquiry based teaching, claiming that they believe it's suitable so as to reach the expected cognitive goals, expressing this way their pedagogical content knowledge (PCK) and mentioned having as a goal to find the way to apply inquiry to their teaching more often. They also expressed the need to be more trained about inquiry by PDP.

Participants' technological pedagogical content knowledge (TPACK)

The inquiry based teaching was linked by the interviewees to ICT integration. We must note that they mentioned using ICT in class in an inquiry based context in few occasions in a month due to equipment or time limitations. Except one teacher who kept his traditional habits, all the rest promoted inquiry and the majority gave their students a worksheet that was part of a teaching scenario with inquiry elements. All worksheets let their students observe, wonder, estimate and conclude. Thus, teachers found the way to express the interactions between all TPACK's components. Notably, they didn't find it necessary to depict this interaction in a written scenario as only some teachers had one, while the rest mentioned not having one by choice, even though they created a scenario data base during B' level. They noted that it makes them feel restricted and less free to change their teaching based on their students' needs.

CONCLUSIONS – SUGGESTIONS

One limitation of this study is that participants were observed only one time given the restrictions of schools' time table and comprised a convenient sample among the trained teachers due to difficulties in reaching classrooms employing ICT. Within such limitations, it seems that teachers are in a transitional phase, where B' level PDP helps them not only to increase their ICT integration but to evolve their teaching of science. Greek science teachers often use traditional teaching but prefer a well-designed "activity" idea –in an inquiry based teaching context- that encourages learning as a process linked to the curriculum context, which they employ occasionally, similarly to Voogt et al (2009). These results were relevant to the results of our previous research that showed that teachers' preference towards traditional methods has decreased and the preference towards the inquiry based has also increased (Samanta & Psillos 2015). Such a conclusion is an indication of considerable teachers' evolution since previous studies in Greece (Demetriadis et al, 2003) and in Russia (Nikolaev & Chugunov, 2012) showed that trained teachers had the tendency to adjust ICT to support traditional teaching but, in our present research, teachers made serious attempts in changing their traditional teaching. It is worth mentioning that the teachers admitted having hard time overcoming traditional methods. Besides, it is noticeable that, within external limitations, due to limited resources, the teachers of the sample employed interactive presentations in order to promote students' engagement showing flexible adaptation of pedagogical knowledge (PK).

Observation showed that the level of ICT integration via activities, worksheets and scenarios was impressively raised by the trained teachers who had planned integration of ICT in their teaching and they used activity worksheets. Yet, they preferred not to have a written scenario, although they were trained to develop them. One explanation is that written scenarios are time consuming and restrictive as mentioned in Samanta and Psillos (2018). This is something to be further searched. Such evidence show expression of aspects of TPACK but also limitations. Similarly, Drossel, Eickelmann and Gerick (2016) mentioned that more than half teachers interviewed (from Germany, Poland, Netherlands, Denmark and Australia) find that there is no time for preparing ICT infused lessons and Hong & Stonier (2014) suggested providing premade lessons due to lack of time.

Listening to the science teachers and their needs, we suggest that the upcoming B' level programs promote more clearly inquiry based teaching and give science teachers the fundamentals to apply inquiry. Moreover, teachers who have been trained need to have continuous support by the PDP because tools and pedagogical ideas are evolving and teachers' knowledge should be up to date. More class observations are in progress in order to compare the everyday practices of teachers trained in previews B' level programs and the practices of newly trained by B' level teachers.

USING PRACTICAL WORK EFFECTIVELY IN THE SCHOOL SCIENCE LABORATORY: A TEACHER TRAINING PROGRAMME BASED ON THE LEARNING COMMUNITY APPROACH

Marta Carli[1] and Ornella Pantano[1]
[1]Department of Physics and Astronomy, University of Padova, Italy

This study describes the design and implementation of an in-service teacher training programme for high school teachers aimed at improving their competence in the use of the laboratory for physics education. A framework for designing the programme was constructed based on PER literature, containing the following features: linking content, practice and research; action research; focus on teachers' beliefs; sufficient duration; and the learning community approach. The intervention aligns with recent international recommendations, and in particular with the need of providing teachers with meaningful, research-based professional development on inquiry teaching and opportunities to work collaboratively. Data for the evaluation of the programme were obtained using multiple instruments. The results suggest that all the identified features were effective, with action research and the learning community approach being decisive for promoting real change.

Keywords: Communities of Practice, In-service Teacher Training, Practical Work in Science

INTRODUCTION

In recent years, a renewed attention to the role of the laboratory in science education has been acknowledged not only by research (Hofstein & Lunetta, 2004; Rundgren, 2018) but also by several international reports and standards. A milestone was the document known as 'Rocard report' (Rocard et al., 2007), that called for "A reversal of school science-teaching pedagogy from mainly deductive to inquiry-based methods" (p. 2). The National Research Council clarified the meaning of inquiry teaching by identifying eight 'scientific practices' that should be developed in the classroom together with disciplinary core ideas and crosscutting concepts (National Research Council [NRC], 2012), and, more recently, the National Academies of Science, Engineering, and Medicine recommended that 'investigation should be the central approach for teaching and learning science' (National Academies of Science, Engineering, and Medicine, 2019, p. 5).

Despite the emphasis placed on inquiry education, the term 'inquiry' is often misunderstood and confused with simply proposing 'hands-on' activities (Crawford, 2014; Osborne, 2014). In contrast, effectiveness in the use of laboratory activities is only achieved if they are well-designed, their purpose is clear, and they are embedded in a carefully planned teaching-learning sequence (Abrahams & Millar, 2008; Millar, 2010; NRC, 2006). The situation is complicated by issues such as the inadequacy of laboratory facilities, classroom organisation, and the need to comply with national standards (Nivalainen, Asikainen, Sormunen, & Hirvonen, 2010).

This situation calls for a reflection about teacher training. Many teachers have had little personal experience in the lab in their education and pre-service training (Yalcin-Celik, Kadayifci, Uner, & Turan-Oluk, 2017) and, on the other hand, few in-service teacher training programmes address the problem specifically using the results of research in physics education (NRC, 2006). For these reasons, actions should be taken in order to provide teachers 'with appropriate instructional resources, opportunities to engage in sustained professional learning experiences and work collaboratively to design learning sequences, choose phenomena with contexts relevant to their students, and time to engage in and learn about inclusive pedagogies to promote equitable participation in science investigation' (National Academies of Science, Engineering, and Medicine, 2019, p.6).

In the light of these considerations, this study aims to provide insights into the following research question: *What features should an in-service teacher training programme have in order to promote an effective use of the school science laboratory, and which of these features are most effective?*

THEORETICAL BACKGROUND

A meaningful model for successful teacher training was proposed by Adey, Hewitt, Hewitt, and Landau (2004), who identified the following characteristics: theoretical justification (research-based); high quality (sufficient duration, coherent methodology, intense/engaging activities, tutoring for implementation); support by the school management; and sharing with colleagues. However, according to many accounts, teacher training courses are often short and factual in nature, which is unlikely to promote real and long-lasting change (Gilbert, 2010; NRC, 2006).

Desimone (2009) identified five 'core features' for effective teacher training, based on the results reported in previous literature: content focus; opportunities for teachers to engage in active learning; coherence between teacher learning and their knowledge and beliefs; sufficient duration; collective participation. In a comparative study, Capps, Crawford, and Constas (2012) investigated the effectiveness of the above-mentioned features in the context of professional development (PD) on inquiry, considering 17 PD programmes. Their results show a general alignment with these features, but also suggested a need of additional research into PD programmes on inquiry, in order to identify which features are more effective in this context.

In recent times, the topic of collective participation has been emphasized and expanded by focussing on teachers' collaboration. Some benefits of teacher collaboration are improved instructional practices, improved student learning, and a better breeding ground for innovation (Vangrieken, Dochy, Raes, & Kyndt, 2015). A structured, bottom-up approach to teacher collaboration are *learning communities*, or communities of practice (Wenger, 1998; Vangrieken, Meredith, Packer, & Kindt, 2017). Even in the context of science education, research suggests that learning communities can promote authentic innovation (Couso, 2008), and a number of teacher training programmes have been developed according to a learning community paradigm (Singer, Lotter, Feller, & Gates, 2011; Lotter, Yow, & Peters, 2014).

Another aspect that has received attention recently is action research (Gilbert, 2010; Laudonia, Mamlok-Naaman, Abels, & Eilks, 2017). Teachers engaging in action research identify a problem relevant to their context, formulate a research question, select the data they need to answer it, design and implement some actions, evaluate their results and draw conclusions in order to identify new research questions. Action research is particularly effective when practitioners are supported by experts who put them in contact with research results, provide coaching and feedback, and offer emotional support (Gilbert, 2010). A positive intercorrelation between action research and the learning community approach has been suggested (LINPILCARE project; Mamlok-Naaman, 2018).

RESEARCH DESIGN AND METHODOLOGY

Based on the background described above, we outlined a revised framework for our teacher training programme. Specifically, we identified five core features, the effectiveness of which was the core of our research question and was investigated using multiple methods and perspectives as described below. Based on the revised framework, we designed a programme, named 'CoLLABORA – a Community of Learners on LABORAtory work', which was implemented between May 2018 and June 2019.

Revised framework

Developing on Desimone's 'core features' we identified a revised set of five 'core features'.

Linking content, practice and research. Laboratory activities was contextualised into the topic 'waves and their applications', one of the core ideas of physics education (NRC, 2012). We proposed and discussed research-based activities and participants had the opportunity to design their own activities. We also discussed the purpose of laboratory activities into a teaching-learning sequence, the construction of effective laboratory worksheets, some issues related to assessment, and specific disciplinary and didactical issues about the topic.

Action research. Each participant designed his/her own action research project to be applied in their classroom. Two sessions at the beginning of the course were devoted to formulating an investigable research question and writing an action research plan. Opportunities from feedback and coaching were given throughout the course.

Focus on teachers' beliefs. We focussed on *self-efficacy beliefs*, i.e. context-dependent judgments about being able to perform a particular task and obtaining the desired outcomes (Bandura, 1986). Teachers who have a high sense of efficacy are more likely to teach effectively (Tschannen-Moran, Hoy & Hoy, 1998; Crawford, 2007; Lotter et al., 2018; Chicherkian, 2016). During the programme we monitored these beliefs using specific instruments.

Sufficient duration. The programme featured 45 hours of contact time over one year.

Learning community. We set up the group as a learning community, sharing expectations, goals, rules, and style. Participation of teachers from the same school was encouraged.

Methods

In order to gain information from multiple perspectives, we used a variety of instruments:

Individual questionnaires. An individual questionnaire was delivered at the beginning and at the end of the programme. The initial questionnaire investigated the participants' background, their use of the laboratory, the presence and characteristics of their school laboratory, their expectations about the programme and their knowledge of the learning community approach. The final questionnaire investigated if and how the participants' use of the laboratory had changed during the course, in which dimensions (physics content, use of practical work, etc.) they thought they had improved the most, what activities they had found more useful, the extent to which the learning community was helpful, and how much the course met their expectations.

Focussed group interview. At the end of the programme, a semi-structured focussed group interview was led, containing five questions: (1) What were the advantages of discussing laboratory practices within a specific disciplinary content? How did research results contribute to enhance the discussion about the use of the laboratory? (2) To what extent, and how, engaging in action-research was useful in order to enhance the use of the laboratory at school? (3) To what extent are self-efficacy beliefs relevant in enhancing the use of the laboratory? (4) To what extent was the course structure (duration, meeting schedule, etc.) relevant to promote enduring change in your practice? (5) What was the added value of setting up our group as a learning community and in what ways did this approach influence your practice?

Teaching Science as Inquiry test. We used the Teaching Science as Inquiry (TSI) test (Smolleck, Zembal-Saul, & Yoder, 2006) for assessing changes in the participants' self-efficacy beliefs about inquiry teaching. Consistently with Bandura's (1986) construct of self-efficacy, the TSI explores both personal self-efficacy (the belief of being capable of doing something) and outcome expectancy (the belief that teaching will have a positive outcome). Moreover, it allows assessing different dimensions and levels of inquiry (NRC, 2000).

Individual action research reports. At the beginning of the programme, each participant formulated his/her own research question and developed an action research plan. During the last meeting, each participant presented a report about their action-research project.

Participants

The programme involved 15 teachers from 11 secondary schools (grades 9-13). Most of them (9) had a degree in Mathematics, while the others had a degree in Physics (3), Engineering (3) or Astronomy (1). The participants' teaching experience ranged from 5 to >20 years.

Programme schedule

The programme, named 'CoLLABORA - A Community of Learners on LABORAtory work', was delivered between May 2018 and June 2019. Table 1 summarises the schedule and content of the meetings. In-between the meetings, collaborative online activities were proposed via the Moodle platform, which also contained all the course resources and a 'course journal'.

Table 1. Programme schedule and content.

Date	Topic/activities
May 11th, 2018	Learning community setup. Pre-course administration of the TSI test. Analysis of a research-based laboratory activity.
May 18th, 2018	Laboratory activity on ray optics + discussion.
September 7th, 2018	Laboratory activity on mechanical waves. Formulation of personal research questions + feedback from peers and researchers.
September 14th, 2018	Didactical issues about 'waves and their applications'. Design of personal action research plan + feedback from peers and researchers.
October 12th, 2018	Disciplinary and didactical issues about 'mechanical waves'. Reflection on scientific practices. Laboratory activity on standing waves + discussion.
November 9th, 2018	Disciplinary and didactical issues about 'sound waves'. Laboratory activity on sound waves + discussion; focus on the use of technology.
December 14th, 2018	Visit to the Museum of the History of Physics and discussion/reflection on learning in out-of-school contexts. Group work on the different purposes of laboratory activities into a teaching-learning sequence.
January 11th, 2019	Reflection+discussion on the assessment of practical work. Co-design of a laboratory activity on ray optics.
February 15th, 2019	Laboratory activities on wave optics according to the three types of experiments + discussion.
March 8th, 2019	Laboratory activity on light sources and their spectra + discussion.
April 12th, 2019	Laboratory activity on atomic spectra + reflection/discussion on the didactical issues of modern physics.
May 10th, 2019	Final workshop: each participant presented the outcomes of his/her own action research project.
June 7th, 2019	Final focussed group interview.

RESULTS

General outputs of the programme

According to the individual questionnaires, 70% of the teachers changed their use of practical work at school since they had started the course. Self-reported changes include using different kinds of activities, adopting a more open inquiry, and developing improved didactic and assessment tools. Besides gaining a better understanding of the role of practical work in physics education, participants also think they became more capable of designing a laboratory activity. The most appreciated activities during the programme were experimenting and constructing research-based experiences. Participants also valued the active engagement, the connection between physics content and scientific practices, and the collaborative approach.

Effectiveness of the five features

Below we report our results with respect to the five features of our framework.

Linking content, practice, and research. The participants considered useful to include the reflection on the laboratory into a content strand that is central throughout the curriculum. The use of research-based materials was relevant 'in order to qualify [their] didactic choices' (Lucia). In particular, discussing the purpose of the different laboratory activities in a teaching-learning sequence provided 'new ways of thinking about practical work […]' and it 'left room to the participants' creativity about how to use them in the classroom' (Sara).

Action research. According to the participants, engaging in action research was effective in fostering a more scientific attitude towards teaching: 'Even when I don't do planned action research, now I look at my everyday practice with a research attitude' (Alberto); 'I have learnt that there are many aspects of my practice I can experiment on' (Giorgio). Action research also fostered the development of positive self-efficacy beliefs, as it is discussed below. The time spent in formulating an investigable research question and developing an action research plan was considered particularly relevant: 'The best part of it was stopping to think about my practice in order to pose the right question' (Maria Rosa).

Focus on teachers' beliefs. The TSI scores at the beginning and at the end of the programme suggest that there was a slight overall improvement for self-efficacy (+0.14 on average for self-efficacy, +0.08 for outcome expectancy), but a large variability among participants was observed. A deeper analysis into the personal path of each teacher would be required in order to identify the factors that contributed to the evolution of their beliefs. However, a connection was suggested between high TSI gains and the completion of action research projects: 'Beliefs change if you try for yourself and you see that you like what you are doing' (Giorgio). The case study described below also supports this hypothesis. Concerning the five dimensions and levels of inquiry (NRC, 2000), the largest average improvement was observed for 'learner gives priority to evidence in responding to questions' (+0.28) and 'learner formulates explanations from evidence' (+0.20), and an overall increase towards a higher students' autonomy was observed (+0.28).

Sufficient duration. Consistently with the literature, the duration of the course was judged 'necessary for letting things settle' (Maria Rosa) and even 'not enough' (Alberto). Participants agreed that real change is a long-term process and that even more opportunities for meeting and working together would be needed.

Learning community. Working collaboratively with colleagues and establishing a relationship environment where ideas and difficulties could be shared 'without the fear of judgement' (Lucia) was decisive: 'I see the foundations for building a community of teachers who share materials and ideas' (Francesco). Participants particularly appreciated the possibility of interacting with colleagues from different backgrounds and contexts, which gave them the possibility to 'experience a wider network of relationships beyond the one in our schools' (Alberto). When two teachers from the same school were present, this was recognised as 'a seed to start a learning community in each school' (Francesco). The learning community was also identified as ‘a powerful strategy for reinforcing the relationship between schools and university’ (Giorgio). Collaborating online was however a critical aspect: according to the participants, part of the problem lay in the specific platform (Moodle, judged ‘not very user-friendly’, but they also acknowledged that working collaboratively is not automatic and requires training.

A case study: Lucia

We describe the experience of one of the participants, Lucia, more in detail, in order to describe how the course influenced a teacher’s practice in her specific case.

Background. Lucia got her degree in Mathematics in 2008; during her degree she followed no laboratory courses. At the beginning of the programme, Lucia had been teaching physics for 8 years and she was teaching in grades 9-10 in a technical high school. According to her initial interview, before the course she ‘occasionally’ proposed laboratory experiences. Lucia’s initial score in the TSI was 2.80 for self-efficacy and 2.90 for outcome expectancy.

Action research plan. Lucia’s action research plan was implemented in her 10th grade classrooms in January 2019. Her research employed a quasi-experimental design involving an experimental and a control classroom. Specifically, she wanted to test the effectiveness of a research-based observational experiment in the context of a teaching-learning sequence on mechanical waves, compared with a traditional laboratory. She evaluated her research using two different rubrics (an observation rubric filled in by herself and by an external observer, and the students’ self-evaluation), the analysis of students’ lab reports, and a test administered three months after the lab. Her results supported the effectiveness of the research-based laboratory and, as the start of a new action research cycle, she refined her research question as how to re-design the lab in order to engage all of the students, including the weakest ones.

Impact of the programme and effectiveness of the five features. In her final questionnaire, Lucia listed some of the new habits she implemented in her classroom: ‘Now I provide the students with the rubrics I use for assessment; I use a larger variety of laboratory activities; I have modified the structure of my lab worksheets in order to give the students more room for inquiry; and I encourage my students formulate their own questions’. Lucia particularly appreciated the research-based proposals, which she ‘thirsted for’: ‘It was like a pat on the back. It is good to know that someone is thinking about it’. She judged the experience of action research a crucial point of the programme: ‘During our pre-service teacher training, we were asked to design imaginary plans for imaginary classrooms; on the contrary, in everyday practice we just do the same things year after year. Engaging in action research gave me the opportunity to design and carry on a real project on a real classroom’. Lucia reported large gains in the TSI test (+0.93 for self-efficacy and +0.58 for outcome expectancy). She connected this improvement to her action research experience: ‘I felt a need for change, but, in my school, there is a traditional approach to lab activities… I used to think, “maybe I am a mathematician and I cannot do practical work, probably I am the wrong one”. This year I have worked on myself and now I believe that I can be comfortable in the lab and that I can promote change in my school’. For Lucia, improving her beliefs meant not only promoting personal change, but also making her think of herself as a change agent in her school. Lucia also appreciated the course organization and the learning community approach: ‘The monthly schedule allowed us to set our goals on a timeline pattern, then meet to build the community and step forward. The yearly duration allowed us to make small changes, with the opportunity discuss them soon after’. According to Lucia, ‘The strength of the programme was to offer stimuli while at the same time bringing out the very best from each participant. In most programmes, we listen to an expert and then we do some group work… here I found room for personal reflection and adequate input based on research, that motivated me to change; I found helpful colleagues and researchers who gave me precious feedback. This year I did not feel alone.’

DISCUSSION AND CONCLUSIONS

From the data collected with multiple instruments, we can conclude that all the features considered in our programme were effective, with action research and the learning community approach being decisive. In fact, engaging in action research impacted the teachers’ attitude towards their teaching (fostering a more evidence-based approach). Moreover, a successful action research project boosted the improvement of self-efficacy beliefs and promoted a sense of agency. Concerning the learning community approach, the participants highlighted the need of a ‘non-threatening, inspiring, trustful and collaborative’ context in which to grow as teachers and persons. These comments reinforce our choice of adopting this approach as out working model and supports us in envisaging actions to further improve it.

The focus on teachers’ beliefs seems relevant as a means to effectively impact teachers’ practice, though personal stories and paths should be taken into account to interpret the results. Qualitative, in depth instruments are needed in order to gain further insights on development of the participants’ beliefs. In the light of the results about action research and programme duration, we argue that even more time and opportunities for action research would be needed as sources of self-efficacy. This will be a priority for the continuation of the programme.

Based on the results of this study, we plan to continue the programme for another year, focussing on action research and experimentation in the classroom. We also plan to introduce more collaborative practices such as co-planning, engaging in micro-teaching sessions, observing and being observed by peers, giving and receiving feedback, with the aim of reinforcing the community and foster collaborative approaches to the teaching of physics. Secondly, we plan to design a revised version of the programme to be implemented with a new group, with the aim of enlarging the community and promote the establishment of local teachers’ networks. We hope that, in the long term, this effort will contribute to the formation of productive links between research and practice, the schools and the university, and foster change and innovation as well as personal and professional development.

ACKNOWLEDGMENT

The study was supported by the “Piano nazionale Lauree Scientifiche” of the Italian Ministry of Education, University and Research.

DEVELOPMENT AND EVALUATION OF A TEACHER TRAINING ADDRESSING THE USE OF EXPERIMENTS IN CHEMISTRY EDUCATION

Henning Krake[1], Maik Walpuski[1]
[1]University of Duisburg-Essen, Essen, Germany

Research on the quality of instruction in chemistry education provides quality characteristics which correlate positively with students' measured cognitive and affective variables. A content-specific individual teacher training using video analysis and focusing on these characteristics has shown efficacy down to student level. In the project at hand we develop and evaluate a comparable teacher training which is independent from the content. The one-day teacher training uses video data from the participating teachers' chemistry lessons. For an extensive evaluation on different levels (e.g. teachers' cognition and practical performance) several instruments have to be developed or adapted. Therefore, the project consists of two studies. In the first study, the instruments are developed and evaluated. The intervention itself is evaluated in a second study using a pre-post-follow up design.

Keywords: In-service Teacher Training, Training and Development, Video Analysis

THEORETICAL BACKGROUND

Research on the quality of instruction provides general or more precisely non subject-specific criteria which correlate positively with students' performance, interest and attitudes (Schulz, 2011; Seidel et al., 2006). From studies in science education, especially chemistry and physics, one can conclude a distinct relation between

a) criteria concerning structuring (e. g. clear separation of the experimentation process into planning, execution and evaluation)

b) target-orientation (e.g. transparency of learning goals and procedure; summary of results) and

c) students' learning outcomes (Schulz, 2011; Seidel et al., 2006).

Tesch & Duit (2004) showed a positive correlation between total duration of the experimentation process and students' learning gains, but no correlation between these gains and the duration of the execution of the experiment. This suggests that a structured embedding with appropriate planning and evaluation of the experiment is necessary for an increase in learning. From the aforementioned video studies (Schulz, 2011; Seidel et al., 2006; Tesch & Duit, 2004), which were conducted in regular lessons at German schools, it can be deduced that structuring plays a central role. This structuring, related to a learning objective according to factual content and functional learning-process-oriented aspects, can also be called sequencing.

Unfortunately, studies assessing science lessons reveal shortcomings in Germany (Schulz, 2011; Seidel et al., 2006) in comparison with other European countries (e.g. Finland and

Switzerland (Börlin & Labudde, 2014) regarding structuring as well as sequencing and target-orientation.

The development of teaching with regard to quality characteristics does not take place on its own. Therefore, learning opportunities for this topic must be created within the framework of pre-service teacher education and also in-service teacher training. According to Radtke (1996), in order to achieve a continuous professionalisation of teachers at this point, teachers' action must be linked and further developed with pedagogical content knowledge. A one-day teacher training to foster hands-on inquiry learning (Schmitt, 2016) was able to show short and medium-term changes in the attitude of teachers towards the content of the training as well as in the pedagogical content knowledge regarding experiments. Coaching with video material from the teachers' own lessons has also proven its worth in several studies (Schulz, 2011; Seidel et al., 2006; Wackermann, 2008). Schulz (2011) showed that a lesson-specific, individual coaching using videos from the teachers' lessons positively influences lesson quality, resulting in a higher learning gain for students. Thus, the learning effectiveness of a topic-specific coaching on quality characteristics of experimental phases at the action level of teachers and at the cognitive and affective level of students is proven.

Nevertheless, for an economic and generalisable teacher training the question has to be answered, if a training in groups independent from the topic of the lesson shows similar results.

RESEARCH QUESTION

The aim of this project is to evaluate an in-service teacher training which mainly focuses on the transfer of research results of Schulz (2011) addressing the optimisation of quality characteristics especially in experimental phases. In order to economise the educational intervention the project evaluates the effects of a non-content-specific training for groups of teachers. In this study, the following research question is addressed:

Does the intervention lead to changes in teachers' epistemological beliefs and in pedagogical content knowledge (PCK) concerning quality characteristics and practical performance in class?

In order to answer this question, appropriate instruments have to be developed and their psychometric criteria have to be determined. This leads to the following research question:

Are the developed test instruments objective, reliable and valid for measuring teachers' epistemic beliefs and pedagogical content knowledge (PCK)?

METHODS AND DESIGN OF THE PILOT STUDY

For measuring teachers' epistemic beliefs and pedagogical content knowledge (PCK) about experiments and their methodical implementation, two instruments were used. Hence, items assessing teachers' beliefs as a part of professional competence Baumert & Kunter (2011) and the PCK test items were constructed or adapted.

Concerning the instrument for measuring PCK, 26 items with four statements each were constructed on the basis of Tepner & Dollny (2014). Each of these statements had to be rated on a four-level Likert scale. In addition, the PCK-items were validated by an expert rating in which educational researchers of chemistry education were asked for their rating.

For the instrument on epistemic beliefs, 17 items with one statement each were selected and adapted from the instrument of Lamprecht (2011). The items that he used to assign teachers to one of the three types of teaching-learning convictions (training, discursive, mediation) were selected (Lamprecht, 2011). Each statement had to be evaluated on a five-level Likert scale.

The teachers of the sample ($N = 23$) were tested online with LimeSurvey. All items were rated in the same order. After the demographic part, the survey continued with the PCK-items and is completed with the items to measure epistemic beliefs. To continue the survey, the teachers were forced to make a choice.

PRELIMINARY RESULTS OF THE PILOT STUDY

In the PCK-test, the expert rating ($N = 3$) using a four-level Likert scale shows only moderate agreement ($\kappa_{Fleiss} = .45$), measured at the statement level for all 104 statements. For a dichotomous coding, summarising (slightly) agreeing and (slightly) disagreeing, the inter-rater reliability improves regarding all statements ($\kappa_{Fleiss} = .67$). Eliminating statements with a broad range in the expert rating left 72 statements. For those, the four-level coding shows an improved inter-rater reliability ($\kappa_{Fleiss} = .67$) and the dichotomous coding leads to a good reliability ($\kappa_{Fleiss} = .91$) without substantially reducing validity. Unfortunately, Rasch analysis of the results of the PCK-test ($N = 23$) leads to insufficient EAP reliability ($rel_{EAP} < .60$), independent from the number of statement and type of coding.

Data analysis of the test for the teachers' epistemic beliefs results in a two-dimensional model (see table 1). The first dimension consists of ten items regarding chemistry education. The second dimension consists of seven items regarding teaching chemistry.

table 1. comparison of unidimensional and two-dimensional model

model	deviance	AIC	chisq	df	p
unidimensional	936.62	1199.99	33.96	2	0
two-dimensional	902.66	1172.31			

For the two dimensions there are moderate to good EAP reliabilities and acceptable infit values. It is noticeable that the variance in the two dimensions is different (see table 2).

table 2. EAP reliability, variance and infit for both dimensions

dim1: chemistry education			dim2: teaching chemistry		
rel_{EAP}	variance	infit	rel_{EAP}	variance	Infit
.862	2.325	0.58 – 1.24	.602	0.162	0.86 – 1.50

Consequences for Main Study

Leading up to the main study, an increase in the sample size is necessary for both the experts and the teachers, since sporadic (poor) statistic parameters may also be related to the small sample size. In addition, it is checked whether the construct which the test instrument for PCK is based on is multidimensional. In any case, a revision of the instrument for PCK is absolutely necessary and at least recommended for the instrument on epistemic beliefs. Possibly, the performance tests for planning and reflecting lessons from the project ProfileP+ (Kulgemeyer et al., 2019) offer an alternative to the PCK test presented here.

OUTLOOK ON MAIN STUDY

First, the intervention materials for the group coaching were developed building upon the individual coaching used by Schulz (2011). The intervention will be evaluated following Lipowsky (2010), levels of evaluation. On the first level the participating teachers' reactions and ratings on the program content are evaluated. The second level assesses changes in teachers' cognition, especially beliefs and knowledge. On the third level practical changes in class are evaluated. Influences on students' knowledge, interests or beliefs are assessed on level four.

For the intervention study, we aim at a sample of 50 in-service chemistry teachers, who are not identical to the sample of the pilot study. Prior to and after the intervention, data for the levels 1 to 4 is collected and one chemistry lesson including an experiment of each participating teacher is videotaped and rated.

The teachers take part in a single day training of six hours intervention time (see figure 1). It starts with a presentation of research results of quality characteristics of chemistry lessons with experimental phases and methods of structuring teaching (Oser & Baeriswyl, 2001), followed by an instruction how to use video data for teaching improvement using a video of a scripted lesson. The remaining time the participating teachers work in groups of two teachers analysing scenes of their own video data, which were preselected by the researchers in order to identify quality characteristics, that are worth improving. Subsequently, they plan a new lesson regarding those identified characteristics.

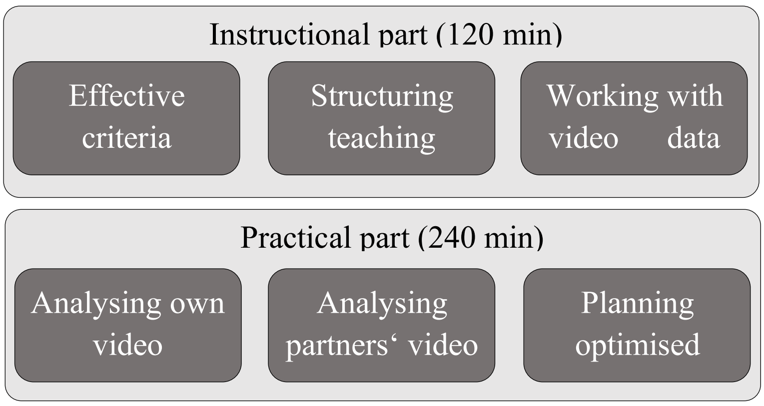

figure 1. Content of teacher training

This new lesson is videotaped a few weeks after the intervention, when post-data for evaluation level 1 and 2 is collected. In a follow-up-test three months after the intervention, medium-term effects of the intervention are assessed (see figure 2).

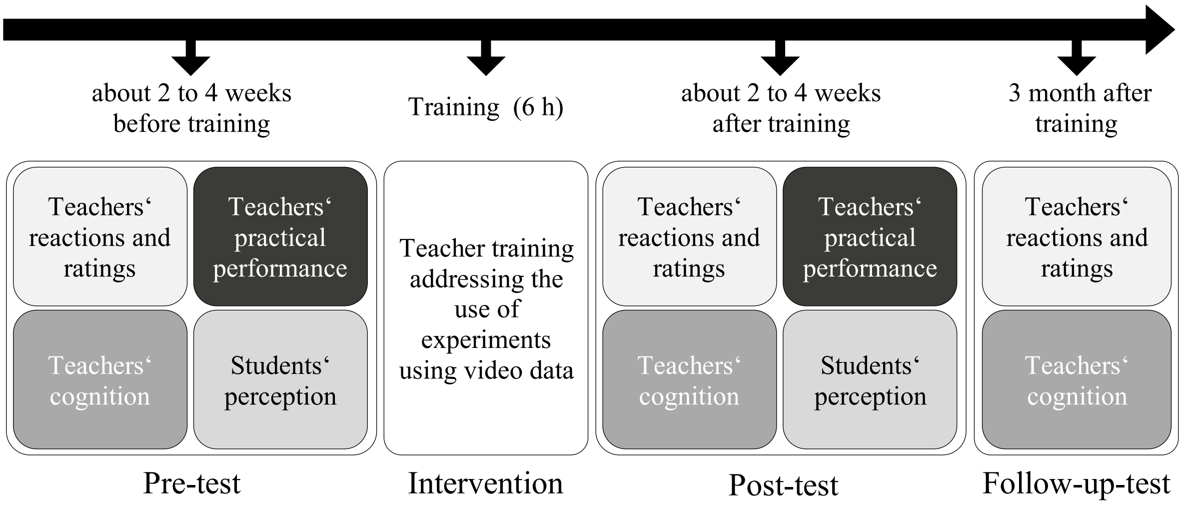

figure 2. Design of the intervention considering four levels of evaluation according to Lipowsky (2010)

Instruments

The success of the teacher training program is operationalised by the following variables considering four levels of evaluation (Lipowsky, 2010) (see figure 3):

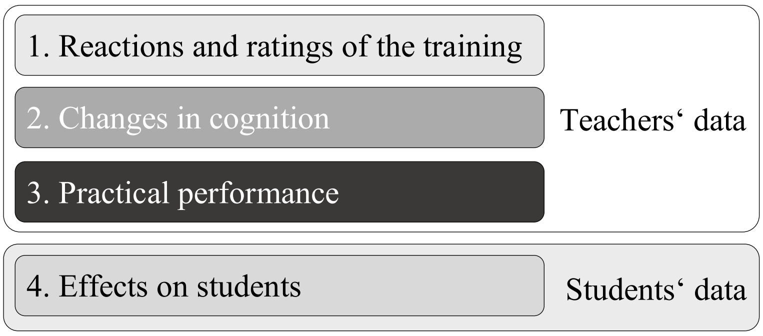

figure 3. Levels of evaluation according to Lipowsky (2010)

Level 1: The teachers' reactions and ratings of the training and its content are assessed by a questionnaire modified from Schmitt (2016).

Level 2: Teachers' changes in cognition are measured by two different instruments. On the one hand, data about their epistemological beliefs is collected by a survey adapted from Lamprecht (2011). On the other hand, teachers' PCK of experiments and their methodical implementation is collected by a self-developed test following Tepner & Dollny (2014).

Level 3: The teachers' practical performance is rated by video analysis applying the video coding system developed, validated and used by Schulz (2011).

Level 4: Data from the students' perception of quality of instruction is collected by a questionnaire also used by Schulz (2011).

EXPECTATIONS AND RESTRICTIONS

Because of the expected heterogeneity of topics and grade levels in the main study, no data of student's knowledge is assessed on evaluation level 4. Consequently, the effects of the intervention on student's knowledge cannot be proved. However, increased learning outcomes as a consequence of enhanced appearance of quality characteristics are already proven (Schulz, 2011).

TEACHER KNOWLEDGE IN A PROFESSIONAL DEVELOPMENT COURSE IN A CURRICULAR REFORM IN BRAZIL

Daniela Lopes Scarpa[1], Danusa Munford[2],
Maíra Batistoni e Silva[1] and Renata de Paula Orofino[2]
[1]University of São Paulo, São Paulo, Brazil
[2]Federal University of ABC, Santo André, Brazil

In this paper we investigate early stages in the processes of implementation of a new curriculum centred on scientific literacy and inquiry-based science teaching for 1st through 9th grades in schools in Southeast Brazil. We have analysed discursive interactions during lessons of a six week long in-service Science Teacher Education course in which primary and secondary teachers developed an instrument to analyse and evaluate teachers' and students' instructional materials elaborated based on the new curriculum and used this instrument to propose changes before its final implementation in schools. Our aim is to understand what knowledge teachers mobilize when evaluating and proposing modifications in science curricular reform materials for teachers and for students. Our analysis shows the tensions between content and demands of the prescribed curriculum, as well as possibilities of practice in science classrooms, especially in relation to how teachers deal with changes in: (i) science educational goals and (ii) the role of teachers and students in knowledge construction in the classroom.

Keywords: Curriculum; Teacher professional development; Inquiry-based teaching

INTRODUCTION

For decades it has been acknowledged that teachers' learning is a long and complex process and that teachers' knowledge is multifaceted and intertwined with social context, experiences and beliefs (e.g. Ellis, Eduards & Samorinsky, 2010; Kincheloe, 1998; Putman & Borko, 1997; Schön, 1983; Shulman, 1986; Tardif, 2014; Zeichner; 1999). However, there are still concerns with hierarchical relationships between teachers' knowledge and academic/expert knowledge, perpetuated throughout the history of teacher education. In particular, curricular reforms – and professional development related to them – too often are oriented by a rationale of implementing "experts" views that can be more effective if they can "resist" to teachers' challenges and practices (i.e. teachers' proof curricula). Thus, they tend to ignore multiple actors involved in the process (e.g. Wallace, 2012) and/or to adopt perspectives of "standards setting" in classrooms that are centered in demanding/informing/teaching teachers and students, not in negotiating and/or arising (Kordalewski, 2000). Science education is no exception to this pattern. There is a consensus that science learning goes beyond subject matter, incorporating dimensions of scientific literacy (SL) like "doing science", "learning about science", and "addressing socio scientific issues" (Hodson, 2014, p. 2537). One of the approaches to promote scientific literacy in the classroom is inquiry-based science teaching (IBST) (National Research Concil, 2012), in which scientific practices and student engagement play a central role. In many countries, these ideas have influenced curriculum development (e.g. Next Generation Science Standards Lead States, 2013).

In this paper we investigate early stages in the processes of implementation of a new curriculum centred on SL and IBST in Southeast Brazil (São Paulo City Secretary of Education, 2017, 2018), as part of a national curricular reform (Franco & Munford, 2018; Marcondes, 2019; Brazilian Ministry of Education, 2017; Sasseron, 2018). The implementation process is still underway and has included several actions of teacher in-service education and elaboration of instructional science materials based on the inquiry cycle (Pedaste et al., 2015).

We have analysed discursive interactions during lessons of an in-service science teacher education course in which primary and secondary teachers developed an instrument to analyse and evaluate teachers' and students' instructional materials and used this instrument to propose changes before its final implementation in schools. Our aim is to better understand how teachers construct knowledge about science curricular change that is informed by key ideas in science education research. In particular we investigate: how do teachers use their knowledge when evaluating and proposing changes in science curricular reform materials?

Various studies have been conducted in the context of science curriculum implementation (e.g. Brown & Sadler, 2018). Frequently, teachers' learning is examined considering how they learn and/or adopt science curriculum/teaching approaches aspects (Wallace, 2012). In this paper teachers' knowledge is examined considering their actions when having some agency to propose changes, and act upon public policy initiatives.

METHOD

São Paulo is a city with more than twelve million habitants, located in Southeast Brazil. It has 555 schools, 12.000 primary teacher and 2.300 science teachers. The implementation of curriculum involved different instances of teacher development, as represented in Figure 1: courses for tutors (in orange), courses that these tutors teach to teachers (in green), and a course to evaluate instrutional material that was offered for both teachers and tutors (in purple). In blue, teachers in science classroom are represented and in red is the prescribed curriculum.

The study was conducted in a six-week long course (total of 24 hours) for 34 teachers from different schools in São Paulo (Brazil). Some of the participants were experienced and others were novice, and some teach at the primary school/elementary level (1st – 5th grades) whereas others at secondary level/middle school (6th-9th grades), and some acted as teacher educators. In the course, teachers: i) discussed and defined criteria for analysing the instructional material based on a preliminary analyses of 5th grade materials; ii) developed one instrument (a form) to analyse and evaluate teachers' and students' instructional materials of the curricular reform; iii) were grouped in accordance to grades they had chosen and used this instrument to analyse curricular materials (each group analysed eight learning sequence); iv) presented their proposals and evaluation to peers.

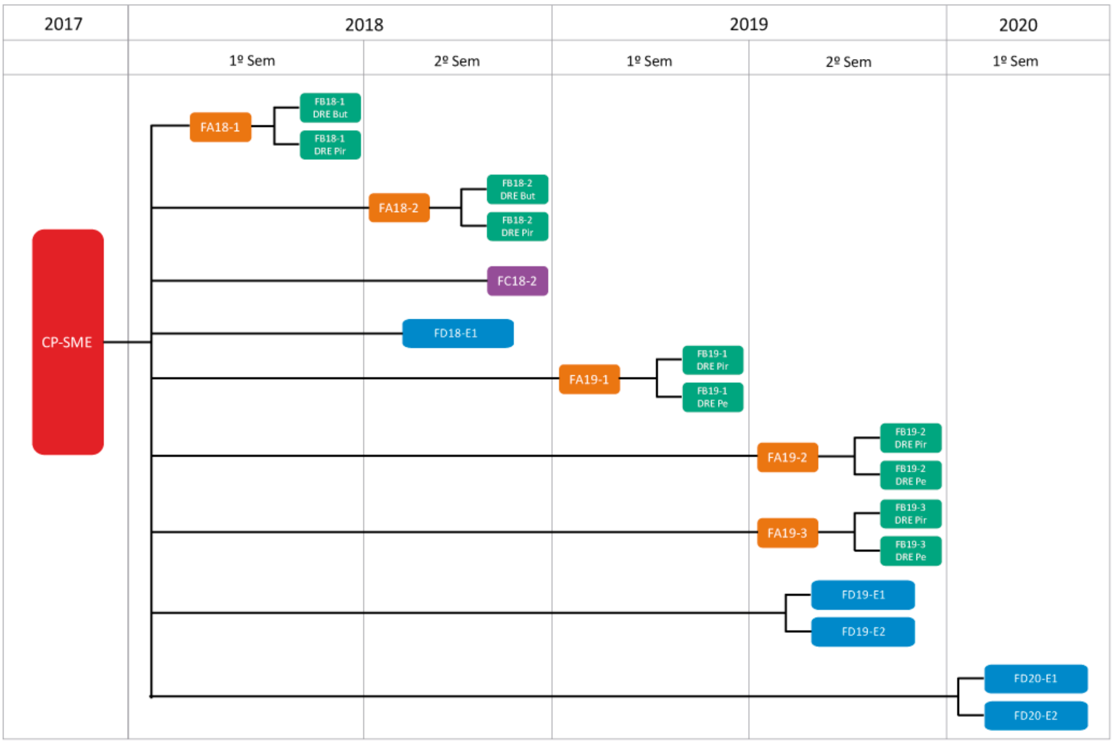

Figure 2. Professional Development Courses involved in Curricular Reform in São Paulo City. (Source: Authors).

The major data sources for this study were participant observation (Spradley, 1980) in science lessons with video/audio recording and field notes. Moreover, the instrument (the form) that teachers filled in during the lessons were analysed to better characterize what were the proposed changes. Our analyses focused on discussions in the groups of 2nd-3rd grade teachers and of 6th grade teachers. We selected events, considered telling cases (Mitchell, 1984), that made visible aspects of the process of evaluating and constructing knowledge about curriculum, in particular those related to inquiry-based teaching, scientific literacy and classroom practices. The discourse was transcribed word-by-word adopting the microethnography approach (Bloome, Carter, Christian, Otto & Shuart-Faris, 2005). Initially, the transcripts were analysed considering the content of discourse with focus on the types of knowledge teachers had been talking about (e.g. characteristics of students, prior experiences, readings about inquiry-based approaches). The categories were constructed during the analyses process.

In a second phase, informed by a social cultural perspective on teacher learning (Putnan & Borko, 1997; Ellis, Edwards, & Smagorinsky, 2010), we took Amanda Berry's (2007, 2008) notion of "tension" that she uses to describe teacher educator's practice and we adapted it to analyse discursive interactions in the context of the professional development course. In accordance with this author, the notion of "tension" has the potential to:

> capture the feelings of internal turmoil that many teacher educators experience in their teaching about teaching as they found themselves pulled in different directions by competing

> concerns, and the difficulties for teacher educators in learning to recognize and manage these opposing forces. (Berry, 2008, p. 32).

Figure 2 represents different types of tensions that are present in the experience of science teacher educators as proposed by Berry (2008, 2007).

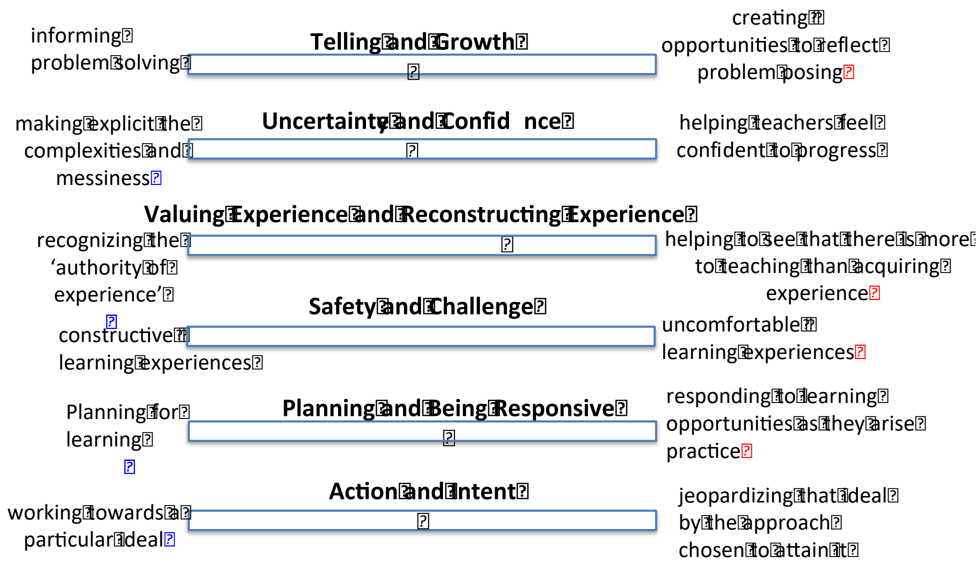

Figure 2: Representation of different categories of tensions in accordance with Berry (2007, 2008) (Source: Authors).

We reframed our initial research question about teachers' knowledge to the following analytical question: "What is the nature of the opportunities for learning to teach science that are constructed during a professional development course for curricular implementation?"

RESULTS AND DISCUSSION

To evaluate and propose changes in inquiry-based learning sequences (IBLS), teachers defined and used the following criteria: valorisation of the students' previous knowledge, adequacy and quality of the language, relevance of practical activities, adequacy of content and skills for the school grade, appropriateness duration, structure of the inquiry cycle, possibilities of student engagement, possibility of working with a diversity of students, adequacy of the orientations to the teacher, consistency between assessments and curriculum elements.

Some of these aspects may be considered as cultural myths (Tobin & McRobin, 1996), that is, they are references to enact science classes in a certain way, in accordance to certain beliefs about how a science class or a science curriculum must look like. The professional development space allowed these myths to surface and interactions between teachers, who had already applied the IBLS, brought up the difficulties, limitations and conceptions of scientific literacy and inquiry-based approach in classroom practices. Therefore, we considered that the aspects that teachers rose revealed tensions (Berry, 2007) between subject matter knowledge, theoretical knowledge demands of prescribed curriculum, and possibilities of science classroom practices.

Our analyses indicate that various types of knowledge were used to construct proposals for revising curricular materials. Frequently teachers' interpretations of the materials and suggestions were supported by their own experience at school, including knowledge about their students' knowledge or abilities (e.g. conceptual knowledge and teaching experiences teaching the lessons from the curricular materials).

Both when working in small groups or in whole class discussions, elementary school teachers often were more attentive to aspects of the written text in curricular materials. Proposals involving changes in written texts were very common in the group. For instance, when they analysed the 2nd grade materials for students, they engaged in a long discussion about the tittle of an activity in a sequence about the water cycle: "The water that was gone"[2]. One of the teachers argued that the title was telling the answer of the inquiry question and a tittle in the format of a question would be more appropriate. She also pointed that the very idea of "water going away" would be "the way kids would talk about it" and "you can imagine drops of water with little legs walking". Thus, this was an inappropriate tittle also to promote conceptual accuracy. They examined the activity and pictures that compose the activity, and pointed out that "the title should help them to see the drops", and proposed titles like "What changed in the mirror?" Moreover, they established relationships with knowledge from the discipline Portuguese/Reading and Writing. For instance, in the same sequence mentioned above, a teacher noticed that a practical activity were similar to a "the genre" food recipe. Later, a colleague noted that the way the text was presented it looked like a list, a genre that they usually did not work with students as much as they should.

The group of teachers working with students in transition to secondary/middle school (i.e. 6th grade) had one teacher who had developed almost all the activities they were discussing. In this case, discussions were often structured around asking him how he did it at his school and how things went. In one occasion he stated "I just know it because I worked with students this", and a colleague agreed. Sometimes details like the use of the materials would receive his attention, and often how students participated and reacted received attention. For instance, when discussing an astronomy activity, he advised colleagues that "You should use play dough" and, enacting what was supposed to be done, he commented that "When you actually do it, they [students] get curious. I found it a good practice. Easy and simple to visualize. They proposed a bunch of theories. They got very excited about it." In various occasions teachers talked about students or school characteristics.

The modifications in the material that received more emphasis in whole classroom discussions involved changes in the sequencing of activities or concepts that should be worked throughout the year.

[2] A Portuguese version of this inquiry-based learning sequence is available at https://curriculo.sme.prefeitura.sp.gov.br/sequencia/as-gotas-de-agua

Two of these aspects called our attention due both to the big discussion in the two groups that were analysed, and their relationship with SL and IBST. First, there were tensions around science educational goals. The new prescribed curriculum places a greater emphasis on socio-scientific issues and on the social and cultural aspects of the production of scientific knowledge. For example, when talking about the place the theme "water" had in the curriculum and in 3rd grade instructional materials, teachers considered that science should address the concepts involved in the water cycle as social issues like water pollution should be addressed in geography lessons. Another example involved teachers analysing a practical activity in the 6th grade material on the role of indirect evidence, imagination and prior knowledge of scientists in the construction of scientific knowledge. Their interpretation was that the activity played just a motivating role, but does not contribute to "learning about science". Although this perspective did not represent a hindrance to perform the activity, it had a different function from a perspective that broadens goals of science teaching. These two examples illustrate challenges for teachers in incorporating dimensions of scientific literacy.

The second aspect to be highlighted is related to teachers' and students' roles in this new curriculum. When they reported the application of practical activities proposed in the instructional material, teachers point out that the room had become more tumultuous when students take a more active role. This required more effort and another way of acting of the teachers themselves. Also regarding students' role of, teachers reported that students didn't feel confortable participating in activities that required interactions and collaboration between students to construct knowledge. In one of the events analysed, teachers in 3rd grade regretted that while some students were arguing, others copied the assignment.

Further analysis of the events, using Berry's notion of tension, evidenced the complexity of the learning opportunities that emerge in the context of professional development courses – an aspect that was not evidenced in the other analysis. As an example we will present aspects of the analysis of an event that took place with 6th grade teachers. One of the teachers, Lúcia, shares her experience of developing the mystery box activity[3] to teach about earth's internal layers as proposed in the instructional material[4].

In this event the interactions among teachers made visible multiple tensions. For instance, the tensions between *value and reconstructing* are presented as we contrast two dialogues that occurred. At the beginning of interactions, teachers discuss impressions about the activity:

Pedro: It is only ludic, right?
Lúcia: Yes.
Júlio: Yes, yes.
Pedro: It is a comparison.
Júlio: It is not very scientific, is it?
Pedro: No.

[3] This is a tradicional activity to explore inquiry-based science teaching approach. An example can be seen here https://media.bscs.org/mss/se/chapter_pdfs/science_as_inquiry_introductory_chapter_for_any_unit/sai_ch1.pdf
[4] A Portuguese version of this inquiry-based learning sequence is available at https://curriculo.sme.prefeitura.sp.gov.br/sequencia/a-terra-viva-formacoes-e-transformacoes-do-solo

These interactions evidenced how participants relied in what happens in their classes and their views to construct a comprehension of the activity without using SL and IBST to frame their understanding of the activity. However, later in the event Lúcia will take another direction:

> Lúcia: So, I... I understood that ... look, for example... here, you have to infer what is inside [the box] in [the same way//(...).
> Júlio: //as what is inside the Earth.
> Lúcia: In the same way that you have to infer, because there is no way to get inside [the Earth], so you have to imagine.

In this case, her understanding of the activity aggregates aspects of the notion of model and modelling related to IBST, practices that are introduced and discussed in the curriculum. Another learning opportunity emerges in another interaction, also involving Lúcia:

> Lúcia: (...) I said [to a student]: "Ok, you said that you thought that it was, let's suppose, a coin. But why did you think that?" Then, he had to argue why. Establish a relationship. So it is nothing like (...).
> Lúcia: Say something like "I think it is a glass, just because I think". Do you get it? (...).
> Lúcia: It had to have some support; otherwise it is not enough just to put it out there.
> Pedro: Yes. "Just because", anything, you cannot [do it].

Again, Lúcia supports his colleagues in understanding the activity by connecting her experience to aspects of IBST.

Another tension that we identified in the same event was related to *uncertainty and confidence*. On one hand Lúcia bring into the conversation "the complexities and messiness" of teaching:

> Lúcia: Now, look at this one, Mystery Box, (...) Did you do it?
> Júlio: no, no, no.
> Lúcia: You have to do it, but in one of these days that you are feeling very well.
> Pedro: but what did you put inside?
> Lúcia: Because they through the box in the air. I put a bunch of coins rapped in paper balls, got it?
> Pedro: aham
> Lucia: Then, they shake it. Thus, I did this activity in homeopathic doses.... One day in two classes... the other day in other two classes... because I wouldn't be able to do it in all my classes.
> Pedro: It's because it becomes too messy.

On the other hand, she helps her peers to feel confident about teaching the activity, and, consequently adopting a different approach that they are used to:

> Lúcia: The other day, there is this class… that is a class with excellent students in terms of behaviour… they do what I ask them. I said: "let's go downstairs". In the school we have three sports courts.
> Pedro: In the sports court?
> Lúcia: Yes. We have three sports courts, and one indoor court, and between them there's a courtyard.

> Pedro: Great... Then you can seat there?
> Lúcia: We made a circle.
> Pedro: It's good because it's different from what we usually do.
> Lúcia: So, it's good. This was the last class that I did it with. Maybe I would do it with the first one, if I had the courage to take the others outside. It would be less messy if they were in the courtyard.

These interactions and the tensions that emerge evidenced the role that peer interactions can have in learning to teach in the context of Professional Development Courses.

CONCLUSIONS

When teachers are in a situation where they take a more active role in proposing and analysing instructional materials, they have opportunities to make sense of their practices, bringing up tensions between subject matter knowledge, theoretical knowledge demands of prescribed curriculum, and possibilities of enacting in the science classroom. In the course analysed here, these tensions became explicit, and teachers had pointed out the relevance of training and a demand for an instructional material specifically produced for theoretical deepening, which shows the consciousness about these tensions and the need to discuss and problematize them, bring up the possibility to effectively support changes recommended by political reforms.

EXPLORING TEACHER'S BELIEFS AND ATTITUDES TOWARDS TEACHING PHYSICS DURING A LESSON STUDY INTERVENTION

Ayodele Ogegbo[1], and Estelle Gaigher[2]
[1,2]University of Pretoria, Pretoria, South Africa

ABSTRACT
This study explored how the beliefs and attitudes of teachers towards the teaching and learning of physics were influenced by participation in a lesson study intervention. Data for this study was collected through semi-structured interviews, and lesson observations conducted with four teachers from three South African schools. Analysis of the data following teacher's participation in the lesson study intervention indicated that teachers became more confident, determined and prepared to teach difficult concepts regardless of the learning situation; openly acknowledged that classroom collaboration could benefit learners' learning, changed their expressed beliefs about learners' difficulties. These findings suggest that creating opportunities for teachers to take ownership of learning activities during professional development programs may positively influence their beliefs and attitudes, as they become more practical, confident and enthusiastic about teaching physics.

Keywords: Attitudes and Beliefs, Lesson study, Physics

INTRODUCTION

The poor performance and low enrolment of learners in physics-oriented courses could be attributed to teachers' beliefs and attitudes developed towards physics (Bhargava & Pathy, 2014; Masood, 2014; Osborne, Simon, & Collins, 2003). Attitude is an essential disposition that directs the nature of human behavior and relates to how individuals manage emotions that occur during the learning process. There has been a global concern on the effect of teachers' beliefs and attitudes on learners' performance. However, less has been written on how teachers change their beliefs and attitude toward teaching. Teachers' attitudes being a component of teachers' emotional dispositions could include constructs like conceptions and awkward behaviors of teachers towards teaching physical science as a subject. Physics is a science subject perceived by some teachers and learners to be too mathematically oriented, too extensive and mostly dependent on textbooks (Bhargava & Pathy, 2014; Masood, 2014). Research indicates that learners' performance and enrolment in physics have been reflecting a decline over many years probably due to the abstract nature of the subject (American Association of Physics Teachers (AAPT, 2013). Teachers' emotional dispositions towards the teaching of science have been well documented (Ualesi & Ward, 2018). Thus, it is an important component required for improving learner's performance, as well as empowering physics teachers' quality and effectiveness. For instance, research has shown that some science teachers lack the educational background in science and consequently, fail to engage learners in hands-on practical activities that are physics-oriented (George, 2017; University of Vermont, 2018).

More so, Hannula, Di Martino, Pantziara, Zhang, Morselli, Heyd-Metzuyanim, Lutovac, Kaasila, Middleton, Jansen, and Goldin (2016) claims that there is a dialectical relationship between teachers' attitudes, beliefs and their classroom practice, as well as how their beliefs changes. Hence, the attitude of science teachers which could be formed by their belief about how learners learn, value teachers hold, classroom management practice, the nature of their scientific knowledge and instruction plays a significant role in improving the quality of physics teaching. Thus, the aim of this paper is to report on how teachers' participation in a lesson study intervention influenced teachers' beliefs and attitudes to teaching the physics part of the FET physical science curriculum within the South African context.

This paper report results from a larger study that focused on improving the teaching of electricity and magnetism in South Africa (Author, 2018). This study is informed by the notion that attitude is a structure of an individual's belief system (Jones & Carter, 2013). Research indicates that teacher's belief system has a direct implication on their classroom actions, which may improve or discourage learners' learning and academic performance (Loucks-Horsley, Stiles, Mundry, Love, & Hewson, 2009). For this reason, it is important to identify and clarify teachers' beliefs influencing their attitudes towards teaching physics (Haney & Lumpe, 1995). Research question: How do teachers' beliefs and attitudes towards teaching Electricity and Magnetism develop during participation in a Lesson Study intervention?

METHOD

A qualitative inquiry using an exploratory case study design was adopted in this study (Yin, 2014). A purposive and convenient sampling was employed in this study to capture specific attributes of four teachers from city and rural schools, knowing that it does not represent the whole population of physical sciences teachers in South Africa (Cohen, Manion & Morrison, 2007; Maxwell, 2013). Teachers participated in a five weeks intervention program designed to improve their teaching of electricity and magnetism. The various phases of the intervention program gave teachers the opportunity to collectively reflect, analyze, plan and discuss difficult physics topics within a community of practice. Teachers engaged in lesson study activities aimed at equipping them with a responsive classroom approach (Lewis& Hurd, 2011). Data were collected using interviews, and lesson observations, and analyzed by content analysis.

THEORETICAL FRAMEWORK

This study is underpinned by the theoretical construct of the adult learning theory (Knowles, 1980). The adult learning theory provides guiding principles that helps to understand how Lesson study as a professional development program was used to introspectively gain insight into teachers' personal beliefs and attitudes towards physics teaching (Peltz & Clemons, 2018). These guiding principles includes teachers' understanding of what learners needs to know, the role of learners' experience, learners' self-concept, learners' orientation to learning, readiness and motivation to learn (Knowles, 1980; Palis & Quiros, 2014). Within the context of this study, Lesson study was chosen and adapted as an In-school training approach to support the development of teachers' scientific skills and abilities in teaching physics.

Lesson study is a research-oriented practice that has successfully contributed to the high-quality teaching and learning practice in the Japanese educational system (Huang, Takahashi, & da Ponte, 2019). Doig and Groves (2011) indicated that the jointly organized classroom lessons conducted during lesson study often tend to develop attitudes, beliefs and understanding among participants. Thus, the various activities implemented during the collaborative phase of the lesson study intervention provided new experiences that created a unique learning opportunity for the teachers. However, the application of teachers' learning during the lesson study intervention was more evident in their ability to solve problems related to learners' difficulties and misconceptions in electricity and magnetism. However, the basis of adult learning theory in this study lies on teachers' motivation, interest, and capacity to work collaboratively; and this collaborative effort proved instrumental to the voluntary change that was observed in teachers' competencies in terms of their individual attitude and opinion about teaching and addressing learners' difficulties in physics.

RESULTS AND DISCUSSION

Data for the study presented in this paper were gathered from the analysis of teachers' interviews, lesson observations and reflective writing. Teachers in this study were observed during the adapted Lesson Study intervention. Prior to the commencement of this study, teachers expressed feelings of unpreparedness which was associated with teachers' lack of interest on specific topics they don't understand, thus affecting their attitude when teaching these topics to learners. For example, Mbali mentioned that she usually avoids answering questions from learners whenever she was teaching the concepts related to electromagnetism. However, the planning and reflection phase of the lesson study intervention helped her to become more prepared and confident, thereby increasing teachers' competency and positive attitude towards teaching physics concepts that appear difficult and confusing.

> *Participating in this program has helped me to a greater extent in bringing down this wall I have built around me when teaching electromagnetism which I initially don't answer some questions that learners tend to ask. I just teach and leave* (Mbali interview).

During the initial interview, Lenox indicated little concern about learners' problems in electromagnetism since learners are not assessed in the final Grade 12 examinations.

> *When we moderate for marking, we hardly consider electromagnetism as a difficult topic because learners are not assessed on that topic at the matric level* (Lenox interview).

This remark revealed a low level of enthusiasm and competence in teaching electromagnetism, caused by his belief. However, during the lesson observations, Lenox did show enthusiasm when teaching the collaboratively planned lesson. Prior to the lesson study, teachers rarely reflect on the effectiveness of their classroom instruction and learners' response to activities. For instance, the initial reply of teachers when reflecting on the difficulties of learners showed that all teachers demonstrated an undesirable attitude towards reflective practice. Nonetheless, two of the teachers mentioned that their rate of reflection shifted during participation in the study. During the initial consultation session with teachers, Martha mentioned that she only reflects and certainly explains a lesson again if she noticed that learners seem not to grasp the fundamental concepts relating to the topic that was taught.

> *I do my reflection whenever I have this feeling that I had a bad lesson and I just go back to re-explain the lesson again but during our first meeting, Mr. Alex's suggestion on the idea of allowing learners to observe, draw and discuss the magnetic field lines around the magnet made me realize that I could develop new methods of teaching the same lesson if I take my time to critically reflect on the previous method used. (Martha, interview)* .

However, participating in the Lesson Study intervention created an experience that helped teachers to reflect on their existing beliefs about learners' difficulties and their teaching methods, as they became open to alternative approaches, thereby improving their willingness to learn and adjust their instructional practices. For example, analysis of Martha's response shows that she often participates in compassion-based reflective actions, but taking part in this lesson study intervention improved her attitude and level of reflective practice. This was observed during the first phase of the intervention program, where she engaged in a relational analysis that accompanied a dialogue during the lesson study consultation meeting. It appears from the preceding findings that lesson study could, however, help teachers to critically examine their values and teaching attitudes, and thus improve their reflective practice. This finding supports Rock and Wilson's (2005) view that Lesson Study improves reflexivity in teachers.

The opportunity to reflect on their attitude towards teaching physical sciences impacted their perception and views about teaching physics concepts that are critical and more challenging to individual teachers.

CONCLUSIONS

In summary, findings of this study indicate that teachers' attitudes towards their classroom teaching was improved through their increased confidence level, increased level of reflection, improved pedagogical knowledge and skills. However, teachers informed attitudes did not always lead to improving their classroom effectiveness.

The result obtained with respect to this should not be generalized due to the small sample used. Nevertheless, results indicate that engaging teachers in research-based activities and giving teachers the opportunity to take ownership of learning opportunities during professional development is a promising way of fostering positive attitudes towards teaching physics within the South African context.

ACKNOWLEDGEMENT

This research is framed within the findings from a Ph.D. study conducted at the University of Pretoria. The support of the University's Postgraduate Research Support Bursary during the completion of the larger study is appreciated.

IN-SERVICE CHEMISTRY TEACHERS' PCK OF ELECTROCHEMISTRY: A CASE IN SÃO PAULO, BRAZIL

Pablo Castro[1], *Carmen Fernandez*[1,2]
[1]Science Education Graduate Program, University of São Paulo, São Paulo, Brazil
[2]Institute of Chemistry, University of São Paulo, São Paulo, Brazil

The aim of this study is to investigate chemistry teachers' PCK of galvanic cells through a mixed-method case study. The sample consisted of 128 in-service chemistry teachers from São Paulo, Brazil, and the data were collected using an adapted version of the PCK of Electrochemistry Test. Teachers' responses to each question were analysed in a five-point scale reflecting the PCK quality. Then, raw scores were analysed by Rasch Partial Credit Model and the teachers were stratified in five levels using the Scale Characteristic Curves methodology. The outcomes of this study revealed that teachers had a good or medium score in questions about learner prior knowledge, curricular salience and difficult aspects to teach; and low score in questions about representations use and conceptual teaching strategies. Concerning the teachers stratification, most of the teachers are in the low levels (3 in the 'no shown', 28 in the 'limited' and 82 in the 'basic'). Thus, in general, teachers presented low scores on the PCK of Electrochemistry Test and, consequently, it is necessary, in the Brazilian context, the production and teaching of continuous professional development courses that covered this topic.

Keywords: pedagogical content knowledge, teaching of electrochemistry, Rasch analysis

INTRODUCTION

In the literature, there have been emerging studies to better understanding the complexity in electrochemistry teaching. In the Brazilian context, Nogueira, Goes, and Fernandez (2017) claim chemistry teachers, students, and textbooks show difficulties in understanding the redox reactions simultaneity and the difference between galvanic and electrolyte cells. In addition, Marcondes, Souza, and Akahoshi (2017) emphasize that although chemistry teachers focus on teaching galvanic cells, this teaching is superficial as these teachers do not prioritize concepts such as salt bridge and half-cell reactions. Therefore, to teach electrochemistry, teachers should improve their knowledge of students' alternative conceptions about electrochemical phenomena, their knowledge about curricular saliency, and their own difficulties in understanding electrochemistry subject matter.

The aspects aforementioned can be studied from the perspective of Pedagogical Content Knowledge (PCK). This knowledge was proposed by Shulman (1986) and is "the ways of representing and formulating the subject that make it comprehensible to others" (p. 9) and also "an understanding of what makes the learning of specific topics easy or difficult" (p.9).

From Shulman's PCK definition, some researchers proposed PCK models (e.g Magnusson, Krajcik & Borko, 1999, Rollnick et al., 2008). Between these models, we decided to use the

Topic Specific PCK model (Mavhunga, 2012) as this one focuses on the subject matter knowledge in a topic-specific level. According to this model, PCK has the following components: a) leaner prior knowledge (LPK); b) curricular saliency (CSL); c) what is difficult to teach (DFT); d) representations (REP); e) conceptual teaching strategies (CTS).

To better know PCK quality of in-service chemistry teachers from São Paulo state, Brazil, in teaching galvanic cells, a central idea of Electrochemistry, this study has the aim to investigate chemistry teachers' PCK of galvanic cells.

METHODOLOGY

The research design to investigate chemistry teachers' PCK of galvanic cells was based on a mixed-methods case study (Creswell & Clark, 2017). In this paper, we will focus on the quantitative part.

Sample

The sample consisted of 128 in-service high school chemistry teachers from São Paulo State, Brazil. The teachers selection was conducted through convenience sampling (Creswell, 2012): almost all of them were personally asked to answer the test when they attended professional development courses offered by the authors; the other teachers were asked by email to answer the test.

Chemistry teachers' characteristics as major degree, gender, and professional experience can be seen in Table 1.

Table 1. Chemistry teachers' characteristics.

Major degree					Gender	
Chemistry	Biology	Science	Physics	Others	Male	Female
96	14	06	02	10	56	72

School kind				Experience teaching Electrochemistry		
Public	Private	Both	NA	Yes	No	NA
108	02	17	01	90	36	02

Experience time				
Mean	S.E.	Range	Minimum	Maximum
15	7.1	35	1	36

Instrument

We collected the data using an adapted version of the PCK of Electrochemistry Test (A-PCKET; Ndlovu, 2014). The adapted version has 07 open-ended questions addressing the TSPCK categories proposed by Mavhunga (2012), namely: Curricular Saliency, What is difficult to teach, Representations, Students Prior Knowledge, and Conceptual Teaching Strategies.

The main modifications we did in the test were: (i) removing Electrolytic Cells questions to focus only in Galvanic Cells, since the latter is more emphasized by Brazilian chemistry teachers (Marcondes, Souza, & Akahoshi 2017) and; (ii) reducing the number of questions to shorten the test accomplishment time. An overview of the A-PCKET can be seen in Table 2.

Table 2. Description of the A-PCKET questions.

Nº	PCK component	Purpose	Source
1	CSL	Identifying and sequencing central ideas in electrochemistry teaching	Adapted of Ndlovu (2014)
2	CSL	Identifying the main chemistry topics necessary for teaching electrochemistry	Adapted of Ndlovu (2014)
3	DFT	Identifying the main difficulties in electrochemistry teaching	Adapted of Ndlovu (2014)
4	REP	Identifying good and bad aspects of representations and how to use them in teaching	Adapted of Ndlovu (2014)
5	LPK	Identifying students' alternative conceptions about oxidation, reduction, cathode, and anode.	Elaborated by authors
6	LPK	Identifying students' alternative conceptions about electrons flow and salt bridge.	Adapted of Ndlovu (2014)
7	CTS	Elaborating a class to confront students' alternative conceptions about galvanic cells	Elaborated by authors

Data analysis

We scored the teachers' responses to the PCKET items using a rubric corresponding to each question. This rubric have a five-point scale reflecting the PCK quality: 0 to 'not manifested' PCK; 1 to 'limited'; 2 to 'basic'; 3 to 'developed' and; 4 to 'exemplary'. The raw score was analysed thought Rasch Partial Credit Model (Boone, Staver & Yale, 2014) using the Winsteps© Rasch Measurement 4.4.1 (Linacre, 2019) software.

Two parameters were used to verify if the test fit the Rasch Model and, consequently, if it is valid to assess the high school chemistry teachers from São Paulo: the mean-square (MnSq) and z-standardized (ZStd) outfit statistics. Moreover, the reliability of the persons and of the questions was calculated.

At last, the teachers were stratified in five strata (the same of the rubric) according to their PCK score. To do that, we used the Scale Characteristic Curve (SCC) methodology (Dogan, 2018). In this methodology, all items characteristic curves are summed to obtain a scale characteristic curve.

RESULTS AND DISCUSSION

Instrument quality

The MnSq and ZStd outfit values asses if the empirical data agree with the expected values given by the Rasch Model. The recommended values are: $0,5 < MnSq < 1,5$ or $-2,0 < ZStd < 2,0$ (Kirschner, et al. 2016). As we can see in Table 3, all questions were between the expected values. Concerning the test reliability, question and person reliability were both calculated. According to Linacre (2018), it is recommended values, respectively, greater than 0.9 and 0.8. The test also achieves the recommended values in this aspect.

Table 3. Questions fit, questions reliability and persons reliability.

Question	MNSQ outfit	ZSTD outfit	Questions reliability
1 (CSL)	1.07	0.55	0.93
2 (CSL)	1.00	0.05	
3 (DFT)	1.15	1.13	**Persons reliability**
4 (REP)	0.93	-0.39	
5 (LPK)	0.96	-0.1	0.81
6 (LPK)	0.83	-1.19	
7 (CTS)	0.83	-0.90	

To increase the test validity, the predictive validity was analysed as well. In this analyse, the theoretical score ordering of teachers is compared with the empirical one (Linacre, 2018). Since the A-PCKET is about Electrochemistry teaching, we expected teachers without a chemistry degree to have low scores. As can be seen in the Item-person map shown in Figure 1, most of the teachers without a chemistry degree are below the teachers' mean (teachers in the square). Moreover, the teachers with the lowest scores are those without a chemistry degree. Thus, the order of theoretical scores, based on the PCK theory, is equal to the empirical one and, therefore, the test validity is increased.

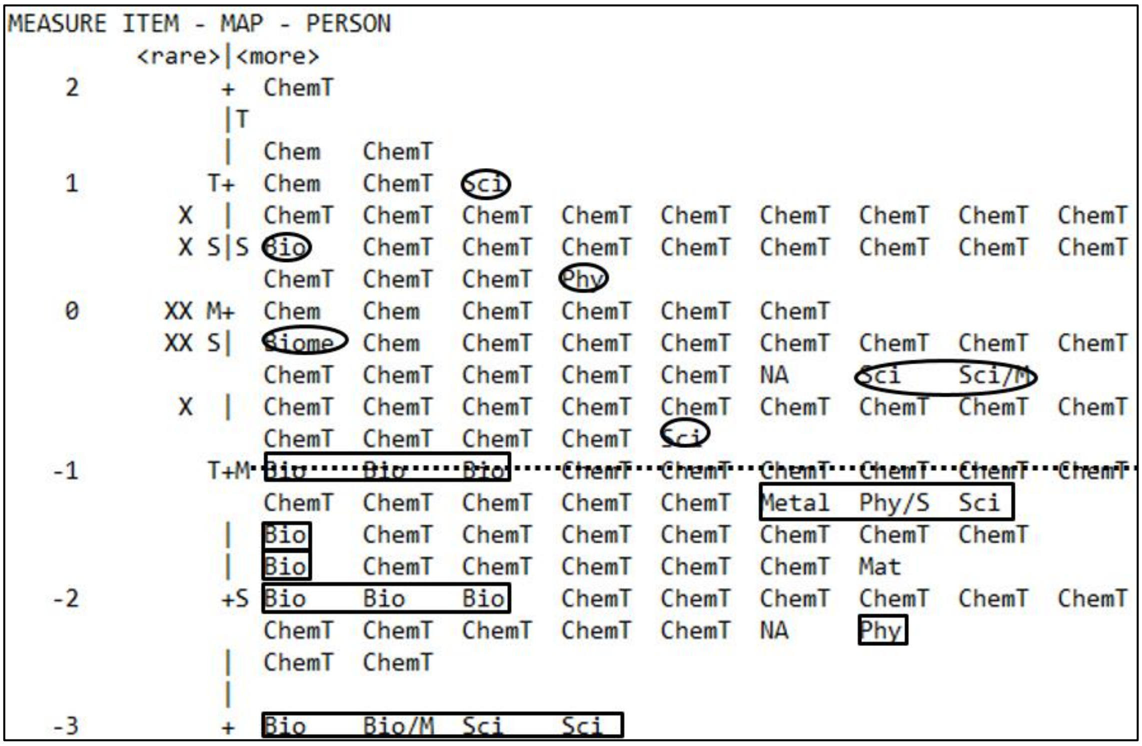

Figure 1. Item-person map emphasizing the scores of teachers without major in Chemistry.

Note: The dashed line represents the teachers' mean. Teachers in the square have a score below the mean. Teachers in the circle have a score above the mean. "Chem" is chemistry, "Sci" is science in elementary classes, "Phy" is physics, "Bio" is biology, "Metal" is metallurgical engineer, and "Biome" is biomedicine science.

Since the test showed fit values (MnSq and ZStd outfits), reliabilities and score ordering (predictive validity) into the expected, we claim the A-PCKET produced validity results and can be used in the São Paulo context.

Items difficulties

Regarding teachers' performance, they had medium scores in DFT, CSL and LPK questions (consequently, these questions had a smaller measure of difficulty), as shown in Table 4. REP and CTS questions proved to be very hard questions and had the highest difficult measure. Since the ability to use representations and conceptual teaching strategies requires the integration of the other components (e.g. using some representations to confront some student difficult) (Rollnick & Mavhunga, 2014), it is expected that those questions to be the most difficult.

Table 4. The measure of questions difficulties and teachers' knowledge.

	1 (CSL)	6 (LPK)	3 (DFT)	5 (LPK)	2 (CSL)	7 (CTS)	4 (REP)	Questions mean	Teachers mean
Measure	-0.65	-0.25	-0.25	-0.09	0.05	0.40	0.79	0.00	-0.99

About the difficulty of the test in general, when the test is easy for teachers, the teachers mean is higher than questions mean; otherwise, if the test is difficult, the teachers mean is lower. Comparing in our case, in Table 3 it is possible to see that PCKET is very difficult for teachers. These results agree with research reports: electrochemistry is, despite teachers' experience, a very difficult topic to teach (Ndlovu, 2014, Rollnick & Mavhunga, 2014).

Teachers stratification

The resulting SCC originated by teachers' answers to A-PCKET is shown in Figure 2. In the Scale Characteristic Curve (Dogan, 2018), the x-axis is the teachers' score in the test, the y-axis shows the expected number of items teachers scored on each curve, and the points where one curve intersects other are the cut-off criteria. For example, a teacher with a measure of 1.6 (the last cut-off point) is more likely to score "exemplary" and "developed" in three questions and "basic" in one.

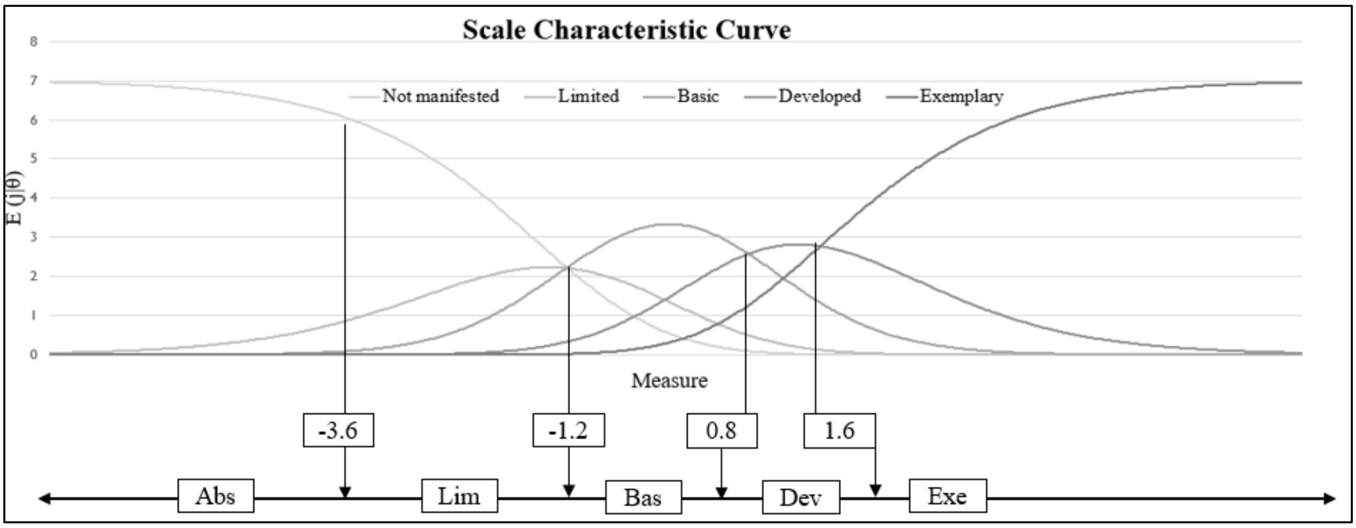

Figure 2. Scale characteristic curve originated by teachers' answers to A-PCKET.

As can be seen in Figure 2, the SCC has three cut-off points related to the intersection of the curves (-1.2, 0.8, and 1.6). However, in addition to these points, we also added one more: -3.6.

We did that because we consider that to manifest a PCK in the test, teachers must get at least one question with a "limited" score. If teachers score all questions with 'not manifested', we consider that teachers did not manifest PCK in the test situation.

Thus, with these four cut-off points, we have five PCK levels. In the first one, 'not manifested', teachers get a 'not manifested' score in all questions. In the second one, 'limited', teachers get at least one item with a 'limited' score, but could have some items with 'basic'. In the third one, 'basic', teachers get mainly 'basic' score and have chances to get 'limited' and 'developed' scores. In the fourth level, 'developed', teachers get mainly developed score and could get 'basic' and 'exemplary'. In the last level, 'exemplary', teachers get more 'exemplary' and 'developed' scores.

The teachers distribution in those five levels can be seen in Figure 3. It is perceived the teachers' low scores on A-PCKET also is reflected in PCK levels: most of the teachers have limited or basic PCK level.

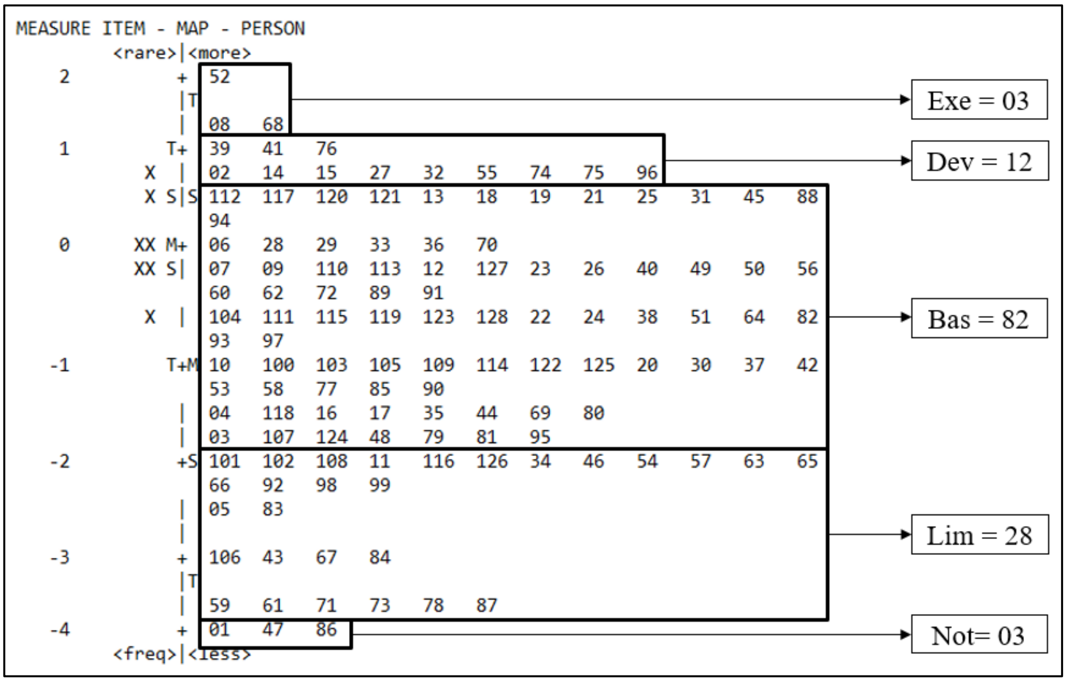

Figure 3. Teachers stratification in four levels: limited, basic, developed, and exemplary.

CONCLUSION

From the outfit, reliability and predictive validity results, it is possible to see that the adapted version of PCKET (Ndlovu, 2014) was able to be used in the São Paulo context and allows us to investigate in-service chemistry teachers' PCK of galvanic cells. The score of teachers was medium in five questions: identifying central ideas and previous content to teach electrochemistry (questions 1 and 2); identifying difficulties aspects to teach electrochemistry (question 3), and recognizing learner prior knowledge about electrons flow/salt bridge and oxidation/reduction (question 5 and 6). Moreover, teachers present great difficulty in two questions: assessment and use of representations (question 4); proposed a conceptual teaching strategy (question 7). Therefore, in general, teachers presented low scores on PCKET, and most of them have limited or basic level on PCK of electrochemistry.

There are two possible explanations for the teachers' low score on PCKET: lack in subject matter knowledge (SMK), which does not allow the PCK development (Rollnick et al., 2008) and; lack in the integration of PCK components, which results in an isolated and, consequently, undeveloped PCK. In this sense, the investigation of the teachers' SMK and integration between PCK components is necessary and is the next step in our research.

Besides that, we will conduct a qualitative multiple case study to investigate the differences between teachers' PCK level. In this sense, we will choose some teachers from each strata and each group of teachers will be a case. From this, we expected to get a better understanding of how PCK of Electrochemistry can be developed though the different levels and then propose continuous professional development courses covering this topic, mainly in use of representations and conceptual teaching strategies.

ORIENTATION TO TEACHING INTRODUCTORY ELECTRICITY – AIMS AND MOTIVES OF TEACHERS

This study investigates the aims and motives regarding the teaching of introductory electricity of 34 physics teachers from parts of Austria and Germany. According to the model of teacher professional knowledge and skill, teacher's beliefs and orientations act as amplifiers and filters when it comes to personalising professional knowledge during their actual teaching practice. The construct of Orientation to Teaching Science (OTS) as one type of such filters serves as a theoretical basis for this study. According to Magnusson, Krajcik, & Borko (1999), an orientation presents a "general way of viewing and conceptualising science teaching". However, recent research suggests that OTS can differ from topic to topic. Hence, the goal of this study is to search for first hints of topic-specific teaching orientations among the teachers participating in a design-based research project on introductory electricity. As a first step we administered an open-ended questionnaire to 34 teachers in parts of Austria and Germany to identify their aims and motives regarding teaching introductory electricity at middle school. The results of the subsequent qualitative content analysis and their relation to Orientation to Teaching Science are reported in this article.

Keywords: Teacher Professionalism, Teacher Thinking, Teaching Practices

INTRODUCTION

The resources teachers draw upon in their daily teaching routine have been one focus in science education research in the past decades. Nearly each study regarding teachers' resources that influence teaching mentions (Shulman, 1987) initial conceptualization of pedagogical content knowledge (PCK). Nevertheless, there was little consensus among science education researchers how PCK should be conceptualised (Loughran, Mulhall, & Berry, 2004; Magnusson, Krajcik, & Borko, 1999). One approach to specifying PCK was developed during the first PCK-Summit held in 2013, which resulted in the formulation of "the model of teacher professional knowledge and skill (TPK&S)" (Berry, Friedrichsen, & Loughran, 2015). The innovations resulting from this frequently-called "consensus model" is a differentiation between personal PCK and skills on the one hand and topic-specific professional knowledge (TSPK) on the other hand as well as a distinction between teachers' PCK and their beliefs and orientations. In this model, beliefs and orientations act as amplifiers and filters that personalise knowledge, which teachers have acquired during their studies and years of teaching practice. As Gess-Newsome (2015) puts it, this knowledge must pass through the lens of teachers. This idea of amplifiers and filters may also account for findings that show that for example professional development does not have a direct effect on teachers' classroom practice (Gess-Newsome, 2015).

THEORETICAL FRAMWORK AND RESEARCH QUESTIONS

In recent years, many studies regarding teachers' beliefs, especially epistemological beliefs, have been conducted. However, the concept of Orientation to Teaching Science (OTS) and its role as an amplifier or filter is underrepresented in research. According to Magnusson, Krajcik and Borko (1999), an "orientation presents a general way of viewing science teaching" and "serves as a conceptual map that guides instructional decisions". However, in an extensive review of literature, Friedrichsen et al. (2011) identified four major problems concerning OTS: "Using OTS in different or unclear ways", "Unclear or absent relationship between orientations and other PCK model components", "Assigning science teachers to one of the nine orientations proposed by Magnusson et al. (1999)" and "Ignoring the overarching orientation component". However, they identify a consensus about three dimensions of OTS. These are (1) beliefs about the goals and purposes of science teaching, (2) beliefs about the nature of science and (3) beliefs about science teaching and learning. Furthermore, Campbell, Melville and Goodwin (2017) found first hints that OTS is, like TSPK, topic specific. Subsequently, the conceptualisation of Orientation to Teaching Science only as an overarching, topic-independent set of beliefs is not satisfactory. We think of OTS as an overarching concept, similar to the description given by Magnusson et al. (1999), but there might be further subcategories of OTS that especially influence the teaching-style of various topics within a subject. Hence, we propose a topic-specific orientation to teaching science, in the case of introductory electricity "orientation to teaching introductory electricity (OTIE)".

The main aim of our study, which is part of a DBR project on teaching introductory electricity in middle schools (Haagen-Schützenhöfer, Burde, Hopf, Spatz, & Wilhelm, 2019) is to investigate whether this conceptualisation is meaningful and if this topic-specific orientation can be captured. To do so, in a first step we administered an open-ended questionnaire to 34 teachers in parts of Austria and Germany to identify their aims and motives regarding the instruction of introductory electricity. Doing so, we want to gain first insights about the topic-specificity of the participants' beliefs about the goals and purposes of teaching introductory electricity and their beliefs about teaching and learning introductory electricity on a superficial level. We interpret the answers to the questions in the questionnaire as hints regarding the teachers' beliefs. Furthermore, these insights form the basis for in-depth interviews, which are not reported in this article. Hence, the analysis was guided by the following research questions:

RQ1: What are the most important key ideas/aspects teachers want to convey in their introductory electricity lessons?

RQ2: How do the participating teachers rate the importance of the use of models, experiments and calculations for their teaching and students' learning of introductory electricity and what are the reasons for their rating?

DESIGN & METHODS

This study is embedded in a large DBR project on introductory electricity carried out in parts of Austria and Germany. In the first year of this project, participating teachers followed their usual approach to introductory electricity in 7^{th} and 8^{th} grade middle school. Different types of data were collected for this study during this period, the results presented in this article are a small part of the overall project. After teaching introductory electricity, participating teachers were asked to fill in an online-questionnaire. In total, 34 physics teachers (M_{age} = 40.4 years, SD_{age} = 9.9 years, N_{female} = 15, N_{male} = 19, $M_{teachexp}$ = 13, $SD_{teachexp}$ = 7.48) filled in the online-questionnaire. Among other questions, which are not reported in this article, the teachers were asked about certain aspects of their introductory electricity lessons which correspond with the research questions of this article. These questions were:

1. What are the three most important key ideas you want to convey in your introductory electricity lessons?
2. a) How important are models for teaching introductory electricity?
   b) What are the reasons for your rating in 2a)?
3. a) How important are experiments for teaching introductory electricity?
   b) What are the reasons for your rating in 3a)?
4. a) How important are calculations for teaching introductory electricity?
   b) What are the reasons for your rating in 4a)?

The first question was formulated as an open-ended question, whereas questions two to four were two-tiered questions. In the first tier, the teachers were asked to rate the importance of models/experiments/calculations in general on a likert scale ranging from one (not important) to four (very important). In the second tier, the teachers were asked for the reasoning behind their rating. All open-ended questions were analysed by means of qualitative content analysis (Mayring, 2010).

FINDINGS & RESULTS

In this section, the results of the ratings from the likert scale items as well as the resulting categories from the qualitative content analysis are reported.

Important key ideas when teaching introductory electricity

In order to answer research question one, the answers regarding the question "What are the three most important key ideas you want to convey in your introductory electricity lessons?" were analysed inductively, some answers were assigned to two categories. The resulting categories are shown in Figure 1. The colour coding represents the priority of the answers from the teachers, the percentages refer to all 34 teachers.

The distribution of the categories shows that the participating teachers follow quite different key ideas in their introductory electricity lessons, since there is no predominant category. Electricity in everyday life is the most frequently mentioned category (53% of all teachers), followed by introducing a model representation of electric current (42%) and thematising the basic quantities voltage, current and resistance (38%). In addition to categories which are specific to introductory electricity, some teachers also mentioned more general key ideas like conducting experiments (24%), enjoying physics (12%) and performing measurements (9%). Only one teacher (3%) mentioned understanding the Nature of Science as one of the three most important key ideas.

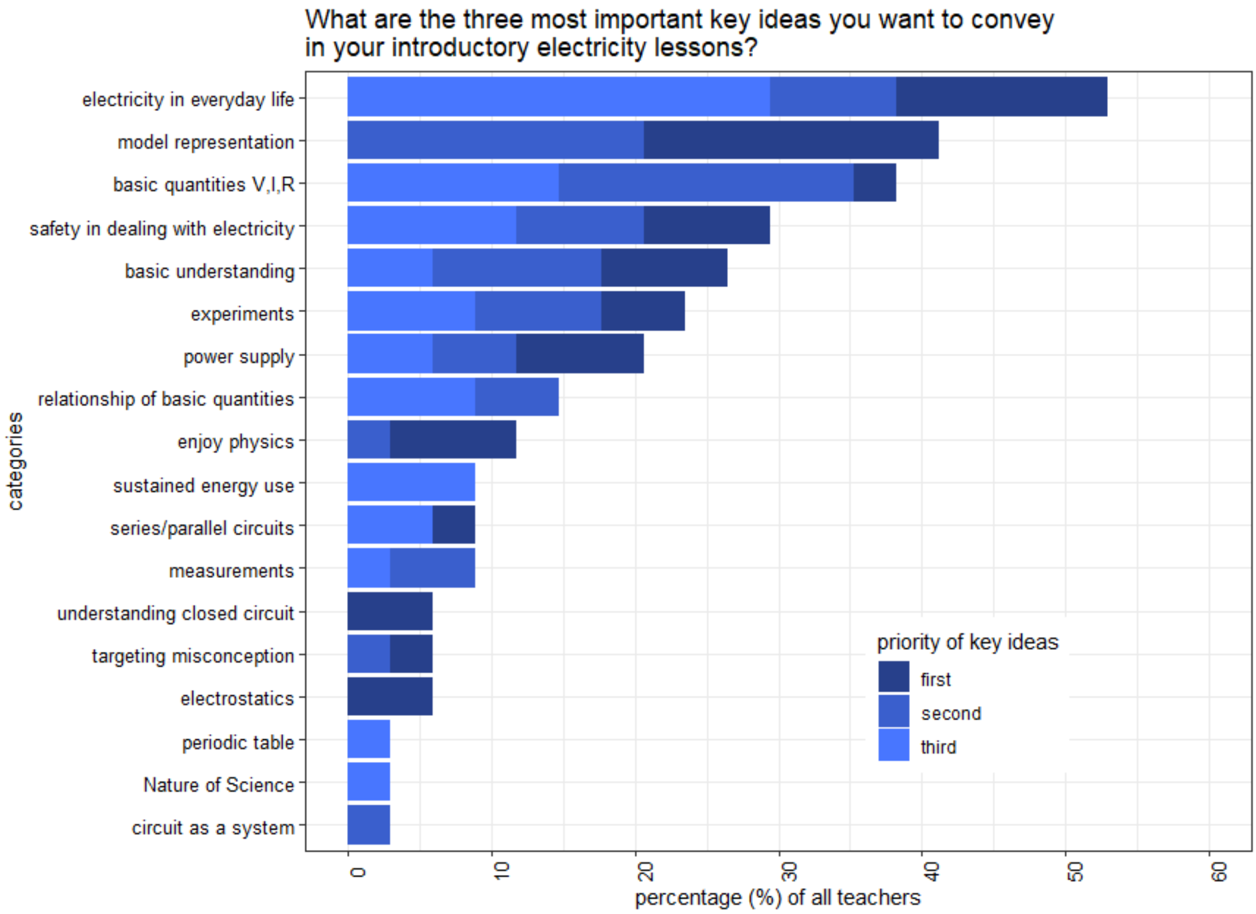

Figure 1. Teachers' answers regarding the question "What are the three most important key ideas you want to convey in your introductory electricity lessons?"

Perceived importance of calculations, experiments and models for teaching introductory electricity

In this section, the distribution of the ratings regarding the questions “How important are models/experiments/calculations for teaching introductory electricity?” are presented. In the subsequent sections, the teachers’ reasonings behind their rating are discussed. The distribution of the ratings is shown in Figure 2.

Regarding the perceived importance of models, almost all of the participating teachers rate the use of models as very (56%) or rather important (38%). A similar result is reported for the perceived importance of experiments, where 59% of all teachers rate experiments as very important for teaching introductory electricity and 35% rate it as rather important.

The results concerning the question “How important are calculations for teaching introductory electricity?” are rather heterogeneous. About half of the teachers rate calculations as rather (47%) or very (6%) important, whereas the other half of the teachers rate calculations as rather not (41%) or not (6%) important.

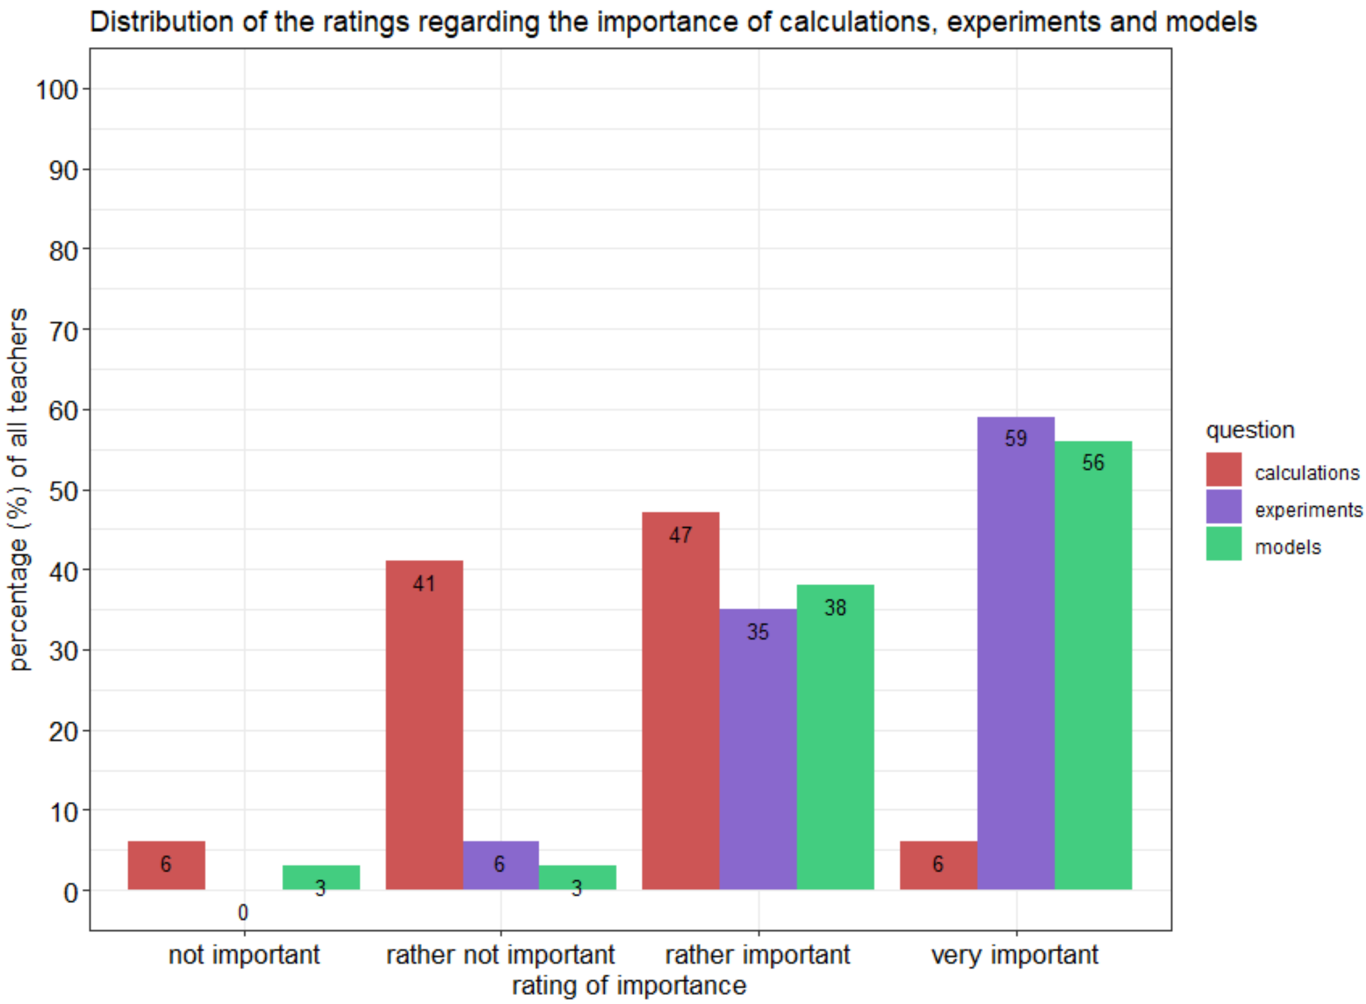

Figure 2. Distribution of the teachers' ratings regarding the importance of calculations, experiments and models for teaching introductory electricity

Perceived importance of models for teaching introductory electricity

Figure 3 shows the resulting categories of the reasoning behind the rating regarding the importance of models. Answers from three teachers were assigned to two categories, resulting in a total amount of 37 codes. However, the percentages reported in Figure 3 refer to the 34 teachers. 65% of the teachers report "models illustrate the abstract" as their reasoning behind their rating, all of them rated models as rather or very important. Answers attributed to this category also frequently mention that electric current is invisible and hence needs to be represented using a model. Hence, this category can be seen as topic-specific for electricity.

In contrast, the categories "models as an important part of physics" (26%) and "models facilitate learning" (18%) are rather general, topic-independent categories. Additionally, one teacher argues that models are not important for introductory electricity because they are too complicated for children at this age (grade 7 and 8). Another teacher argues that models are not central for his or her teaching without any further explanation.

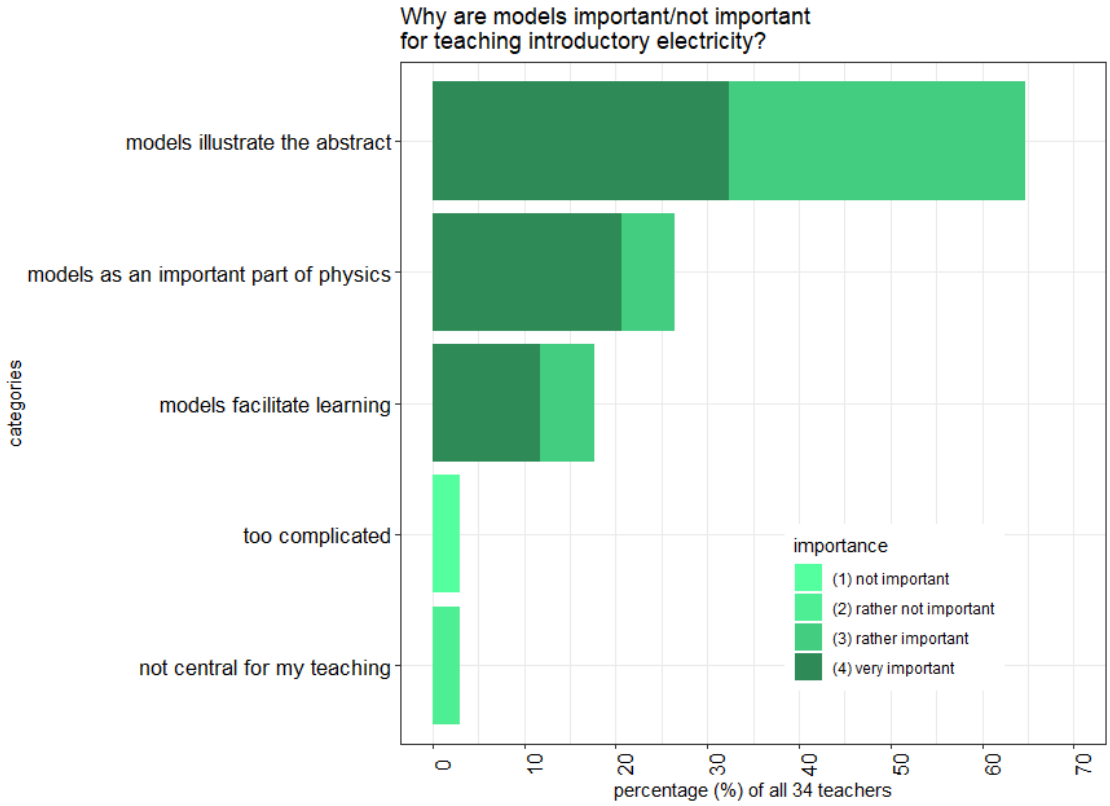

Figure 3. Teachers' reasonings regarding the question "Why are models important/not important for teaching introductory electricity?" The rating refers to the general importance of models for teaching introductory electricity, while the categories represent the different reasonings behind the rating of the importance

Perceived importance of experiments for teaching introductory electricity

Almost all of the teachers rate experiments as rather (35%) or very (59%) important for teaching electricity, whereas only two teachers (6%) rate them as rather not important. The latter group argues that experiments are overestimated for learning content knowledge, as shown in Figure 4. Again, the answers from some teachers were assigned to multiple categories, however the percentages in the figure refer to the 34 teachers. Although there is consensus among the teachers that experiments are important, the reasons for their opinion are quite diverse.

Similar to the findings concerning the use of models, some reasonings for the use of experiments are of a topic-specific nature whereas others are more general and topic-independent. For example, the most dominant category “experiments facilitate learning” (32%) is a general category and reasonings that were assigned to this category do not refer to any topic-specific aspects. This also applies to the category “interest/motivation” (24%). Reasonings assigned to this category explain that experiments spark interest or improve the motivation of students. However, the categories “electric current is invisible” (32%) or “experience electricity phenomena” (9%) are clearly topic-specific for (introductory) electricity. An additional, interesting, finding is that while teachers perceive models as important for teaching introductory electricity because models are an important part of physics, experiments are important due to other reasons. Only one teacher emphasises that experiments are important because they are a crucial part of physics.

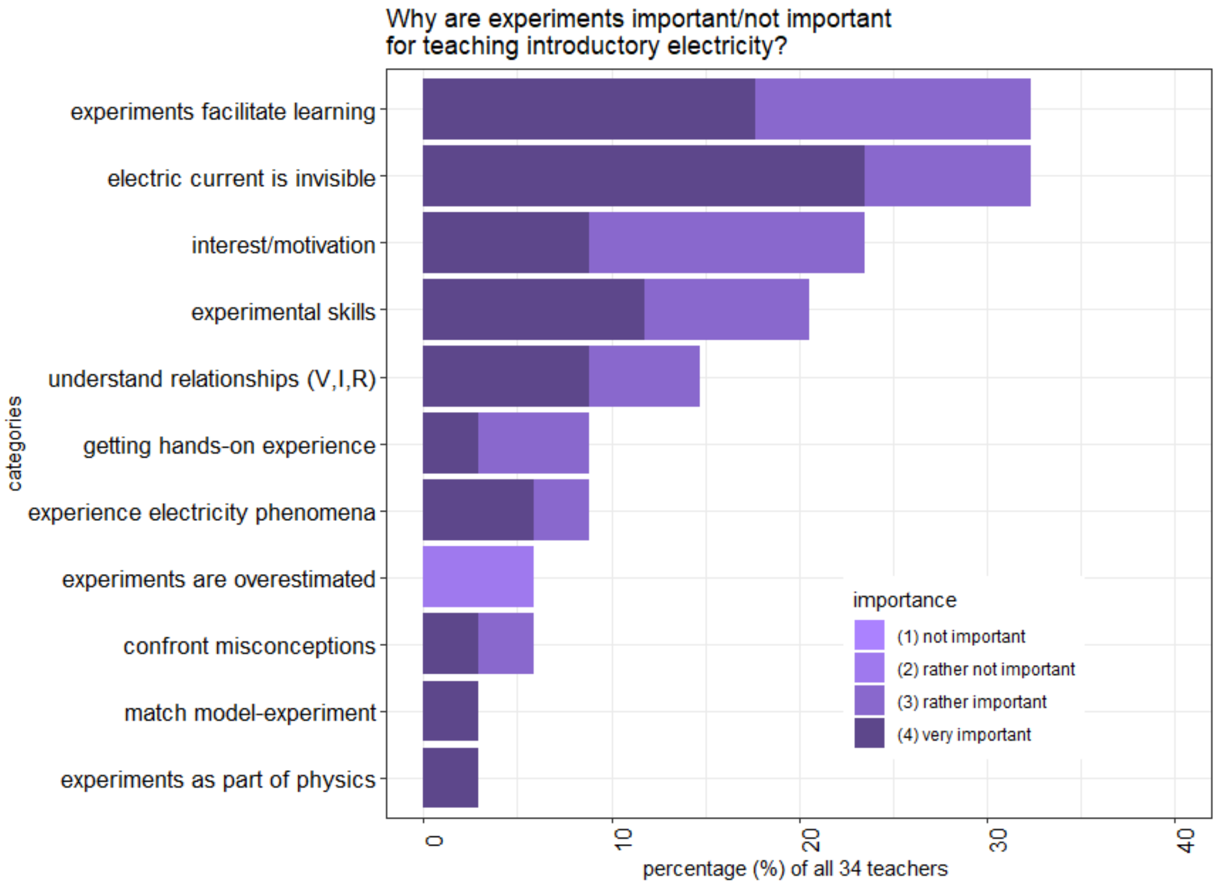

Figure 4. Teachers' reasonings regarding the question "Why are experiments important/not important for teaching introductory electricity?" The rating refers to the general importance of experiments for teaching introductory electricity, while the categories represent the different reasonings behind the rating of the importance

In total, the resulting categories concerning the use of experiments can be attributed to three overarching themes:

1. Experiments facilitate learning, interest and motivation
2. Experiments make electric current “visible” or “perceptible”
3. Experiments are important for hands-on experience and experimental skills of students

Perceived importance of calculations for teaching introductory electricity

Since the results regarding the reasoning behind the rating of the importance of calculations for teaching introductory electricity are diverse, the resulting categories are presented in two separate figures. Figure 5 shows the resulting categories for teachers who rated calculations as rather or very important. Figure 6 shows the results for teachers who rated calculations as rather not or not important. The percentages displayed again refer to the total amount of 34 teachers.

These resulting categories presented in Figure 5 and Figure 6 indicate that a conceptual or qualitative understanding of introductory electricity is more important for many teachers (38% in total) than performing quantitative calculations. Interestingly, these reasonings can be found for teachers who have rated calculations as rather important (15%) but also rather not or not important (23%). None of the teachers explains his or her rating of the importance with topic-specific reasons.

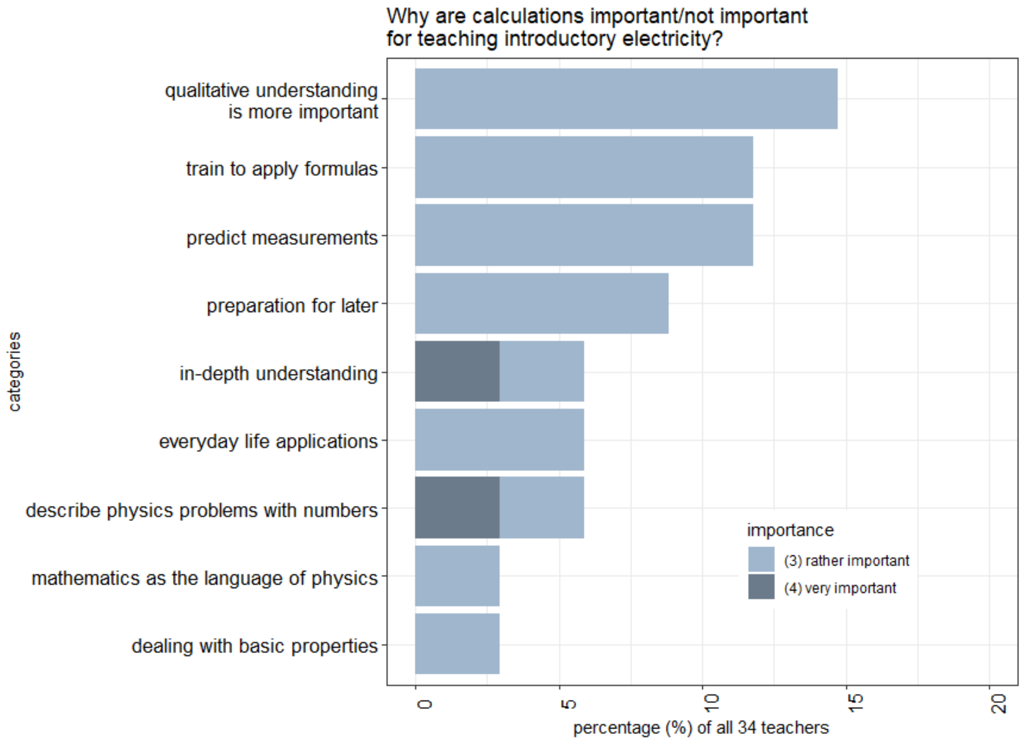

Figure 5. Teachers' reasonings regarding the question "Why are calculations important/not important for teaching introductory electricity?" The figure shows reasonings behind the ratings "rather important" and "very important". The rating refers to the general importance of calculations for teaching introductory electricity, while the categories represent the different reasonings behind the rating of the importance

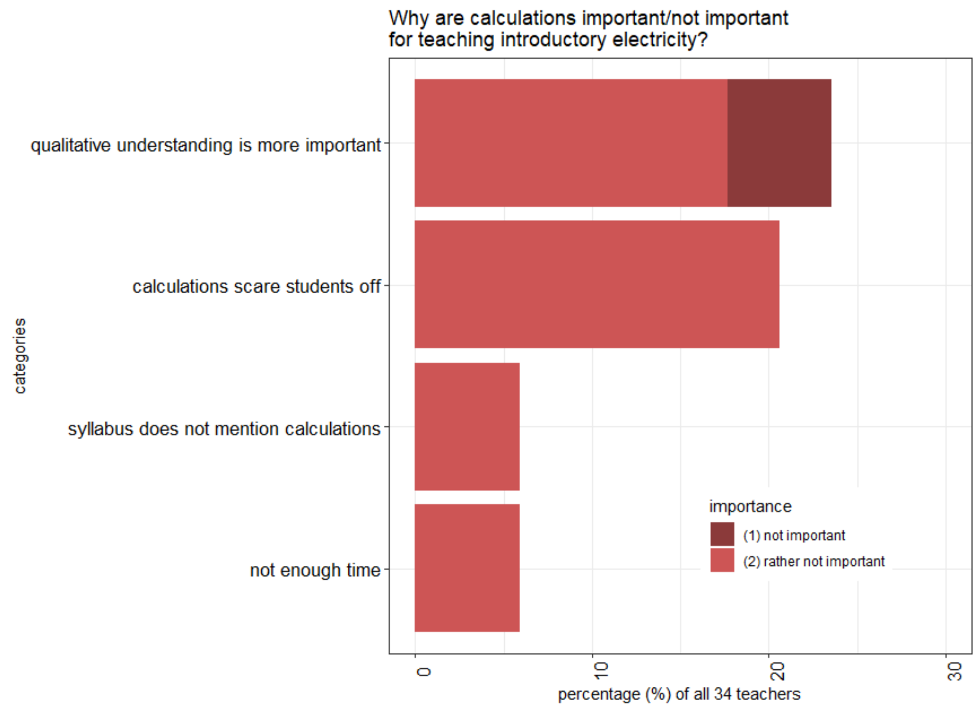

Figure 6. Teachers' reasonings regarding the question "Why are calculations important/not important for teaching introductory electricity?" The figure

shows reasonings behind the ratings of "rather not" and "not important". The rating refers to the general importance of calculations for teaching introductory electricity, while the categories represent the different reasonings behind the rating of the importance

DISCUSSION UND CONCLUSION

The findings presented in the previous section will be discussed now with respect to their topic-specificity and in relation to two dimensions of the conceptualisation of Orientation to Teaching Science proposed by Friedrichsen et al. (2011). The two dimensions we focus on are beliefs about the goals and purposes of science teaching and beliefs about teaching and learning science. Although the reasonings and answers to the open-ended questions of questionnaire can neither represent nor describe the teachers' beliefs thoroughly, the presented results can act as first hints whether there are certain topic-specific elements to the afore mentioned beliefs.

We interpret the answers to the question "What are the three most important key ideas which you want to convey in your introductory electricity lesson?" as indicators for the participants' beliefs about their most important goals and purposes of introductory electricity teaching. The results presented in the previous section indicate that there are some general goals or aims teachers follow, for example to "enjoy physics" or to understand the "Nature of Science". However, there are also goals or key ideas which are topic-specific. For example, reasonings that were assigned to the category "safety in dealing with electricity" are topic-specific reasonings which do not refer to a specific concept (e.g. voltage) but rather represent why it is important to teach introductory electricity in general.

This can only be seen as a first hint that teachers' individual beliefs about the goals and purposes of teaching science vary for different topics in some aspects. Still this leaves room for the idea that the teaching style of a single teacher, for example how they approach experimental work, might differ between two topics. This idea can be illustrated with a concrete example: A teacher may have a different approach to experiments when teaching electricity and mechanics because he/she believes that experimental work is more important when teaching electricity since the students need to learn how to handle electricity safely. We think that this idea should be addressed in future research.

While we certainly cannot provide a detailed picture about the teachers' beliefs about science teaching and learning, the perceived importance of models/experiments/calculations for teaching introductory electricity is certainly related to the participating teachers' beliefs about science teaching and learning. The results regarding the perceived importance of both experiments and models indicate that teachers' beliefs about science teaching and learning may have topic-specific elements. For example, some teachers highlight that experiments are important when teaching introductory electricity because electric current is "invisible" or models are important because they illustrate the abstract (like electric current).

Overall, this implies that studies that intend to capture Orientation to Teaching Science need to consider a potential topic-specificity. Future studies should further explore whether teachers' orientations to teaching science differ for different topics.

The findings reported in this article are furthermore interesting for researchers focusing on curriculum innovation. While it is broadly known and accepted that general beliefs about teaching and learning science influence the implementation of curricula and/or teaching materials, this might also be true for beliefs about teaching and learning a specific topic. Imagine developing a curriculum for introductory electricity which heavily focuses on electricity in everyday life but neglects experiments and models of electric current. It might very well be possible that the fidelity of implementation (O'Donnell, 2008; Stains & Vickrey,

2017) of this curriculum might subsequently be non-satisfactory since most of the teachers think that models and experiments are important for teaching and learning introductory electricity and hence divert from the proposed curriculum.

TEACHER-LEADERS' LEARNING WHILE LEADING A PLC OF PHYSICS TEACHERS – THE CASE OF THE INQUIRY-BASED LABORATORY

Smadar Levy, Esther Bagno, Hana Berger and Bat-Sheva Eylon
Department of Science Teaching, Weizmann Institute of Science, Rehovot, Israel

Teacher-leaders (TLs) play a major role in teachers' Professional Development (PD) and in building effective Professional Learning Communities (PLCs). However, the PD of the TLs themselves is rarely discussed in the literature. This study examined the learning of high-school physics TLs in a program involving PLCs. The program has been operating since 2012, using a "Fan Model": the TLs participate in a PLC led by a team from the Weizmann Institute of Science (TL-PLC), while they simultaneously teach in high school and lead regional PLCs of physics teachers all over Israel. We extended the Interconnected Model of Professional Growth (Clarke and Hollingsworth, 2002), adjusted it to the professional world of physics TLs, and used it to study the learning of three TLs that were chosen as case studies. We studied for four years (2014-2017) the changes in their knowledge, attitudes, and practice, in the context of the inquiry-based laboratory. For each case study we created a chronological map based on our Extended Interconnected Model of Professional Growth. The results show significant changes in the three TLs' knowledge, attitudes, and practice, and their ongoing professional growth. The TLs' learning was promoted by the mechanisms of "Enactment" and "Reflection", which were implemented in the program in a specific rational order and at appropriate times, in all the aspects of the TLs' practice. The alternating meetings, every other week, of the TL-PLC and the regional PLCs, helped to integrate the TLs' learning into their practice, both as teachers and as PLC leaders. The TLs successfully implemented the inquiry-based activities in their teaching routine for a long period. Our results enhance our understanding of the TLs' learning, as well as features in the program that promoted it, and can contribute to the design of effective PD programs for both teachers and TLs.

Keywords: Continuing professional development; Learning Communities; Laboratory Work in Science.

INTRODUCTION

It is widely agreed that effective teachers' Professional Development (PD) programs should be ongoing, challenging, focused on student learning, and situated in teachers' practice (Borko, 2004; Darling-Hammond & Richardson, 2009; Desimone, 2009). Professional Learning Communities (PLCs) are an essential component of high-quality PD (Grossman, Wineburg & Woolworth, 2001; Shulman, 1997; Vescio & Adams, 2015). Teacher-Leaders (TLs) play a major role in teachers' PD and in building effective PLCs (Klentschy, 2008; National Academies of Sciences, 2015; York-Barr & Duke, 2004). However, the PD of the TLs themselves is rarely discussed in the literature (Criswell, Rushton, McDonald & Gul, 2017; Even, 2008). This study is part of a larger research (Levy, Bagno, Berger & Eylon, 2018) aimed at bridging this gap.

We examined the PD of high-school physics TLs that participated in a program involving PLCs. The program has been operating since 2012, by using a "Fan Model" (described in Fig. 1): the TLs participate in a PLC led by a team from the Weizmann Institute of Science (TL-PLC), while they simultaneously teach high-school physics and lead regional PLCs of physics teachers.

Figure 1. The "Fan Model" used in the PLCs program

The TLs' learning is "evidence-based": They enact each new instructional activity in their classes and in the regional PLCs, collect and analyze data about students' and teachers' learning, as well as reflect collaboratively on the evidence from classes and from the regional PLCs. Each PLC operates by face-to-face meetings lasting 4 hours each, twice a month during the school year. In the 2019 school year there were 24 TLs in the program, and 12 regional PLCs with about 250 high-school physics teachers.

The context of the current study is inquiry-based laboratory, aimed at moving away from the widespread contrived instructional laboratory (Abrahams, 2015) towards inquiry-oriented activities that represent aspects of authentic research, and give students more responsibility for their work (American Association of Physics Teachers, 2015; Etkina et al., 2010). Each inquiry-based activity lasts two lab-lessons, in which the students work collaboratively in small groups, and experience a variety of inquiry practices, such as asking questions, formulating hypotheses, planning and carrying out experiments, analyzing data, constructing explanations, and finally sharing their results with the whole class. The inquiry-based activities were new to all TLs and fundamentally differed from their traditional teaching methods, pushing them beyond their "comfort zone".

Theoretical frameworks for research on TLs' PD should take into consideration the multiple contexts of their practice, both as teachers and as PLC leaders. Situative perspectives serve as a powerful research tool, taking into account both the individual teacher-learners and the social systems in which they participate, including PLCs (Borko, 2004; Putnam & Borko, 2000). Our theoretical framework is based on the Interconnected Model of Professional Growth (Clarke & Hollingsworth, 2002), shown in Fig. 2. This model recognizes the complexity of teachers' learning and suggests the perspective of teachers as active learners who shape their professional growth through reflective participation in PD programs and in practice.

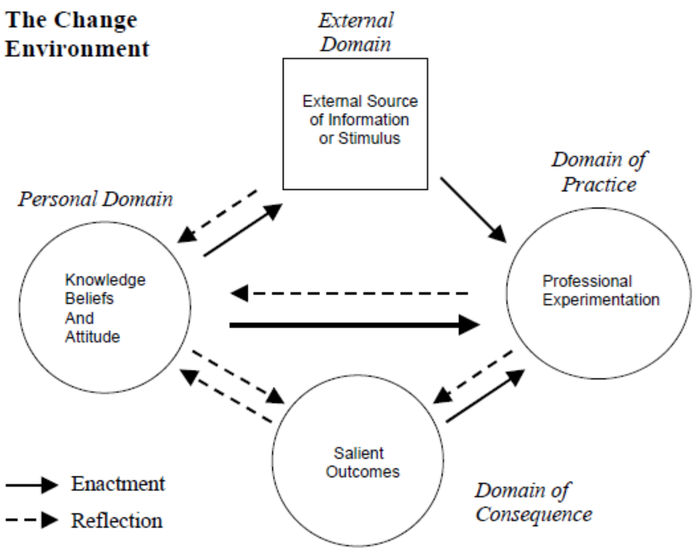

Figure 2. The Interconnected Model of Professional Growth (Clarke & Hollingsworth, 2002)

According to the model, four distinct domains encompass the teacher's world: the Personal Domain, referring to teacher's knowledge, beliefs and attitudes; the Domain of Practice, referring to professional experimentation; the Domain of Consequence, referring to salient outcomes, such as student learning or student motivation, and changes at the school level; and the External Domain, referring to sources of information, stimulus or support. A change in one domain is translated into another domain through the mediating processes of "Reflection" and "Enactment", which are represented in the model as arrows linking the domains.

We extended Clarke & Hollingsworth's model to an Extended Interconnected Model of Professional Growth (EIMPG), adjusted it to the professional world of physics TLs, and used it to study the TLs' professional growth, focusing on changes in their knowledge, attitudes and practice in the context of the inquiry-based laboratory.

Our main research questions are as follows: 1) what changes occurred in the TLs' knowledge, attitudes, and practice, in the context of inquiry-based laboratory; 2) how were these changes related to features of the PLCs' program?

METHODS

This longitudinal study lasted four years (2014-2017). We used a case-study methodology that provided us with a prolonged and in-depth exploration of processes in the TLs' learning within the different aspects of their practice: their classrooms, their school, and the regional PLC that they led. Three TLs: Roy, Dana, and Sofia, were chosen for the case studies. All three are high-school physics teachers, who joined the program in different years, and differed from each other regarding their background as teachers and as TLs. Dana joined the TL-PLC in 2014, after 19 years as a teacher, and had no former experience as a TL. Sofia and Roy joined the TL-PLC in 2012. Sofia has been a teacher for 25 years, has been a district teachers' facilitator for 15 years, and has participated in many former PD programs. Roy has been a teacher for 18 years, graduated from a special M.Sc. program designed for excellent physics teachers, and had no former experience as a TL. Thus, Sofia was a senior teacher and had leadership experience, whereas the other two did not; Roy had research experience, whereas the other two did not.

Data were collected from a variety of sources, e.g., video records of TL meetings, reflection papers, interviews, and annual portfolios. The data related to Roy, Dana, and Sofia in the context of the inquiry-based laboratory were sorted and categorized (using Atlas.ti software) according to the different domains of the EIMPG, focusing on the different aspects of the TLs' practice. The mediating processes of "Enactment" and "Reflection" were identified, numbered in chronological order, and presented in a map that was created for each case study. The categorization, as well as the EIMPG maps, were validated by four researchers. Our results were discussed with Roy, Dana, and Sofia.

RESULTS

Roy, Dana, and Sofia's professional growth over the four years, both as teachers and as PLC leaders, was a complex, ongoing process. We will first examine the changes in the knowledge, attitudes, and practice of each case study in the context of the inquiry-based laboratory, using the EIMPG maps. Then we will consider features of the PLCs' program that promoted these changes.

Changes in Roy's knowledge, attitudes, and practice

The EIMPG map for Roy, in the context of the inquiry-based laboratory, is shown in Fig. 3. The mediating processes of "Enactment" and "Reflection" are represented, respectively, as solid and dashed arrows linking the different domains of the EIMPG. The colors denote different aspects of Roy's professional experimentation: as a teacher in class, as a TL in school, as a TL in the regional PLC, and as a member of the TL-PLC.

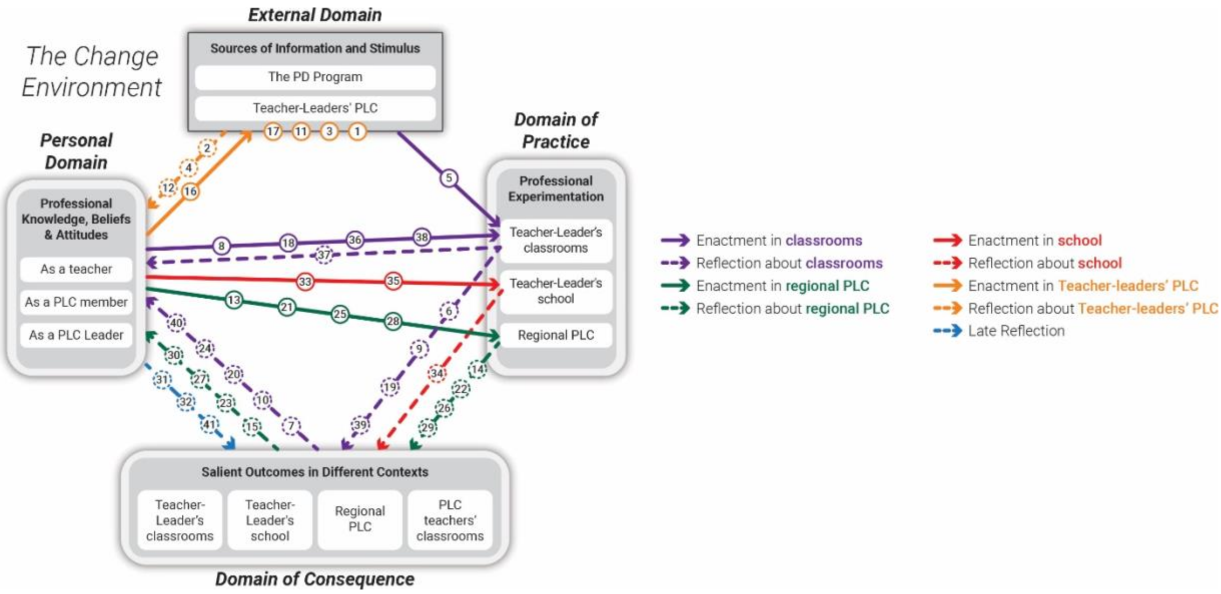

Figure 3. Roy's EIMPG Map

Roy's initial experience with an inquiry-based lab activity was as a learner in the TL-PLC (1). His reflection was (2):

> *I had the notion that an inquiry-based lab is a long and grandiose process, and requires expensive instruments. I really liked the experience today of inquiry with such simple equipment.* (Roy's reflection paper 1, September 2014).

At the following TL meeting, Roy experienced another inquiry-based lab activity (3) and reflected on that experience (4):

> *Our group had a frustrating half an hour because it took us a long time to figure out how to take measurements. It made me feel like my students when they face difficulties in the lab… It was an important experience for me.* (Roy's reflection paper 2, September 2014).

A few days later, Roy enacted his first inquiry-based activity in a 12^{th} grade lab-lesson (5), described the outcomes (6), and referred to the challenges that he faced (7):

> *I wasn't sure what to emphasize in the class discussion: the needed lab-skills? The theoretical aspects? I'm afraid my students remained confused".* (Interview, September 2014).

Roy enacted the same activity in another 12^{th} grade class (8) and reflected on it (9 and 10):

> *The students focused on the challenge of taking measurements and getting results. This second experience in class made me ask myself what are the main goals of this activity and when is the best time to enact it.* (Interview, October 2014).

After his third experience at the TL meeting (11), Roy reflected (12):

> *It was the first time I really understood the whole process of inquiry and now I feel much more confidence with it.* (Roy's reflection paper 3, November 2014).

Then Roy enacted an inquiry-based lab activity in his PLC for the first time (13) and reflected on it (14-15):

> *The teachers really liked this activity. They enjoyed the team work and said that the challenges that they faced were frustrating*. (TL meeting, November 2014).

Roy also advised other TLs how to enact the activity in their regional PLCs (16), and the challenges were discussed with the leading team (17). Roy's map presents many more sequences of "Enactment" and "Reflection" (18-32; 36-41), both in his classes and in the regional PLC. He helped other teachers in his school to enact inquiry-based activities as well (33-35), and was pleased with the outcomes.

The repeating enactments, following changes in Roy's knowledge and attitudes, were more mature, and included personal adaptations of the activities. Roy reflected on the changes in his attitudes towards the inquiry-based laboratory:

> *At the beginning of the year I thought that inquiry activities require a lot of time and expensive equipment. However, after all my experimentations this year, I definitely changed my opinion – we can do inquiry activities even with the limited time we have and also with cheap and simple equipment. I even managed to persuade the teachers at my school and at my PLC to use inquiry activities.* (Roy's portfolio, July 2015)

In addition, Roy gained more confidence as a TL:

I feel much more confident now. Here I am leading teachers, they try the new activities in their classes and they come back with positive feedback. It makes me feel that I can influence both teachers and students. (Interview, April 2016).

Roy, attributed great importance to his experiences in class before the enactment in the regional PLC:

We must try everything in class before introducing it in the PLC. It helps us find the best way to enact each activity. For example, how much time is needed for the inquiry activity, what difficulties are expected? When I tell the teachers that I tried it with my students and it worked well, it motivates them to try it in their classes too. (Interview, July 2016)

Roy successfully implemented the inquiry-based activities in his teaching routine, developed new inquiry-based activities for his students, and shared these activities with the other TLs.

Changes in Sofia's knowledge, attitudes, and practice

Sofia's EIMPG map is shown in Fig. 4. Sofia participated in a former summer PD and had some experiences with inquiry-based activities, which are not presented in the map. Her first experience in that context within the PLCs' program was at the TL meeting (1), and she reflected on that experience (2):

It was very challenging because our results were different from our predictions, and we struggled to understand our mistake. I really enjoyed the activity, but I don't think I will use it with my students. It is too complicated. (Sofia's reflection paper 1, September 2014).

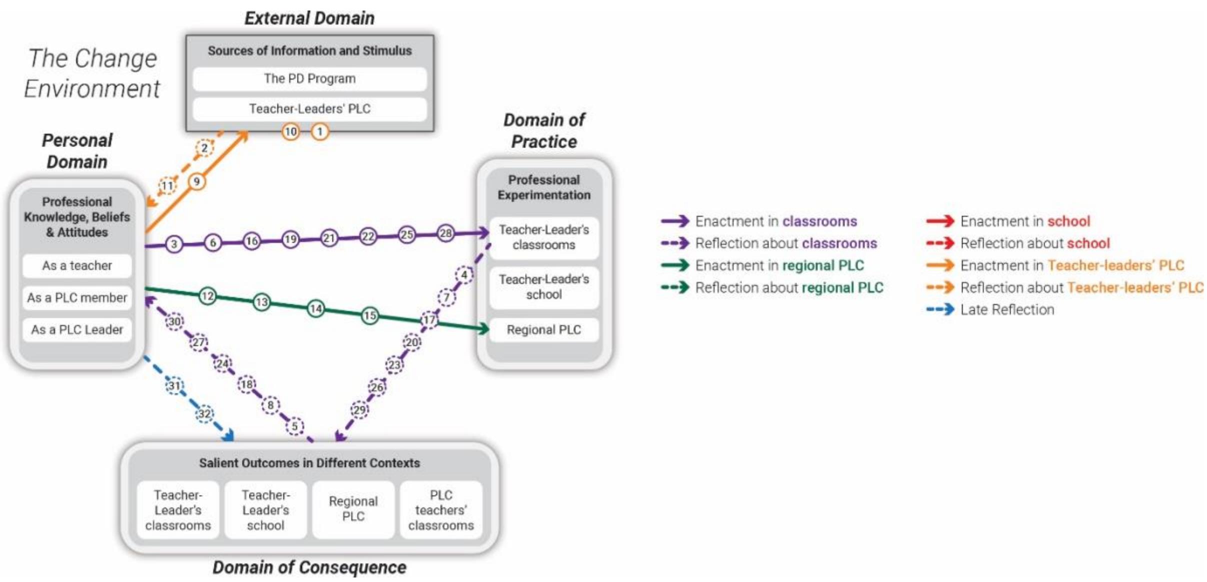

Figure 4. Sofia's EIMPG Map

Sofia made some changes in a traditional activity that she used before, designed it as an inquiry-based activity, and enacted it in her 9th grade class (3). Her reflection was (4 and 5):

Each group decided on its own inquiry question… It was interesting for me to realize that some of them understood the experimental system and some of them didn't…We had a rich discussion regarding measuring skills, and it was amazing. (TL meeting, October 2014).

Sofia enacted another inquiry-based activity in another class (6) and reflected (7 and 8):

> *It was so good! I am enthusiastic about this way of working in the lab.* (Interview, October 2014).

At the TL meeting, Sofia suggested how to design another familiar experiment as an inquiry-based activity (9). In the following TL meeting, she experienced another new activity (10) and reflected on it (11):

> *I really like it; I intend to use it with my students next week*. (TL meeting, November 2014).

Sofia enacted some inquiry-based activities in her regional PLC (12-15), but did not reflect on these experiences. She kept using inquiry-based activities in class for a long period, and her EIMPG map presents multiple enactments and reflections (16 - 32).

Changes in Dana's knowledge, attitudes, and practice

Dana's EIMPG map is shown in Fig. 5. Dana's initial experiences with inquiry-based activities were as a learner in the TL-PLC (1 and 2). She reflected on these experiences (3):

> *We felt like students. It was very frustrating that we didn't manage to take measurements at first*. (Dana's reflection paper 2, September 2014).

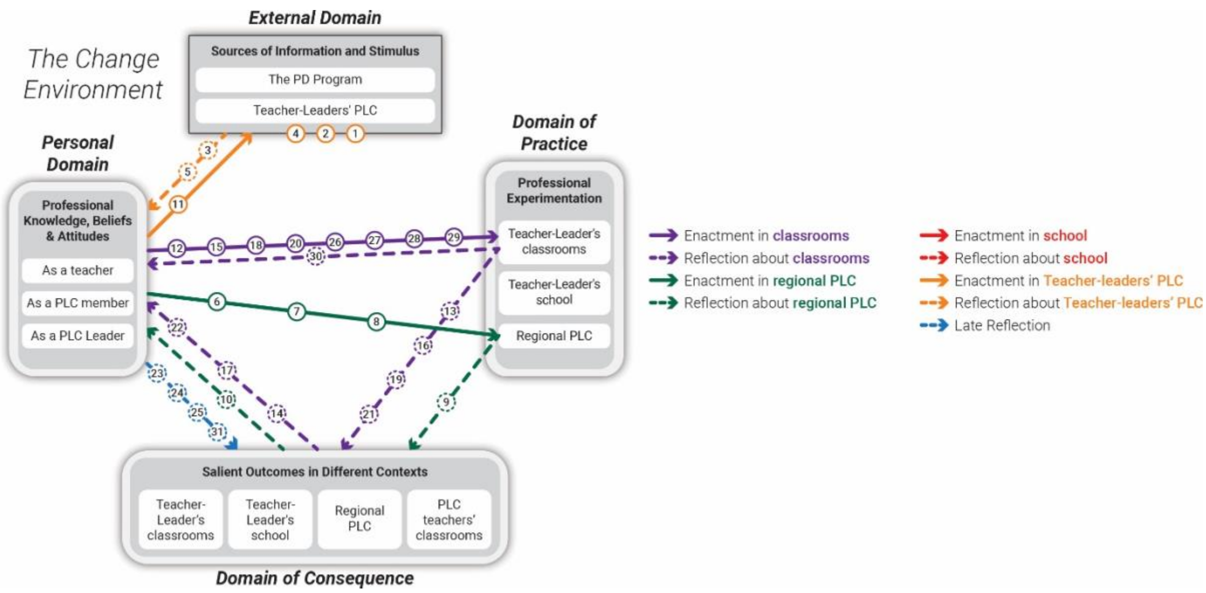

Figure 5. Dana's EIMPG Map

Dana experienced a third inquiry-based activity in the TL-PLC (4), and her reflection this time was (5):

> *I think that this activity is easier for students.* (Dana's reflection paper 3, November 2014).

She enacted two of these activities in the regional PLC and reflected on them (6-10):

> *The teachers were enthusiastic about this new approach of inquiry-based lab activities*. (TL meeting, January 2015).

Unlike Roy and Sofia, who immediately implemented the inquiry-based activities in their classes, Dana needed to undergo several experiences, both in the TL-PLC and in the regional

PLC, in order to enact an inquiry-based activity for her class for the first time. She shared her plans with all the TLs (11), enacted the activity in her 11th grade class (12-13), and reflected about what motivated her to do so (14):

> *I heard the other TLs and the teachers in my regional PLC reflecting on their experiences after they had begun to use inquiry-based activities with their students, and I told myself that I can't stay behind.* (Interview, January 2015).

After many sequences of "Enactment" and "Reflection" (15-31, January 2015 – July 2017), in different classes, Dana learned how to implement the inquiry-based activities successfully and continued to do so, in many variations, even after three years.

Features of the PLCs' program that promoted changes in the TLs' knowledge, attitudes, and practice

Roy, Dana, and Sofia implemented the inquiry-based laboratory in their teaching routine, in spite of the many challenges, and the changes in their practice lasted for more than three years. Examination of their EIMPG maps reveals that individual pathways exist for Dana, Sofia, and Roy's professional growth, as well as several similar patterns in all three EIMPG maps. For example, (1) repeating sequences of "Enactment" and "Reflection", in a certain order, which promoted changes in the Personal Domain, in the Domain of Practice, and in the Domain of Consequence; (2) experiences in the TL-PLC, accompanied by personal and collaborative reflection, and a change in the Personal Domain; (3) interactions between the Personal Domain and the External Domain, indicating the important role of the TL-PLC as a meaningful learning environment. We suggest that these similar patterns are related to features of the PLCs' program.

The TLs' learning, and the changes in their knowledge, attitudes, and practice, were promoted by the mechanisms of "Enactment" and "Reflection". The implementation of "Enactment" and "Reflection" in the program in a specific rational order and at appropriate times, in all aspects of the TLs' activity, enhanced their long-term professional growth.

The engaging experiences of the TLs in all aspects: as learners at TL meetings, as high-school physics teachers, and as regional PLCs' leaders, encouraged them to try the new activities in their classes, and to acquire the confidence needed for their successful implementation in class as well as in the PLCs.

The alternating meetings, every other week, of the TL-PLC and the regional PLCs helped to integrate the TLs' learning into their practice, both as teachers and as TLs. The evidence from the TLs' own classes, from the classes of other TLs, and from the PLC teachers' classes, provided the TLs with a wide perspective about the new activities. The collaborative reflection enabled the TLs to share insights, successes, and difficulties, and to get support, both moral and practical, from their peers and from the leading team.

The "Fan Model", as well as the features of the PLCs program, provided the TLs with opportunities to actively investigate their teaching and leading, consistently reflect on their practice and its consequences, and learn from one another in a supportive and non-judgmental environment.

DISCUSSION AND CONCLUSIONS

Roy, Dana, and Sofia's professional growth demonstrate professional "growth networks", as defined by Clarke and Hollingsworth (2002), who distinguished between local or short-term changes and lasting, long-term, teacher growth. Our results contribute an important aspect: the professional growth of TLs. In all three case studies the mediating processes of "Enactment" and "Reflection" were, as in the Clark & Hollingsworth's model, mechanisms that promoted changes in the knowledge, attitudes, and practice of the TLs. Roy, Dana, and Sofia's learning was based on their enactments and multiple reflections as learners at TLs' meetings, as high-school physics teachers, and as regional PLCs leaders.

The interactions we found between changes in the TLs' knowledge and changes in their practice demonstrate the significance of the construct "Knowtice" (a combination of Knowledge and Practice), introduced by Even (2008), which applies to the learning and development of physics TLs who lead regional PLCs.

Our results indicate the challenges of developing physics TLs as reflective practitioners, as described by Criswell et al., 2017, highlight the special needs of physics TLs, and emphasize the importance of responding to their needs and challenging their habits and views (Etkina, Gregorcic & Vokos, 2017; Timperley, Wilson, Barrar & Fung, 2008), particularly in the context of inquiry-based activities (Holmes & Wieman, 2018; Luft, 2001).

The TL-PLC turned out to be a meaningful and enriching learning environment. The supportive and non-judgmental environment helped the TLs to dare to try new things and cope with the challenges they were facing. These results support PLCs as a sustained, practice-based, and collaborative setting for effective teachers' PD (Vescio & Adams, 2015), in particular a TL-PLC.

Can the cases of Roy, Dana, and Sofia be generalized to other TLs in the program? Case studies always raise this question. However, the results of this study are in line with our research regarding the TLs in our program (e.g., Levy, Bagno, Berger & Eylon, 2018).

Having a better understanding of the learning processes and professional growth of physics TLs can contribute to the design of effective PD programs for both teachers and TLs.

A NANOSCALE SCIENCE AND TECHNOLOGY TRAINING COURSE: PRIMARY TEACHERS' LEARNING ON THE LOTUS AND GECKO EFFECTS

Lotus and gecko effects are considered as appropriate for introducing Nanoscale Science and Technology (NST) topics in compulsory education. Under this lens, we investigate primary teachers' (PTs) learning on the two effects after their participation in a NST training course. PTs completed a written questionnaire before and after the implementation. The analysis of the responses revealed that PTs' explanations shifted from a sensory perception-based to a more scientific view level. The common explanations involved the structural aspects of the two effects. Other abstract concepts such as forces were less internalized.

Keywords: primary school, in-service teacher training, teacher thinking

INTRODUCTION

Nanoscale Science and Technology (NST) consist of a modern field that focuses on the understanding of the behavior of materials having length scale in the range of 1-100nm, often denoted as the nanoscale. Due to the progress in the nanoscale materials domain, a plethora of applications in several sectors (materials science, electronics, medicine, etc) can be witnessed (Kumar & Koumbhat, 2016). A significant number of these advancements come from the field of biomimetics. Self-cleaning windows, superhydrophobic textiles have been driven by the inspiration from the superhydrophobic property of the lotus leaf (lotus effect). Efficient adhesive tapes, robots that can climb vertically, super adhesive gloves that may be used by firemen replicate the strong adhesion of the gecko lizards on to ceilings (gecko effect) (Bhushan, 2010).

Figure 1 and 2 represent aspects of the two effects. The lotus leaves present structural multi-scale roughness, having micro-bumps and nano-bumps which are covered with epicuticular wax, resulting in a high repellence between water droplets and the surface (Figure 1). Superhydrophobic lotus leaf exhibits self-cleaning properties showing high static water contact angle and low contact angle hysteresis (Kim et al 2018). The gecko lizard possesses one of the most effective adhesion mechanisms in nature regarding to its body mass. One single toe of the gecko consists of microscale hair-like structures (called setae). Each seta ends to even smaller structures, the spatulae, whose width lies at the nanoscale dimension (Figure 2). When they come into contact with the ceiling a large number of van der Waals forces are sufficient enough for the gecko to defy gravity and adhere on the ceiling (Bhushan, 2010).

Introducing nanophenomena of the natural world and their related applications such as those described above are considered suitable for introducing salient NST concepts (e.g. size dependent properties, forces & interactions) to school students ("easy to digest" approach, Lin et al., 2015, p. 25). This approach has a positive impact to students' interest and it has the potential to excite and inspire schoolchildren about modern and future innovations. Both the effects have been included under the umbrella of the NST concept "Nanophenomena in the natural world", which has been acknowledged as a core concept for primary nano-education (Lin et al., 2015; Blonder & Sakhnini, 2016).

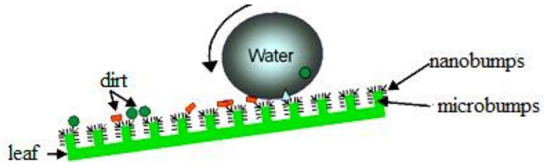

Figure 1. Representation of the lotus effect.[5]

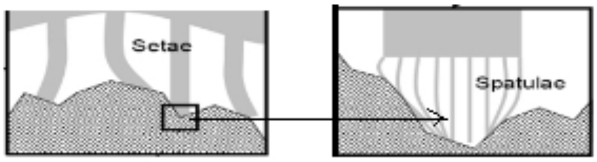

Figure 2. Representation of the gecko effect.[6]

However, in practice introducing NST at the primary level can turn out to be challenging. A major cognitive barrier for learning NST is the lack of intuition. The problem is conceptual & practical; objects –concepts are hard to visualize, difficult to describe, their relationships to the observable world can be counterintuitive (Sabelli et al., 2005, p.3). There is a consensus amongst scientists and educators in the field of NST that education of NST concepts relies on models and modeling. To be specific using, creating and understanding aspects of the nature and role of models are considered as a means for the construction of knowledge in nanoscale science education (Daly & Bryan, 2010).

Apart from the cognitive barriers, teacher preparation has been recognized as salient research topic. Undeniably, teachers play a pivotal role in the integration of NST in education. However, research findings indicate that teacher acknowledge their insufficient content knowledge about NST whereas several studies address that NST content learning is a critical aspect of teachers' learning. Research findings indicate that In order to help teachers to increase their understanding of fundamental NST concepts, they have to engage in appropriate learning environments (Healy 2009; Bryan et al., 2015).

Taking into account the above considerations we have designed and implemented a NST training course in order to educate primary teachers (PTs) about concepts and phenomena at the nanoscale, among them the lotus and the gecko effect. In this paper, we examine whether the course changed PTs' knowledge concerning the two effects. The research question that guided this study was: Did PTs' explanations about the lotus and gecko effects get improved after their participation in the NST training course?

RESEARCH METHODOLOGY

The training course consisted of nine lessons. The first five lessons were structured in a way to scaffold PTs to approach the nanoscale via macro- and micro- scale. During the sixth, seventh and eighth lesson lotus and gecko effects were introduced. The content of the two effects was transformed so that it could be approached by the primary teachers. Specifically, we introduced concepts that were related to their structural and physical properties (Kim et al., 2018). The former included micro- and nano-bumps/ setae-spatulae for the lotus and gecko effect respectively. The latter (physical properties) included concepts such as superhydrophobicity, self cleaning, contact angle, surface contact area for the lotus effect and electrical force and

[5] http://bioimicryreport.blogspot.com/2014/02/lotus-leaves-inspire-self-cleaning.html

[6] https://www.powershow.com/viewfl/ff23b-ZDc1Z/Gecko_Adhesion_powerpoint_ppt_presentation

surface contact area as well for the gecko effect. In addition for both of the effects, relevant applications that had clear connections to the everyday life were introduced. For example, the lotus effect was connected to superhydrophobic and self cleaning fabrics and the gecko effect to gecko pads and sticky gloves (table 1).

The lotus effect lesson can be divided into two phases. During the first phase, primary teachers collected data by studying animations, drawings and electron micrographs and by conducting experimental activities as well in order develop understanding about the salient concepts that relate to the phenomenon. During the second phase, they created and presented to the class their own models, that represented certain aspects such as, the structure of the surface leaf in the micro- and nano- scale, the superhydrophobicity, the self cleaning property, the contact angle etc (table 1). In figure 3, a group of teachers using a protractor measures on a printed image the contact angle between the water droplet and a wooden surface in order to clarify whether the surface is hydrophobic or hydrophilic. Figure 4 associates with the second phase of the lotus effect lesson. A group of teachers builds a concrete model using everyday materials, such as wooden sticks, egg cartons etc.

Table 1: The content and the activities that were conducted by the PTs during the lotus and gecko effect lessons.

The lotus effect lesson		
Lessons	Content	Activites
Lesson 6 -7	● Structure of the surface leaf in the micro- and nano- scale ● Superhydrophobicity ● Self cleaning property ● Contact angle ●Surface contact area ● Applications in everyday life	● Collecting data studying animations, drawings, electron micrographs & experimental activities ● Discussion ● Models Creation & Presentation: Suggest their own models in order to represent aspects of the lotus effect
The gecko effect lssson		
Lesson 8	● Structure of the gecko feet in the micro- and nano-scale ● How the gecko can adhere to a ceiling ● Applications in everyday life ● Surface contact area between surfaces	● Collecting data studying animations, drawings & electron micrographs ● Discussion ● Demonstration to the PTs of a model (Figure 7)

The gecko effect lesson consisted of two phases also. In the first phase, teachers collected information about the effect studying animations, drawings and electron micrographs (Figure 5). Then the whole discussed about the structure of the gecko feet in the micro- and the nano-scale, the mechanism that the gecko lizard exploits in order to adhere to the ceiling and about related applications in everyday life. In the second phase, the educator demonstrated a concrete model in order to represent the importance of the gecko foot structure in the maximization of the surface contact area between the foot and the ceiling (Figure 6).

Figure 3. A teacher measures the contact angle of the surface and the droplet.

Figure 4. A group of PTs create a model to represent the lotus effect.

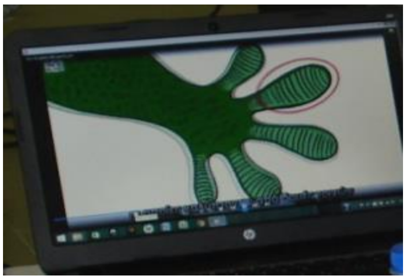

Figure 5. A snapshot of a video that PTs studied in order to collect data about the gecko effect.

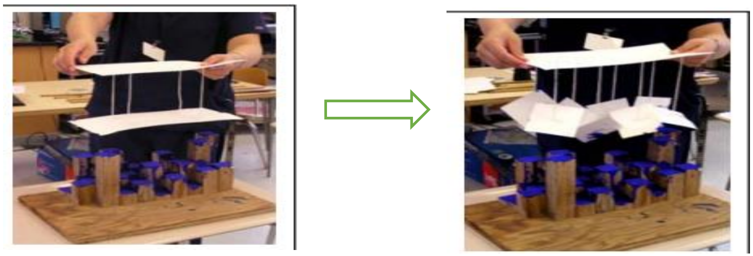

Figure 6. The model that was demonstrated in order PTs to develop understanding about the importance of the surface contact area to the adhesion of the gecko lizard to ceilings.

A total of 13 PTs (9 female) of several primary schools of Northern Greece participated in the training course. The years of teaching experience ranged from 6 to 21 years with a mean of 15 years.

A pre-post written questionnaire consisting of 7 items was created in order to assess primary teachers' NST knowledge. In this study, we present the first results from the two items that corresponded to the lotus and gecko and effect respectively. (i) Explain by using your own words and/or by a drawing *the spherical shape of a water droplet that rests on the leaf surface,* (ii) Explain by using your own words and/or by a drawing *the ability of the lizard to "stick" to surfaces even if upside down.* We consider that these two items can serve as a means for examining PTs' learning about key learning goals of the lotus and gecko effects' units: PTs to understand the superhydrophobic and strong adhesion property of the lotus and the gecko effects respectively and to appreciate the importance of the micro- and nano-scale in the determination of the two properties.

PTs' written responses were analyzed using the content analysis method. Specifically, within the participants' responses, significant words or phrases that provided a coherent explanation about the two effects were highlighted (Flick, 2009).

RESULTS

The table below depicts the words or phrases that were included in PTs' explanations concerning the lotus effect before and after the implementation.

Table 2. Terms that PTs expressed before and after the implementation in order to explain the lotus effect.

Explanation	PRE (terms)		POST (terms)	
Surface	Smooth, soft surface	7	Terms associated with the structure of the surface leaf in the micro- and nano- scale (micro- & nano-bumps)	6
	Hair-like structure	1		
Phenomena			Terms related with hydrophobicity	6
			Surface contact area	3
			Contact angle	1
Forces	Forces	3	Terms related with Forces	1
	No explanation	2	Vague terms about the structure	1

It is evident that PTs at the beginning of the training, expressed mostly perception-based explanations, such as the leaf has a soft or a smooth surface, while 4 of them attributed the spherical shape of the droplet to hair-like structure or to forces between the droplet and the leaf, without specifying the nature or the origin of these forces. After the training, PTs expressed their interpretation in much richer form, including several notions of the scientific knowledge, referring (for example) to the structure of the leaf in the micro- and the nano-scale and the superhydrophobic wetting state. As far as the drawings that PTs provided, either they did not draw any aspect of their explanation, either they provided vague drawings (Figure 7 left part). After the implementation, PTs draw exclusively the structural characteristics of the leaf at the micro- and nano-scale, fact that demonstrates explanations that are far from the sensory perception (Figure 7 right part).

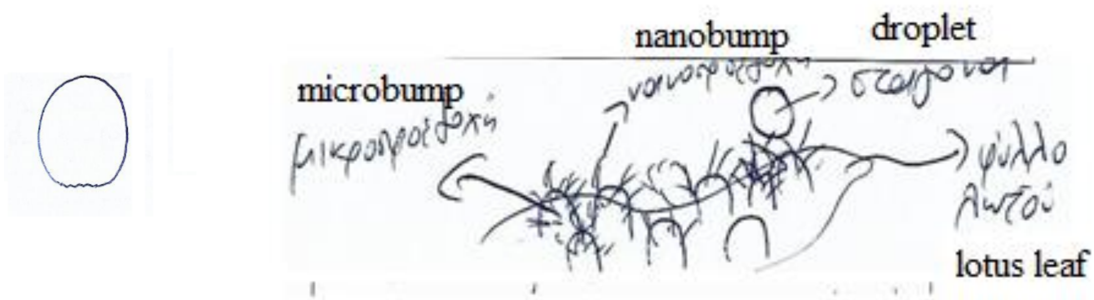

Figure 7: Representative drawings PTs provided in order to represent the lotus effect before (left) and after (right) the implementation.

Concerning the gecko effect at the beginning the highest concentration of PTs' explanations included adhesion mechanisms influenced by systems that are used in our daily life to hang objects, such as suction cups, claws and glue (Table 3 left part). After the training, PTs departed from intuitive-type of reasoning, and similar to the "lotus-effect" case, they expressed interpretations in much richer form, including several elements of scientific knowledge. For example, they referred explicitly to the structure of the toe at the micro- and the nano- scale and to the surface contact area (Table 3, right part). Furthermore, 4 PTs attributed the gecko adhesion to electrical forces, whereas 3 PTs characterized them as “attractive”.

Table 3. Terms that PTs expressed before and after the implementation in order to explain the gecko effect.

Interpretation	PRE (terms)		POST (terms)	
Intuitive	Claws, suction cups, glue	16		
Surface	Rough wall surface	3	Terms regarding the structure in the micro- and nano- scale (seate-spatulae)	11
			Surface contact area	8
Forces	Forces	1	Electrical forces	4
			Attractive forces	3
	No explanation	2		

In Figure 8, a representative drawing that was created by a PT in order to explain the adhesion property of the gecko lizard is presented. The drawing in the left part depicts suction cups on the gecko toe. In the left part, the same PT drew the structure in the micro- and the nano- scale.

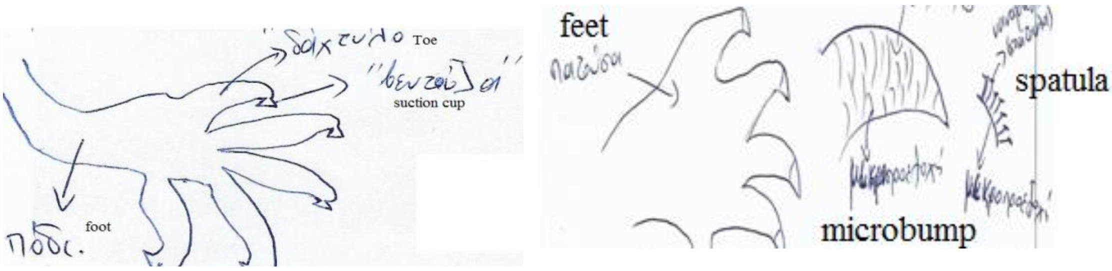

Figure 8. Representative drawing PTs provided in order to represent the gecko effect before (left) and after (right) the implementation.

DISCUSSION

Concluding, the focus of this study was to investigate primary teachers’ learning on lotus and gecko effects after their participation in a NST training course. It consists of a preliminary analysis, which aims to highlight the terms that PTs used in order to explain the two effects before and after their participation in a NST training course. Until now, little has yet been published about teachers’ learning on NST concepts and phenomena, and we anticipate that this research to contribute to this missing.

Our findings indicate that for both of the effects there was a shift from perception- or daily experience – based explanations to more informed ones, relevant with nano-related vocabulary. We consider this as an encouraging finding that shows that PTs’ explanations actually got improved after the instruction.

For both of the effects, primary teachers seem to meet no difficulties to acknowledge the structural aspects, since they used relevant terms. However, concepts related to physical properties (surface contact area, contact area, electrical forces) aspect were more underestimated. This finding indicates that PTs met some difficulties to explain how the structural properties affect the behavior of the effects. Similar results are obtained from the related literature (e.g. Bryan et al.2012; Sockman et al. 2012)..

In particular, the difficulties regarding the role of the structure to minimize/maximize the surface contact area (lotus and gecko effect respectively) were less for the case of the gecko effect explanation (table 2 and 3 right part). This finding suggest that appropriate model-based inquiry activities, such as the demonstration via a concrete model regarding the increase of the surface contact area that occurs in the gecko effect may foster effective understanding (figure 6). Of course, a further research is needed to support this view.

In addition, for the gecko effect case, aspects regarding the type of forces that act upon the gecko lizard were less reported. This finding suggests the need to support PTs to develop understanding specifically about this aspect of the effect.

PRIMARY SCHOOL TEACHERS EXPERIENCE OF THE DIGITALIZATION OF TEACHING

Pernilla Josefsson, Clara Eisenhow
Department of natural science, technology and environmental studies, Södertörn University, Huddinge, Sweden

The aim of this study is to understand primary school teachers' experience of the ongoing process of digitalization of teaching. The study is done in a Swedish context and includes eight interviews with teachers from six different municipal schools. The results showed that the teachers were positive toward integration of technology and that some of the teachers experienced an increased use of digital teaching, which is in line with the recently revised school curriculum. However, they reveal a lack of prerequisites for digital teaching that can hinder the goals to be fully achieved; these are of both internal and external character and emphasizing, among others, the need to increase the elements of digital teaching in the teacher education programs, as well as offer competence development courses for active teachers.

Keywords: ICT enhanced teaching and learning, Primary school, Educational reform

INTRODUCTION

Discussions about digitalization and the school system have been on the agenda in the Swedish context for a while now. As a result of these discussions the government presented a national digitalization strategy which included an update of the school curriculum, taking effect from July 1, 2018 (The Swedish ministry of education and research, 2018). The overarching goal with the strategy is to position Swedish schools in the lead when it comes to capitalizing on opportunities for digitization. This means to use "the possibilities of digitization in the best way to achieve a high digital competence among children and pupils and to promote knowledge development and equivalence." (The Swedish ministry of education and research, 2017, p. 4). The introduction of digital teaching in the curriculum presents new challenges for the schools. Above all, using digital technology has gone from being a voluntary teaching method to be a compulsory component in all activities. For example, it means that all schools have to acquire materials to meet the requirements and that all the staff at Swedish primary schools have been commissioned to implement digital tools in their teaching. It also states that it is the principal's responsibility to follow up the school's results and to ensure that teachers receive the skills training required to reach the national goals, including learning from each other and conducting a discussion to develop the education. As the revised regulation of the curriculum was only recently presented, the process of change and adaptation is in its initial phase.

By turning our attention to teachers at six different municipal schools in Sweden, we wanted to understand more where in the digitalization process the schools are, as well as how teachers initially relate to digitalized teaching.

THEORETICAL FRAMEWORK

The main purpose with the introduction of digital tools in schools is to raise students' performance. But in order for this to happen, the technology needs to be used in a way that makes learning more efficient. According to Blackwell et al (2013), researchers disagree on the positive effect of digital education and this in turn affects teachers' use in their teaching. Hylén (2013) explains that the disagreement may be due to the fact that technology use in the school has been too scarce for studies to prove positive results. Furthermore, Hylén says that since many schools introduced one computer per student, the positive results have increased. The introduction of digital education will not provide improved results immediately and Hylén emphasizes that when new technology is presented, it may take years before the positive development begins to take shape. This is affected by other issues such as, for example, the technology, service agreements, licenses, competence development and more. According to this author, studies indicate that the importance of school management taking an active role in the transformation is great and therefore it is important that teachers and school leaders discuss together how the new working methods should be adapted to the new situation.

Drivers and barriers for ICT implementation

Several important factors for how the teachers implement and use technology in education have been discovered in earlier research. Drossel et al. (2017) emphasize factors such as the degree of collaboration between colleagues, the teachers' self-confidence in the use of digital tools, and the teachers' attitudes towards the use of technologies in education. They further suggest that understanding the teachers' attitudes towards information and communications technology (ICT) is important for a successful implementation of digital tools aimed at improving student results. In other words, the teachers are key figures in the implementation process. This view is also reported by Hylén (2013) who argues for competence development among teachers as necessary to impact their attitudes, and by Tallvid (2014) who emphasizes that teachers are the ones that need to realize the objective, even when the initiatives most often come from school leaders or policymakers. Perrotta (2013) argues that there is a clear connection between teachers' perception of school management's support in technology education and their perception of usability. Also, the school culture affects teachers' experiences and expectations of the use of technology, perhaps even more than what the teacher's personal qualities, such as age, gender and teacher experience, do. The same finding was done by Li et al. (2018), showing that teachers' professional competency and perception of benefits on use of ICT are significant factors affecting the actual use in student-centered education; teacher cooperation is affecting teachers' perceptions on use of digital contents for student-centered education; and endogenous teacher level factors such as teacher's job satisfaction and self-confidence are affecting teachers' perception on the use of ICT for student-centered education.

Just as research has demonstrated several important factors for successful implementation, a number of barriers that teachers encountered when integrating technology in the curricula have also been found. Ertmer (1999) sorted these barriers into first-order barriers and second-order barriers. First-order barriers refer to the barriers which are external to teachers such as lack of access to hardware and lack of support. Second-order barriers are internal to teachers, such as the teacher competence and willingness. Ertmer highlighted that if teachers were to become "effective users of technology, they will need practical strategies for dealing with the different types of barriers they will face."

METHOD

This study was conducted during the winter of 2018 at six different municipal schools in Stockholm County, Sweden. Our initial step to reach out to the schools were to contact the principal at each school with a request for primary school teachers whom to talk with. All together eight semi-structured interviews were conducted, respectively with five female, and three male teachers. Each interview lasted for approximately 30 minutes and were recorded and annotated. The interview consisted of seven main questions, each of them followed by sub-questions and asked the teachers, among other things, to answer questions that related to their view on digital competence, the introduction of digitalization in the curriculum at their specific school, and to give examples of perceived challenges with the implementation of digitalization. The recording was approved by the respondents by signing an interview agreement. In the case teachers could not be available for a face-to-face interview, we also prepared to conduct telephone interviews. This happened for half of the interviews.

The teachers' work experience ranged between 6 months and 32 years, and all were involved in teaching several different subjects (such as English, Swedish, social science, mathematics, and science). Teacher 7 (T7) had only six months experience and could thus not reflect about the time preceding the curriculum revision. For further information see Table 1.

Table 1. Participants in the study. Last column shows the tools the teachers have access to and the school's strategy of for instance a 1:1 relationship between number of computers and students.

Teacher	Gender	Age (years)	Teaching experience (years)	Interview	Digital tools and profile
T1	Female	30	7	Telephone	iPad, 1:1
T2	Female	55	18	Telephone	Desktop computer, 1:1
T3	Female	54	32	Face-to-face	iPad, 1:2
T4	Female	38	6	Face-to-face	iPad, Bee bots
T5	Male	39	7	Face-to-face	Desktop computer, 1:1
T6	Male	30	2	Face-to-face	iPad
T7	Male	25	<1	Telephone	iPad
T8	Female	31	7	Telephone	iPad

FINDINGS

In the following section the teacher's views are presented. First, we account for the teacher´s attitudes, then how they relate to the term digital competence. This is followed by their view of their own opportunities for educational development. Then we identify their experienced barriers towards digital teaching. The section ends with a summary of the teachers' reflections on their own digital teaching.

Teachers´ attitudes

All the teachers in this study showed an interest in digitalization of teaching. However, this result might have been affected by the selection process. One might expect that the teachers who showed interest in participating in a study about digitalization in teaching, also have a higher interest in general of the subject.

Digital competence

The way digital competence was understood among respondents could be described as multifaceted given the various perspectives presented during the interviews. While some teachers explained digital competence as knowledge of handling digital tools, other participants formulated themselves using words to describe the ability of understanding how digitalization affect students´ everyday life. For example, T5 explained digital competence to be "that students can deal with a computer, be able to communicate, use a computer when writing, use a search engine, be source critical.".

The most common way to motivate the presence of digital tools was by arguing that schools need to keep up with the society. An example is T4 who explained that the reason for it to be important is that the schools need to keep up with the surrounding society and that digitalization is part of this work. In addition, T8 also expressed digitalization as a way of "following reality".

Background in digital teaching

The teachers generally lacked formal education in how digital tools can be used. They viewed the lack of training as negative, pointing towards that they are expected to keep up with the technological developments but are not offered strategies to handle this. However, the fact that six out of eight teachers responded that their teacher education did not include any course on digital competence was excepted as several of them had worked as teachers for many years. Only two of the teachers had worked less than six years, and in both these cases ICT had been included in their training. However, both these teachers regarded this insufficient as they did not consider the courses to be adequate as they were only introduced to digital tools and were not taught in what and how digital tools should be used in practice. One of the teachers had only used digital tools it in connection with science subjects, thus lacking knowledge on how to use digital tools in other subjects.

All, except for one teacher, had been offered voluntary courses on digital tools by their employer. The courses have been given in various forms, from courses lead by a colleague at the school to courses outside the workplace during afternoons. Despite this, seven of the teachers brought up that the courses only go on for a limited time and then they experience a lack of continuity.

Only one teacher, T1, had a work situation that differed considerably. T1 was part of an IT group at the school, which works actively with digitalization issues. However, there is no reduction in time or compensation for the extra work, resulting in that T1 was not entirely satisfied with the support from the management side.

Perceived barriers – access and time

Even though most of the teachers in this study were employed at schools where digital tools such as smartboards, bee-bots, computers and tablets have been around for a long time, they all agreed that the implementation of teaching using such tools was still problematic. Two main reasons, were mentioned, namely access and time, and both of these were beyond their influence and control.

Regarding access to technology, teachers from two of the six schools stated that they do lack digital tools that facilitate digital teaching. To solve the lack of technology, in a school task where students were to make stop-motion movies, T4, who only had one iPad to share among 30 pupils, confessed that she lets the students borrow her own mobile phone. The reason was that she felt she had no other option. Another implication mentioned by T6 was the access to educational software. As the school had a business agreement and rented tablet computers all teachers had to go through the external company in order to install and download applications.

Regarding time allocated to teaching with technology, all eight teachers said that there is a widespread interest among colleagues and themselves to use technologies, however the time to develop their competence does not exist. And so far, none of the participants had been given time to develop their digital skills. Rather, it has been introduced as an addition to the tasks that teachers already have. This can, according to the respondents, in turn inhibit the teachers who need support in their planning of digital teaching.

Reflections on their own digital teaching

The teachers were asked to estimate the amount of their own use of digital tools along a 10 graded scale and to compare their use today with their use the previous school year (T7 had only been employed for six months and could therefore not make the comparison). Four of the teachers estimated their use to be higher today, one had not changed, and two estimated their use to be lower today than last year. In total, only a small increase in use of digital tools can be seen after the point where the new requirements took effect.

When the teachers were asked about the positive side of the use of digital tools, six of them mentioned that digital tools increase the motivation of students and makes it easier to obtain commitment in the classroom. One specific example mentioned by T7 was how they in geography class used the three-dimensional map provided by Google. The map, which makes it possible to rotate and view a point of interest from different angles had resulted in less confusion among the students and that he as a teacher spends less time on explanations. T5 provided an example from math class and emphasized how the use of digital tools had improved the students understanding of math. T1 highlighted that the use of digital tools had made it easier for teachers to work with different subjects simultaneously. Both T1 and T4 mentioned the possibility for students to create their own material, and T2 and T5 emphasized increased collaboration in the classroom as students helped each other. Digital tools were also described in positive terms by T2 who explained that students engaged themselves with digital tools in anticipation of help from the teacher. Similar situations were described by T1 and T3, as both stated that students used the tools to look for information while waiting for the teacher to arrive. Furthermore, the teachers reported on advantages with digitalization of teaching in terms of easier administration tasks such as that student assessment had become smoother (T5), it was easier for the teachers to take contact with students after school hours via e-mail (T4, T5), and it was easier to share documents (T4, T5).

Although much of what was mentioned during the individual interviews were similar opinions, there were also things that differed. One such difference was whether the use of digital tools affects students' written language: T6 emphasized that digital tools helped students in their writing development by providing the opportunity for the student to concentrate on the content of the story, such as developing the action of the story. T5 experienced that the students´ written language had approached the speech language when they write. The reason to this, as understood by T5, was that the students read shorter texts online than they would do on paper.

DISCUSSIONS AND CONCLUSIONS

The results showed that the teachers were positive towards the integration of digital teaching in the curriculum, and they also showed a positive attitude towards using it in their own teacher practice. However, the teachers experienced both external and internal barriers to the integration, such as lack of time (external), lack of technology (external) and lack of knowledge (internal).

Since digital education now is a requirement in Swedish primary schools, teachers must be given the opportunity to work towards more digitized education. This emphasizes the need to implement courses or increase the elements of digital teaching in the teacher education programs, as well as offer competence development courses for active teachers. Another suggestion, based on the results from this study, is to find means for having continuous meetings with colleagues, which has been pointed out as an important factor for personal development. This is also in line with the changes in the school curriculum pointing towards the principal's responsibility to ensure that teachers receive the skills training required (The Swedish ministry of education and research, 2017). Having access to further education should also be seen as an opportunity for the teachers to develop their own strategies to deal with the different types of barriers they will come across (Ertmer, 1999)

This study has contributed to understanding the factors affecting Swedish primary school teachers' perception on digital teaching after the implementation in the school curriculum. Although untried, the authors expect that the findings may have a wider validity as many countries now face similar challenges.

ACKNOWLEDGEMENT

We would like to thank the Teacher education and the Department of Media Technology at Södertörn University for financing attendance at ESERA.

BRINGING BIOINFORMATICS TO SECONDARY EDUCATION: A WORKSHOP FOR SCIENCE TEACHERS

Ana Martins[1,2], Leonor Lencastre[3] and Fernando Tavares[1,2]

[1]FCUP, Faculdade de Ciências, Departamento de Biologia, Universidade do Porto, Porto, Portugal

Having in mind the technological world we live in, scaffolding teachers to integrate computer-based resources in their classes is an important endeavour when it comes to teacher professional development. In this context, a workshop on bioinformatics to address gene regulation, molecular biology and genomics in high school gathered a group of 18 high-school science teachers. Following the workshop, the participants answered a questionnaire aiming to diagnose teachers' perceptions about bioinformatics; to identify the main constrains that are preventing teachers from successfully implementing bioinformatics in their classes; and to evaluate the potential to integrate basic bioinformatics exercises in their educational practices. Data were subjected to descriptive statistics and to content analysis. The results showed that the teachers attending the workshop were highly motivated and interested in learning more about bioinformatics and about strategies to integrate bioinformatics in their classes. Despite teachers highlighted the adequacy of bioinformatics to the educational context, most of them mentioned that their academic background was not sufficient to confidently implement bioinformatics-based exercises in their classes. Teachers claimed for more training courses in this area and approximately half of the participants admitted that schools are equipped with the necessary resources to integrate bioinformatics. Overall, this study emphasizes the importance to foster more initiatives to integrate bioinformatics in secondary education curriculum and highlights the need to increase the offer of teachers' training on bioinformatics.

Keywords: Computer Based Learning, Teacher Professional Development, Technology in Education and Training

INTRODUCTION

Despite technology is now acknowledged as a helpful tool for teaching and learning science, many science teachers got their academic qualifications for teaching at a time in which technology, namely computers, were rarely used or inaccessible for most of the people. It is therefore with no surprise that in-service teachers feel uncomfortable or not motivated to use computers in their classrooms, being urgent to scaffold teachers to develop their Technological Pedagogical Content Knowledge (TPACK) (Koehler & Mishra, 2009; Mumtaz, 2000).

Having this need in mind, professional development programs for science teachers should focus on helping them to integrate the use of the technology in the teaching practices. An opportunity to integrate computers and digital resources as a didactic tool based on real research procedures is to approach genomics and molecular biology based-on bioinformatics tools (Chiovitti et al., 2019; Gelbart & Yarden, 2006; Martins, Fonseca, & Tavares, 2018; Nunes, Júnior, Menezes, & Malafaia, 2015). Despite genomics being one of the most important revolutions of late 20th century and at the beginning of this century, the lack of literacy on genomics and molecular biology in the general population is reported in several studies (Eklund, Rogat, Alozie, & Krajcik, 2007; Kirkpatrick, Orvis, & Pittendrigh, 2002; Kolarova, 2011; Lock, 1996; Tarver, 2010). While an effort is being made to integrate bioinformatics in high-school science curricula in different countries, it is unquestionable that more teacher's training opportunities in bioinformatics is needed (Attwood, Blackford, Brazas, Davies, & Schneider, 2017; Kovarik et al., 2013; Machluf, Gelbart, Ben-Dor, & Yarden, 2017; Marques et al., 2014).

In this context, the workshop "*From DNA to Genes and to Comparative Genomics: Bioinformatics in the classroom*" was aimed to instruct science teachers about the suitability of bioinformatics activities to their teaching practices. Teachers were challenged to explore bioinformatics-based exercises particularly chosen to teach basic molecular biology concepts, to address gene regulation and to discover the usefulness of comparative genomics (Martins, Fonseca, & Tavares, 2018). This training workshop on bioinformatics allowed to boost teachers' TPACK, since teachers developed their technological knowledge by learning how to use bioinformatics tools and, concomitantly, they enlarged their pedagogical and content knowledge, by discussing new strategies to teach curricular contents and additionally introduce key concepts in genomics such as Open Reading Frame (ORF) or Basic Local Alignment Tool (BLAST) (Martins & Tavares, 2018). The workshop was promoted in the context of an international meeting for teachers (Casa das Ciências, 2018) that occurred in Portugal in 2018.

OBJECTIVES

The main objectives of this study were to diagnose teachers' perceptions about bioinformatics; to infer the potential of its integration in educational practices; and to identify the main constrains that are preventing teachers to successfully implement bioinformatics in their classes.

RESEARCH QUESTIONS

This study was driven by two main research questions: "*Which are the teachers' perceptions about bioinformatics and its integration in science teaching practices*?" and "*Which are the main constrains that are preventing teachers from integrating bioinformatics in their teaching practices*?"

METHODS

Participants

The sample included 18 science teachers (14 female and 4 male) from 14 different schools that voluntarily enrolled at the workshop. Seven of the 18 teachers hold a master's degree. Participants have an average of 26.61± 7.48 years of teaching experience. Between 2016 and 2018, 4 teachers taught at elementary school level (students between 12-15-year-old), 6 taught at secondary school level (students between 16-18 years old) and 8 taught both elementary and secondary school levels.

Materials

Framed within the curriculum for biology in secondary education (Council, 2013), the four hours workshop "*From DNA to Genes and to Comparative Genomics: Bioinformatics in the classroom*" drives teachers to explore the potential of bioinformatics as a didactic tool to approach contents, such as the organization and regulation of genetic material, and to carry out evolutionary inferences. From an *in silico* analysis of a DNA sequence it is proposed to identify genes and to determine the putative functions of their products. Additionally, using comparative genomics platforms such as *MaGe – Magnifying Genomes* (MicroScope), the participants were challenged to evaluate the presence of certain genes in different taxonomic groups aiming to infer evolutionary relations. This activity contributes to a holistic approach to genomics, genes and proteins, as well as to propose evolutionary hypotheses (Martins, Fonseca & Tavares, 2018). Each teacher was asked to bring their personal computers to carry out the exercises.

To diagnose teachers' perceptions about bioinformatics and its integration in science teaching practices as well as to identify the main constrains that are preventing teachers from integrating bioinformatics in their classes, a specifically designed questionnaire, adapted from the survey previously described by Martins, Lencastre and Tavares (2018), was implemented. The questionnaire, including 35 questions in various formats, namely dichotomous, Likert-type (ranged from 1 to 5) and open-ended questions, and is divided into three parts: *Part A*: socio demographic data; *Part B*: assessment of teachers' training and academic background on bioinformatics, and appraisal of teachers' attitudes towards bioinformatics integration and of their perceptions regarding workshop attendance; *Part C*: teacher's opinions about the questionnaire: objectivity, comprehension of the items, and suggestions.

In Part B, questions were designed according to the objectives defined for this study. Questions 1 and 5 (Q1; Q5) were aimed to diagnose teachers' definition of bioinformatics as well as to characterize the importance of bioinformatics to the current research. The assessment of teachers' interest and perceived knowledge about bioinformatics were addressed through questions Q3, Q12.1., Q12.2. Another dimension evaluated was teachers' perspectives on the importance of integrating bioinformatics in their teaching practices as well as to identify the main obstacles to this integration. In this regard, questions Q2, Q6, Q7, Q9, Q9.1., Q9.1.1., Q10, Q11, Q12.3., Q12.4. were included in the questionnaire. Question Q8 was intended to characterize the use of technology in the classroom by teachers. Lastly, and having in mind the main findings of previous studies highlighting the importance of promoting teachers training actions in the area of bioinformatics (Machluf et al., 2017; Machluf & Yarden, 2013; Martins, Lencastre, & Tavares, 2017, 2018), questions Q4.1., Q4.2., Q12.5., Q13, Q14, Q15, Q16 and Q17 were introduced to characterize the impact of the workshop on teachers perceived knowledge about bioinformatics as well as to evaluate the workshop, identifying the potential of the action but also having feedback on possible improvements.

Teachers rated the questionnaire as an objective instrument (4.76±0.44) and easy to understand (4.76±0.44). One participant added the following suggestion for improvement: "*In question 12.4., you should specify if the classes are lectures or if they are practical classes of biology* *including wet lab and experiments*". This suggestion will be taken into consideration in future questionnaires.

Data Collection and Analyses

The questionnaire was implemented after the attendance of the workshop, i.e. when participants finished the proposed exercises. The aims of the research as well as the objectives of the questionnaire were explained to teachers who voluntarily agreed to answer the survey. Descriptive statistical analysis was performed for quantitative data (Punch, 2009). For qualitative data, a thematic content analysis of the participants' responses to open-ended questions was carried out (Roberts, 2015; Schuster & Weber, 2006).

RESULTS AND DISCUSSION

Teachers' background on bioinformatics

The majority of the teachers (94.44%) correctly defined bioinformatics (Q1), and one teacher mentioned that bioinformatics is "*a didactic tool for science classes*". Among all listed notions (49), teachers mentioned frequently the following: informatics (12.62%), biology (8.74%), data (6.8%), tools (6.8%) and applications (4.85%). This analysis revealed that teachers recognized the scope of bioinformatics as the scientific field which develops or uses tools and applications of informatics to understand the biological data, which fits well with a general definition of bioinformatics (Luscombe, Greenbaum, & Gerstein, 2001; Sadek, 2004).

Teachers revealed to be interested in bioinformatics (Q3) and recognized its importance for scientific advances (Q5) (Figure 1). However, teachers considered that their academic background is not sufficient to feel prepared to teach using bioinformatics tools (Q12.1.) and highlighted the added-value of professional training (in-service) (Q12.2.) to implement bioinformatics activities in their classes (Figure 1). These results are in line with the literature (Machluf, Gelbart, & Yarden, 2012; Machluf & Yarden, 2013; Martins, Lencastre & Tavares, 2018; Wood & Gebhardt, 2013) and reinforce the importance of promoting initiatives of professional development oriented for bioinformatics training.

Attitudes towards bioinformatics integration

The importance of integrating bioinformatics in elementary (Q6) and secondary education (Q7) was highlighted by the participants (Figure 1), as well as the potential to use bioinformatics both at Biology classes and Information and Communications Technology (ICT) classes (Q2), mentioned by 77.78% of the teachers. It is acknowledged that bioinformatics-based activities foster students' hybrid abilities in computation and biology, nurturing a wide range of skills such as using bioinformatics to find, retrieve and organize data by identifying an appropriate data repository, to understand evolutionary related processes or to develop their critical thinking namely in which concerns open data access (Foster & Sharp, 2007; Mariano, Martins, Santos, & Minardi, 2019; Oliver et al., 2012; Sayres et al., 2018).

The majority of teachers (94.44%) assumed to use computers to explore online resources in their classes (Q8), but only 5 out of 18 (27.78%) revealed to have autonomously explored bioinformatics resources in order to implement them in their classes (Q9). Among the teachers who had previously explored bioinformatics resources, 3 out of 5 (60%) actually implemented the activities in their classes (Q9.1.). The two teachers who did not (40%), listed as the main reasons "*Lack of computers available*" and "*The need to better understand the explored bioinformatics tools". However, their intention is "to apply the activities in the classroom soon*" (Q9.1.1.).

Around half of the participants (55.56%) considered that the school/institutions where they were teaching have the necessary conditions to integrate bioinformatics-based activities in their classes (Q11), which is in agreement with recent reports indicating that most schools in Europe are equipped with technological devices (European Comission, 2013). In contrast with this result, the main constrains identified by teachers to carry out the implementation of bioinformatics activities in the classroom (Q10) were: computers (7.87%) and internet (6.74%). Only 2 out of 18 teachers (11.11%) revealed positives attitudes regarding the possible constrains that can arise when implementing bioinformatics in their classroom mentioning that "*cannot identify any constrains. The school has the necessary resources (…) and students are motivated*" and "*the management of the time is possible especially in the 11th grade*". 66.67% of the participants indicated that the main constrains to implement bioinformatics-based activities in their classrooms were related with logistics aspects (resources and time) answering that "*computers are lacking in schools*"; "*the number of students per class is too high*"; "*the internet connection is weak*"; and "*bioinformatics resources are not in Portuguese*". Teachers mentioned that schools are well prepared to carry out bioinformatics exercises, however logistics aspects were mentioned as the main hinder to not apply these tools in the classrooms. This result stresses the importance to better characterize schools' reality in which concerns technology use.

16.67% of the participants identified both logistic constrains and lack of teacher's confidence as the main difficulties to implement the proposed approached in the classroom. Teachers emphasized their lack of confidence to approach some curricular topics using bioinformatics resources and highlighted their need to acquire specific training, which is corroborated by other studies (Cebesoy & Oztekin, 2018; Machluf & Yarden, 2013; Martins, Lencastre & Tavares, 2018). One teacher (5.56%) mentioned that "*The complexity of some processes and their interpretation by the students requires strong orientation and motivation, which should be taken into account when organizing the activity.*" This perspective was included in category: Constrains related with the student's performance.

Furthermore, the data showed that teachers considered that planning and implementing bioinformatics-based activities is more time-consuming and requires more resources than other activities (Q12.3.; Q12.4.) (Figure 1). These notions can be related with the lack of opportunities for teachers' training in bioinformatics. Training is crucial for teachers to feel more acquainted with bioinformatics tools and to clarify that planning and implementing bioinformatics-based activities can be framed within the time schedule for a class (90 minutes) as described by Martins, Fonseca and Tavares (2018). Another reason that can explain this result is the absence of didactic bioinformatics resources in Portuguese. In fact, the idiom of the majority of the platforms and of the exercises available is English which was previously reported as a barrier to non-English speakers (Machluf & Yarden, 2013; Martins, Lencastre & Tavares, 2017, 2018). This result highlights the importance of creating a portfolio of bioinformatics-based activities, in this case adapted to Portuguese, and making it available for the educational community in other to emphasize the adequacy of integrating bioinformatics in educational approaches.

Perceptions regarding workshop attendance

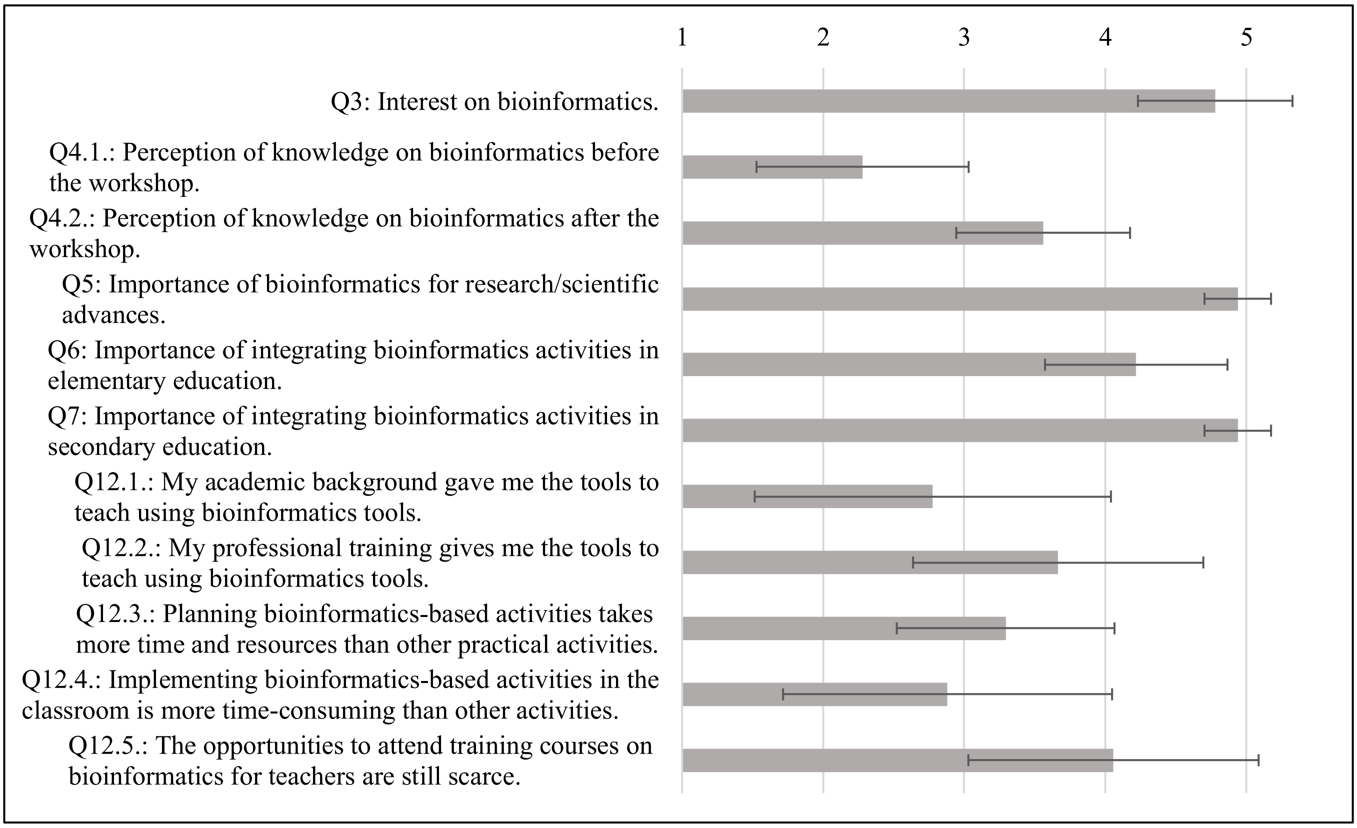
A careful analysis of teachers training on bioinformatics was carried out having in consideration the previous results reported by Martins, Lencastre & Tavares (2017, 2018), by Machluf et al. (2012, 2013) and by Marques et el. (2014). Despite the interest of all the participants in attending training courses on bioinformatics for teachers (Q16), it was mentioned that the availability of these courses is still very scarce (Q12.5.) (Figure 1). In fact, the importance of adequate teachers training in this scientific field, is further supported by the higher perception teachers have about their knowledge in bioinformatics after attending the workshop (Q4.2.), in comparison with that perception before the workshop (Q4.1.) (Figure 1).

Regarding the workshop itself, teachers were asked about the reasons that motivate them to attend this workshop and to choose this workshop among others (Q13). They were asked to list the main difficulties found when they were performing the workshop activities (Q14) and suggestions were collected in how to improve the workshop (Q15).

The 18 participants listed the main reasons that motivated them to attend the workshop (Q13). By carrying out an analysis of the five most frequent words mentioned, it was possible to list: class (6.84%); application (5.98%); classroom (5.13%); learn (4.27%); and utilization (4.27%). This general analysis suggests that teachers wish to learn how to apply and how to use the bioinformatics tools in their classes. Adding to this analysis, it was possible to identify three main categories of answers. "*To learn to apply*" – was mentioned by three participants (16.67%). These participants revealed that they chose this workshop in order to learn "*how to implement the tools of these area*" in their classrooms. Six out of the 18 participants (33.33%) highlighted as the main reason to attend this workshop "*Curiosity*". Teachers justified their attendance as an opportunity to learn more about bioinformatics, by curiosity and because they were "*interested in related topics such as genetics and all the fields that are related with DNA*". This result reinforces teachers' interest in this scientific topic. The third category is particularly important in the context of this study: "*The need of updating*". Mentioned by 9 participants (50.00%), this category included answers such as "*I felt the need of learning about this area* (…) *and to explore bioinformatics in a scientific and right perspective*" or "*I urgently need to improve my skills* (…) *to follow the quick development of these applications* (…) *and to implement them with my classes*". This result is in line with the considerations about the urgency of training courses reported above. Teachers are interest in this scientific area and the adequacy of the proposals to the schools is recognized, although they do not feel prepared to proceed with the implementation of the tools without previous specialized training (Machluf & Yarden, 2013; Martins, Lencastre & Tavares, 2018; Shuster, Claussen, Locke, & Glazewski, 2016; Wood & Gebhardt, 2013).

In which concerns with the main difficulties found by the participants while performing the activities of the workshop (Q14), three categories of answers were defined. 50.00% of the participants (9 out of 18) listed as the main difficulties' technical aspects such as internet access, and the lack of time or difficulties to read the paper version of the guidelines. In fact, these constrains were related with the organization of the workshop itself and not with difficulties related with the bioinformatics-based activities performed. However, the internet connection was fixed even during the workshop and the digital version of the guidelines was sent by email to the participants. In this regard, we can assume that the logistic constrains were solved and the workshop work-flow was not affected. Two out of 18 participants (11.11%) revealed to have difficulties in interpreting "*aspects associated with gene sequences/nucleotides*" and to "*understand the steps to follow*". In contrast with these results, 38.89% (7 out of 18) reported no difficulties and one teacher did not answer this question.

Figure 1. Answers given by participants according to a Likert Scale (Range 1 to 5). Grey bars represent the mean value and the error bars refer to the standard deviation.



Finally, suggestions for workshop improvement were asked to the participants (Q15). 44.44% of the participants did not answer this question. 33.33% of the participants listed suggestions for improvement. Essentially participants claim for: "*More exercises*"; "*I would like to attend a training course (longer) in this area, once 3 hours are not sufficient to understand all the information discussed*"; and "*to increase the font size of the text in the guidelines – paper version*". 22.22% highlighted that "*do not think that the workshop needs to be changed*".

CONCLUSION

Teachers revealed to be interested in bioinformatics and recognized its importance for scientific advances, which is in frame with the expected teachers' perceptions about bioinformatics as a scientific discipline. Teachers were open and motivated to integrate bioinformatics in their teaching practices. Regardless their will, teachers believe that key constrains have to be overcome, emphasizing the need of suitable training through dedicated courses. Thus, the main take-home message from this workshop is the urgent need of training courses for teachers in order to fuel the integration of bioinformatics in the curriculum and education daily practices. Adding to this, it is important to better understand the reasons why teachers admitted that their schools have the necessary conditions to implement bioinformatics-based approaches, but contradictorily they indicated as the main constrains to this implementation: poor internet connection and lack of computers. A reedition of the workshop occurred in July 2019 with 40 participant teachers. In this workshop, new data were collected in order to increase the robustness of this study. Adding to this, a website is under construction and will be soon available for teachers, with bioinformatics-based exercises in Portuguese in order to meet the participants request of having more available resources in their native language.

We believe that the current study is a wakeup call for educational stakeholders to boost bioinformatics educational integration aiming to meet the challenges of a society capable to understand the scientific advances and take informed decisions.

ACKNOWLEDGEMENT

The authors are grateful to all participants of this study and to Casa das Ciências (https://www.casadasciencias.org/) for the invitation to present a workshop and for creating the opportunity to perform this research. Ana Sofia Martins is supported by a fellowship from Fundação para a Ciência e Tecnologia – FCT (SFRH/BD/112038/2015).

PROFESSIONAL DEVELOPMENT FOR ICT-BASED TEACHING

Kai-Mikael Jää-Aro, Pernilla Josefsson, Sofia Lundmark, Ann Mutvei Berrez
Department of natural science, technology and environmental studies, Södertörn University, Huddinge, Sweden

Using information and communications technologies (ICT) in the classroom requires new skills on the part of educators. We have elicited current best practices for professional development of educators from the participants in this workshop, what knowledge teachers need and how it is best imparted. We found that even given their different starting points, teachers in different regions are often feeling unsure about how to use ICT in a pedagogical context, and there is no clear consensus on how to best train teachers in this use, but that the digitalisation of schools will require a long-term commitment from school management and political leadership.

Keywords: Teacher Professional Development, ICT Enhanced Teaching and Learning, Technology in Education and Training

INTRODUCTION

The increased use of information and communications technologies (ICT) in the classroom to support students' learning places new demands on teachers at all levels, from pre-school to graduate school. This in turn increases the expectations on the teachers' abilities to develop their own proficiency of using this technology: internationally, such proficiency is commonly referred to as *digital literacy*, while within the Scandinavian educational context the term *digital competence* is more common (Hanell, 2018; Ilomäki et al., 2016; Krumsvik, 2008). Digital competence refers here to a holistic perspective incorporating proficiency with pedagogical judgement and with the focus on pedagogy and subject matter. In other words, digital competence is knowledge about how digital tools affect our everyday life, and how to use digital tools to support critical thinking, creativity, and innovation.

Teachers are now required to have a working understanding of:

- hardware, in the various forms of computers, mobile phones, and electronic tablets, but possibly also peripherals such as network routers, digital projectors, and printers;
- software, from word processors and drawing programs to specialised educational software, and learning management systems;
- the limitations of computer systems, being able to critically evaluate claims of current and future functionality, the impact of social media on rumors, social unrest, and political events.

For most teachers, having these skills is not a goal in itself, but a prerequisite for developing new learning situations. Many are uncertain of how to best use digital systems for best effect on students' learning or may even be uncertain whether they are helped at all by digital systems. In many cases, there might also be a considerable learning effort required simply to start using a digital tool, and often enough, the actual use requires some skill and effort. These issues may make such tools less suitable for use in the educational situation by students, but also divert time from the actual teaching effort. The use of technology is also limited by personal factors such as teaching vision and understanding of the technology's influence on teaching (Hylén, 2013). Still, the digital competence of teachers is required and we need to find ways to develop digital skills in teacher education and in-service training to meet the goals regarding digitalisation in the curriculum. These ways should be based on the priorities of teachers, we thus need to elicit information on what knowledge teachers feel they lack and how they would prefer to address this.

Despite governmental expectations of increased digital competence among teachers, there is still much to do to assist teachers with accessing knowledge on what might enhance their practice. The purpose of this workshop was therefore to address teachers' professional development by encouraging the sharing of knowledge among teachers (Ertmer et al., 2012) and to address both local and global settings (Albion et al., 2015).

BACKGROUND AND PREVIOUS RESEARCH

Previous studies show that digital tools, defined as word processors, spreadsheet programs, drawing programs, programming environments, etc., develop creativity, problem solving and critical thinking (Albion et al., 2015). Various aspects of digitization and digital tools have therefore been integrated into the school curriculum in most countries in the Western world. According to the curriculum in for example Sweden, students are to develop an understanding of how digitalisation affects individuals and society, develop the ability to use and understand digital systems and services, relate to media and information in a critical and responsible way, and solve problems and translate ideas into action in a creative way (Skolverket, 2017). Digital tools are already used to varying degrees in primary school education, and there is a great deal of research on learning and digital tools that shows both the educational potential of digital tools (Newhouse, 2017), as well as the new challenges that teachers face when tools are to be integrated into practical teaching situations (European Schoolnet, 2017; Skolverket, 2019). In the STEM subjects, ICT has been reported to enhance engagement, motivation, and learning by stimulating inquiry-based learning, and enhance communication between students and teachers (Newhouse, 2017). In addition, it has been demonstrated that ICT lets students investigate subjects relevant to their lives and control their own learning (European Schoolnet, 2017).

In line with the previous studies, the Erasmus+ project Functional Information and Communication Technology Instruction On the Net (FICTION) investigates how science teachers in primary and secondary schools currently use digital tools in their teaching practice, how they can be supported in their choice of digital tools within their teaching practice, as well as what additional professional training they need in order to be able to use these tools. Further, the project aims to develop guidelines for what type of tools that are most useful within the teaching practice of STEM education and how to best acquire the requisite skills in using these tools. The FICTION project partners come from three countries: Södertörn University and the Ronna school from Sweden, Limerick Institute of Technology and Coláiste Mhuire Co-Ed from

Ireland, and the University of Genoa, Liceo statale Niccolò Machiavelli Firenze, and Pixel from Italy.

Initial results by the Swedish partners have shown that schools have invested in infrastructure and equipment to support ICT and the use of digital tools for teaching. However, there are still obstacles of administrative character such as scheduling, lack of time, insufficient competence development, and lack of choice on what platforms and systems to work with (Josefsson et al., 2019). Swedish public school teachers are required to use digital tools in their teaching, however there is a lack of knowledge among teachers on how to use digital tools that needs to be taken into account when promoting the use of digital tools in teaching (Josefsson et al., 2019). In line with these findings and based on previous research on digitization and digital competence (Albion et al., 2015; Ertmer et al., 2012; Hanell, 2018; Ilomäki et al., 2016; Krumsvik, 2008) the purpose of this workshop was to address teachers' professional development by encouraging the sharing of knowledge among teachers (Ertmer et al., 2012), and to address settings other than the ones involved in the FICTION project. To interpret the participants' statements and reasoning during the workshop we mainly draw on the previous research presented and the initial findings from the FICTION project.

DESIGN OF THE WORKSHOP

The workshop started with a ten-minute presentation of the organisers and the FICTION project by the moderator. The introduction was followed by an outline of the questions to be addressed during the workshop and why these were of interest to discuss.

The participants were divided into three groups and were asked to discuss the following issues during the workshop:

- What is the current approach to teaching digital competence in your region? What are the driving forces?
- What are your personal experiences of using digital tools in schools? What works, what does not?
- What do teachers feel they need in order to perform well?

There was in total seventeen participants, mainly teachers and researchers at university level. As such, the participants were not necessarily directly involved in teaching at a primary or secondary school level, but had an interest in the questions that the workshop concerned. The workshop participants were associated with universities in Australia, Finland, Germany, Japan, South Africa, Spain, and Sweden.

The discussion lasted for one hour and during that time the two attending organisers circulated among the groups and took part and notes in the discussions. Any errors in our notes are fully our responsibility.

RESULTS OF THE WORKSHOP

Our assumption, as noted in the introduction, that there is a strong need for additional training, in particular for in-service teachers, was confirmed by the participants. Not only was training in the technology itself perceived as important, but also time to practice using it and working out how to best fit it into everyday teaching practices. The benefits for the students have to be the primary focus. Working out all this requires contact with other teachers for exchanging experiences on best practice. The time required to do this should not be underestimated, as it encompasses multiple stages: learning practical ICT skills, understanding the purpose of ICT in teaching and finally changing teaching styles and examination methods to make effective use of ICT. There are large individual variations in attitudes among teachers—it was noted that pre-service teachers tend to be more open to the use of ICT for teaching and might eventually work as catalysts for the introduction of ICT at their respective schools. An important point is that since technology is in constant flux, periodic retraining is necessary. The necessary resources for training and reflection require the long-term commitment of school management and school politicians. It must be understood that digitalisation is a tool for improving teaching, and should not be used as an excuse for cutting down on resources for schools—teachers are still necessary. Indeed, a suggestion was made that future teaching teams may need to be interdisciplinary, with both technology and pedagogy experts.

The discussion made clear that there is a wide variation in access to technology in different regions. Almost all schools in Australia and Sweden were reported to have Internet access, and digital competence written into the national curricula. In contrast, Internet access and resources varies a lot among schools in South Africa depending on socio-economic differences: from well-equipped schools to those with hardly any digital technology. An estimated 60% of South African schools have Internet access. A complication is that while the technology may be present, it is not always available for use: in one school, for example, the computers were locked up in a special room to which most of the teachers did not have access. The result was that the computers were unused and eventually not up to date.

Teacher skills vary from those who are competent in computer use to those "who do not know how to switch on the computer". A comment was made that many in-service teachers might not even be interested in using computers, not from lack of exposure to them, but from the attitude that computers will not contribute to teaching, something which has been noted in previous research as well (Blackwell et al., 2013; Drossel et al., 2017; Prestridge, 2012; Young, 2016).

In Spain, the main use of digital tools by in-service teachers is indicated to be the use of interactive smartboards for presentations, which does not necessarily imply changing or improving existing teaching practice. Rather, it was reported that many teachers use their smartboards simply as projectors. Making use of the full potential of the smartboard requires designing the learning situation accordingly (Simó et al., 2018). In order to help teachers understand how to organise their teaching around ICT tools, our Spanish participant's team had formulated guidelines for in-service teachers to increase the use of digital tools, with an emphasis on a deeper understanding of production tools. Summer courses have also been provided to in-service teachers to enhance their digital competence.

The situation in Germany is described as lacking a systematic approach: schools have received money to invest and buy technology, but no instructions for teachers on how to use potential tools. Specifically schools in Southern Germany were described as passive, waiting for others to take the lead and supply ready recipes for digitalisation. There is a feeling that Germany has fallen behind and lacks infrastructure, maybe only 50% of schools have Internet access. Teachers are uncertain and sometimes fearful of technology. In order to alleviate those fears there have been local efforts at staging ”impulse” workshops for teachers (Institut für Qualitätsentwicklung an Schulen Schleswig-Holstein, 2020), showing what can be done with digital tools in the classroom. As the technology becomes more familiar, teachers develop pedagogical creativity.

One of the participants reflected on why some teachers change their teaching practices and integrate ICT, while some do not, and summed up their thoughts on whether it is the teachers' views or the access to technology that drives the change. In the beginning, they stated, “I was thinking exposure was the problem.”—if teachers were only given the opportunity to try different ICT tools, they would see new opportunities and integrate the new tools into their teaching. However, today they have changed their mind on the issue and emphasize the importance of teachers' attitudes towards technology. That said, they still do not deny the importance of exposure to ICT tools.

CONCLUSION

The consensus was that (strategic investments in) professional development were considered important in enhancing teachers' digital skills. The workshop participants agreed that this will continue to be important as these technologies will be constantly changing, hence teachers will have to constantly develop their teaching practice to respond to these changes. The participants also agreed that one of the big benefits with this investment was that digitalisation has the potential to empower students to work more effectively, giving them more control over how to learn a subject. This said, it should be taken into account that both Internet access and resources vary a lot among schools. The same applies to the teachers' knowledge and attitudes towards technology integration and the support from school management and school politicians. All these are important components if we aim to use ICT in classrooms to its full potential.

ACKNOWLEDGEMENTS

We thank all workshop participants for their input, in particular Helena Lennholm of the Royal Institute of Technology, Carme Grimalt Álvaro of the Autonomous University of Barcelona and Silke Rönnebeck of the IBN Leibniz Institut for supplying additional information after the event. We also thank the Department of Media Technology at Södertörn University for financing our attendance at ESERA. FICTION is Erasmus+ project number 2018-1-SE01-KA201-039098.

IN-SERVICE TEACHER MENTORING FOR THE IMPLEMENTATION OF MODULES ON CUTTING-EDGE RESEARCH TOPICS

Emily Michailidi and Dimitris Stavrou
University of Crete, Rethymno, Greece

The negotiation of cutting-edge research topics in science courses may contribute to the scientific literacy of students. However, incorporating such an approach into teaching practice requires appropriate preparation and support, for teachers to meet the challenges of such a venture. In this context, this study examines the support provided by mentor-teachers to other in-service teachers who are called to implement in their classrooms modules on cutting-edge scientific subjects with social implications. In total 5 mentors and 32 in-service teachers participated in the study. The mentoring meetings were recorded and the discussions were analyzed in terms of content and mentoring roles assumed by mentors. Data indicate that mentors focused their support on science-specific instructional knowledge and tended to do so using mostly directive skills, but also trying to adapt their role according to mentees' needs.

Keywords: Mentoring in Teacher Education, In-service Teacher Training, Teaching Innovations

INTRODUCTION

One of the long-established aims of research on science education is the improvement of educational practice through the operationalization and dissemination of the research results. Yet, spreading innovations in a wide range of educational contexts requires an ongoing supportive training procedure that would guide teachers throughout the whole implementation period, as they often have to change their attitudes and beliefs, to expand their professional knowledge and repertoire of teaching practices while addressing the restrictions imposed by the school context (van Driel et al., 1998). In order for teachers to meet the demands of educational innovations and to be able to effectively integrate them in their teaching, they should receive appropriate training and support.

Subjects related to cutting-edge research usually define an area of science that is uncertain and incorporates issues around which the scientific community has not yet come to commonly accepted conclusions (Levinson, 2006). Integrating such topics in science classes familiarizes students with the process of scientific research and provides them with the opportunity to experience scientific knowledge as an ongoing procedure and to elaborate on its social implications (Wong et al., 2008). However contemporary scientific research topics have not yet been broadly incorporated in school science curricula and teaching practice. Therefore, there is a need to disseminate the implementation of such innovations to more school contexts and also to train teachers on these issues in order to overpass the entailed difficulties.

Certainly the task of applying modules associated with cutting-edge research topics entails a series of difficulties on behalf of the teachers, which are mainly focused on their content knowledge scarcity and on the lack of specific teaching strategies to approach such topics (Peers et al., 2003).

One of the methods that have shown encouraging results as a means of teacher professional development is *mentoring in collaborative settings* (Feiman-Nemser, 2012). Through mentoring conversations, teachers grow professionally by collaboratively inquiring and reflecting on their everyday practice, exchanging ideas and paving the way for change (Bradbury & Koballa, 2007). Therefore, the content of these conversations as well as the mentor's style (directive or not) determine to a great extent the effect of this interaction.

Even though research on science teacher mentoring is growing, it is mostly related to pre-service or early career teachers and the studies that employ mentoring as a means for in-service science teacher training are still few (e.g. Appleton, 2008). Based on this approach, the aim of the present study is to give an insight on the support mentor-teachers provide to other in-service teachers in order to implement modules on cutting-edge research topics. The specific research question is:

How do mentor-teachers support in-service mentee-teachers in order to implement modules on cutting-edge research topics in their classrooms?

and it is examined through the following sub-questions:

(i) *What topics do mentoring conversations focus on?*

(ii) *What roles do mentor-teachers assume during their mentoring conversations with the mentee-teachers?*

METHOD

Research design

The study was carried out in the framework of the EU IRRESISTIBLE project (www.irresistible-project.eu) which aimed to develop and implement teaching material on contemporary scientific research topics and their social implications.

According to the design of the project, 5 highly skilled teachers (one primary education teacher and 4 secondary education physics and chemistry teachers) developed and piloted a teaching module on Nanotechnology, with the support of nanotechnology experts and science education researchers. Afterwards, these 5 teachers (hereinafter referred to as "mentors") acted as multipliers and trained 32 mentee-teachers serving in primary and secondary schools in implementing a module on a cutting edge research topic.

The 3 modules that the mentees were trained on and applied were: *Nanotechnology Applications* , *Microplastics in the ocean* and *Carbohydrates of baby formulas*. As all three modules were developed within the IRRESISTIBLE project, they dealt with contemporary scientific research subjects and their social implications and used an inquiry-based approach for learning.

The mentoring process lasted for about 9 months (during which each group held about 8 mentoring meetings) and was divided in three successive phases.

- In the *orientation* phase, mentors and mentees elaborated on (i) the scientific content of each module, (ii) the involved social implications and (iii) aspects of inquiry-based learning.
- In the *redesign* phase, mentees thoroughly examined the modules and then re-designed them in order to adapt them to each school context.
- The *implementation* phase concerned the enactment of the modules in real class conditions and the mentees' reflection on the mentoring experience.

During each phase, mentors supported their mentees by 2-5 group mentoring meetings and with personalized support.

Data collection and analysis

In an effort to investigate the mentoring interactions, our main data source was the audio-recordings of all the group mentoring meetings.

Due to the explorative nature of the research, qualitative methods of content analysis were used.

First, all recorded mentoring conversations were transcribed verbatim. As regards the topic of mentoring conversations, we used as categories the knowledge bases of teacher professional knowledge (Gess-Newsome, 2015) that were addressed, namely: subject-matter knowledge, general pedagogical knowledge, instructional knowledge, knowledge of students and curricular knowledge. Issues that referred to organizational and administrative aspects of the mentoring process formed a sixth category entitled organizational issues (Table 1). Then, we calculated the percentage of mentoring discussions' extent that was dedicated to each topic.

Table 1: Categories of analysis regarding the topic of mentoring conversations

Categories	Description
Subject-matter knowledge	Discussion on the scientific subject of each module & social aspects
General Pedagogical Knowledge	Discussion on classroom management & learning theories
Instructional knowledge	Discussion about inquiry-based learning, negotiation of social aspects and ways to explore students' ideas Assistance in lesson redesign Demonstration of experiments and activities Providing feedback on teaching
Knowledge of students	Discussion of students' cognitive abilities, common alternative ideas and skills
Curricular knowledge	Discussion on the modules' objectives
Organizational Issues	Organizing visits, Sharing materials, Meetings arrangement

For the characterization of mentors' roles in these conversations, we based our analysis on the

MERID model (Crasborn et al., 2011; Figure 1), which identifies the mentor's use of directive skills and his/her initiative in introducing the topics as two behavioral dimensions that, vertically arranged, define 4 complementary mentoring roles: initiator (introduces topics & uses non-directive skills), imperator (introduces topics & uses directive skills), advisor (responds to issues introduced by mentees & uses directive skills) and encourager (responds to issues introduced by mentees & uses non-directive skills).

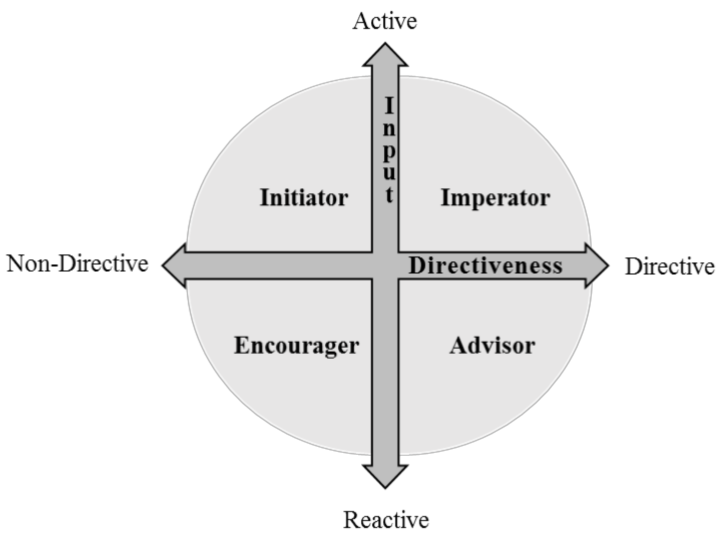

Figure 1: Representation of the MERID model (Crasborn et al., 2011)

In that way we constructed two coding keys, one addressing mentors' degree of directiveness and one addressing their degree of input (see Table 2). Analysis continued by recording the percentage of mentors' extent of speech that belonged to each category. Combining these two dimensions, we were able to define the percentages of the resulting mentoring roles.

Table 2: Categories of analysis regarding mentoring roles

Categories		Description
Directiveness	Directive	The mentor provides directions, confirms / rejects , evaluates, expresses opinion , gives advice, demonstrates activities, gives information
	Non-directive	The mentor asks questions, enhances reflection .
Input	Active	The mentor introduces the topic for discussion
	Reactive	The mentor responds to issues introduced by mentees

RESULTS

The results regarding the content of mentoring conversations (Figure 2) show that the most discussed topics were related to the negotiation of instructional knowledge (teaching strategies, negotiation of social implications and lesson design) and organizational issues. Issues regarding scientific knowledge have been discussed to a limited extent, as well as students' pre-existing knowledge, ideas and interests. Equally limited was the negotiation of issues of general pedagogical knowledge, fact that is mainly attributed to the increased teaching experience of the in-service mentee-teachers. On the other hand, mentors dedicated a significant extent of their conversations to the explanation and clarification of the innovative elements of the modules.

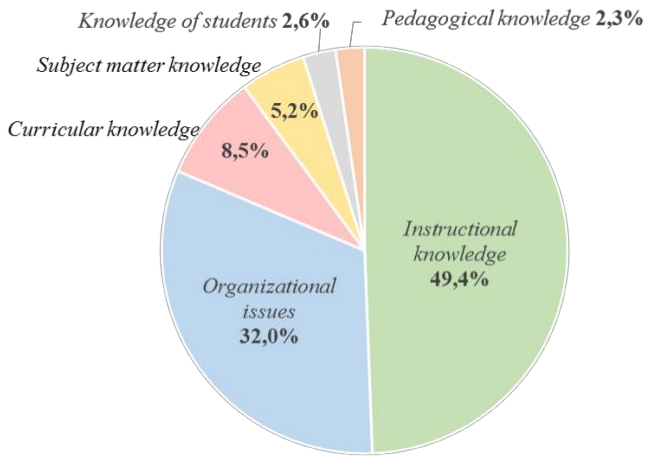

Figure 2 : Percentage of mentoring discussions dedicated to different areas of professional knowledge

Regarding the roles adopted by the mentors (see Table 3), we should first point out that the mentors participated in the mentoring discussions with all four different roles, with a tendency to use more frequently directive skills and to introduce discussion topics, adopting the imperator role. The second more frequent role was the advisor, according to which mentors shared their opinion on issues raised by the mentees. Finally, mentors assumed the initiator and encourager role, only during a small extent of the conversations.

Table 3: Percentages of mentoring roles assumed by each mentor

	Mentoring Roles			
	Initiator	Imperator	Advisor	Encourager
Mentor-A	9,8%	59,3%	26,5%	4,4%
Mentor-B	14,9%	51,5%	26,1%	7,5%
Mentor-C	10,1%	48,5%	34,3%	7,1%
Mentor-D	9,0%	35,2%	44,4%	11,4%
Mentor-E	8,3%	43,4%	40,6%	7,7%

Moreover, mentors tended to adapt their practices to the mentees' needs, and particularly to limit their directional practices when mentees had the necessary background knowledge on a subject that allowed them to participate more actively in the discussion. Specifically, as shown in Figure 3, when mentors discussed about the innovative scientific content of the modules, they tended to utilize almost exclusively directional practices. Therefore, in these cases they only adopted the imperator and advisor role.

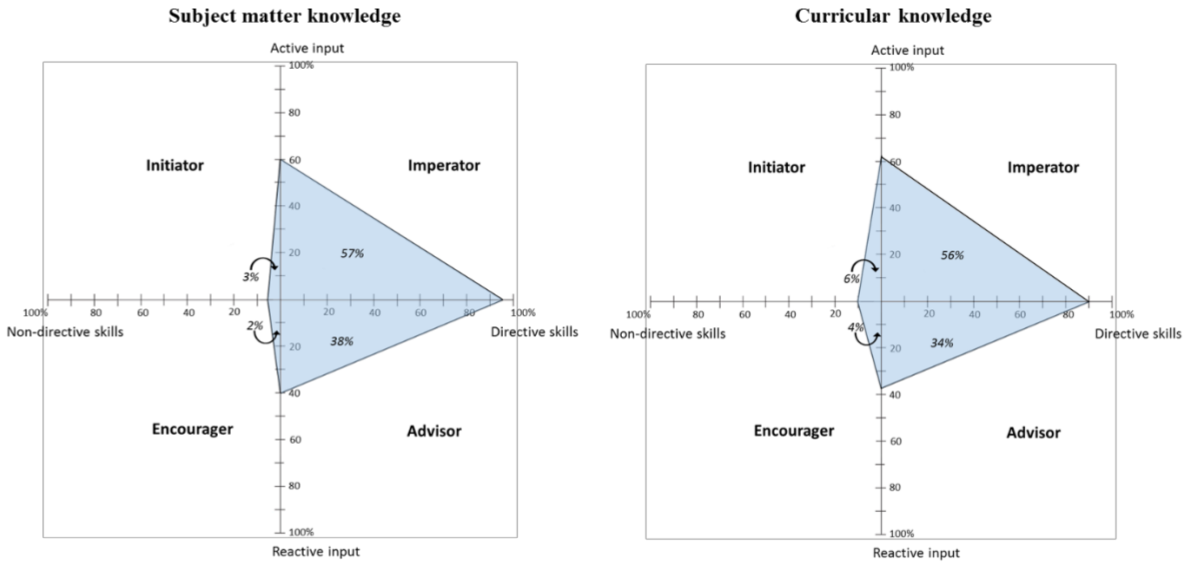

Figure 3: Pictorial representation of mentoring roles during the negotiation of issues related with subject matter knowledge and curricular knowledge

On the other hand, their use of directional practices was significantly limited when discussing topics on which mentees had profound background knowledge, like general pedagogical issues or students' ideas and interests. In these cases mentors adopted more dominantly the encourager role (Figure 4).

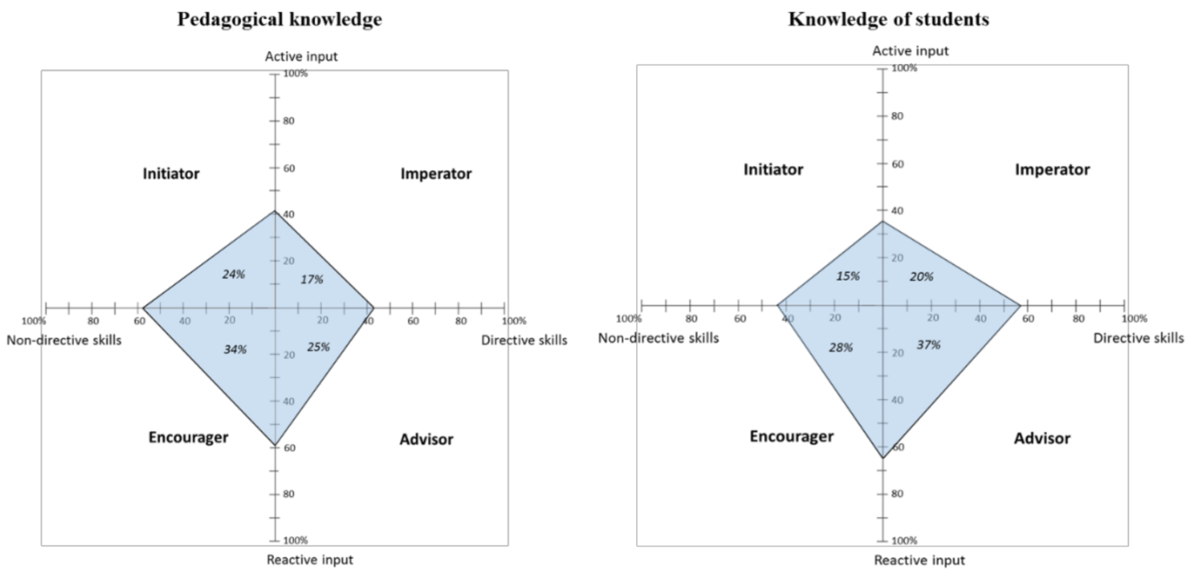

Figure 4: Pictorial representation of mentoring roles during the negotiation of issues related with general pedagogical knowledge and knowledge of students

DISCUSSION AND CONCLUSIONS

The results regarding the content of the mentoring discussions initially showed a strong tendency of mentors to discuss issues that were oriented towards different aspects of science teaching strategies, such as inquiry-based learning, lesson planning etc. Adding to the above, the long discussion of issues related to the teaching objectives of the modules, the students' ideas and the scientific content, the results show a strong orientation of the mentors' discourse on science-specific topics. Although these findings contradict those of related studies that reveal a mentoring focus on general teaching skills or general pedagogical knowledge (Bradbury & Koballa 2007; Bang & Luft 2014; Barnett & Friedrichsen 2015), this divergence can be attributed to the fact that in our study mentees were not novice but experienced teachers and to the very clear and specific targeting of the mentoring relation, which was the provision of suitable support to mentees in order to implement innovative modules in their classes.

Concerning mentoring roles, the participating mentors more frequently adopted directive practices to support the mentees, often resorting to advice giving and demonstrating. Moreover, the majority of mentors provided active input to the discussions, leading to the overall adoption of an imperator role. These results are in line with findings from other studies that highlight the predominance of imperator role among mentors (Hennissen et al., 2008; Crasborn et al., 2011; Mena et al., 2017). In fact, Hennissen et al. (2008) argue that this tendency is even more overt among untrained mentors, as in the case of the participants in the present study.

However, even if mentors adopted mostly the imperator role, they also managed to adapt themselves to the evolving needs of the mentees and to their degree of expertize on each subject. The dynamic shift of the roles is particularly interesting, taking into account that one of the most important and influential factors determining the success of a mentoring process is the extent to which the mentoring approach is flexibly adaptive to the learning needs of the trainee (Hobson et al., 2009).

From the above we can deduce that the mentoring process unfolded on the background of the implementation of modules on contemporary scientific research, was a dynamic process which provided mentee-teachers with professional development opportunities and concentrated features of an effective science teacher education effort. Therefore, mentoring could be used for the professional growth of experienced science teachers, beyond the limited scope of the induction phase, as a means of disseminating educational innovations, provided that teacher-mentors have previously received training on the novel practices.

ACKNOWLEDGEMENT

This study has been supported by the IRRESISTIBLE (http://www.irresistible-project.eu), European project, in the context of the European Union's Seventh Framework Program for research, technological development and demonstration under grant agreement no 612367.

Financial support to this work by the Greek State Scholarships Foundation through the program "Enhancement of human scientific resources though implementation of PhD research" with resources of the European program "Development of human resources, Education and lifelong learning", 2014-2020, co-funded by the European Social Fund and the Greek State, is gratefully acknowledged.

RELATIONSHIP OF EMOTIONS WITH ASSOCIATED VARIABLES TO THE SCIENCE TEACHING ON IN-SERVICE TEACHERS

Pedro Membiela Iglesia[1], *Katherine Acosta García*[2] *y Antonio González Fernández*[1]

[1]Facultade de Ciencias da Educación de Ourense. Universidad de Vigo. 2Universidad de Arica. Email membiela@uvigo.es

A research has been carried out with 339 Chilean in-service teachers (early childhood, primary and secondary education) of science teaching. In relation with the emotions of teachers, highlighting the influence of variables associated with election to be teachers, such as intrinsic career and working with student's value, and self-efficacy as teachers, such as in instructional strategies, classroom management and student engagement.

Keywords: emotions, in-service teachers, science teaching.

INTRODUCTION

Although there is a remarkable amount of research dedicated to the quality of teaching or the classroom environment generated by teachers, attention has hardly been paid to teachers as human beings who have their own motives, goals and emotional experiences (Frenzel, 2014). An exception is research on burnout, associated with the high risk that teachers present.

Although all workers experience emotions during their work (Weiss and Brief 2001), teaching can be especially emotional work (Frenzel 2014; Hargreaves 1998; Saunders 2013; Schutz 2014; Schutz and Zembylas 2009; Uitto, Jokikokko, et al. 2015). According to Schutz and Lanehart (2002), emotions are intimately involved in virtually all aspects of the teaching and learning process and, therefore, an understanding of the nature of emotions within the school context is essential. Teachers' emotional ties with students are often at the centre of their work (Day and Leitch, 2001), and teachers often experience enjoyment, anxiety and anger as they teach (Frenzel, Becker-Kurz, et al. 2015; Frenzel, Goetz, et al. 2009a, Taxer and Frenzel, 2015). In addition, teachers 'emotional experiences during class can directly affect their behaviour (Day and Leitch, 2001; Kunter, Tsai, et al. 2008), students' emotional experiences (Becker, Goetz, et al. 2014) and learning outcomes (Frenzel, Goetz, et al. 2009b). It follows that the emotional experiences of teachers could influence the configuration of their interactions and the implementation of what they learn in professional development. Emotions are to some extent dispositions, although they are also very context sensitive (Schutz, 2014, Schutz, Aultman, et al. 2009). On the other hand, teachers' emotions are related to a variety of important outcomes related to teaching, including teacher effectiveness in the classroom (Sutton, 2005), their well-being and health (Chang, 2013; Taxer and Frenzel 2015), and the emotions and motivation of the students (Becker, Goetz, et al. 2014; van Doorn, van Kleef, et al. 2014).

The research confirm that teachers' emotions are related to the effectiveness of instruction in terms of cognitive and motivational stimulation, classroom management and social support (Pekrun, Muis, et al. 2018). The enjoyment of teaching by teachers is positively related to appraisals of monitoring, development, understanding, support for autonomy, enthusiasm and support of students. On the contrary, negative relationships have been found between the anger and anxiety of teachers and the perceptions of students about the instructional behaviour of teachers, including the elaboration, understanding, support for autonomy, enthusiasm of students, and teachers support after failure (Frenzel, Goetz, et al. 2009a, 2009b; Frenzel, Pekrun, et al. 2016). However, negative emotions can sometimes have beneficial effects. Thus, Stough and Emmer (1998) discovered that beginning teachers, whose students showed hostile reactions to their comments, experienced negative emotions such as frustration and anger. As a result, some of them altered their classroom management strategies by modifying their comments to better control student interactions.

Importantly, teachers often exercise some level of control over their emotions through emotional regulation (Sutton 2004; Taxer and Frenzel 2015). As with other types of self-control, emotions are regulated to achieve goals, and different strategies can be used to achieve those goals. Existing research on how teachers modify their emotions has focused predominantly on teachers' use of deep-acting emotional work strategies, such as the act of internalizing the desired emotion so that the expressed emotion matches the emotion felt (Grandey 2000). Also, superficial action such as the act of expressing an emotion not felt (Grandey 2000; Hülsheger, Lang, et al. 2010; Näring, Briët, et al. 2006; Näring, Vlerick, et al. 2011; Philipp and Schüpbach 2010; Yin, 2015).

The three basic emotions that have been found to be the most notable and most frequent among teachers (Frenzel 2014; Hagenauer, Hascher, et al. Volet 2015; Sutton and Wheatley 2003) are enjoyment (pleasant, related to activity and results), anxiety (unpleasant, related to the result) and anger (unpleasant, activity and related to the result). Using two daily studies, Frenzel, Becker-Kurz, et al. (2015) analysed the frequency of each teacher's emotions by calculating the proportion of class periods in which each of the emotions was present. On average, teachers reported that they experienced enjoyment in 97%, anger in 44% and anxiety in 25% of their classes.

In summary, the well-being of the teachers and students, and the good functioning of the classrooms are related to the emotions of the teachers. The participation of teachers in cognitive and motivational stimulation, in classroom management and in social support, in turn, affects the cognitive growth, motivation, social and emotional behaviour of students in class and relationships with the teacher. Consequently, the behaviours of students and teachers in class can be seen as a cause and an effect of the emotional experiences of teachers during teaching.

Therefore, given the relative shortage of available research on teachers' emotions, the main objectives are to know the emotions of teachers, and how they can be affected, as well as affect other dimensions of classroom processes in a group of in-service Chilean teachers.

METHODOLOGY

The research has been carried out with 339 in-service teachers of Early Childhood (90), Primary (166) and Secondary (77) during science teaching training course. Age is between 23 and 65 years old (mean = 39,5), with a predominance of women (270) in relation to men (69).

It has been used to research emotions the Teacher Emotions Scales (TES), and various constructs to know attitudes and beliefs in relation to the teaching of science: Factors Influencing Teacher Choice (FIT-Choice), Dimensions of Attitude Toward Science Instrument (DAS), Ohio State Teacher Efficacy Scale (OSTES), Science Teaching Efficacy Belief Instrument (STEBI-A).

In the analysis and interpretation of the results, an analysis were carried out with the SPSS 24 program of calculation of bivariate correlations between emotions and the remaining dimensions to show significant correlations.

RESULTS

1) There are numerous significant correlations (See Table 1) between the three dimensions of emotions studied and the factors that influence career choice, and beliefs associated with the teaching of science in the group of in-service teachers. In general, the correlations are positive in relation to enjoyment, while they are negative with the other emotions studied (anger and anxiety). The difficulty in teaching science and the perception of social status correlates negatively with enjoyment but also with anxiety.

Table 1. Significant bivariate correlations of emotions with other dimensions, positive in brown and negative in green (r> | .111|* p <.05) N = 339).

OUTCOME EXPECTANCY	-0,004	0,045	0,020

DISCUSSION AND CONCLUSIONS

In relation to teachers' emotions, highlight the influence of variables associated with control, such as in instructional strategies, in the management of classes and in the engagement of students; and the influence of valuation variables, such as intrinsic value of the career or the value of working with students; and the influence of dimensions associated with achievements, such as satisfaction with the choice of career, relevance or difficulty of teaching science.

As previously noted (Frenzel, 2014), teachers 'emotions are related to the effectiveness of instruction in terms of teachers' cognitive and motivational stimulation, classroom management and social support. As Baird, Gunstone, Penna, Fensham and White (2007) conclude, a balance between affection and cognition is important for effective teaching.

Measures should be taken to improve emotions in practicing teachers, starting them already in the initial training. In this sense, they should take actions that clearly protect against negative emotions and/ or enhance positive ones such as promoting the intrinsic value of the career of being a teacher, the valuation of work with students, self-efficacy in instructional strategies, classroom management and in student engagement.

As previously indicated (Frenzel, 2014), teachers' emotions are related to the effectiveness of instruction in terms of cognitive and motivational stimulation of teachers, classroom management and social support. As Baird, Gunstone, Penna, Fensham and White (2007) conclude, a balance between affect and cognition is important for effective teaching.

RESULTS OF IMPROVED PROGRAM TO DEVELOP TEACHERS' ABILITIES TO CONSTRUCT AND EVALUATE ARGUMENTS

Tomokazu Yamamoto[1] and Shinichi Kamiyama[2]
[1]Hyogo University of Teacher Education, Kato, Japan
[2]Osaka University of Health and Sport Sciences, Sennan, Japan

A teacher who introduces argumentation into his or her classes must have the ability to construct his or her own arguments, as well as the ability to properly evaluate the arguments of his or her students. However, even though some Japanese teacher training programs include constructing and scoring arguments, it has been reported that teachers' confidence in teaching argumentation has not improved enough (Yamamoto & Kamiyama, 2018). In this research, we developed an improved program for training teachers that includes a proposal for teachers to introduce argumentation into their own classes. We then demonstrated the effectiveness of the program in developing teachers' abilities to construct and evaluate arguments, as well as improving teacher confidence in teaching argumentation. In addition to the lectures and exercises included in the program prior to improving it, we also added sessions on "proposal to introduce argumentation into classes (30 min.)" and "exchanging proposals (40 min.)." The program was implemented for 35 teachers working in primary schools, middle schools, and high schools during 2017 and 2018. Surveys conducted on teachers' abilities to construct and evaluate arguments as well as on teacher self-efficacy before and after the program showed improvement in teachers' abilities to construct and evaluate arguments as well as in teacher self-efficacy ($p<.01$ for all results). These results indicate that this program is effective at having teachers properly construct and evaluate arguments. The results also indicate that the program is beneficial in improving teachers' confidence in teaching. However, roughly one-third of the teachers provided a negative response with regard to confidence; thus, confidence has not been improved enough. The program will therefore need to be further developed with practical activities, in which teachers will further introduce argumentation into their actual classes and then reflect on the results.

Keywords: argument, teachers' abilities, confidence

INTRODUCTION

When introducing argumentation into science classes, importance is placed on the teacher's own understanding of argumentation and on his or her ability to construct arguments (Zohar, 2008). A teacher who introduces argumentation into his or her classes must also have the ability to properly evaluate the arguments of his or her students. For example, Osborn, Erduran, and Simon (2004) have incorporated activities into a teacher training program where teachers themselves construct and evaluate arguments. Iordanou and Constantino (2014) report that putting into practice activities in which evidence is used to engage in argument over pairs of contrasting opinions and constructing arguments using more evidence than in a standard curriculum had the result of increasing the meta-level awareness of teachers.

Similar activities have been put into practice even in East Asia. In Japan, Yamamoto and Kamiyama (2018) have implemented a teacher training program that incorporates explaining, constructing, and grading arguments. However, this program is composed only of lectures and drills on provided material. Teachers do not engage in practical activities to incorporate argumentation into their own classes, and thus teachers were not able to build enough confidence to teach argumentation in their classes. Previous research indicates that confidence to teach argumentation is a factor contributing toward teachers introducing argumentation, and that it is also affected by the teacher's experience teaching argumentation and his or her level of knowledge on his or her students (McNeill, Katsh-Singer, González-Howard, & Loper, 2016). Therefore, teachers can expect to not only improve their abilities to construct and evaluate arguments, but also to gain confidence in introducing argumentation into their teaching, by gaining experience in imagining the students in their own classes, and in proposing arguments to be constructed by their students and the situations in which these arguments are introduced.

In this research, we develop an improved program for training teachers based on the program implemented by Yamamoto and Kamiyama (2018), in which we have also included a proposal for teachers to introduce argumentation into their own classes. We then shed light on the results of this program. Our research questions are as follows:

· Was the improved program effective at developing teachers' abilities to construct and evaluate arguments?

· Did the improved program increase teachers' confidence in teaching argumentation?

METHOD

Subjects

The subjects for this research included 35 teachers currently working in Japan (18 elementary school teachers, 8 middle school teachers, and 9 high school teachers). The program was conducted for 12 teachers (6 elementary school teachers, 4 middle school teachers, and 2 high school teachers) from April through May 2017 and then again for the remaining 23 teachers from April through May 2018.

Program

The program comprised three sessions. The first session was a "lecture on what argumentation means and its significance (20 min.)," while the second session included a "lecture on grading exercises and the current state of students' abilities to construct arguments (20 min.)," "exercises to gain first-hand experience in teaching and evaluating argumentation (40 min.)," and a "briefing on actual class conditions (10 min.)." Although the first two sessions were the same as the program implemented by Yamamoto and Kamiyama (2018), a third session was added covering "proposal to introduce argumentation into classes (30 min.)" and "exchanging proposals (40 min.)" as a means for teachers to consider arguments to introduce into their own classes. Figure 1 shows one of the arguments for a teacher to introduce into his class.

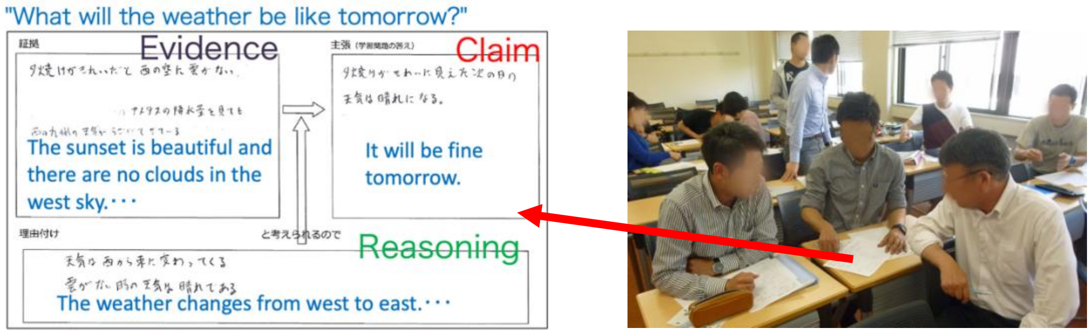

Figure 1. One of the arguments for a teacher to introduce into his class.

Test and survey

The 35 teachers participating in the program were provided with questions on constructing and evaluating arguments, both before and after the program was conducted. Each took around 10 minutes. A survey was also conducted on teachers' confidence in teaching argumentation (teacher self-efficacy) in order to gauge their beliefs on argumentation.

Figure 2 shows the argument construction question, and Figure 3 shows the desirable answer. The question was taken from Sakamoto et al. (2012). Teachers were asked to provide an explanation in their own words of a question in which a circuit in a hidden area was to be selected from two choices. Teachers were assigned a score out of two points in three areas (for a total of six points), based on a rubric evaluating "whether an answer was given (presence/absence of component)" and "whether the answer was scientifically correct (correctness of contents)." The three areas were the following: their "claim" as an answer to the question, their "evidence" mentioning the brightness of miniature light bulbs in each circuit (the fact of the matter), and their "reasoning" mentioning the size of each current (voltage/power) connected in parallel. These answers were judged by two independent judges with a concordance rate of 98.1%.

The circuit of ① and ② has the part of the cell hidden.

In the circuit of ①, the brightness of the light bulb was brighter than that of one cell. In the circuit of ②, the brightness of the light bulb was the same as that of one cell.

Which of the following A and B applies to how to connect the cells of each of the circuits 1 and 2? And why did you think so?

Explain these things scientifically. Write an explanation.

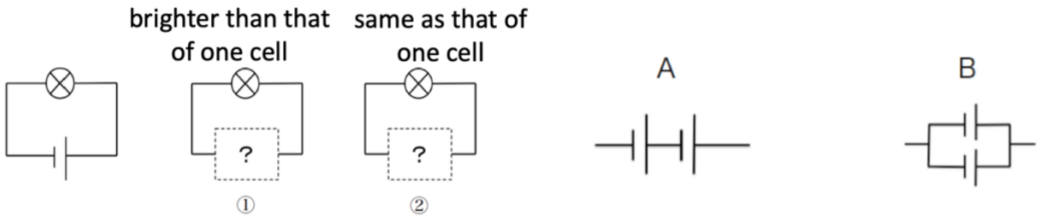

Figure 2. Argument construction question.

Claim: ① is A, ② is B.

Evidence: In the circuit of ①, the brightness of the light bulb was brighter than that of one cell. In the circuit of ②, the brightness of the light bulb was the same as that of one cell.

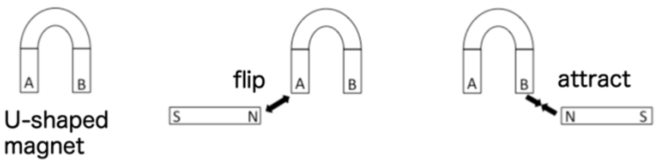
Reasoning: If you increase the number of cells to two in series connection and turn on the light bulb, the current (or any of voltage, power and electricity) will increase compared to when connected to one cell.

Even if you increase the number of cells to two and connect the light bulb with parallel connection, the current (or any of voltage, power, and electric quantity) does not change compared to the time when one cell is connected.

Figure 3. Desirable answer in the argument construction question.

Figure 4 shows the argument evaluation question. For the question on evaluating arguments, teachers were asked to evaluate answers from child X, Y, and Z (cases X, Y, and Z hereafter), who were presented with a U-shaped magnet of unknown polarity and told to determine the polarity by bringing the north pole of a bar magnet into contact with the U-shaped magnet. In judging these answers, teachers were asked to focus on students' "claim" as answers they gave for each pole, their "evidence" mentioning how the bar magnet reacted in the way it did (the facts of the matter), and their "reasoning" indicating that magnets of the same polarity are repulsed while magnets of opposite polarity are attracted. Teachers were then assigned a score of either zero or one point based on their "judgment" that all cases X, Y, and Z were found insufficient and then their "reason" mentioning why they were insufficient as arguments. These answers were judged by two independent judges with a concordance rate of 99.5%.

What are the poles of A and B of the U-shaped magnet? And why did you think so? Explain these things scientifically.



If you can judge that the children's descriptions X, Y and Z are sufficient for scientific explanation, enter ○ in the "judgment" column. If you judge that it is not enough, enter △. And briefly state in the "reason" column why you have judged that.

【Child X】 judgment [ ] reason [ ]

A is N pole and B is S pole.

When the N pole was brought close to A, the magnets was flipped, and when the N pole was brought close to B, the magnets attracted each other.

【Child Y】 judgment [ ] reason [ ]

When the N pole was brought close to A, the magnets was flipped, and when the N pole was brought close to B, the magnets attracted each other.

The magnets have the same poles are flipped and the other poles attract each other.

【Child Z】 judgment [ ] reason [ ]

A is N pole and B is S pole.

The magnets have the same poles are flipped and the other poles attract each other.

Figure 4. Argument evaluation question.

Teachers were also asked before and after the program how they felt about the seven belief categories from Katsh-Singer, McNeill, and Lope (2016), and were instructed to rate each category as "strongly believe so" (four points), "believe so" (three points), "do not believe so" (two points), or "strongly do not believe so" (one point). Of these categories, we provide a report on teacher self-efficacy in this research.

RESULTS

Argument construction question

Table 1 shows the score distribution for the argument construction question. The results of a Wilcoxon signed-rank test revealed component elements with significant improvements to score distribution between the pre- and post-tests. These are indicated in bold. For "claim," teachers mostly received full scores for both "presence/absence of component" and "correctness of contents" during both the pre- and post-tests. For "evidence," a significant improvement was observed for both "presence/absence of component" and "correctness of contents" (p<.01). For "reasoning," although teachers mostly received full scores for "presence/absence of component" during the pre- and post-tests, only 20 teachers received full scores for "correctness of contents" during the tests.

Argument evaluation question

Table 2 shows the score distribution for the argument evaluation question. Nearly all teachers received full scores during the post-test for both their "judgment" and "reason" for case X (in which the student's reasoning was lacking) and case Y (in which the student's claim was lacking). For case Z (in which the student's evidence was lacking), the number of teachers who received full scores increased from the pre-test to the post-test (p<.01).

Survey on beliefs on argumentation

Figure 5 presents "teacher self-efficacy" before and after the program. A Wilcoxon signed-rank test showed a significant improvement between the pre- and post-tests (p<.01).

Table 1. Score distribution for the argument construction.

		pre-test			post-test			
	score	2	1	0	2	1	0	
presence/absence of component	claim	32	1	2	35	0	0	
	evidence	13	0	22	**26**	**3**	**6**	**
	reasoning	27	3	5	32	1	2	
correctness of contents	claim	30	1	4	33	0	2	
	evidence	14	0	21	**26**	**2**	**7**	**
	reasoning	19	3	13	20	1	14	

Note: Components that showed significant improvement in the score distribution between pre-test and post-test are shown in bold.

Table 2. Score distribution for the argument evaluation.

		pre-test		post-test		
	score	1	0	1	0	
judgment	case X	32	3	35	0	
	case Y	32	3	35	0	
	case Z	**16**	**19**	**28**	**7**	**
reason	case X	28	7	34	1	
	case Y	30	5	34	1	
	case Z	**11**	**24**	**26**	**9**	**

Note: Components that showed significant improvement in the score distribution between pre-test and post-test are shown in bold.

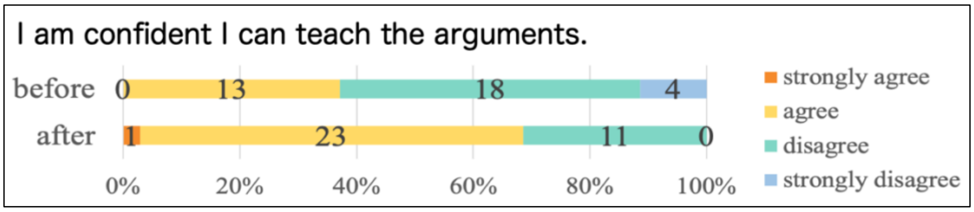


Figure 5. Confidence in teaching arguments.

DISCUSSION AND CONCLUSIONS

As a result of implementing this program, teachers were able to obtain overall good scores during their post-tests for the argument construction question and argument evaluation question. Teachers maintained an awareness of component elements when writing their arguments, and were able to check these component elements when evaluating arguments. This is likely a direct result of their activities during the program, in which they constructed arguments and scored the arguments of students. The teachers were able to properly construct and evaluate arguments even when the content changed.

Furthermore, the survey conducted on beliefs on argumentation showed that scores increased for "teaching confidence" after the program, so it can be inferred that the program had the effect of improving teachers' confidence in teaching. However, roughly one-third (11) of the teachers responded negatively ("do not believe so") during the post-test, suggesting that confidence was not sufficiently improved. In order for teachers to improve their confidence in teaching argumentation, a program accompanied by activities that are more practical will be required, in which teachers introduce argumentation into their actual classes and then reflect on the results.

AN EMPIRICAL PILOT IN ASSESSING STUDENT TEACHERS' BIOGRAPHY AND INSTRUCTIONAL BELIEFS

Alexander F. Koch
[1]University of Teacher Education, Fribourg, Switzerland

Switzerland is undergoing a curricular change. Curriculum 21 has been ratified by all 21 German-speaking and is currently being implemented. With this innovation, German-speaking Switzerland will move toward a more technology-oriented education. What has been Manual Training or Wood/ Metalwork Classes is now replaced by composite subjects such as Nature and Technology. These subjects now structurally anchor technology-oriented content at the compulsory school level (Stuber, Heitzmann, & Käser, 2013) and are supposed to be implemented in the sense of the Anglo-Saxon concept of Science – Technology – Society – Environment (Labudde, 2012, p. 86). The technology orientation includes an instructional orientation toward a technical understanding or understanding technology, which, eo ipso, needs to be part of teacher education programs (Keller, 2017). To put things bluntly: Who else than technology/ technics-oriented teachers should teach technology and technics? Yet, technics or technology is not explicitly part of their initial studies, perhaps because in "the mandatory school, i.e. K-12, there is no specific subject 'Technology', but there is a subject called 'Textile and Technical Design'" (Kruse & Labudde, 2016, p. 62). Therefore, student teachers may at the most specialize in textile and technical design or in information technology/ computer science and teach technics and technology in an integrated way. But what are factors they would consider to impede tech instruction? In other words: What are factors that hinder high quality technology instruction by means of teacher beliefs? In this presentation we will give insights to a quantitative exploratory study.

Keywords: Science & technology education, pre-service teacher education, technology instruction

INTRODUCTION

Currently, Switzerland is moving toward a more technology/ engineering-oriented education. What has been *Manual Training* or *Wood/ Metalwork Classes* is replaced by composite subjects such as *Nature, Man, Society*, *Nature and Technology* or T*extile and Technical Design*. These subjects now structurally anchor technology at the compulsory school level (Stuber et al., 2013) and are supposed to be implemented in the sense of *Science – Technology – Society – Environment* (Labudde, 2012, p. 86). Also the subject area of media & information technology education touches the general technology branch, especially when informatics is extended to computer programming, digitalization of work routines and robotics. All this includes an instructional orientation toward a *technical understanding* or *understanding technology* (National Research Council, 2002), which, eo ipso, needs to be part of teacher education programs (Keller, 2017). Current cohorts of student teachers at the Swiss universities of teacher education are supposed to be educated toward these contents. But in praxis, who else than technology-affine teachers should teach technology? Technology was not explicitly part of their initial studies, and even current students do not receive a uniform technology-oriented education. Perhaps because in "the mandatory school, i.e. K-9, there is no specific subject

‘Technology’, but there is a subject called ‘Textile and Technical Design’” (Kruse & Labudde, 2016, p. 62). Also, *Textile Design* is not pure technology and technology is not solely design-oriented. The same is true for media and information technology, digital technology, engineering or any other area.

At the moment, student teachers may – at the most – specialize in textile and technical design or in information technology/ computer science, and consequently teach technology in an integrated way. From the fact that there is no systematic technology education in the course of their university studies, the question arises under which circumstances student teachers individually integrate technology-oriented instruction into their teaching. Thus, we need to know about predictors of technology-oriented instruction. Our question is: What are preconditions that support student teachers pursue technology-oriented instruction in compulsory K-9 school, i.e. primary and lower-secondary school?

THEORETICAL BACKGROUND

It is generally difficult to draw a comprehensive picture of instructional integration processes, especially in terms of a rather opaque field of “technology” education. Thus, in first part of the theoretical section, we want to clarify our conception of technology. In the second theoretical part – because we ask the question “What are preconditions that support student teachers pursue technology-oriented instruction in compulsory K-9 school, i.e. primary and lower-secondary school?” – we want to focus on holistic theories of behavior prediction and integrate them into a framework of technology education.

The term technology

The most debatable term in this study is *technology*. Looking at a large body of research in technology integration in instruction, we see that the term *technology* is mainly used to refer to computer-like systems, digital devices or applications that are programed to substitute analog antecedents. For example the use of computers in classrooms, the implementation of tablets or apps, or having online examinations (e.g. Lumpe et al., 1998; Palak & Walls, 2009; Ottenbreit-Leftwich et al., 2010; Ertmer et al., 2012; Kim et al., 2013; Hutchison & Woodward, 2014; Beschorner et al., 2018). In sum, most studies find teacher beliefs, values, pedagogical self-concept, reflected, goal-oriented intentions, and value for learning outcomes as main factors for technology implementation.

Yet, the term technology not solely refers to digitalization. Although there may be various understandings around the world and particularly within European countries, and also differences between US and Europe, we want to employ a definition that, to our knowledge, addresses most conceptions: “Technology comprises the entire system of people and organizations, knowledge, processes, and devices that go into creating and operating technological artifacts, as well as the artifacts themselves.” (National Research Council, 2002, p. 3). Thus, *technology* and *technics* are defined as a construct of informatics & digital literacy as well as technical & engineering knowledge and any innovative combination of any of these fields. Within this broad conception of technology one needs to consider engineering school education, too. Yet, this has been hardly explored. Van Haneghan et al. (2015) find that teachers' experience with engineering is of advantage when it comes to teaching engineering topics. Also, the value teachers see in teaching engineering has an effect on the implementation of engineering topics (Park et al., 2016). Similarly to technology integration, engineering instruction is also related to how well prepared (content-wise and pedagogically) the teachers feel themselves (Wang et al., 2011; Rich et al., 2017)

Pedagogical knowledge, beliefs, socialization, and motivation as instructional predictors

Teachers work within a context of not-well-structured problems and infinite variability of outcomes. By definition, "well-structured problems are constrained problems with convergent solutions that engage the application of a limited number of rules and principles within well-defined parameters. Ill-structured problems possess multiple solutions, solution paths, fewer parameters which are less manipulable, and contain uncertainty about which concepts, rules, and principles are necessary for the solution or how they are organized and which solution is best" (Jonassen, 1997, p. 65). To solve ill-structured problems teachers need a broad spectrum of reactions, competence, and experience. Jonassen (1997) argues that ill-structured problems are solved best if one can a) articulate the problem space and contextual constraints, b) identify and clarify alternative opinions, c) assess the viability of alternative solutions by argumentation and beliefs, and d) apply, monitor and adapt the solution. Taking into account that this whole process is situational, the most relevant predictors of solving an ill-structured interaction may be the teachers' mindset and their ability to consider the contextual/ interactional constraints (i.e. pedagogical knowledge). A prominent model of teacher resources for instructional practice has been proposed by Kunter et al. (2013). It integrates professional cognitive competences (e.g. pedagogical content knowledge), beliefs and motivational variables as the most valuable predictors of instruction:

a) *Pedagogical (content) knowledge* represents what the teacher knows about teaching content matter to students in a particular stage of development. Thus, pedagogical content knowledge includes knowledge about the content area, knowledge about instructional methods, and knowledge about the developmental stage of the students.
b) *Teacher beliefs* of instruction can be seen an interactive process guided by individual norms, one needs to understand the beliefs of the involved individuals (Raymond, 1997; Pane, 2010). Beliefs are often formed by prior teaching experiences, e.g. how they were taught to teach in their teacher education program or even how they were taught themselves during their schooling. Especially the latter reaches out into the wide field of socialization and biographical backgrounds.
c) Hurrelmann (1986, 2002) draws on socialized cognition, knowledge, biography and social contexts in order to explain purposeful behavior and decision-making. General, but also family and school socialization develops motivation and interest in any domain, also in technology (Deci & Ryan, 2000; Renn et al., 2009; Ardies et al., 2015; Adenstedt, 2016).

Therefore, we want to emphasize home, school and hobby/ interest as major predictors of technology socialization.

d) *Motivation* can be defined as the result of situation-belief interaction (J. Heckhausen & Heckhausen, 2018). Motivation results in action. In the motivational process intention plays a central role: The Rubicon model of action phases (H. Heckhausen & Gollwitzer, 1987; Gollwitzer & Oettingen, 2001; Achtziger & Gollwitzer, 2007) – a sequential, psychological model – predicts a person's behavior. In the model, the intention-building is central as it activates planned behavior. Based on van Hooft, Born, Taris, van der Flier, and Blonk (2005), who articulate that planning is essential and can be assessed in a questionnaire. This methodological idea is in line with Fishbein and Ajzen (2010) who argue that asking a person is a good proxy for the person's true intentions.

Based on the above mentioned, we developed a research framework that includes the major dimensions of instruction and their relevance in general educational contexts. In our case we focus teacher prerequisites related to their instruction in compulsory school (see Figure 7).

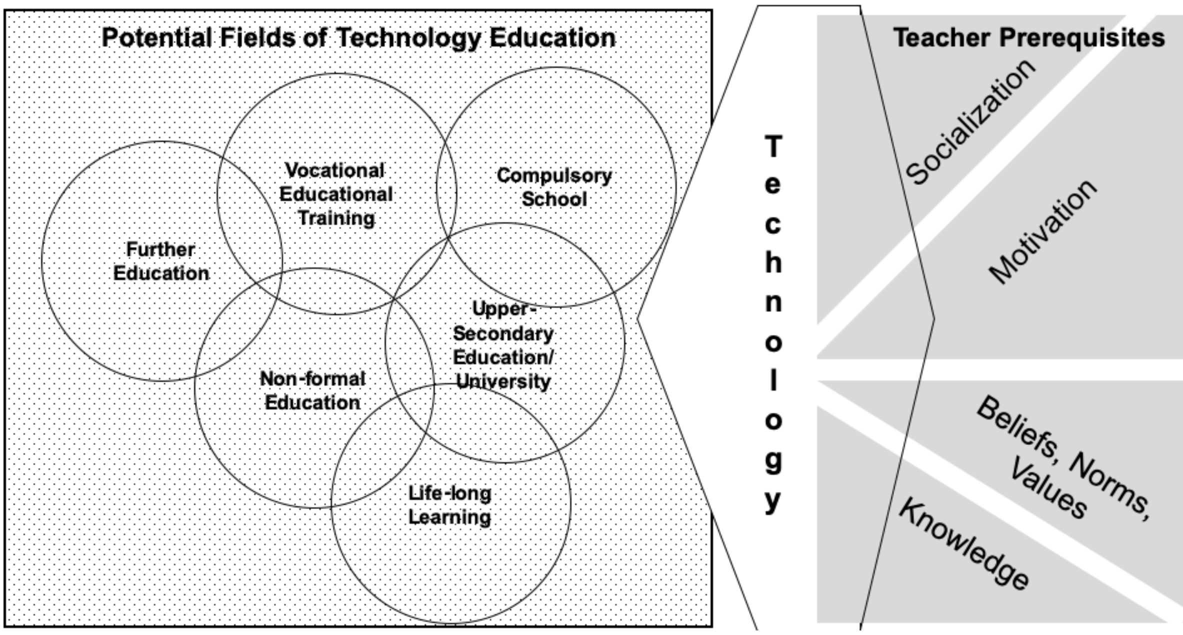

Figure 7: Framework of teacher prerequisites and implementation fields for technology education

In Figure 7 the major variables for successful technology implementation are teacher socialization, motivation, beliefs, and knowledge. These variables combine self-attribution as well as objective evaluation.

METHOD

Instruments

We used a questionnaire to assess the biographical background (socialization) and the intention to implement technology instruction and self-confidence in technology instruction. All items were rated on a 5-point Likert scale (do not agree --- fully agree). The instruction included clarification of the term, i.e. it means digital technology as well as engineering.

Technology socialization was newly developed, has 4 items (e.g. Technology played a role in my family during my childhood"), showed uni-dimensionality in principal component analysis and reliability was α=.78; The intention to implement technology instruction was adapted from van Hooft et al. (2005), included 4 items (e.g. "I know exactly how to implement technology in my instruction"), showed uni-dimensionality in principal component analysis and reliability was α=.78.

In addition to the two theoretical variables above, we assessed a lack professional and instructional self-confidence as hindering elements to implement technology instruction. These single item indicators were "I think my content knowledge is insufficient." and "I think my pedagogical competence does not suffice."

Sample and context of data acquisition

In autumn 2016 we deployed questionnaires to 69 student teachers (66% kindergarten & primary level, 34% lower-secondary level; 2 courses in primary level – 4-4.5% male students; one course in lower-secondary – 64% male students). All participants were enrolled in a class on "quantitative research methods". As the class was compulsory in the education program the backgrounds of the students were manly randomized, i.e. they were neither biased in terms of interest, nor preferred subjects. 77% of the students were female, kindergarten and primary level are dominated by female students (Phi=.66, p.000). On average, they were in their second year of study. Data were analyzed with SPSS 24. Two-tailed Spearman-correlations were computed and Kruskal-Wallis test/ separate Mann-Whitney U tests were used for comparisons between the three groups. Because of the small sample and the exploratory purpose of the study, we give exact p-values that need to be interpreted carefully, but also with tolerance.

RESULTS

The implementation intention correlation was .24, p=.066, the correlation between the single item indicators was .46, p=.000. The pedagogical confidence was not associated to the socialization (r=.20, p=.118), but the confidence in content knowledge was (r=-.27, p=.035). With reference to the implementation intention, both pedagogical confidence (r=-.35, p=.006) and confidence in content knowledge (r=-.50, p=000) showed statistical significance. The the Kruskal-Wallis test for overall comparison resulted in two-sided p-values for technology socialization (p=.006) and the other variables in a range of p=[.366;.515]. Mann-Whitney U tests with corrected alpha level of p=.05/3 tests=.017 showed that the group of lower secondary students scored higher on technology socialization than any of the primary teacher groups (p=.010; p=.004), the two primary teacher groups did not differ (p.=872).

DISCUSSION

This study framed the term "technology" in a content area of informatics & digital literacy as well as technical & engineering knowledge and any innovative combination of any of these fields. We also picked up the issue of technology instruction without a subject named "technology" in Switzerland and investigated the relation of a technology-oriented socialization and the implementation of technology instruction. Furthermore, we explored the association of pedagogical and professional self-confidence with respect to socialization and implementation. The results seem promising and showed that a stronger self-reported technology orientation during childhood is associated with how technology education enters instruction. Confidence in pedagogical and professional knowledge share a stronger association with the implementation than socialization does, but it seems that socialization can play an important role. As this is a pilot study with a small sample size we still need to be careful in interpretation. But if the effect holds true in a large sample we have evidence that school sets itself into a vicious cycle of technology education and its mandate to educate kids toward a good fit into society. The reason is that technology at school is part of the socialization, and if it is left out we will not have teachers with sufficient technology socialization that trust themselves to teach technology. A second exploratory finding is that lower-secondary teacher students rate their technology socialization higher than the primary school peers, but they are not more confident in their abilities. Thus, a "women underrate their abilities" explanation in which the female-dominated primary teachers do not trust their abilities as much as the male students, does not apply. We speculate that this effect may rather appear because students perceive subjects in different way: in lower-secondary education they have separate subjects, in primary/ kindergarten they teach holistically. We hope for more research on this assumption, especially because it is just out of an exploratory approach in a small sample pilot study.

EVALUATING SCIENCE TEACHERS' TEACHING PRACTICES: STRENGTHS AND WEAKNESSES

Angelos Sofianidis and Maria Kallery
Aristotle University of Thessaloniki, Thessaloniki, Greece

Teacher's evaluation is considered critical for teachers' professional development. Evaluation systems with different characteristics are used worldwide. According to the literature, the most common practice to collect data for the evaluation of teachers is classroom observation. Despite students' perspectives being considered as a viable and reliable source of teachers' evaluation, students' insights have not been used for teachers' evaluation. Within this context, the aim of the present study was to highlight the strong and weak aspects of science teachers' teaching practices. For this purpose, we designed and implemented an evaluation system for secondary education science teachers. Our data were collected with classroom observations and with questionnaires for exploring students' perceptions. Thirty-two (32) science teachers serving in secondary education were evaluated and 1154 students completed the questionnaire. The results indicated that teachers' strengths are related to the subject matter knowledge, the use of representations, questioning, the instructional objectives, classroom management, and the knowledge of students' difficulties. Their weaknesses concern some of the instructional strategies and methods, students' alternative conceptions, and assessment. These findings provide an overview of teachers' everyday practices and indicate the aspects of teaching in which teachers need support as well as potential areas that future professional development programs could focus on.

Keywords: Evaluation, Teacher Professional Development, Science Education Policy

INTRODUCTION

There is a strong correlation between the quality of education and the quality of practices in teaching. The quality of teachers' classroom practices constitutes a central issue for those who are concerned with teachers' professional development (Kallery & Psillos, 2001, p.166). Teachers' knowledge, teachers' practices, and teachers' professional development have been the subject of studies by many scholars (e.g., Van Driel & Berry, 2012).

In modern education, evaluation is seen as a meaningful and essential process for teachers' professional development. To highlight the strengths and weaknesses of teachers' practices, different evaluation systems have been applied worldwide. The most common method to collect data for teachers' evaluation is classroom observation with the use of a scoring rubric. (Isoré, 2009). However, scholars highlight that "classroom observation, no matter how well-focused, can only capture certain aspects of what a teacher has planned and indeed is undertaking in the classroom" (Shinkfield & Stufflebeam, 1995, p. 228).

On the other hand, students spend most of their school life behind a desk or participating in activities designed by the teachers. In turn, they can provide a more holistic look at teachers' teaching practices. Despite students' opinions perceived as a reliable and viable source of data (e.g., Peterson, Wahlquist, & Bone, 2000, Aleamoni, 1999), they are not systematically used as a source for teacher's evaluation (Isoré, 2009, Santiago, 2009).

Based on the above, we designed and applied an evaluation system specifically for science teachers using both a student questionnaire and an observation tool (scoring rubric), and we formed evaluation criteria (see Table 1), based on aspects of Pedagogical Content Knowledge (PCK). The present study aims to evaluate science teachers serving in secondary education and to highlight the weaknesses and strengths of their everyday practice. Based on this closer examination of individual teacher's needs, we provide a foundation upon which the future development of professional upgrading programs could be based.

METHOD

Evaluation criteria and levels of achievement

The evaluation system uses 21 criteria (see Table 1) in which teachers' practices are evaluated. The criteria are divided into four categories based on the PCK analysis of Jang (2011): Subject Matter Knowledge, Instructional Representations and Strategies, Instructional Objective and Context, and Knowledge of Students Understanding. In each criterion, the evaluation is based either on results from classroom observations or on students' opinions or both.

Tools of the evaluation system and data collection

Classroom observations were recorded using a scoring rubric designed by the authors and evaluated by experienced educational advisors. Students' opinions about teachers' performance were collected with the use of a questionnaire originally designed by Jang (2011) and adapted to the context of our study. Both tools use a five-point Likert scale. For each teacher, the observer performed direct first-hand observations of two one-hour lessons and scored the teachers' performance for every aspect of teaching. Students of two different classes answered the questionnaire. The science teachers were evaluated during the lesson of their major subject (e.g., Physicist – Physics).

Data were collected from both observation and students' questionnaires to collect data for the quality of the practices that teachers use in everyday teaching and the frequency that these practices are used, respectively. Furthermore, students' perceptions of the usefulness of some methods that their teacher use is essential for the evaluation of the teacher in some aspects of teaching.

Sample

The study was conducted in Central Northern Greece. Thirty-two (32) science teachers from Gymnasium and Lyceums participated in the study. Seventeen (17) of the teachers with major in Physics, twelve (12) with major in Chemistry, and three (2) with major in Biology. The sample was representative. The questionnaires were completed by 1154 students (579 male and 571 female), 484 Gymnasium students (12-15 years old) and 571 Lyceum students (16-18 years old).

Table 3: Evaluation criteria and the aspects of teaching recorded (R for scoring rubric and Q for students' questionnaire

Domain 3:Instructional Objectives and Context	
Criteria	**Aspects included in each criterion**
Instructional objectives and goals	*Instructional objectives and goals (communication and understanding) (R)* *Understanding of the lesson goal (Q)*
Interactive atmosphere	*Teaching Adjustment based on students' reaction (Q and R)* *Discussion on students' questions (Q)*
Students participation	*Students participation (R)*
Motivation for learning	*Motivation for learning (Q)*
Additional teaching material	*Additional teaching material (Q)*
Classroom management and mutual respect among students	*Classroom management (Q and R)* *Mutual Respect (R)*

Domain 4: Knowledge of Students Understanding	
Criteria	**Aspects included in each criterion**
Alternative conceptions investigation	*Teachers' Questions before introducing a new topic (Q)* *Alternative conceptions investigation (R)* *Strategies to handl students' alternative conceptions (R)*
Knowledge of students' difficulties	*Knowledge of students' difficulties (Q and R)*
Assessment during the lesson	*Use of different ways to access understanding (Q)* *Formative Assessment during lesson (R)* *Variety of assement methods and adjustment related to students' diversity (R)*
Summative assessment (test, etc.)	*Summative Assesment (tests, etc) (Q)*

Domain 1: Subject Matter Knowledge	
Criteria	**Aspects included in each criterion**
Knowledge of the content	*Knowledge of the content (Q)* *Adequete presentation of the topic (Q)* *Adequately answering of students' questions (Q)*
Quality of the language used during the lesson	*Quality of the language used during the lesson (R)* *Didactic tranformation (Q)*
Connection between the teaching notion or phenomenon and everyday life	*Connection between the teaching notion or phenomenon and everyday life (Q and R)*

Domain 2 : Instructional Representation and Strategies	
Criteria	**Aspects included in each criterion**
Instuctional Strategies	*Instructional Strategies (Variety and appropriateness) (R)* *Strategies maintaining students' interest (Q and R)*
Students' attentiveness related reactions during instruction	*Students' attentiveness related reactions during instruction (Q and R)*
Instructional representations	*Use of examples, analogies, graphs, everyday objects (Q)* *Appropriateness and usefulness of instructional respresentations (R)*
Use of ICTs	*Use of ICTs (Q)*
Use of experiments	*Demonstration of Experiments (Q)* *Students' experiments*
Inquiry	*Type of Inquiry (R)*
Scientific skills promoted by the teacher	*Scientific skills promoted by the teacher (R)*
Questioning	*Conceptual Level of teaching questions (R)* *Students' participation in questioning (R)*

Data analysis

The data from the questionnaire were statistically analyzed for each teacher and the mean of students' responses was calculated. The results from the scoring rubric and the means were inserted in a Sheet of Personal Evaluation. The evaluator compared and synthesized the results for each aspect of teaching recorded and made decisions about teachers' level of achievement on every criterion based on the following scale: Exceptional (Q:4.00-5.00, R:4 & 5), Adequate (Q:3.00-3.99, R:3), Weak (Q:2.00-2.99, R: 2) and Inadequate (Q:1.00-2.99, R:1). After the individual evaluation of teachers, a descriptive statistical analysis was performed to describe the strengths and the weakness among the science teachers of the total sample.

RESULTS & DISCUSSION

Subject Matter Knowledge

The results showed that the teachers were rated as exceptional or adequate in the criteria included in Subject Matter Knowledge (see Table 2). Teachers have good knowledge of their subjects. The quality of the language used during the lesson was exceptional for the majority of the teachers (Table 2, *Quality of language use during the lesson: Exceptional*) while the minority of them use some inappropriate expressions (mirror mistakes in verbs or expressions that seem to represent animistic views) but theu use does not seem to affect learning (Table 2, *Quality of language use during the lesson: Adequate)*. The connection of the topic to everyday life seems to be a common practice for a large percentage of the teachers (Table 2).

Table 4: Evaluation results' statistics for criteria included in the SMK domain

Level of achievement	Knowledge of the content		Quality of language use during the lesson		Connection to everyday life	
	Frequency	Percent	Frequency	Percent	Frequency	Percent
Exceptional	32	100	24	75	14	43.8
Adequate	0	0	8	25	14	43.8
Weak	0	0	0	0	3	9.4
Inadequate	0	0	0	0	1	3.1

Instructional Representations and Strategies

Teachers use a variety of teaching methods and techniques in which students are engaged and maintain students' interest in the lesson (Table 2: *Instructional Strategies*). Most of the teachers give students the opportunities to express their opinions (Table 2: *Opportunities for students to express their opinions*).

Moreover, teachers make proper use of instructional representations that seem to have a positive effect on the learning process. However, weaknesses are found in ICT-based teaching and the use of experiments during instruction. The vast majority of the teachers either use experiments rarely or never in their practice (Table 4: *Use of experiments, Weak and Adequate*) while another large percentage of them avoid using Information and Computer Technologies in their everyday practice (Table 3: *Use of ICT, Weak and Adequate*).

Table 5: Evaluation results' statistics for criteria included in the IRS domain

Level of achievement	Instructional Strategies		Opportunities for students to express their opinions		Instructional representations		Use of ICTs	
	Frequency	Percent	Frequency	Percent	Frequency	Percent	Frequency	Percent
Exceptional	18	56.3	14	43.8	24	75	6	18.8
Adequate	7	21.9	12	37.5	4	12.5	8	25
Weak	7	21.9	6	18.8	4	12.5	7	21.9
Inadequate	0	0	0	0	0	0	11	34.4

Teachers use mainly structured inquiry to promote basic skills (Table 4: *Types of Inquiry and Scientific Skills promoted by teacher*). Most of the teachers were rated as adequate or excellent in questioning. Teachers escalate the conceptual level of their questions (from basic to high level) in order to guide students to understand and explain the ideas or phenomena of the taught topic.

Table 6: Evaluation results' statistics for criteria included in the domain IRS

Level of achievement	Use of experiments		Types of Inquiry		Scientific skills promoted by the teacher		Conceptual level of teachers questions	
	Frequency	Percent	Frequency	Percent	Frequency	Percent	Frequency	Percent
Exceptional	7	21.9	4	12.5	4	12.5	9	28.1
Adequate	6	18.8	13	40.6	13	40.6	15	46.9
Weak	14	43.8	7	21.9	11	34.4	0	0.0
Inadequate	5	15.6	8	25	4	12.5	8	25.0

Instructional Objectives and Context

Teachers are also positively evaluated in the criteria included in the domain of Instructional Objectives and Context. Most of the teachers communicate the instructional objectives in multiple ways and achieve an understanding of them for most of the students (Table 5: *Instructional Objectives)*.

Table 7: Evaluation results' statistics for criteria included in the domain IOC

Level of achievement	Instructional objectives and goals		Interactive atmospheres		Students participation	
	Frequency	Percent	Frequency	Percent	Frequency	Percent
Exceptional	22	68.8	11	34.4	16	50
Adequate	10	31.3	11	34.4	15	46.9
Weak	0	0	10	31.3	1	3.1
Inadequate	0	0	0	0	0	0

Most of the teachers are successful in creating an interactive atmosphere in the classroom for the students to participate in the lesson, a not so palatable percentage of them is found weak in creating an interactive atmosphere. Also, as we can see in Table 6 (*Additional Teaching Material*) almost half of the teachers rarely or never provide additional teaching material.

Table 8: Evaluation results' statistics for criteria included in the domain IOC

Level of achievement	Motivation for learning		Additional teaching material		Classroom management and mutual respect among students	
	Frequency	Percent	Frequency	Percent	Frequency	Percent
Exceptional	4	12.5	7	21.9	20	62.5
Adequate	20	62.5	12	37.5	11	34.4
Weak	8	25	6	18.8	1	3.1
Inadequate	0	0	7	21.9	0	0

Knowledge of Students Understanding

In the domain of Knowledge of Students Understanding, the results highlight the most significant weaknesses of teachers' everyday practice. The majority of the teachers don't investigate and therefore do not handle students' alternative conceptions. Also they rarely assess students during the lesson and when they do it is for the students' compliance (Table 7: *Assessment during the lesson: Weak)*.

Table 9: Evaluation results' statistics for criteria included in the domain KSU

Level of achievement	Students alternative conceptions		Knowledge of students difficulties		Assessment during the lesson		Summative assessment	
	Frequency	Percent	Frequency	Percent	Frequency	Percent	Frequency	Percent
Exceptional	7	21.9	21	65.6	9	28.1	9	28.1
Adequate	4	12.5	9	28.1	10	31.3	17	53.1
Weak	5	15.6	2	6.3	13	40.6	6	18.8
Inadequate	16	50	0	0	0	0	0	0

However, teachers seem to have a good knowledge of the difficulties of the students in the topic they teach, and they focus on these in order to address them properly (Table 7: *Knowledge of Students' Difficulties)*.

Regarding students' summative assessment most of the teachers are evaluated as adequate (Table 7). However, because the findings of this specific criterion are based only on students' responses, students seem to question the usefulness of the type of assessment that teachers employ.

CONCLUSIONS

The findings of the present study provide an overview of the Greek science teachers' weaknesses and strengths regarding their everyday practices. This closer examination of the individual teacher's needs indicates potential areas that future professional development programs could focus on.

Even though this study focuses on the strengths and the weaknesses of teachers' practices, if we take into account the theoretical background of the Greek teachers and the lack of pre- and in-service teacher education in the country, we believe that we could describe some potential reasons for science teachers' strengths and weaknesses. On the one hand, the weaknesses observed and described above may be connected to a lack of teachers' knowledge related to *General Pedagogy* (e.g., Shulman, 1986)*, Knowledge of students* and *Knowledge of Assessment* (Magnusson, Krajcik, & Borko, 1999), and students beliefs about learning and the aim of teaching science (Van Driel, Beijaard, & Verloop, 2001). On the other hand, the strengths of the teachers are related to aspects of teaching that could be developed through their experience (Clermont, Borko, & Krajcik, 1994) as a kind of *craft knowledge of teachers* (Van Driel et al., 2001).

From the methodological point of view, the combination of the students' views with observations using a tool (scoring rubric) designed in collaboration with experienced educational advisors who have a good knowledge of the educational system in which teachers act in their every-day work, seems to be fruitful as it produces a holistic view of the practices that take place in the real everyday classroom (Shinkfield & Stufflebeam, 1995, p. 228).

INTERDISCIPLINARY REFLECTIVE TOOL ON SCHOOL SCIENCE AND MATHEMATICS

Georgios Kritikos[1], Andreas Moutsios-Rentzos[1], Vasileia Pinnika[1] and Fragkiskos Kalavasis[1]
[1]University of the Aegean, Rhodes, Greece

In this paper, we focus on the importance of interdisciplinary communication between the teachers' didactical interaction with textbooks of school science and mathematics. We adopt an interdisciplinary approach to argue that the scientific learning needs to be realised through making explicit the use of mathematical symbolism, as well as the mutual conceptual compatibilities or incompatibilities between science and mathematics. We argue that the students may face concrete learning obstacles for each discipline due to the lack of appropriate didactic communication between science and mathematics teachers. Drawing upon this perspective, we focus on the mathematical signs that co-appear in school science and mathematics, with the purpose to identify the divergences and the convergences between the associated meanings and intentionalities for each course. For this purpose, we introduce an interdisciplinary reflective tool that we developed, in order to create a communicational space between the teachers of science and mathematics.

Keywords: Interdisciplinarity, Reflection, Teacher Thinking

INTRODUCTION

The interdisciplinary approach presented in this study highlights the need for reflection on the common signs that appears in textbooks. We consider the epistemological framework of interdisciplinarity as a dynamic process of integrating the distinction and the connection of disciplines, recognising and highlighting the different methodological and conceptual approaches, as well as their common formal language and symbolism. Interdisciplinarity in education aims to link departmental pedagogical approaches in a convergent teaching framework (Nikitina & Mansilla, 2003).

We adopt a systemic approach to didactic situations, which allows us to focus on the interactions between official documents, research results and school practices to facilitate the emergence of the implicit teaching-learning processes in science and in mathematics which are explicitly linked to common symbolisms and, thus, to study its reverse effects on the construction of academic knowledge in each area. In this paper, we discuss a reflective tool that focuses on the importance of linking the teaching of science and mathematics.

We present the reflective tool that we have developed to emphasize the importance of linking science and mathematics education by managing the variety of alternative or complementary points of view that is compressed in the apparent commonality of terminologies or expressions. The first results of its application with teachers of the two disciplines seem to support our design, as it helped in creating a common space for communication and didactic collaboration.

THEORETICAL FRAMEWORK

In the school reality of a class, the students receive distinct, though invisibly interactive, messages from teachers of different disciplines. The interactions of the messages and their decoding are not explicitly considered during the teaching process. The artificial fragmentation of the scientific knowledge as realised through the (we argue misconceived) separation of disciplines is reflected on the compartmentalisation of the respective school courses, which creates invisible obstacles to the understanding of scientific concepts. Consequently, the students may construct alternative ideas generated from arbitrary interconnections between the meanings that are extracted from the discrete teachings of different courses. In our work, we adopt the systemic approach of the school unit (Davis & Simmt, 2003), which allows the exploration of the teaching-learning processes in the school Mathematics and Physics through their common signs.

In addition, we adopt an interdisciplinary approach of teaching that highlights the need for reflection on the common signs of school textbooks. The aim of this approach is the interconnection of teaching practices of different disciplines in an integrated teaching programme (Nikitina & Mansilla, 2003). We assume that interdisciplinary teaching and communication (Watzlawick, Beavin & Jackson, 1967) amongst the teachers of a school unit are essential for the learning of scientific concepts. We posit that the mathematical and scientific signs that appear in the school science and mathematics textbooks may be utilised to create a communication space within which the teachers of different disciplines may start sharing the meanings that they assign to each sign and their reflections about these meanings.

Our theoretical perspective focuses on the phenomenology of signs in an interdisciplinary teaching-learning approach (Moutsios-Rentzos, Kritikos & Kalavasis, 2017), based on theories that have been developed especially for mathematics education (Radford, 2006; Steinbring, 2005). In line with these ideas, we introduce a communicational semiotic system, which consists of a basic communicational triad “epistemic object – interpreter – sign” (Moutsios-Rentzos, Kritikos & Kalavasis, 2019; Moutsios-Rentzos, Pinnika, Kritikos & Kalavasis, in press) as shown in Figure 1.

A *sign* includes all the means of signification that may be employed within a communication and activates the communicative triad. For example, it could be a symbol, an image, a natural language word, as well as their combination as a complex whole constituting a phrase, an equation etc.

Interpreters are the participants in the communication processes. In the case of a school class, they usually are teachers or/and students. In our present study, we focus on the teachers-interpreters. Figure 1c represents the case in which the same teacher acts in a different way when teaching different disciplines. For example, in Greece, primary school teachers teach both Science and Mathematics. In addition, the same student may behave in different ways when attending different courses, because of the different teaching framework that activates specific representations from the corresponding representational registry (Duval, 2006).

Objects are the epistemic objects, fields, or courses, whilst the *meaning* includes the entirety that emerges from the communication interactions. Our conceptualisation allows for an important identification that occurs in everyday classroom teaching. The students are constantly asked to assume different roles, to be different interpreters in different courses, as for the same sign they have to assign meanings appropriate for the specific course. For example, the concept of “area” functions in ways that do not necessarily converge in Science and Mathematics. Consequently, in the proposed approach, we explicitly acknowledge and build upon the fact that the students do encounter the same mathematical symbolism in different disciplines, positing that the communication between the teachers of different courses is crucial for the students to give to their experiences of the phenomena distinct, yet connected, uni-disciplinary and inter-disciplinary meanings.

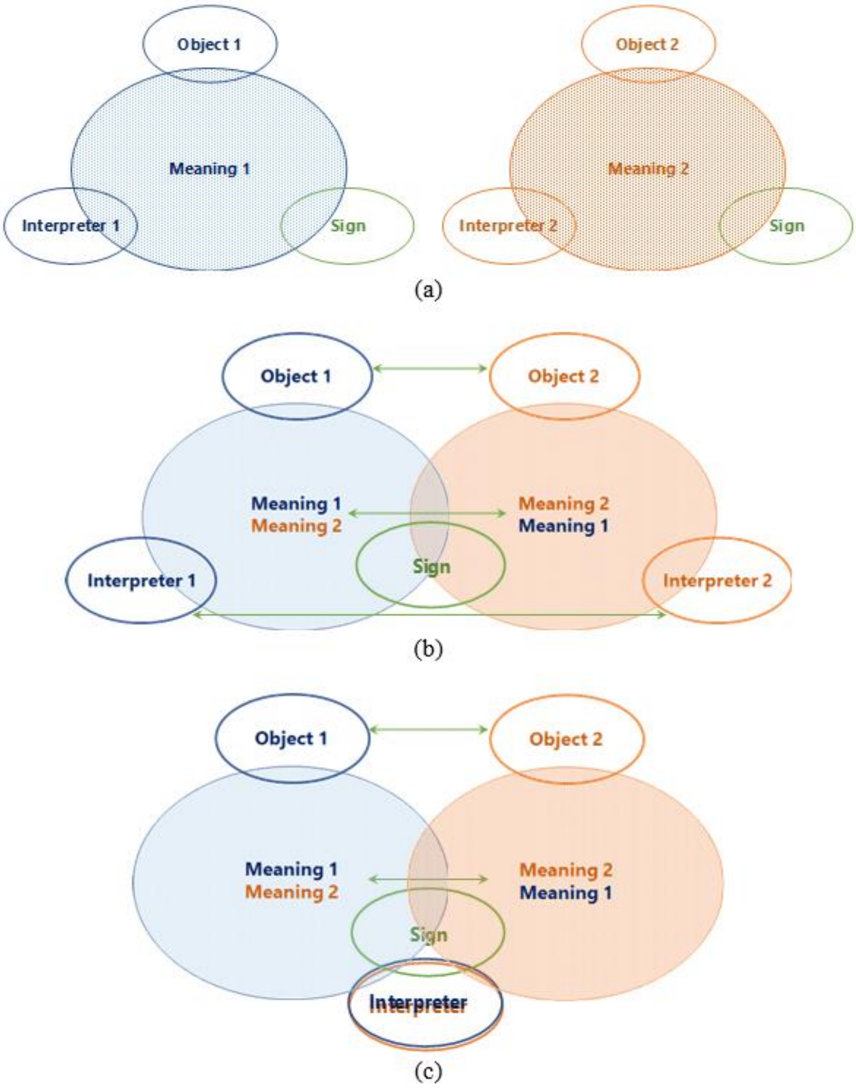

Figure 1. The proposed perspective of communicational space (adopted from Moutsios-Rentzos, Kritikos & Kalavasis, in press).

RESEARCH

The construction of the Interdisciplinary Reflective Tool (IRT) was based on a series of pilot studies that we had designed, focusing on the importance of the interconnection between Mathematics teaching and Physics teaching. In this paper, we present one of these pilot studies that is based on the case of the capacitor's capacitance. Our sample consisted of 28 teachers [6 Kindergarten teachers, 10 Primary teachers, 8 Mathematics teachers (Mathematicians), 3 Physics teachers (Physicists), and 1 Chemistry teacher (Chemist)] who attended the postgraduate programme "Didactics of Mathematics, Science and Information and Communication Technologies in Education: Interdisciplinary Approach" of the University of the Aegean, Greece. Moreover, we in included in our study the Greek school textbooks of Physics and Mathematics of the respective school grades.

The main research question was "Does the lack of interconnection between Mathematics teaching and Physics teaching affect the construction of Concepts in Physics?". We chose as example the concept of capacitor's capacitance, because we knew that this concept is taught only for a few lectures in high school Physics, without any explicit linking with Mathematics teaching, whilst the conceptually linked hyperbola equation y=a/x had been taught in depth in Mathematics. Therefore, our hypothesis was that the participants may incorrectly link the capacitance's formula C=Q/V to the hyperbola equation y=a/x, due to the apparent commonalities of the *form* of the employed signs.

In such situation, as shown in Figure 2, the same students receive messages from Mathematics and Physics courses, with seemingly similar signs, usually without appropriate links between the distinct Mathematics and Physics teachings. As a result, the students may incorrectly think that the calculating formula C=Q/V for the capacitance is conceptually similar to the hyperbola equation y=a/x. Besides, research from science education suggests that one of the common alternative conceptions that the students hold about the capacitance C is that C is proportional to the capacitor's charge Q (Kritikos & Dimitracopoulou, 2017).

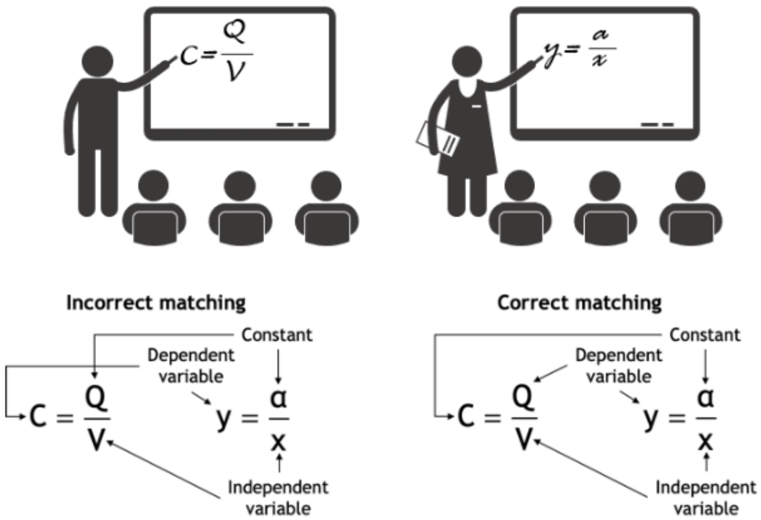

Figure 2: Interacting meanings in non-communicating discrete Mathematics and Physics teachings.

Methodology

Considering that most of the participants did not have any knowledge of the capacitor and its capacitance, we illustrated a short superficial instruction. In particular, we mentioned that the capacitor is an electrical element that has the capability to store charge when connected to a voltage source. In addition, the calculating formula C=Q/V for the capacitance was given, explaining the symbols C, Q and V. Notice that that we deliberately did not mention that the capacitance was not affected by either the load or the voltage, since it was a demand of the workshop activity (Figure 3) that the participants were involved with.

A capacitor is charged by a battery of voltage V. Thus, it stores charge Q. The capacitance C of the capacitor can be calculated by the formula:

$$C = \frac{Q}{V}$$

If we replace the battery (V) with another of double voltage (2V), then the capacitance C will be:

a) doubled. b) halved. c) the same.

Choose the correct answer by marking X in the corresponding cell in the table below. For each incorrect answer, write in the corresponding cell the grade (maximum of 10) that you would give to a student who had chosen it.

a	b	c

Figure 3. Workshop activity: Capacitor's capacitance.

The purpose of this activity was to investigate whether the semiotics of the formula y= a/x and the school mathematical knowledge "when the denominator of a fraction changes, then the fraction changes inversely" affect the learning of a concept in Physics. This mathematical knowledge is incomplete, as the numerator is not declared –though considered to be– as a constant. As a result, this could constitute an interdisciplinary learning obstacle in the students' paths towards constructing appropriate scientific meanings about the capacitor's capacitance.

In this pilot study, we focused on identifying the diversity of sources that appear to be related to students' alternative conceptions. For this reason, we reviewed and studied the sections about capacitor's capacitance in the Physics school textbooks, as well as the sections about the proportional quantities and the straight-line equation y=ax in the Mathematics school textbooks.

RESULTS

Findings from the workshop activity

The results from the workshop activity showed that only Science teachers (4 out of 28) responded correctly (answer c; see Figure 3). Among the 24 incorrect answers, 21 were that when the voltage gets doubled, the capacitance gets halved (answer b), whilst 3 thought it would get doubled (answer a; see Figure 3). For the 24 non-Science teachers, the question had not any conceptual content compatible with the physical meaning of the capacitance, as their knowledge was superficial from their school years. However, they spontaneously answered, relying mainly on their mathematical knowledge. Therefore, the conceptual content that they activated was based on Mathematics rather than Physics. Those who chose "b" as the correct answer were particularly strict in evaluating the students who would choose answer "c", whilst they were lenient about those who would choose "a". One of the participants justified his evaluation with the following explanation: *"…The student who chose (c) did not realize that changing V would result a change on the fraction, whilst the one who chose (a) at least saw that something would change…*". We argue that in this phrase, it is evident the crucial interdisciplinary effect of the mathematical knowledge "when the denominator of a fraction changes, then the fraction changes inversely" (implying that the numerator remains constant), which is also related to the hyperbola equation. Note that in Greece the same students that have been taught the hyperbola equation y=a/x, have been also taught the calculating formula C=Q/V for the capacitance; nevertheless, they have been taught in different courses, by different teachers, in different learning contexts. The apparent commonality of the empoloyed signs between the two writings may be incorrectly matched by the students, as shown above in Figure 2. As a result, the symbol C in the left-hand member of the relation is assigned to the independent variable y, which is also in the left-hand member. The symbol Q is assigned to the constant a, as fraction numerators. The only correct match is between the symbol V and the independent variable x. As indicated by the participants' responses, semiotic form (in this case mathematics) matching (even incorrectly) prevailed over the conceptual content (in this case physics), as no one sought to investigate the physical meaning, nor the relationship between Q and V magnitudes.

Findings from school textbooks

An additional issue arises from a phrase in a Physics school textbook (Alexakis et al., 2013), related to the quotient and the role of equality: "*Capacitance C of a capacitor is called the scalar physical magnitude that is equal to the quotient of the capacitor's electrical charge Q by the capacitor's voltage V. C=Q/V*" (p. 32). Mathematics education researchers (Jones & Pratt, 2012; Knuth et al., 2008) identify two main functions of the equality sign: relational and operational. Relational equality refers to the equivalence relationships (y is equal to x), whilst operational refers to the result of an operation. The quotient refers to operational equality, so that capacitance is considered to be the result of an operation, in this case the operation of division. However, the value of the symbol C does not depend on the Q/V operation, since the capacitor's capacitance exists even if there is no voltage or charge at its terminals. Instead of the term "quotient", a more legitimated term would be the "ratio", which refers to relational equality and imposes a proportional correlation of the numerator with the denominator. Of course, the problem of indeterminate form 0/0 arises when the voltage and charge are 0. To avoid this teaching barrier, but also the confusion caused by incorrect matching, we consider the mathematical form Q=CV to be more appropriate. Thus, the equation y=ax is recalled from Mathematics. In a Mathematics school textbook (Vlamos, Droutsas, Presvis & Rekoumis 2013), a paragraph is entitled "*The function y=ax*" and begins with the subparagraph "*Proportional quantities – The function y=ax*". The same paragraph refers to a ratio rather than a quotient: "*We see that in the straight-line y=ax the ratio y/x is always constant and equal to a, that is: y/x=a, for x ≠ 0*" (p. 68). Drawing on their mathematics knowledge of the equation y=ax students can move on to the relation Q=CV, where the common signs is compatible with the correct matching, as shown in Figure 4.

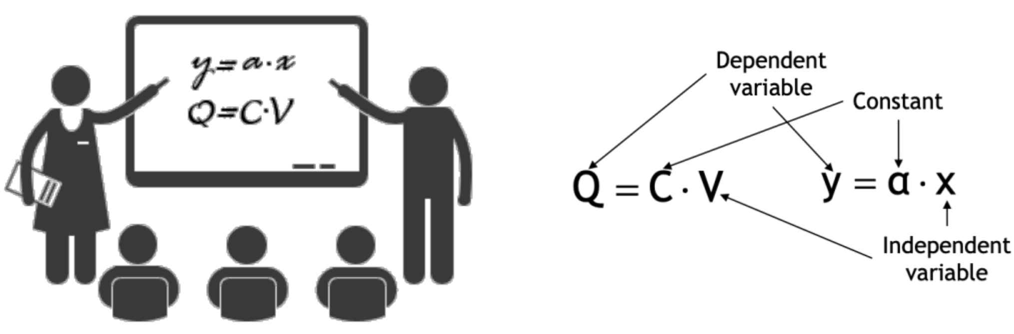

Figure 4: Interacting meanings in communicating Mathematics and Physics (co)teachings.

This is in line with our finding that teachers, who did not activate any physical meaning, they activated a mathematical meaning. Therefore, it is important the spontaneous mathematical meaning, which is activated anyway, to assist in the construction of the intended physical meaning. In an interdisciplinary (co)teaching environment, the role of the independent variable x may be emphasized in combination with the voltage V of the battery, the value of which is independent of the capacitance. Furthermore, the analogy between dependent-independent values and results-cause could be shown up as follows. The value of the dependent variable y is determined by the value of the independent variable x, such as the value of the charge Q is the result of the cause V. Thus, an additional matching arises that concerns not only the magnitudes but also the relationships between them. In addition, in the formula Q=CV the pair of values V=0, Q=0, is allowed regardless of the value of C.

At this point, we have to make clear that the use of the formula Q=CV instead of C=Q/V does not promise the correct physical meaning, but at least it avoids the creation of incorrect meaning through incorrect matching.

DISCUSSION – TOWARDS THE INTERDISCIPLINARY REFLECTIVE TOOL

The artificially imposed compartmentalisation of disciplines creates barriers to the communication of teachers of different disciplines. However, students make links between meanings with similar semiotics. We posit that when these links are scientifically incompatible, learning barriers emerge, which are often not attributed to the incorrect linking between the different disciplines, since the search for the didactical causes within a discipline is made with reference to the didactics of that particular discipline exclusively. For example, if a student expresses the alternative idea that the capacitor's capacitance is proportional to its charge, often the search for the factors of the student's holding this conception is limited to the didactics of Physics. Even in the case that mathematical causes are sought, they will rarely be found in the didactics of Mathematics. With our proposed interdisciplinary approach of (co)teaching in Mathematics and Physics, we look for the causes of learning barriers, through both didactics of Mathematics and Physics (Moutsios-Rentzos et al., 2017; Moutsios-Rentzos et al., 2019; Moutsios-Rentzos et al., in press). This search requires the collaboration of teachers from both disciplines, where each one contributes from its own perspective. Therefore, we do not refer to the unification of teaching disciplines, but to the convergence of teaching practices when common signs appear, which if not presented in a converge way (either by parallel teaching or by coteaching), can lead to learning obstacles in both of the two cognitive disciplines.

In order to assist teachers of different disciplines to communicate their teachings, we designed the Interdisciplinary Reflective Tool (IRT), which aims to highlight the importance of linking Science and Mathematics teaching. According to the protocol of the tool, the participants initially work individually, answering questions in a questionnaire. Questions refer to selected pieces from science and mathematics school textbooks. Subsequently, the participants work in groups of the same discipline, answering group questionnaires, based on the same pieces of the textbooks. In this way, we aim at interdisciplinary reflection amongst teachers of the same discipline. Then, we ask the participants to choose the two most important problems that converge both for the teaching of science and mathematics. Finally, we ask all the groups of different disciplines to reflect interdisciplinary, presenting in the plenary session the two most important problems that they had chosen before as a group. The final step includes a discussion on the solutions of the problems, using the resources of each lesson, but also between them, as the boundaries between the disciplines have been permeable. Below, we cite a sample of questions of the protocol, based on the concept of "area".

- Based on your experience as a teacher, think about the uses and meanings of the concept of "area" in Physics and Mathematics.

- Do you think that the meaning of concept of “area” is different in Physics than in Mathematics?
- Do you consider that the uses of the concept of “area” are different in Physics than in Mathematics?
- Study the following examples on the meaning of the concept of “area” from the school Physics and Mathematics textbooks. Concentrate on the impressions of the concept of “area”, its uses and its meanings.

1. Could you identify any representations of area and signs of measurement units that may cause problems in the students’ understanding of Mathematics ideas? In specific:

   In the representations you identified, according to your opinion, which problems about learning Mathematics derive from inappropriate already taught/learnt Mathematics knowledge?

   In the representations you identified, according to your opinion, which problems about learning Mathematics derive from inappropriate already taught/learnt Physics knowledge?

2. Could you identify any representations of area and signs of measurement units that may cause problems in the students’ understanding of Physics ideas? In specific:

   In the representations you identified, according to your opinion, which problems about learning Physics derive from inappropriate already taught/learnt Physics knowledge?

   In the representations you identified, according to your opinion, which problems about learning Physics derive from inappropriate already taught/learnt Mathematics knowledge?

3. What would you advise:

   a fellow Mathematics teacher, in order to help her/him to avoid the aforementioned potential problems that the students may face?

   a fellow Physics teacher, in order to help her/him to avoid the aforementioned potential problems that the students may face?

   the textbooks authors?

   the curriculum designers?

Concluding, the IRT supports teachers of different disciplines to communicate and reflect in various ways of interdisciplinary reflection. One way is self-reflection, when separately each member of a group studies the given examples. Another way is group (collective) reflection when the members of a group express their opinion about the obstacles in learning. In the framework of a single-discipline group, the reflection is one-perspective, whilst in the plenary session, the reflection is cross-perspectives. Finally, we plan to design a web-supported IRT platform, in which teachers may communicate either asynchronously or in real time and reflect in any of the aforementioned ways.

ACKNOWLEDGEMENT

EVALUATION CONCEPTIONS AND SCIENCE TEACHING CHALLENGES IN THE CONTEXT OF TEACHING PLANNING

Nicole Glock Maceno[1] and Marcelo Giordan[2]
[1] Laboratory of Research in Chemistry Teaching and Educational Technology,
Faculty of Education, University of Sao Paulo, University of State of Santa Catarina, Brazil.
[2] Laboratory of Research in Chemistry Teaching and Educational Technology,
Faculty of Education, University of Sao Paulo, Brazil.

This work discusses the relevance and the planning of the learning evaluation by four secondary chemistry teachers from the Joinville city (Brazil) starting from twenty-two questions formulated weekly in a continuing formation course and the use of Topological Model of Teaching. The questions were analyzed by inductive coding and classified into two categories: (1) Evaluation Conceptions and (2) Science Teaching Challenges. The problem of the study was focused on the conceptions and models of teachers´ learning evaluation from the questions elaborated in a context of continuous formation, and how the planning of didactic sequences by socio-scientific issues and the use of a teaching model allowed them to develop and qualify the evaluation in its planning.

Keywords: Evaluation, models in science, teacher preparation.

THE RELEVANCE OF TEACHING PLANNING AND THE EVALUATION MODELS

The planning and use of evaluative models has been emphasized in the literature as a possibility of structuring and orienting important processes to scientific education, as well as promoting teaching contexts based on interactivity and on the production of knowledge about human learning. The quality of the evaluation developed by the teacher depends, to a large extent, on the socio-scientific themes, concepts and activities chosen and the use of models that allow teachers to create authentic and original curricula and teaching proposals, and they must be meaningful in the situated context in terms of the different educational contingencies of educational systems (Giordan, 2008; Maceno, Lara & Giordan, 2018).

It is an important part of investigations the attention to the models in order to characterize and explain the nature of the evaluation planning and how teachers drive the evaluation processes during the teaching (Bell & Cowie, 2001). One of the essential aspects of understanding an evaluation model is to analyze the relationships between planning, conceptions and teaching purposes, since models and theories guide the teaching activity in the classroom (Giordan, 2008; Bell & Cowie, 2001). Equally relevant is to study the dilemmas (Bell & Cowie, 2001) and the challenges in the planning of learning evaluation (Grob, Holmeier & Labudde, 2018) that can be analyzed by the questions addressed by science teachers as socioscientific problems and reflection on diverse teaching situations. Thus, the main purpose of learning evaluation is to contribute to improving education and schooling in various aspects, elements and factors.

The evaluation also requires the analysis of processes and the judgment of the evidence, productions and quality standards. In this sense, the guidance and use of teaching and evaluation models allow teachers to interpret and understand human development. The models, with characteristics, comparative traces and functions, produce conceptions and meanings to the phenomena and processes of the classroom, besides the accompaniment, justification and strategies for the improvement of the learning environments (Giordan, 2008).

When used a teaching model, reference standards are established by the teacher, which allows understanding the related phenomena and guiding action by a paradigm of understanding about educational processes. Through support and guidance according to a model, the teacher uses theory, be it learning, language or philosophical, and creates explanatory modes for classroom phenomena. A model is meant the more it is used by the teacher so that it has use value to conduct daily teaching activities. By analogy, a teaching model can become an evaluation model, given the intrinsic relationship between them. It is expected that a teacher, by valuing a teaching model used to guide his action and for his own purposes, also establish new explanatory ways for the evaluation of learning. Thus, reflecting about teaching oriented by one model is a first step in reframing pedagogical practice, and it is also necessary to create new ways of understanding and conducting the evaluation.

The Topological Model of Teaching and the teachers' questions as data source

The scientific literature has several teaching models that guide the concepts and the knowledge of evaluation by science teachers. Among them, the Topological Model of Teaching (TMT) is a socio-cultural approach based to the theory of mediated action, which assumes that a classroom is endowed with its own culture, organization and characteristics (Giordan, 2008). It is configured as a model of teaching organization for the planning of activities, lessons and didactic sequences from the articulation of socio-scientific issues with a problem that is developed and solved along the sequence. The main objectives of the TMT highlighted in this work are to make use of questions to encourage and accompany the learning, to analyze in the conceptual dimension the rules and reasoning used, to contextualize the challenges of the classroom, to foment the questioning and debate of central issues to scientific education (ibidem).

When discussing a teaching model in a continuing formation course, teachers ask questions that, in addition to various topics, can be a source of information about their professional needs and the daily dilemmas they face in the classroom. Considerable part of the discursive interactions in a continuing formation course stem from teachers' questions. The use of questions helps in the elaboration of meanings, mastery and appropriation of other cultural tools by teachers as well as the understanding of educational processes. The question is crucial for the triggering of teaching action, being used with various functions. For Wertsch (1998), the question is considered a specific type of statement and is succeeded by its partner - the answer - as it is expected to occur. Questions are a discursive marker in different types of interaction, as well as being a link in interactional sequencing and can be used for initiation, development or termination of dialog units. When asked by teachers, questions can provide information about self-satisfaction with work, school climate, doubts and professional needs.

In this sense, the study problem was:

1. What are the conceptions and models of learning evaluation of the teachers from the questions elaborated in a context of continuing formation?

2. How did the planning of didactic sequences for socio-scientific problems and the use of the teaching model allowed them to develop and qualify the evaluation in their planning?

The problem of this study was to analyze the themes, contingencies and challenges that science teachers pointed out about the classroom through the analysis of questions elaborated during a continuing formation course. The questions were elaborated in a context of discussion of teaching plans based on the TMT and explored curriculum, discursive interactions, evaluation and other issues related to teaching.

METHODS

The study was conducted in one semester with four science teachers from the city of Joinville (Brazil) who worked in public high school. During one semester, a continuing formation course based on the TMT was developed, in which the teachers weekly produced questions about the texts read. Twenty-two questions were elaborated, analyzed and classified in two categories: (a) *Evaluation conceptions* and (b) *Science Teaching Challenges*. For the first category, one has considered four subcategories proposed by Hargreaves, Earl & Schmidt (2002) and to the second, the subcategories were emergent and inspired by the study of Grob, Holmeier & Labudde (2018).

According to Hargreaves, Earl & Schmidt (2002), there are four evaluation conceptions: the *technological*, focused on the organization, strategies, uses of techniques and methodologies to evaluate; *cultural*, focused on the interpretation of evaluations and their integration with the social and cultural context of schools under a socioscientific problem; *political*, focused on the incorporation and dynamics of power and control between administrators and schools for accountability; and *postmodern*, focused on experiences, multiculturalism, and questions about the impact of complexity, diversity, and uncertainty on evaluation.

In the study by Grob, Holmeier & Labudde (2018) it was investigated how peer evaluation affects student learning in science education. In the study, the researchers analyzed the teaching plans, individual interviews and focus groups of 17 swiss elementary and high school teachers and identified eight evaluation challenges from the perspective of the interlocutors. Based on the study by Grob, Holmeier & Labudde (2018), the second category of this work was proposed to identify the main challenges pointed out by teachers in science education.

The questions was analysed by Nvivo 12® software with the tecniches of word frequence, automatic analisy of *themes* and *sentiments*. Automatic coding by *themes* groups coded references and indicates possible nodes for analysis. Automatic *sentiment* coding indicates the overall tone of the content as positive or negative by coding entire sentences, paragraphs, or documents (Qualitative analysis software international, 2016).

DISCUSSION

For the twenty-two questions asked in the course of continuing formation, eleven explored the relation between teaching and evaluation (1, 2, 3, 5, 6, 7, 8, 9, 12, 15, 17), five encompassed exclusively evaluation (4, 11, 13, 14, 20) and six were not categorized because they were doubts about specific terminologies of texts read (10, 16, 18, 19, 21, 22).

Among the conceptions of evaluation (Table 1), the teachers indicated mainly the *cultural* one, with questions about curricular planning and development, how to explore real problems in the classroom, how to promote learning and interaction in social and cultural contexts facing the particularities of schools, how to contextualize topics, how to select concepts, the language forms, strategies and approaches to be used by the teacher to benefit students' curricular and cultural development, as well as the analysis of their productions and results achieved. In few questions, the *political* conception of evaluation was explored, with mentions to the dilemmas and challenges of discourse control, relationships and roles of teachers and students in the process of elaborating answers to the questions that aim to understand the learning situated in the classroom. Questions about structuring activities, teaching planning and the impacts of student diversity and information and communication technologies on culture and society were rare, but were asked by teachers.

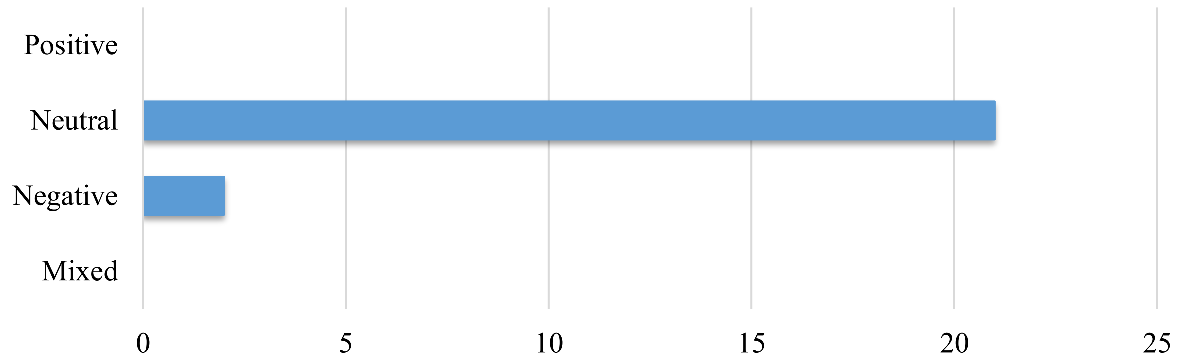
Subcategories	Description	Question
Technological	Structuring and development of measurement techniques	7, 20
Cultural	Interpretation and meaning of ideas, reflections, problematizations and judgments in school socialcultural contexts	1, 3, 4, 5, 6, 8, 11, 12, 15, 17
Political	Result of negotiation and dynamics of power and control in human interactions and by institutional requirements	2, 9, 13
Postmodern	Complexity, uncertainty and questioning in the culture and society caused by information and communication technologies and by the students´s diversity	14

Table 1. Evaluation conceptions of chemistry teachers. Source: the authors using the manual coding using Nvivo 12® software.

Complementing Table 1, when proceeding with word frequency analysis and automatic analisy of *themes* using the Nvivo 12® software, it was observed that the teachers presented questions about the following themes: problematization, environment, meanings, learning difficulties, contextualization, discursive interactions, evaluation, language, diversity, concepts and mediation. Such themes mainly evoke the conceptions of evaluation of *cultural*, *political* and *postmodern*. Complementing the ideia, the word cloud is show in the Figure 1 using the word frequency tool.

Figure 1. Frequency of words in chemistry teachers´ questions. Source: the authors using the word frequency tool using Nvivo 12® software.

The Graphic 1 show the automatic coding by *sentiments* of paragraphs indicated that the overall tone of the 22 questions was eminently neutral and in rare cases negative. The software identified 23 coding references in the document with all questions.



Graphic 1. Automatic coding by sentiments of 22 questions elaborated by teachers. Source: the authors using the automatic coding by sentiments using Nvivo 12® software.

Comparing the conceptions of teacher evaluation highlighted in this study with the results found in the literature, the differences are noticeable, since in most studies teachers evoke a *technological* perspective (Hargreaves, Earl & Schmidt, 2002; Celik & Walpuski, 2018; Freire & Fernandez, 2018) rather than *cultural*, *political* or *postmodern*.

Considering that the teachers in this study indicated more questions about the *cultural* perspective of evaluation under a predominantly neutral, it is possible to understand that their main concerns are about how to interpret learning in school contexts and how to integrate these contexts into scientific culture. According to Hargreaves, Earl & Schmidt (2002), from a *cultural* perspective, the challenge to evaluation is to rethink its nature and purposes in the classroom and how to integrate teachers 'collective judgment with their students' learning potentials. From this perspective, teachers seek to assess under a common understanding through dialogue to detect students' representations and ideas when seeking to solve authentic problems, which demands equally authentic evaluations (ibidem).

Among the challenges facing teaching science (Table 2), teachers mentioned the difficulties in contextualizing current issues while at the same time observing national curricular guidelines and the time available for teaching (challenge 1), which should also consider students´ diversity (challenge 2) and the language used by the teacher in the classroom (challenge 3).

In this way, the evaluation can be qualified from the creation of strategies and approaches by the teacher to overcome the students' lack of participation in the classroom dialogues and the incompleteness or limitation of the short answers expressed by them (challenge 4), also benefiting the relationship inside the classroom (challenge 5) and the understanding of making meaning, the analysis of student performance (challenge 6), the production of authentic answers to the questions addressed (challenge 7), and the constructive reflection on mistakes, problems and failures identified in the teaching of planning and the evaluation process (challenge 8).

Challenge	Description	Question	Total
1	Contextualization of current themes, national curricular guidelines and teaching time	1, 5, 6, 12	4
2	Teaching for diversity	2, 14	2
3	Forms of language used by the teacher	3, 8	2
4	Lack of participation in class discussions and incomplete / short answers of the students	4, 7	2
5	Relationship and roles of teacher and students	9, 17	2
6	Elaboration of meanings and analysis of students´ performance	11, 15	2
7	Elaboration of authentic answers by students	13	1
8	Identification and reflection on errors, failures and planning problems	20	1

Table 2. Science Teaching Challenges of chemistry teachers. Source: the authors using the manual coding using Nvivo 12® software.

In part, the results of this study are close to those obtained by Grob, Holmeier & Labudde (2018) regarding teachers' challenges in judging and making decisions about student performance and how to create plans for evaluation activities. As in this study, the need for progress at different levels of learning from evaluation and teacher-student relationships were also two challenges identified in the research by Nielsen, Dolin, Brunn & Jensen (2018).

CONCLUSION

In a context of professional development and planning of original proposals on socio-scientific issues from a teaching model, the questions addressed by the teachers explored the evaluation mainly as a cultural conception, that is, they were centered on the creation of pertinent curricula to the school and that could be at the same time, feasible, problematizing and propitiate the collective discussion about the selected issue, the elaboration of meanings and the learning. Nevertheless, concerns were raised about how to conduct the dynamics of negotiations and about the control and power of teachers and students in a shared way, such as considering the cultural diversity and current social demands for the classroom, the influence of technologies and how to organize activities and concepts in teaching planning.

One of the concerns in teaching planning is also the evaluation organization. In general, the study reported different challenges about evaluation: related to teaching (contextualization of planned subjects, available time, student diversity, teacher language, student performance analysis techniques), questions and answers, the answer authenticity, elaboration of meanings, errors, problems´ learning) and to the interactional dynamics (rules, participation, interpersonal relationships). Similarly, studies by Grob, Holmeier & Labudde (2018), Hargreaves, Earl & Schmidt (2002) and Bell & Cowie (2001) point out teachers' dilemmas in making evaluation a learning opportunity, requiring new teaching strategies as the classroom challenges emerge, it expands and qualifies the planning of teaching initially developed, providing a continuous and reflective creation of the teaching plan.

Although there are limitations on the information obtained by teachers' questions and their conceptions and models of evaluation, it can be said that they evoke a *cultural* perspective, which is congruent with TMT's purposes and indicates teachers' attention to social conventions, language and how to plan teaching proposals that enable the elaboration of meanings considering diversity and contextualization. The planning of didactic sequences for socio-scientific problems using TMT as a teaching model also allowed teachers to develop and qualify the evaluation in their planning by reflections on performance, the use of socio-scientific problems, the language in science teaching, the interactions discursive and think about mediation. By considering these aspects, teachers were able to introduce thematic of their interests in the continuing formation course and to reflect on how studies from the sociocultural perspective can contribute to science teaching.

ASSESSING NOVICE AND EXPERIENCED STEM TEACHERS' PROFESSIONAL GROWTH

Effrat Akiri[1], *Yehudit Judy Dori*[1,2]
[1]Faculty of Education in Science and Technology, Technion, Haifa 3200003, Israel
[2]Samuel Neaman Institute, Haifa 3200003, Israel

Supporting novice STEM teachers during their first two years in the classroom is crucial for their occupational retainment. Experienced teachers that mentor them can also benefit from the mentoring process. This study examines a three-tier support system for novice teachers, including: 1) personal mentoring by experienced teachers, 2) participation in professional development workshops, and 3) being part of a STEM teachers' professional community formed through participation in a workshop. The study included novice STEM teachers (N=104) and experienced teachers (N=102). To understand the support system effect on both novice and expert teachers' growth, we used the framework of teacher development which identifies key aspects of social, professional, and personal growth. Interviews and a questionnaire with open- and closed-ended questions were utilized. Results showed that all three tiers of support facilitate substantive social, professional, and personal growth.

Keywords: Teacher Induction, Communities of Practice, In-service Teacher Training.

INTRODUCTION

Various induction programs that support novice teachers have been implemented worldwide (Bower-Phipps, Klecka, & Sature, 2016; Geva-May, & Dori, 1996; Luft, Firestone, Wong, Ortega, Adams, & Bang, 2011), because such support can make the difference between retention and attrition. Novice teachers require support in building competency for many of the aspects of successful teaching, including pedagogical knowledge (PK), pedagogical-content knowledge (PCK), and classroom management. Methods of support can include mentoring by more experienced teachers, professional development workshops, and being part of a community of teachers. Science, Technology, Engineering and Mathematics – STEM novice teachers' retention can be promoted by interpersonal support of other teachers, which can foster their morale and sense of belonging (Aspfors & Fransson, 2015). Communities of teachers provide an opportunity to learn and develop in an environment where novice and experienced teachers' voices have an equal impact, thereby empowering the novice teachers (Vangrieken, Meredith, Packer, & Kyndt, 2017).

The Teacher Induction Unit at our university supports novice STEM teachers’ transition into the classroom, during their first two years of teaching. Most of these teachers are recent graduates of our undergraduate or graduate programs in STEM Education. As part of the unit’s initiatives, these novice teachers receive three tiers of support: 1) personal mentoring by experienced teachers, 2) participation in professional development workshops, and 3) being part of a STEM teachers' professional community that is promoted by participation in our ongoing workshops. We analyzed the data collected based on the theoretical model of teacher development (Bell & Gilbert, 1994; Dori & Herscovits, 2005), which consists of three distinct aspects of growth over the course of one's career: *social* – interpersonal interactions with colleagues, such as valuing collaborative ways of working, *professional* – learning and developing new ideas and teaching activities (Avargil, Herscovitz, & Dori, 2012), and *personal* – emotional characteristics, including those needed to overcome the challenges inherent in integrating new ideas and methodologies into one's teaching. The three aspects are dynamic and interact with each other. Within each aspect of growth are three levels.

Self-efficacy, rooted in the social-cognitive theory (Bandura, 1986), is one's belief in her own ability to act in order to achieve desired performance. Self-efficacy develops by personal direct and indirect experiences, verbal persuasions by others, and self-belief, based on the emotional and physical feeling of the individual. Teaching self-efficacy is the teachers' belief of in his/her own ability to bring a positive change and students' learning outcomes (Siwatu, 2007). Science teaching self-efficacy relates to the teachers' belief in their ability to teach science (Ramey-Gassert, Shroyer, & Staver, 1996). Novice teachers have been found to have lower levels of teaching self-efficacy. A mentor, a role model with whom the teacher can identify, can contribute to a higher level of teaching self-efficacy through modeling and supporting. Support by colleagues and community can also make a significant contribution to the teachers' self-beliefs (Tschannen-Moran & Hoy, 2007).

Our research goal is to assess novice STEM teachers' professional growth as well as the professional growth of their mentors who are experienced STEM teachers. In what follows, we use the term 'teachers' growth' to refer to changes and development teachers go through, because the term 'professional development' is used to describe the workshops the teachers attended rather than their actual influence on the teachers.

METHOD

The research participants included 104 novice and 102 experienced STEM teachers who attended a series of professional workshops conducted in the Teachers' Induction Unit at our university. All the participants were involved in mentoring partnerships, either as a mentor—the experienced teachers—or as a mentee—the novice teachers. Mentors were expected to meet the novice teachers weekly, observe them in their classrooms, and provide feedback and support. The workshop duration was 60 hours for novice teachers and 30 hours for 2nd year teachers and mentors. Workshops consisted of four-hour sessions, in which real-life issues were discussed and support was offered by workshop facilitators and peers. Some of the sessions combined novice, 2nd year, and experienced teachers together to form a heterogeneous community. To build the community, novice teachers (first and 2nd year) met with the experienced teachers to develop strategies for addressing content-specific and pedagogical topics and to share their knowledge and perspectives about the many personal and professional issues that arise over the course of a teaching career. The sessions included discussion of STEM content-related topics, class management issues, and navigating a STEM education career path.

Table 1. Research setting

Activity	Frequency	Content
Mentor-Novice meetings	weekly	Lesson planning Best practices and instruction pedagogies Observations Feedback
Novice teachers' workshops (N=104)	bi-weekly	Class managements practices Emotional support Pedagogical topics
Mentors' workshops (N=102)	bi-weekly	Mentoring skills Emotional intelligence Pedagogical topics
Teachers community meetings	bi-monthly	Emotional intelligence Content knowledge Pedagogical topics

*Data collected along three years

Research tools included open- and closed-ended questionnaires for all of the participants and semi-structured interviews with four novice teachers and their four mentors. The interviews included questions such as "Describe your relationship with your mentor/mentee," and "In what ways do you think you contributed to the mentor-mentee relationship?" The questionnaires included three parts: questions regarding the novice teachers' teaching self-efficacy (N=205), questions included in the Mentoring for Effective Primary Science Teaching (MEPST) instrument (N=88), adapted for secondary school (Hudson, Skamp & Brooks, 2005), and perceptions of the novice teachers regarding the workshops' effect on their professional growth (N=166). It is important to note that unlike the novice teachers who responded to the teaching self-efficacy questionnaire, the mentors were asked about their mentees' teaching efficacy. The data were collected and analyzed in a convergent parallel mixed methods design. Combining data from the interviews and questionnaires enabled deeper understanding and data triangulation (Creswell & Creswell, 2017).

RESULTS

Our findings show a gradual elevation in the novice teachers' teaching self-efficacy. We also found a significant difference between the novice teachers' teaching self-efficacy and the perceptions of the mentors regarding the novice teachers' teaching efficacy ($F_{(2, 202)} = 4.25$, $p<.05$), see Figure 1.

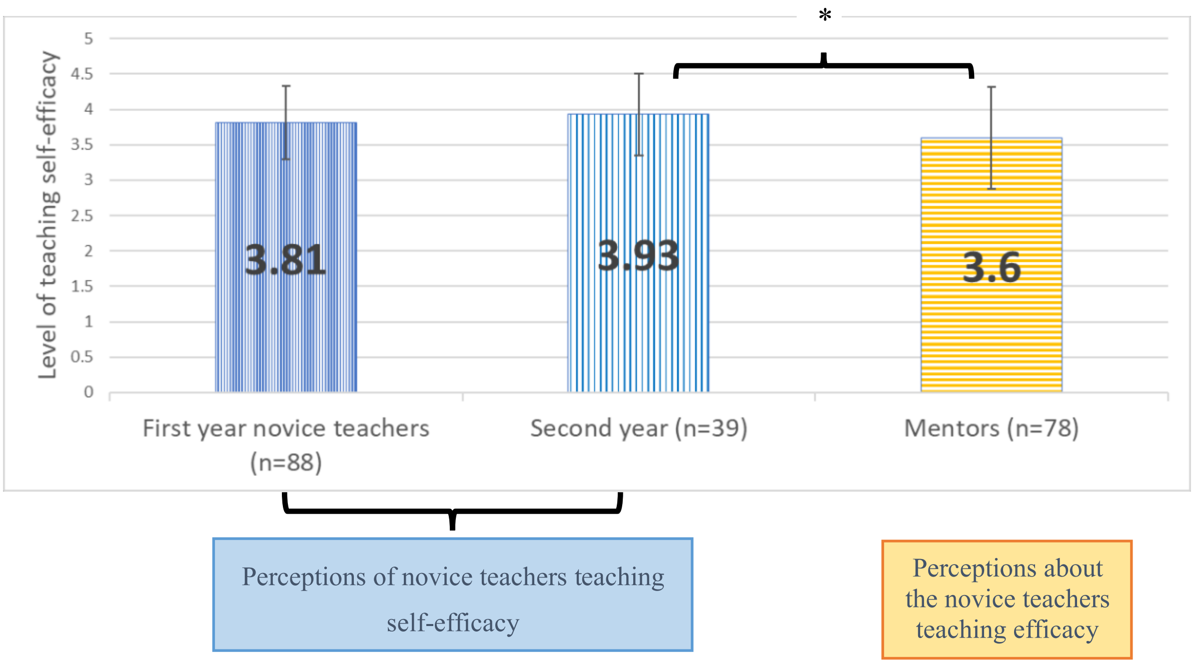

Figure 1. Perceptions regarding novice teachers' teaching self-efficacy

In order to compare the novice teachers' and mentors' perceptions of the mentoring factors, we used the MEPST instrument, adapted for secondary school (Hudson, Skamp & Brooks, 2005). Using this instrument, teachers grade mentoring elements of the mentoring process in a scale of one through five. The mentoring elements are grouped into five factors: personal attributes, system requirements, pedagogical knowledge, modeling, and feedback (see Table 2).

Table 2. Novice teachers' and mentors' perceptions on effective mentoring factors

Factors	Novice Teachers (N=40) M(SD)	Mentors (N=47) M(SD)
Personal Attributes	3.95 (.87)	4.11 (.92)
System Requirements	3.51 (.96)	3.68 (.87)
Pedagogical Knowledge	3.55 (.85)	3.95 (.71)
Modeling	3.75 (.83)	4.05 (.72)
Feedback	3.97 (.75)	3.89 (.76)

Novice STEM teachers and mentors viewed four of the five factors of effective mentoring with similar importance, as a significant difference in the mentoring process was found only between the perceptions of the experienced teachers—the mentors (M=3.95, SD=.71) and the novice teachers (M=3.55, SD=.85) in the pedagogical knowledge factor (t=–2.42, p<.05). The Modeling factor differences were borderline (t=-1.83, p=0.07).

Grouping the mentoring factors into personal, professional (system requirements and pedagogical knowledge), and social (modeling and feedback), we found correlations between these three factor groups and teaching self-efficacy. Teaching self-efficacy is also correlated to general self-efficacy.

Table 3. Self-Efficacy and Mentoring Factors Pearson correlation (N=87)

Factors Group	Teaching Self-Efficacy	Personal	Professional
Self-Efficacy general	.354**		
Personal personal attributes	.229*		
Professional system requirements and pedagogical knowledge	.301**	.766**	
Social modelling and feedback	.230*	.871**	.801**

*p<0.05, **p<0.001

Significant correlations between the teaching self-efficacy of the novice teachers and the mentoring factors show that development in a certain factor group is correlated with development in the other factor groups, as well as with the teaching self-efficacy.

Evidence for professional growth presented below is arranged by the three tiers of support – mentoring, workshops, and community.

(a) **Mentoring** facilitated the professional and personal growth of novice and experience teachers in different aspects.

(b) **Workshops** provided the novice teachers with both professional and social support. Meeting other teachers with difficulties like their own (social) helped them accept their struggle (personal) and seek solutions together (professional). As one participant [417221]said: "*I met other teachers in my situation, with similar struggles. I was exposed to many suggestions and examples of coping strategies.*"

(c) **Community** activities in the meetings showed a gap in novice and mentor teachers' perceptions regarding the needs of novice teachers during their first years and their expectations from the mentoring process. Teachers discussed the mentoring factors in the community meetings and analyzed the gaps in expectations and perceptions of the mentoring relationships aims. The discussion helped communicate the needs and improve the communication and mentoring processes. Reflections about perceptions of the workshops' effect revealed that the community meetings enabled the teachers to understand a different perspective and to develop new classroom practices (professional). A novice teacher [417210] said: "*I watched how she was managing her very busy schedule and learned how to form habits*". In some cases, mentors initiated development activities (professional). An experienced teacher [417414] stated: "*...but* *now I can do more things, I can combine something I learned in a different program and create something new…".*

Table 4. Aspects of teachers' growth

Expression of growth	Techers' Statements
Personal Establishing a mentoring relationship based on equal partnership which contributes to the empowerment of the novice teacher	A novice teacher [50001820213]: "*I bring my ideas, she [the mentor] brings her ideas, we have a partnership.*"
Professional Mentor and novice thinking about possible solutions	A novice teacher [510011921211]: "*One of the ideas I found with the help of my mentor was to have a tutoring session after each subject I teach, and guide them in the subject via teamwork.*"
Social The experienced teacher is exposed to innovative ideas (professional), while the novice teacher feels meaningful	A mentor [511191720221]: "*Working with him and the other teacher felt like working as a team…his main contribution was in the green chemistry project, based on his prior knowledge and experience.. I consulted with him regarding the data analysis and we drew the conclusions together.*"
Development of Mentoring Practices A mentor learned how to focus her feedback to make it productive	A mentor [50519821223]: "*although I saw the wider picture in terms of things I wanted to say [in the observations reflection on her lesson], I highlighted one or two aspects for improvement and two things that were good and she should continue to do, I neutralized background noises.*"

DISCUSSION AND LIMITATION

The three tiers of support address complementary needs of novice and experienced teachers, cultivating the social, professional, and personal growth of novice and experienced teachers. Each tier addresses different levels of the aspects, contributing to the growth of novice and experienced teachers (Bell & Gilbert,1994). The induction years include a process of learning to teach and a process of socializing (Luft et al., 2011).The interactions between the three tiers provided the teachers with personalized support, a peer group in which they could see that their struggle was universal, and an opportunity to participate in a wider forum in which they could learn and contribute as equal members of the community (Vangrieken et al., 2017). Growth was enabled through learning content-specific STEM and pedagogical discussions. Empowering the novice teachers can enhance also the veteran teachers' self-efficacy and refines their teaching skills (Aspfors & Fransson, 2015).

A limitation of the research was that due to ethical constraints posed by the Ministry of Education, classroom observations could not be obtained.

CONCLUSIONS AND IMPLICATIONS

Retaining novice teachers in the school system requires providing them with effective support. Experienced teachers the partners for this mission. Creating a supportive community provides opportunities and scaffolds for the novice and experienced teachers to grow successfully in the teaching professions (Richmond, Bartell, Floden, & Jones, 2020).

The contribution of this research is the elucidation of the intertwined support tiers that provide a scaffolding to the novice teachers, while facilitating the growth of the experienced teachers.

DESIGN AND ASSESSMENT OF A SCORING RUBRIC FOR EVALUATING SCIENCE TEACHERS' CLASSROOM PRACTICES

Angelos Sofianidis and Maria Kallery
Aristotle University of Thessaloniki, Thessaloniki, Greece

The aim of the present study was the development of an evaluation system for secondary science teachers teaching practices based on PCK. In the present work, we present the evaluation framework, the evaluation criteria and the development of an observation tool and an evaluation scoring rubric for classroom observations. The evaluation criteria were designed to constitute aspects of teachers' PCK. A pilot study was carried out aiming at examining the reliability of the rubric and of the observation tool. In this pilot application two evaluators used the rubric and the observation tool independently to evaluate twelve science teachers. The data recorded by the two evaluators have a strong positive correlation as indicated by the values of the correlation coefficient Spearman rho. The results showed that the use of the tools led to reliable and objective findings.

Keywords: Evaluation Methods, Teaching Practices, Science Education Policy

INTRODUCTION

Over the last 30 years, researchers have formed and developed a notion that describes the aspects of teacher knowledge, namely Pedagogical Content Knowledge (PCK). PCK is α widely accepted notion among researchers (e.g., Berry, Friedrichsen, & Loughran, 2015) and teachers as it creates possibilities to find common bases upon which criteria for teacher evaluation systems can be build.

Data gathering differs among evaluation systems but the most common source of data is classroom observation (Isoré, 2009; Santiago, 2009), which provides data on teaching practices in real classroom settings. Concerning classroom observations, it is a common practice for evaluators to use a scoring rubric. A rubric contains the criteria and descriptions of performance, which define levels of achievement that match a score. Rubrics are used because they can guide evaluators in focusing on specific aspects of teacher performance and enhance a common scoring strategy. Additionally, rubrics can reduce the possibility of arbitrariness and misunderstanding and connect the evaluation procedure to a post-evaluation program of professional development (Panadero & Jonsson, 2013).

In what follows, we present the design and development of an evaluation scoring rubric and an observation tool and the assessment of these tools through a pilot study.

THE EVALUATION SCORING RUBRIC AND THE OBSERVATION TOOL

Evaluation criteria

The evaluation criteria are based on a PCK analysis that was first introduced by Jang (2011). The evaluation criteria are divided into four domains, namely: Subject Matter Knowledge (SMK), Instructional Representations and Strategies (IRS), Instructional Objectives and Context (IOC) and Knowledge of Students Understanding (KSU). Data are collected through classroom observations for 15 evaluation criteria. The domains, the criteria and the aspects of teaching recorded through observation (scoring rubric) are described in Table 1.

Table 1: The domains, the evaluation criteria and the aspects of teaching recorded through observation and included in each criterion

Domain 1: Subject Matter Knowledge	
Criteria	**Aspects included in each criterion**
Quality of the language used during the lesson	*Quality of the language used during the lesson*
Connection between the teaching notion or phenomenon and everyday life	*Connection between the teaching notion or phenomenon and everyday life*
Domain 2 : Instructional Representation and Strategies	
Criteria	**Aspects included in each criterion**
Instuctional Strategies	*Instructional Strategies (Variety and appropriateness)* *Strategies for maintaining students' interest*
Students' attentiveness-related reactions during instruction	*Students' attentiveness-related reactions during instruction*
Instructional representations	*Appropriateness and usefulness of instructional respresentations*
Inquiry	*Type of Inquiry*
Scientific skills promoted by the teacher	*Scientific skills promoted by the teacher*
Questioning	*Conceptual Level of teaching questions* *Students' participation in questioning*
Domain 3:Instructional Objectives and Context	
Criteria	**Aspects included in each criterion**
Instructional objectives and goals	*Instructional objectives and goals (communication and understanding)*
Interactive atmosphere	*Teaching Adjustment based on students' reaction*
Students' participation	*Students' participation*
Classroom management and mutual respect among students	*Classroom management* *Mutual Respect*
Domain 4: Knowledge of Students' Understanding	
Criteria	**Aspects included in each criterion**
Alternative concepts investigation	*Alternative concepts investigation* *Strategies to handl students' alternative concepts*
Knowledge of students' difficulties	*Knowledge of students' difficulties*
Assessment during the lesson	*Formative Assessment during lesson* *Variety of assessment methods and adjustment related to students' diversity*

Development and Description

The observation tool, a part of which is presented in Figure 1, is a practical guide for the observer. It helps him/her focus on specific aspects of teaching, record data by ticking the appropriate boxes, and take notes on them. These notes help the observer keep track of all the teacher's practices and the decisions he/she makes during instruction when the observer grades the teacher's performance in the rubric. The observer/evaluator uses an observation sheet for each separate lesson. Data are collected from two observations of each teacher by completing the score in the evaluation scoring rubric.

In the scoring rubric, the observer finds the aspects of teaching that have to be recorded and five short descriptions of the teacher's performance. Based on the observation tool and his/her recorded notes, the observer decides which description best fits the teacher's actions.

Observational Tool

Class: Subject:

Number of students: Time of observation:

Instructional Representations and Strategies

Note 1 for the main teaching practice and 2, 3, etc. for the other practices observed during the lesson.

Strategies

	Lecture		Students' Presentations		Experiments conducted by students
	Demonstration of experiment		Discussion or work in small groups		Use of models to introduce a notion or an idea
	Discussion led by the teacher		Inquiry		

Type of student involvement during instruction

	Passively attends teacher's lesson		Participates in discussion (led by the teacher or in small groups)		Carries out an experiment
	Participates in an inquiry activity		Completes work sheets as part of an activity		Writes a laboratory report
	Writes an assessment test		Uses a simulation		Uses lab equipment and technology to conduct an experiment
	Uses a PC program to analyse data		Makes a presentation or attends other students' presentations		Develops or uses a model to comprehend an idea

Use of Instructional Representations

☐ Examples ☐ Analogies ☐ Graphs and Diagrams

☐ Everyday objects ☐ other: ....

Observer Recordings

Appropriateness (manner and time of their use):

....

Usefulness for the students:

....

Figure 1: Part of the Observation Sheet

Each description corresponds to a score that the observer inserts under the name of each aspect. Figure 2 shows two of the aspects of teaching recorded, which concerns appropriateness and usefulness of instructional representations (IRS).

The development of the evaluation scoring rubric and observation sheet was done through a long collaboration with expert Science teachers, Educational Advisors, and Evaluators.

Criteria	Aspects of teaching recorded	5	4	3	2	1
Instructional Representations	**Appropriateness of the instructional representations (IR)**	IR: * Were appropriate for the activity * The time and the manner of their use was appropriate and consistent with the lesson goals	IR: * Were appropriate for the activity *The time of their use was sufficient and the manner was consistent with the lesson's goals	IR: were appropriate for the activity but not consistent with the lesson's goals	IR: were generally appropriate for the activity, but other IR could be more appropriate and more consistent with the lesson's goals	IR: were inappropriate for the activity and inconsistent with the lesson's goals
	Score:					
	Usefulness of instructional representations	IR seemed to help all the students understand	IR seemed to help the majority of students understand	IR seemed to help half or more of the students understand	IR seemed to help a minority of the students understand	IR seemed not to help the students understand
	Score:					

Figure 2: Part of the Evaluation Scoring Rubric

The implementation of the evaluation scoring rubric and the observation tool

The implementation of the evaluation, using the observation tool and the scoring rubric, is conducted through direct, first-hand observations of two one-hour lessons. The evaluator performs these observations as a spectator (Gay, 1992) and records them on the observation tool. After the observation, the evaluator grades the teaching in the evaluation scoring rubric.

METHODOLOGY

The aim of this study was to evaluate the reliability of the tools designed and the objectivity of the findings from the observation-based data. In order to assess the reliability of the evaluation scoring rubric simultaneous observations were carried out by two observers/evaluators. The first evaluator was an Educational Advisor and trained Evaluator serving in Secondary Education and the second one was the first author of the presented work.

Sample

The observations were carried out in six Gymnasiums and Lyceums, representative of the different context of the Greek educational system, which were proposed by the Educational Advisor. The two evaluators observed twelve (12) Science teachers (eight Physics and four Chemistry Majors) using the observation sheet and they independently evaluated every teacher using the Evaluation Scoring Rubric.

Data analysis

The data of the Scoring Rubrics were statistically analysed. The reliability of the rubric was assessed through the calculation of the Spearman rho coefficient between the two independent scores of the evaluators. The above mentioned methodology is the most common practice to assess the reliability and the objectivity of the findings of a rubric (Jonsson & Svingby, 2007). The data collected by the two observers were, also, analyzed with regard to everyday teachers' practices.

FINDINGS

A significant positive correlation was found between the scoring of the two observers/evaluators ranging from 0.704 to 0.894 ($p<.0001$). Additionally, the mean of the differences of the observers was calculated and was found 0.1905 (N: 252, St. Deviation 0.414, N refers to the number of scores for all teachers) indicating very small differences between the two observers. These findings suggest that the observers, using the scoring rubric and the observation tool, were led to score similarly teachers' performance based on their observations.

With regard to teachers' practices, the findings from the observations indicated that all or almost all teachers who participated in the study use appropriate language, a variety of teaching strategies that maintain students' interest, make proper use of instructional representations, communicate the instructional objectives, manage their classroom efficiently, promote mutual respect, know the students' difficulties regarding the teaching topic and succeed in having most of their students actively participate in the lesson (these teachers are evaluated as 'Excellent' on these criteria). On the criteria concerning the connection between the subject being taught and everyday life, the type of inquiry used (mainly structured inquiry), the scientific skills promoted, the questioning and the use of formative assessment during the lesson, the majority of the teachers were evaluated as 'Adequate' and a minority as 'Excellent'. One third of the teachers were evaluated as 'Weak' on criteria related to their knowledge of the students' understanding, specifically regarding investigating and handling students' alternative conceptions and the use of a variety of assessment methods.

However, the specific findings produced by the Observation Tool and Scoring Rubric cannot be generalized, as the sample of teachers observed is not big enough. The future use of our tool in a larger and more representative sample will provide a clearer picture of the teachers' practices.

CONCLUSIONS

The results indicate that the observational tool and the scoring rubric created a framework within which the observers, using a common scoring strategy, produced the same findings when evaluating the same teacher.

Based on the findings concerning the reliability of the tools and teachers' practices, we consider that the evaluation of the teachers through the proposed procedure and tools could provide rich and objective findings about teachers' every day practice.

PART 15: STRAND 15

Early Years Science Education

Co-editors: *Christina Siry & Bodil Sundberg*

CONTENTS

STRAND 15: INTRODUCTION

EARLY YEARS SCIENCE EDUCATION

Strand 15 is dedicated to highlighting research focusing on Early childhood science education, specifically science education for children aged between 0 and 8 years of age. Young children's learning, participation, and engagement is a growing research field within the international science education community, and the studies presented in this strand explore numerous aspects and perspectives related to early childhood science education.

29 oral paper presentations and 13 poster presentations were accepted for ESERA 2019. Taken as a whole, the presentations in Strand 15 for the 2019 conference demonstrate a diversity of foci examining the complexities of science teaching and learning at the early childhood levels, revealing how early childhood science education has grown to reflect a vast amount of common topics within science education research, but with a special focus on the nuances of policies and practices of early childhood education. Session themes represent some of the international trends in the field, specifically as related to early childhood science education, such as: Emotional engagement, interest and motivation; Engineering and computational thinking; Learning in early childhood science; Modeling and representation; Play and inquiry; Support for learning outside the classroom; and Teacher education and beliefs as related to early childhood science. Eight papers that were submitted for inclusion in the e-proceedings met the technical requirements and are reproduced in the sections that follow.

The papers explore a variety of issues based on different theoretical perspectives and give examples of qualitative and quantitative as well as mixed methods approaches. Their authors come from Denmark, Greece, Spain, Sweden, Turkey and the United Kingdom.

Five of the papers present the results of interventional studies. In the paper A proposal for learning healthy nutrition with four-years-old schoolchildren, Luisa López-Banet, Isabel Baños-González, Belén Guardiola Haro and Athanasios Pappous present the results of an intervention aiming at introducing preschoolers to healthy nutrition. The results show that the pupils not only acquired knowledge about food that composes a healthy diet, but also were able modify breakfast and lunch menus so as to reduce the amount of unhealthy food while increasing healthier food choices. In Developing a robot-supported inclusive education (rosie): a play-based approach to STEM-teaching and inclusion in early childhood education Lykke Brogaard Bertel, Susanne Dau and Eva Brooks explore the possibilities of the play-based approach of Robot-Supported Collaborative Learning (RSCL) for facilitating inclusion and improving the challenging educational transfers in children's early life.

Kalliopi Kanaki and Michail Kalogiannakis present a further example of research focusing on interventions and STEM education for young children. In the paper Enhancing computational thinking skills in early childhood education, they explore a novel framework that aims to familiarize children in the first two grades of primary school with fundamental competencies of computational thinking. The next paper in the group of interventional studies is The examination of questioning methods on young children's conceptual understanding of astronomy by Sinem Güçhan-Özgül, Mesut Saçkes and Berrin Akman. The focus of this study is methodological, and the results show how different methods used for discovering children's mental models about scientific phenomena might generate different results, conflicting with each other. In the fifth contribution, Case studies of collaborative model-based reasoning for conceptual change in preschool children, Eleni Sakellaridi and Spyros Kollas investigate whether a collaborative model-based problem-solving learning environment may facilitate preschool children's conceptual change regarding the phenomenon of day and night cycle.

The next group of contributing papers explore children´s learning, reasoning and motivation. Drawing on theories of different cognitive learning styles Maria Kallery, Angelos Sofianidis, Popi Pationioti, Kaliopi Tsialma, Xristina Katsiana examine children´s motivation for science in the paper Cognitive style and motivation and learning in inquiry based early-years science activities. The findings indicate that structured inquiry activities may serve to trigger motivation and learning in science for young children. In Young children and personifying reasoning, Marida Ergazaki, Aggeliki Dimitrakopoulou, Alexandra Spai and Dimitra Nousi report on a case study that traces children´s reasoning about properties, behaviours or reactions of living things that they are not familiar with.

Strand 15 contributions culminate with a focus on preschool teacher´s views on science in preschool with particular focus on chemistry. In Characteristics of science teaching in preschool, Jesper Sjöström and Ann-Christine Vallberg Roth present results from a questionnaire and discuss a didactic model for preschool science teaching, drawn from the teachers' responses.

In summary, the eight papers representing this strand give important perspectives and provide diverse approaches to early childhood science education, each contributing new understandings to this diverse area of research. The contributions demonstrate a commitment within ESERA to researching facets of early childhood science teaching, learning, and learning to teach. We hope that you will enjoy reading the papers.

DESIGN AND IMPLEMENTATION OF A PROPOSAL FOR THE LEARNING OF HEALTHY NUTRITION BY FOUR-YEAR-OLD CHILDREN

Luisa López-Banet[1], Isabel Baños-González[1], Belén Guardiola Haro[1] and Athanasios Pappous[2]
[1]University of Murcia, Murcia, Spain
[2]University of Kent, Canterbury, United Kingdom

The data showing the increase in diseases associated with food in recent decades are alarming. The World Health Organization has announced that childhood obesity is one of the most serious public health problems of the 21st century, its prevalence rising at a startling rate. The development of healthy habits in childhood is essential to maintain good health in the future, and for this schools and families are primarily responsible; therefore, both must work together in the concept of healthy eating. The present work explains a learning proposal on healthy nutrition, implemented in the classroom for 4-year-old children. The sequence of activities is structured in several stages, which have specific scientific and didactic objectives. The ultimate purpose of this work corresponds to a global and relevant objective for children, closely related to the initial development of their scientific competence. The results show that the pupils not only acquired knowledge about the food that composes a healthy diet, but also were able to carry out appropriate modifications to the menus of their breakfast and lunch, such as reducing the amount of unhealthy food and introducing the most appropriate food.

Keywords: Health Education, Preschool Education, future teacher training

INTRODUCTION

In wealthy societies, characterized by the availability of highly caloric foods, refined sugars, and saturated fats and by the emergence of sedentary leisure habits, numerous authors have pointed out the existence of an ‘obesogenic environment’, even at early ages (Díaz, 2017). Our children are becoming more overweight, and those estimated to be overweight or obese tend to remain this way as adults and will be more likely to suffer non-transmissible diseases, such as diabetes, or to have cardiovascular problems at younger ages (Baker, Olsen, & Sørensen, 2007; Lorenzo-Bertheau et al., 2017). Furthermore, several studies suggest a positive relationship between tooth decay and free sugars intake (Eley et al., 2019), with regard to sugars added to foods and drinks by the manufacturer, cook or consumer. For these reasons, the World Health Organization has enunciated certain recommendations aimed at reducing free sugar intake to below 10% of total energy intake (World Health Organization [WHO], 2015), involving health interventions, food labeling, and, above all, education. Besides, it is recognized that interventions aimed at reducing childhood obesity by improving nutrition and physical activity should be a priority for public health (Katz, 2009). It is widely acknowledged that prevention is an indispensable strategy to turn the tide of the global epidemic of obesity (Caballero, 2004). However, lifelong acquired behaviors are resistant to change and, therefore, acquisition of healthy habits should begin as early as possible. Thus, school-based interventions from early childhood are considered the most effective way to promote healthy behaviors (Peñalvo et al., 2013).

The preschool period is a time when children begin to develop lifelong habits related to proper and balanced nutrition (Başkale, Bahar, Başer, & Ari, 2009; Eley et al., 2019), and so nutrition is included in the Spanish Curriculum for children of 3-6 years of age (Ministry of Education and Science [MEC], 2007). Therefore, it is essential to promote proposals on current eating habits and physical practices (Arriscado-Alsina, Muros, Zabala, & Dalmau, 2015) which involve the entire educational community and which are put into practice using an inter-institutional and multidisciplinary approach (Espin, Pérez, Sánchez, & Salmerón, 2013). As pointed out by Hesketh and Campbell (2010), the literature on educational interventions with respect to prevention of obesity in early childhood is still limited; this suggests that more effort should be made in this research area (Reinoso, Delgado-Iglesias, & Fernández, 2019) to face the reality of this issue, and that specialized staff are necessary for this. In order to contribute to the didactic research regarding children at this age, in this work we show the design and implementation of a specific teaching intervention and explore its potential impact on children's learning about healthy food.

Educational interventions and learning about food

Nutritional proposals aimed at preschoolers (3 to 5 years old) are still scarce. It has been shown that interventions are more likely to succeed when the degree of family involvement is greater and when they are initiated at early ages (Skouteris, McCabe, Swinburn, & Hill, 2010). According to Summerbell et al. (2012), the most sustainable interventions reach out to the children's most proximal environment: their families, teachers, and school.

Parents act as models for young children and play an essential role in their children's nutritional behavior, shape children's eating patterns by determining what foods are available and in what quantities, and constitute a critical component in the preschool environment. In fact, some studies have shown that involving the children's proximal environment yields better results, by means of developing parents' knowledge about healthy food (Zarnowiecki, Sinn, Petkov, & Dollman, 2012), promoting healthier behaviors among adults and children (Herman, Nelson, Teutsch, & Chung, 2012), or increasing the intake of fruits and vegetables, while reducing that of fats and sugars (Epstein et al., 2001).

Nevertheless, teachers often complain about the lack of parental involvement in and/or support for the nutrition education taught by teachers at school, by not encouraging positive, healthy behaviors at home (for example, consumption of fruits and vegetables). In fact, they even consider that parents may represent a barrier to proper learning, likely because parents do not understand the importance of nutrition, are not interested in the subject, or have poor knowledge of it (Stage et al., 2018). Given the vital role of parents in facilitating real and sustainable behavioral changes during this early childhood period, some authors have suggested various strategies to improve the parental influence, including their participation in the classroom -with the provision of materials to take home, such as 'nutrition bulletins and healthy monthly recipes'- or in workshops and nutrition education classes (Hesketh & Campbell, 2010; Stage et al., 2018).

Other barriers to educational interventions have been found, such as the insufficient training of teachers, the scarcity of material to work with, or educational approaches that try to transmit information instead of reflecting on it. With respect to the educational material, different resources such as healthy stories, educational and audiovisual games, activities that families can participate in at home, or an annual School Health Fair have proven their effectiveness (Peñalvo et al., 2013). On the other hand, we suggest that isolated activities have a very limited impact, so we advocate the implementation of didactic sequences for diet, physical activity, parts of the human body, and contents to address the management of emotions (Peñalvo et al., 2013). In addition, schools should implement projects at the center level to promote healthy practices, such as the replacement of candy at birthdays and parties, involving parents in school activities, or improving the adequacy of the playground to promote physical activity during recreation.

The stage when children are 3-6 years of age is recognized as essential in the initiation of the progressive development of competences related to decision-making concerning, among other aspects, hygiene habits and healthy eating (García-Carmona, Criado, & Cañal, 2014). But, we must bear in mind that when children start school they have already established certain food preferences and eating behaviors, as a result of various influences, such as sensory, genetic, temperamental, social, and cultural factors and environmental learning (Xu & Jones, 2016), which will affect all their food experiences and their willingness to try new foods. In accordance with the relationship between children's early food preferences and eating-related behaviors, some studies have shown that the preferences and food consumption of preschoolers are strongly influenced by those of other children (Birch, 1980). Hence, when adults and partners act as active and positive social models, this can be effective in fostering healthier eating and the introduction of new foods; for instance, by brief, repeated tasting of food in a positive social context (Gibson et al., 2012). Therefore, it seems that people's dietary patterns will be determined by their exposure to certain actions, as well as their own personal choices (Ventura & Worobey, 2013). As a consequence, it is highly recommended that fresh fruits and vegetables be available daily, both at home and at school, while eliminating both junk food and sugary soft drinks (Katz, 2009).

OBJECTIVES

In this work, we describe the design of a didactic proposal for healthy eating that takes into account the current opinions of experts in nutrition and didactics, in order that children better recognize ingredients that are appropriate for their diets. Besides, we analyze the results of its implementation in a preschool classroom, and discuss how these activities might favor the initial development of healthy eating knowledge in Early Childhood Education.

METHODOLOGY

The sequence of activities was developed in a preschool classroom. The participants and context are described below, as are the characteristics of the activities and the analysis of the results obtained.

Design of the didactic sequence

The sequence was designed by a student teacher in her last year of the period of initial training, following Jorba and Sanmartí (1996). It is necessary to establish useful models to help teachers to develop educational interventions where the new information is connected to the previous ideas of children, in a constructivist model (López-Banet, Ayuso, & Martínez, 2020). This structure allows teachers to organize the educational interventions, not only taking into account the previous ideas of children regarding healthy practices and their respective cognitive development, using concepts and vocabulary relevant and comprehensible to them, but also involving families in activities in different points of the teaching and learning process. The new knowledge about healthy nutrition was organized in a sequence which was structured in four stages. Therefore, the implemented proposal consisted of a total of seven activities, developed in seven sessions of 45 minutes duration, distributed over two weeks (Table 1).

Table 1. Sequence within a competence framework.

Stage of the sequence	Main Objectives (sessions)
1. Explicitly state previous ideas and specify work proposals	To verbalize the previous ideas of the children about eating habits by means of guided questions during the assembly, coloring, or cutting and pasting of images of different foods and products that are usually included in their diet. To introduce children to the proposal of work on healthy eating by means of collective conversations (sessions 1 and 2) and to ask for collaboration that involves their families.
2. Introduction of new information	To discuss different types of foods, differentiating dairy-based food from unhealthy products. To compare menus elaborated by their families at home. To look at photographs of food and other industrial products that contain sugar, in order to promote considerations on reducing the sugar consumption (sessions 3, 4, and 5).
3. Structuring of information	To collectively reflect on the consumption of different sorts of foods and review the knowledge acquired, by comparison with their initial ideas and drawings (session 6).
4. Application	To apply the acquired knowledge by creating a recipe for a dessert that does not contain sugar; this recipe will be delivered to the families, so that they can prepare it in their homes, together with several pieces of advice on healthy eating (session 7).

The idea we pursued with this sequence was the participation of the children in activities with specific objectives that, globally, were focused on achieving their reflection on the problem of the consumption of sugary products, such as candies or sweets, encouraging them to select healthy recipes in their respective homes, with the involvement of their families in this learning process.

Participants and context

The didactic unit was designed and developed in a classroom of 4-year-old children of Preschool Education, with a total of 24 pupils. Among the several projects that the school follows, one is named the 'School Health Education Plan'. This is intended to gradually increase the consumption of fruit and vegetables by children, to develop other actions aimed at promoting healthy eating by them, and to raise the awareness among families and the educational community in general of the importance of a healthy and varied diet in the early acquisition of healthy habits.

Analysis of the results

In order to analyze the changes that the designed activities brought about regarding the kind of food chosen by the children, we collected their contributions at the beginning and end of the sequence for comparison. Thus, in relation to the previous ideas that the children expressed during the activities of stage 1 of the sequence, regarding the foods that they considered to be adequate, they had to identify them by coloring pictures in Figure 1. Besides, they selected the products that they had consumed the previous day by cutting out pictures of food from a large list and pasting them in their respective menus.

Figure 1. Initial activity to recognize food.

The respective families repeated the same activity by writing down the correct menu consumed, in order to check if all the important components were included and for comparison with those selected by the pupils. We elaborated a table including the results of not only the children but also their families. Finally, two recipes created by a sequence of pictures were given to the children; the idea was that they would color the one they chose after the implementation of the activities. Thus, we could identify the number of children that opted for the healthier one.

RESULTS

With this work, we set out to develop and design a didactic sequence of activities intended to achieve the overall objective of identifying less healthy food products and choosing more appropriate alternatives for the children's welfare. As a result, a proposal has been elaborated that includes contents related to healthy eating and, more specifically, that allows the identification, among the different food groups, of some ingredients that should be consumed in moderation, to finally select a recipe that can be prepared without the incorporation of the aforementioned ingredients. Specifically, the most notable results were obtained after the implementation of the sequence.

Regarding the results of the first stage, concerning the foods that the children initially preferred, all the children selected the packaged juice (100%), followed by fish (86%) and cookies, hamburgers, and pizza (73%). Chicken and muffins were chosen by 68%, followed by legumes (64%), vegetables, and bread (59%). Among the foods they considered less suitable were donuts (45%), French fries (41%), and olive oil (36%), explaining that 'the oil is not good' during the activity, while treats (32%) were the food selected least. In the next activity, the children selected some products that they consumed on a daily basis, from a list containing several kinds of food. They had to paint and cut the pictures corresponding to the products they had eaten the previous day, and paste them in a table representing the times of day when they usually ate (Figure 2). In addition, the collaboration of their parents was required, since they also had to choose the food corresponding to their children's menus, in order to later compare the two lists, the children's and the parents', and thus find important products on which to reflect during the sequence of activities; it was ascertained that most products selected by the parents were coincident with those mentioned by the children.

Figure 2. Food ingested by a child: breakfast, mid-morning snack, lunch, afternoon snack, and dinner.

When we compared the two lists, although the coincidence was not exact, we found that they corresponded to a large extent, especially in the main meals. As an example, data provided by a child (number 12) and his family are shown in Table 2.

Table 2. Menu selected by a child and his family.

	Child	Family
Breakfast	Milk with cereals	Milk with cereals
Mid-morning snack	Sandwich	Sandwich
Lunch	Macaroni and crème caramel	Macaroni
Afternoon snack	Sandwich	Omelet and ham
Dinner	Milk	Milk

The most ingested foods were milk (73%) and cookies (41%) for breakfast, a snack (68%) and packaged juice (36%) for the mid-morning snack, and a hot dish (55%) at lunch, along with meat (18%), fish (32%), or pasta (32%). For the afternoon snack, 36% of the children indicated a sandwich, followed by donuts, fruit, and muffins at the same percentage (18%), while for the dinner, milk (27%) and pizza (23%) were the most frequent foods; it must be highlighted that no child chose fruit for dinner. Despite being aware of the consequences of not eating correctly, such as '*having cavities*' or '*not growing up*', the pupils recognized their intake of some unhealthy products. It was striking that 41% of the participants selected a product of an industrial bakery as a regular element in their diet.

In the next stage, the realization of various activities involving the introduction of new knowledge favored the reflection by the children on the kinds of foods and diets which would be most suitable for them. For example, we built a food train by means of large wagons that represented the foods that had to be incorporated daily into the diet, such as fruits and vegetables, legumes, carbohydrates, water, meat, and fish, followed by a very small car with elements undesirable because of their sugar content, such as industrial products. Moreover, we analyzed the menus elaborated by the schoolchildren, which the families had to complete at home, in order to reflect on the main products present on a daily basis in all homes. As part of these activities, we showed the children, next to each high-sugar product that they had selected or mentioned in the previous activities (muffins, cookies, candies, soft drinks, juice), the equivalent number of sugar cubes contained in each of them. Then, we discussed with them what the cubes represented, so that they recognized the amount of sugar in their favorite foods. Their comments showed that they became worried, since they realized their diets were not so good.

In the third stage, the children had to reflect on the new knowledge acquired and complete a menu, which would be compared to the one they had completed initially, again by pasting images of a series of given foods. In this way it was found that all the children, except one, increased the amount of photographs that included fruits, while the number of children that selected cookies and industrial pastries fell, compared to the initial results. Finally, in the application stage, the children were individually provided with two recipes for a dessert by means of a prepared sequence of images. Thus, taking into account the ingredients that each one included, they identified and colored the one that they wished to prepare at home together with their families. On this occasion, 100% of the children colored, without difficulties, the appropriate (healthy) recipe, which was delivered to each family, along with a booklet of tips related to food that should be phased out of the schoolchildren's diets.

CONCLUSIONS

Early childhood constitutes a critical time to establish food preferences and eating habits. It is necessary that people around children (family, teachers, and health professionals) understand the ways in which preschoolers learn about food and encourage them to reflect on their own tastes and preferences, as a step prior to the acquisition of healthy habits. School-based interventions at this stage are widely considered the most effective way to promote healthy behaviors. For these reasons, in this work we show the design and implementation, in a class of 4-year-old children, of a sequence with a constructivist perspective in this education related to healthy foods.

It should be noted that, at the initial stage of the intervention, when activities aimed at verbalizing the previous ideas of the children about eating habits were performed, we realized that, for all the schoolchildren in our sample, juice was considered a healthy product despite the high sugar content, while vegetables were not valued so highly. Olive oil was considered an unhealthy product, practically at the same level as sweets, which demonstrates the importance of early childhood education in the development of the children´s evaluation of an adequate diet. However, after carrying out the proposed activities, the children seemed to realize the amount of sugar in many of the products they usually ate, according to their own data and those provided by their parents. In fact, at the end of the sequence practically all of them included many more healthy foods, such as fruits and vegetables, while drastically reducing those that should be consumed in moderation. Therefore, the teaching sequence described in this work seems to have made it possible to achieve the objectives of the different stages in which it was structured, reaching the overall goal of selecting a recipe containing healthier ingredients, since the pupils seemed to have acquired the most basic notions of healthy eating and to have been able to make critical judgments. In future work further activities for the learning of these contents will be developed, discussing with children their preferences for fruits and vegetables and trying to show them the need to eliminate sugar from their diets. The introduction of sessions where children must taste, smell, and touch fruits and vegetables could be useful in teaching programs that allow them to recognize a wide variety of healthy food while improving their preferences and the provision of this food.

To sum up, a school-based initiative should include not only a high-quality intervention but also a long-term, sustainable system to gradually introduce children to healthy choices, in order to boost the success in the learning of these contents. Moreover, not only is a close collaboration between families and schools required but also the current recommendations of experts and nutritionists need to be taken into account, by inviting them to visit schools.

ACKNOWLEDGEMENT

This research has been carried out within the project PGC2018-097988-A-I00 funded by: FEDER/ Ministry of Science and Innovation (MCI) of Spain - State Research Agency (AEI). Luisa López-Banet is grateful for the grant within the call for short stays in foreign centers aimed at the staff of the University of Murcia (young R2 researchers) and researchers in training (R1), for the year 2019 (R- 655/2019). The authors would also like to thank the Pre-school and Primary Education School of Cieza (Murcia, Spain) for its collaboration and for allowing these activities to be carried out in the classroom of 4-year-old children.

ROSIE: ROBOT-SUPPORTED INCLUSIVE EDUCATION - A PLAY-BASED APPROACH TO STEM EDUCATION AND INCLUSION IN EARLY CHILDHOOD TRANSITIONS

Lykke Brogaard Bertel[1], Susanne Dau[2] and Eva Brooks[3]
[1]Aalborg University, Aalborg, Denmark
[2]University College Nordjylland, Aalborg, Denmark
[3]Aalborg University, Aalborg, Denmark

The presence of educational robots in preschool and early primary school settings is getting stronger and has shown to have powerful playful qualities and to support interest in STEM. The question is whether it is possible to make use of these advantages and apply a play-based approach to Robot-Supported Collaborative Learning (RSCL) to facilitate inclusion and improve the challenging educational transfers in children's early life (5-8 years of age). Based on research in inclusive education, playful learning and educational robotics as well as an empirical pilot study on the educational robot KUBO in Denmark, this paper proposes a design-based research approach to the development of situated and practice-based RObot-Supported Incluve Education (ROSIE) specifically aimed at the transition between preschool and primary school. The aim is to support and empower children's essential life skills including imagination, collaboration and communication skills and to provide pathways capable of including and detecting a diversity of children's needs, skills and interests in STEM early and in a more advanced way than currently offered by traditional usage of educational technology.

Keywords: STEM education, robot-supported learning, inclusion

BACKGROUND

Getting ready for school is a crucial life change in a child's life. Yet, teachers experience challenges in finding ways to include all children in activities targeting a smooth transition between preschool and primary school as well as developing inclusive learning environments (Larsen, 2014). In Denmark, studies have concluded that bigger shifts in learning environments, such as in the transition between preschool and primary school, include risks of a child experiencing difficulties and failures (UVM, 2016). An unsuccessful transition can result in socio-economic and individual difficulties, e.g. becoming an early leaver from the school system, social and work life alienations, and passive citizenship. To give all children equal chances of developing into active participants in their own learning, as well as experiencing success and progression in learning activities, teachers and pedagogic professionals need competences in designing inclusive learning environments and adequate pedagogical practices. Institutions offer various approaches and methods to education and transitions in early childhood, all promoting the benefits of their own particular methods (Broström, 2013). However, the inclusion of digital tools and technologies in these processes is usually limited to information distribution when 'handing over' the child from one institution to another and does not include technology-supported and play-based learning designs that promote cross-disciplinary collaborations between these institutions (Larsen, 2014).

Educational Robotics and Robot-Supported Collaborative Learning (RSCL)

The presence of robot technology in educational settings is becoming more prevalent, often with the aim of supporting what is generally referred to as 21st century skills; collaboration, communication, critical (and computational) thinking and creativity (Rusk, Resnick, Berg, & Pezalla-Granlund, 2008; Toft & Nørgård, 2015). Research within educational robotics and hands-on robotic kits show, that working with programmable robots can influence children's development of cognitive, conceptual, language and social (collaborative) skills, however research has mostly been outcome-focused with robots as instrumental means to support other subjects in STEM (Science, Technology, Engineering and Math) teaching, particularly programming (Bertel & Rasmussen, 2013). When it comes to human-robot interaction and socially assistive robotics, on the other hand, research in special needs education and inclusion specifically suggests that social robots may facilitate social engagement as robotic tutors particularly in autism education (Robins & Dautenhahn, 2014; Feil-Seifer & Matarić, 2009; Scassellati, Admoni, & Matarić, 2012), however with the risk of reinforcing the enactment of specific user groups as passive/disabled 'consumers' as opposed to active/able 'producers' of digital practice (Hansbøl, 2016).

Some research in social robots for education indicate a potential in bridging the two; sustaining a process of integration and social inclusion through collaborative learning while also developing key competencies in educational practices and STEM (Tosato & Baschiera, 2013; Alimisis, 2013; Mubin et al., 2013; Majgaard et al., 2014). Thus, the past clear distinction between robots in general education and special needs education carries the risk that the benefits children with diverse needs and skills could have from robot-supported collaborative learning (RSCL) is overlooked.

Play-Based RSCL and Inclusive Educational Ecosystems

One approach that has gained momentum in recent years is play-based learning (Brooks, 2019). Research shows that play-based learning has an inclusive character and enhances children's academic and developmental learning outcomes, setting them up for essential skills in children's life in the 21st century (Eguchi, 2014). A play-based approach builds on children's natural engagement and interest, using play as a context for learning, where children can explore, experiment, discover and solve problems in imaginative and playful ways (Bers, Seddighin & Sullivan, 2013). Such an approach involves both child-initiated and teacher-supported learning, for example by encouraging children's learning and inquiry through interactions that aim to include and, at the same time, stretch children's thinking to higher levels (Brooks, 2019).

To summarize, programmable, embodied robots do have the potential to encourage playful inquiry and problem-solving and facilitate experiences of meaningfulness and creativity, however due to the cross-disciplinary character of a play-based approach to Robot-Supported Collaborative Learning (pRSCL), implementation may challenge institutional practice greatly. Thus, there is a need for research-based models and methods for teacher support, situated development and practical implementation of pRSCL as well as evidence-based knowledge and studies validating such learning designs and models (Bertel, Rasmussen, Majgaard &

Hannibal, 2016). Thus, this paper suggest an ecosystem approach to Robot-Supported Inclusive Education (ROSIE) as a whole in which teachers, pedagogic professionals, teacher trainers and researchers jointly develop inclusive technology-enhanced and play-based learning designs, methods and models across educational institutions and embedded within specific pedagogic practices related to early childhood transitions.

CO-DEVELOPING PRSCL DESIGNS: A CASE STUDY ON KUBO

As part of identifying needs and challenges in the development of pRSCL designs for inclusion, we applied a design-based research approach to a cross-case study on the educational robot KUBO implemented at ten different pre/primary school institutions in Denmark. In the following, we will describe the platform and case study design as well as report findings from one particular case study involving two institutions focusing on early childhood transitions.

The KUBO Robot

KUBO is a mobile educational robot developed by Danish startup company KUBO Robotics (KUBO Robotics, 2019) designed to support learning for children in preschool and early primary school in various subjects such as coding, language, and music through a tangible coding language; TagTiles with commands in the shape of puzzle pieces (see figure 1). KUBO consists of two separate units attached through a build-in magnetic mechanism. The body has two motorised wheels and an RFID scanner underneath. The head (control unit) has eyes that light up in response to certain commands and when KUBO moves. When placed on a TagTile, the RFID scanner reads the chip corresponding to the symbol on the tile and executes a command, e.g. turning left in response to "left arrow". With the KUBO kit comes an activity map with coordinates, illustrated on one side and blank on the other.

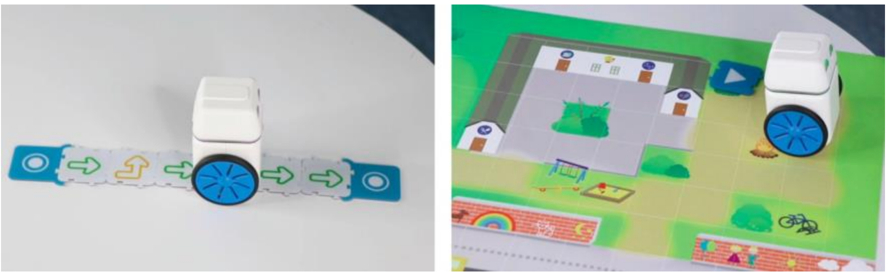

Figure 1. Kubo reading the TagTiles (left) and on the activity map (right)

There are two different ways to code KUBO; *Sequences* in which the robot is placed directly onto the tile, e.g. an arrow tile and moves in the direction of the arrow; and *Functions* in which the sequence of the tiles is organized as code in between two function tiles and replayed when placed on the ‘play’ tile. There are two sets of functions and play tiles in addition to loop tiles, so KUBO can be used to teach *subroutines* and *recursive functions* as well as *loops*.

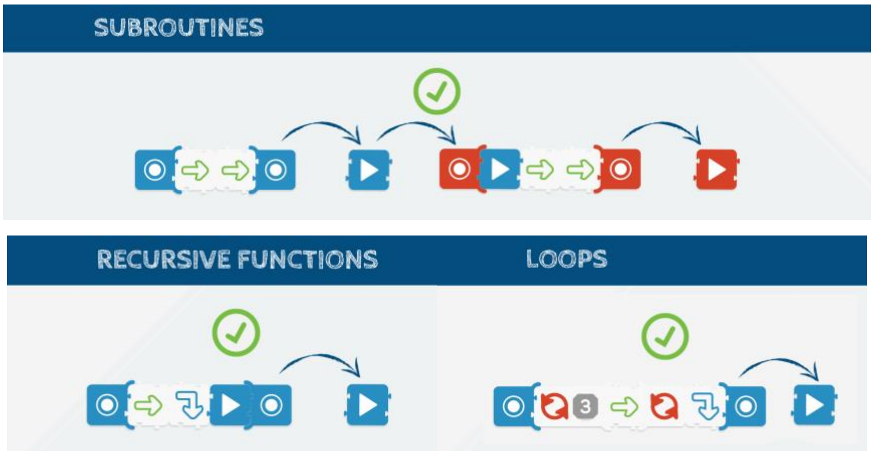

Figure 2. Programming Subroutines, Recursive functions and Loops with TagTiles

The purpose of KUBO like most other educational robots for STEM-teaching is to teach children the basics of coding, however in addition to this, humanoid features such as eyes and a head as well as the assigned intention-driven coding tasks on the activity map invites social robotic narratives and frames KUBO within a social robotic context. This seems to invite children with diverse needs and interests in playful learning scenarios, however the potential of KUBO to support inclusion specifically, have yet to be explored in a systematic way.

Case Study Design

In this specific case study, two sets of ten KUBO robots each were tested at two different locations; a school in the city of Odense and a kindergarten close to the school with which the school was attempting more cross-disciplinary collaboration focusing on early childhood transitions. A total of 24 children participated in the study. The teachers and pedagogic professionals co-developed a robot-supported learning collaborative design in which sixteen 2nd grade pupils (age 8-9) would teach eight so called 'school ready' kindergarten kids (age 5-6) how to code using KUBO over the course of three weeks. The older children spent two math classes preparing and worked in pairs or groups of three to design programming tasks and exercises for the preschoolers to complete as well as accompanying narratives involving the TagTiles and the activity map. After an introductory visit at the kindergarten, they were then paired with one of the preschoolers to teach the concept of coding using KUBO and the map.

Data collection in this case study consisted of four instances of participatory observations including pictures and notes over the course of three weeks as well as interviews with the math teacher, the school's headmaster about transition policies, and interviews with two pedagogic professionals at the kindergarten as well as in-situ interviews with the children.

In the following, we will present and discuss some of the valuable insights this case study provided into both existing and emerging inclusive practices in relation to the implementation of this particular robot-supported collaborative learning design and pRSCL in general.

PRSCL FOR INCLUSION: PRELIMINARY FINDINGS

In the case study we observed inclusive practices both in the preparation for the specific playful collaborative learning activity (i.e. when school children were preparing programming tasks to bring to the kindergarten), as well as during the activity itself and in informal or ‘in between’ formal learning settings. We have divided these inclusive practices into three categories related to; *structure*, *play* and *social status or self-efficacy*, respectively.

Inclusion through structure

In this first category, the teacher or pedagogic professional were facilitating inclusion specifically through *structure*. For instance, utilizing a story-telling approach to facilitate computational thinking and understanding of coding concepts and by this including groups of students who were motivated specifically by creating stories rather than designing the movements of KUBO on the designated map itself. This way, students were engaged either with writing stories, building code with building blocks or ‘reverse engineering’ through analyzing the behavior of the robot and formalizing it in simple written code.

Other inclusive practices facilitated by structure included reflections regarding group size (a maximum of three) to facilitate participation, limitation of and clear communication about the TagTiles availabability on the whiteboard at any given time to reduce complexity (see figure 3), classroom layout and spatial limitations when working with the robots (e.g. at the table, on the floor) as well as general classroom management, e.g. assigning different roles and responsibilities (e.g. who is in charge of the robot, the TagTiles, the map etc.) as well as specific and clearly communicated practices for common activities and information distribution (e.g. all students were sitting on their hands briefly when receiving essential information).

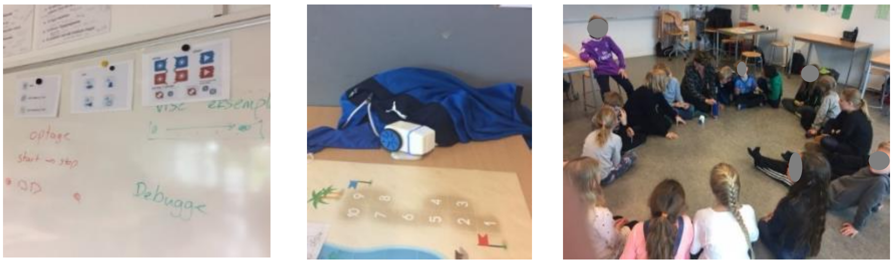

Figure 3. Examples of existing and emerging inclusive practices through structure

Inclusion through play

In the second category*,* imagining games and *play* scenarios with KUBO, such as designing new looks for the robot was a way to facilitate inclusion of children with diverse interests. Furthermore, in some instances playful inquiry as an approach to coding with the TagTiles showed potential to reveal a particular child’s specific needs and skills. For instance, a child was special needs was testing the limitations of KUBO’s perception by building code impossible to execute. When interviewed, the child explained trying to ‘confuse’ or ‘hack’ the robot. The same child would then later the following week be able to build a loop (without instruction) to ‘make the robot run forever’ (see figure 4).

T

Figure 4. Examples of existing and emerging inclusive practices through play

Inclusion through social status and self-efficacy

In the final category, the act of teaching others became an inclusive practice in of itself. For instance, the responsibility of having to prepare and explain coding exercises for younger children emerged as an inclusive practice (see figure 5), giving children who were otherwise considered 'vulnerable' (in terms of socio-economic status, learning ability etc.) the opportunity take on the role as the 'more knowledgeable other' and to develop in the role as the facilitator and 'teacher'. This also allowed for valuable discussion between the children about what it means to 'learn' and the value of failure in trial-and-error exercises.

Figure 5. Examples of existing and emerging inclusive practices through social status and self-efficacy

DEVELOPING A ROSIE MODEL: NEXT STEPS

In addition to the three categories of inclusive practices existing around and emerging from this particular KUBO-supported collaborative learning design, findings from the case study highlighted particular potentials and challenges in relation to developing Robot-Supported Inclusive Education (ROSIE) specifically targeted at the transition between preschool and primary school. For instance, the exercises developed in the classroom and applied by the students in kindergarten were very much task-based and solution-oriented, whereas pedagogic professionals at the kindergarten level emphasized and encouraged a more open-ended, problem-oriented and curiosty/inquiry-based pedagogic approach, which suggests the need for a more systematic co-designing and co-development process between teachers and pedagogic professionals preceding implementation of pRSCL in practice. Similarly, findings indicate that to successfully develop and adjust such learning designs to the needs and skills of individual children and teachers, it must include highly contextual knowledge and be embedded within and address a situated, cross-institutional practice. Finally, the case study highlighted the need for evidence-based methods and models for assessing the effects of pRSCL designs on e.g. learning, collaboration, self-efficacy and overall well-being in early childhood transitions.

CONCLUSIONS AND FUTURE WORK

Based on these preliminary findings, we claim that to develop Robot-Supported Inclusive Education (ROSIE) it is necessary to: (1) engage with children, teachers and pedagogic professionals in focused interactions to mobilize tacit knowledge about existing inclusive and collaborative learning practices within a particular context; (2) explore in-situ how novel robot technology can facilitate the emergence of new inclusive practices within set context; and (3) ongoing assess how existing practices change by introducing this new technology.

Thus, for future work we aim to co-develop a participatory and value-sensitive ROSIE-model specifically focused on early childhood transitions and test it in three iterations, allowing for continuous cycles of validation and re-design to ensure that playful robot-supported collaborative learning (pRSCL) designs and activities meet the expectations of all stakeholders, and that valuable feedback and findings gained through this participatory process is effectively incorporated into pRSCL designs and development regardless of the choice of robotic platform.

ENHANCING COMPUTATIONAL THINKING SKILLS IN EARLY CHILDHOOD EDUCATION

Kalliopi Kanaki[1], *Michail Kalogiannakis*[2]
[1,2]University of Crete - Department of Preschool Education, Rethymno, Greece

Nowadays, cultivating computational thinking in PK-12 emerges as a compelling vision. In this sense, we introduce an educational framework that aims to familiarise children in the first two grades of primary school with fundamental competencies of computational thinking, such as: collection, organisation and analysis of data, algorithmic thinking and abstraction. The basis of the proposed framework is a novel computational educational environment, which establishes an innovative hybrid schema of visual and text-based programming techniques, focusing on object-orientation. We also suggest a relevant assessment tool, in order to examine if the objectives of our educational approach are met. This paper reports two pilot studies, conducted within the context of physical and natural science courses in a first and a second grade class, in a primary school in Crete, Greece, in May 2018. Findings provide very promising indications for meeting our goals to introduce and practice computational thinking concepts in the first stages of schooling, actualising at the same time a mild first contact of young students with object-oriented programming syntax.

Keywords: computational thinking, early childhood education, science education

INTRODUCTION

Computational thinking is expected to be a fundamental skill for everyone by the middle of the 21st century, just like reading, writing and arithmetic are at the moment (Wing, 2006). Over the last two decades, the idea of introducing computational thinking in compulsory education has gained the attention of educators, researchers and policymakers (Barr et al., 2011; Barr & Stephenson, 2011; Grover, 2015; Kalogiannakis & Kanaki, 2020; Kalogiannakis & Papadakis, 2020). In fact, contemporary literature proposes its systematic cultivation even from the first stages of schooling, starting from kindergarten (Angeli et al., 2016; Kanaki & Kalogiannakis, 2018; Kazakoff et al., 2013; Papadakis et al., 2016; Sullivan & Bers, 2016; Sung et al., 2017). Furthermore, a substantial body of literature has been developed designating computational thinking as an essential ingredient of studying a plethora of disciplines in PK-12 (Grover & Pea, 2013). It is worth mentioning that Next Generation Science Standards (https://ngss.nsta.org/Practices.aspx?id=5) include computational thinking, together with mathematics, in the list of well educational practices in the case of science courses in K-12.

Elements that are widely accepted as comprising computational thinking are: collection, organisation and analysis of data, algorithmic thinking and abstraction (Barr et al., 2011; Barr & Stephenson, 2011). These elements constitute the basis of policies that aim to cultivate computational thinking and provide means of assessing its development (Barr & Stephenson, 2011; Grover & Pea, 2013).

The essence of our research is enhancing the above-mentioned computational thinking elements in the elementary grades, since these elements correspond to skills applicable and beneficial in everyday life. Our main research question can be formulated as follows: "Can fundamental computational thinking elements be introduced in the first and second grade of primary school within the context of physical and natural science courses, through the creation of digital games using a developmentally appropriate computational environment?" To answer this question we developed a novel educational framework established on the theory of constructivism (Mattar, 2018; Richardson, 2005) and game-based learning (Akman & Özgül, 2015; Sung & Hwang, 2013). Its backbone is the educational computational environment PhysGramming (an acronym derived from Physical Science Programming), which we implemented from scratch for children ages 5-8, based on their needs and skills (Kanaki & Kalogiannakis, 2018). Its innovative feature is that, while children create their own digital games within the context of physical and natural science courses, they become familiar with basic computational thinking concepts, even though no specific reference is made to them (Kanaki & Kalogiannakis, 2018).

Through PhysGramming we also focus on familiarising young children with object-oriented programming syntax, establishing a novel hybrid schema of visual and text-based programming techniques, following the recent years' trend of encouraging cultivating the basic programming skills as soon as possible in schooling, starting from kindergarten (Voogt et al., 2015). We opt in favor of object-oriented programming since it is inseparable from object-oriented thinking, a skill people cultivate from the beginning of their lives (Hillar, 2015).

The educational framework we propose is accompanied with a relevant assessment tool that enables educators to assess the potential development of skills related to computational thinking. We paid extra attention to constructing an assessment tool that provides valid and reliable results, since we are aware that without attention to assessment, no research effort could ever gain a serious role and place in the academic and educational scene (Grover & Pea, 2013). Enriching the assessment tool to evaluate learning of object-oriented syntax is one of our near future research interests.

This paper presents the proposed educational framework and its relevant assessment tool. It also reports two pilot studies, conducted in a first and a second grade class, in a primary school in Crete, Greece, in May 2018, aiming to answer the research question and, supplementally, to assess the feasibility of PhysGramming and to detect its impact on students regarding their satisfaction.

METHOD

In this section, we are going to briefly present the functionality of PhysGramming, the relevant assessment tool we propose and the methodology of the pilots conducted.

PhysGramming

PhysGramming is a computational educational environment compatible with any operating system. It is also compatible with smart mobile devices, taking advantage of the benefits of using mobile devices in the classroom (Zhu et al., 2016). It was implemented using the Java programming language (Arnold et al., 2015), in the Eclipse programming environment (Wiegand, 2004). It can be used in the classroom without the need of pre-educational interventions for the enhancement of computational thinking.

It should be mentioned that the term classroom refers to the human resources, i.e. the students and does not imply spatial constraints. The proposed educational framework can not only be applied in the school's Information Technology laboratory, but in any place, provided that smart portable devices are available. It can even be applied outside the school during educational visits and school trip activities, taking advantage of the benefits of outdoor learning activities (Dillon et al., 2006).

PhysGramming provides a writing and audio mode. Audio mode is suitable for students who have not developed writing skills yet. In attempting to briefly describe it, we should mention that, through PhysGramming, students practice assigning values to the attributes of a group of entities, within the context of a thematic unit. Which entities will be studied is the students' own choice. The entities are visualised through images embedded into PhysGramming by the teacher, while preparing the lesson. In the case of outdoor learning activities, students can photograph the entities under study with their smart portable devices and then use the photographs they took. Alternatively, students can paint their own pictures using a painting application we implemented and embedded into PhysGramming. When the assignment of the values of the entities' attributes is completed, PhysGramming automatically creates puzzles, matching games and group games. The uniqueness of these games is ensured by the uniqueness of the students' paintings and photographs, as well as by which entities each student chooses.

To understand the functionality of PhysGramming, as well as the methodology for integrating it into the educational process, let's focus on the study of the animals and especially on their eating habits. The content of this lesson must be presented to the students by the teacher before using PhysGramming. The example is illustrative, since PhysGramming is designed to allow the study of any entity, living or non-living. In any case, the teacher chooses what characteristics of the entities are going to be studied, but the students themselves define the values of the attributes. For example, if the subject of the lesson is material objects, the teacher may specify that the characteristics under study will be the "NAME" and the "MATERIAL" of the objects. The attribute "MATERIAL" has three possible values (solid, liquid, gas), which are entered into PhysGramming by the students.

In the case of studying the animals, and particularly their eating habits, the first thing the student/user of PhysGramming must do is to select and/or paint the pictures of the animals they want to deal with. When the selection and/or creation of the images is completed, a number of command lines appear on the screen (Figure 1). The next step is to determine the value of the attribute "NAME" for each animal. The child can add as many lines as they wish and delete some of the lines they have already added. As shown in Figure 1, through PhysGramming we propose a hybrid schema of visual and text-based programming techniques, with emphasis on object-orientation. However, no direct reference is made to programming concepts and practices.

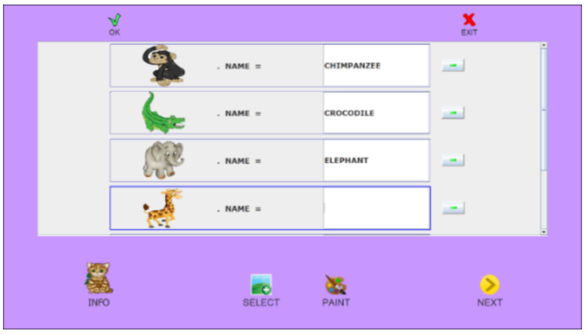

Figure 1. Assigning values to the attribute NAME

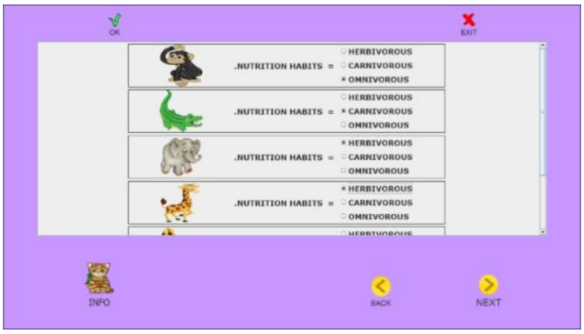

Figure 2. Assigning values to the attribute NUTRITION HABIT

Once the student/user of PhysGramming has identified the names of the animals, they must identify their eating habits (Figure 2). For each animal, the attribute "NUTRITION HABIT" can get a unique value from a set of three values: herbivorous, carnivorous and omnivorous. These values are given by the child as an entry into PhysGramming through a form specifically designed for this purpose.

When the assignment of values to the attribute "NUTRITION HABITS" is completed, all the information needed for the creation of the digital games has been entered into PhysGramming. Thus, it automatically creates puzzles, matching games and group games and the students choose which games they want to play with.

In group games, the pictures of the animals the student has selected to deal with are arranged randomly into groups that are defined by the values of the attribute under study. The child has to rearrange the pictures by dragging and dropping them into the right group (Figure 3).

In matching games, the student has to drag and drop the values of a particular attribute into the panel of the right entity (Figure 4).

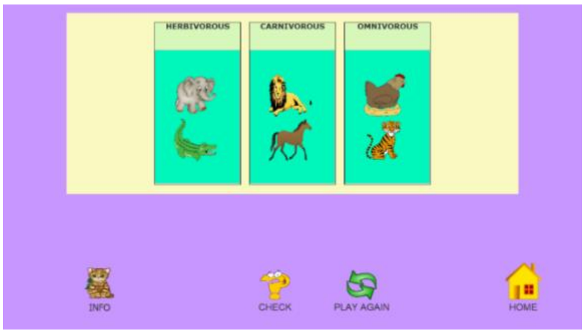

Figure 3. Group games

Figure 4. Matching games

PhysGramming creates puzzles for each animal image that the student has selected or painted. The user can choose the picture of the puzzle and its pieces: 4, 6, 9 or 12. Each puzzle (Figure 5) is a grid that contains mixed pieces of an animal's image. But, a part of the picture is missing. Thus, a cell of the grid is empty. Each piece can be moved horizontally, vertically or diagonally, provided that a neighboring part of the grid is empty. The piece to be moved will occupy the empty part of the grid and the previous part of the grid occupied by the piece moved will be empty. The user must reposition the pieces of the image until the puzzle is solved. The difficulty of solving the puzzles increases as the number of their pieces increase.

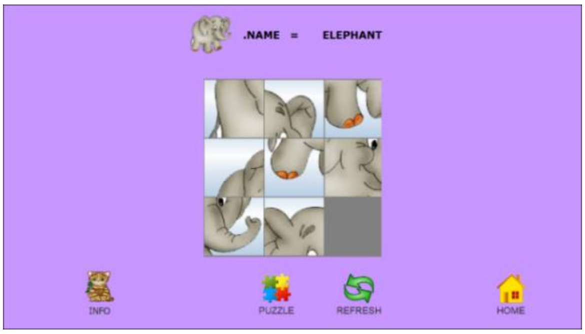

Figure 5. A puzzle game

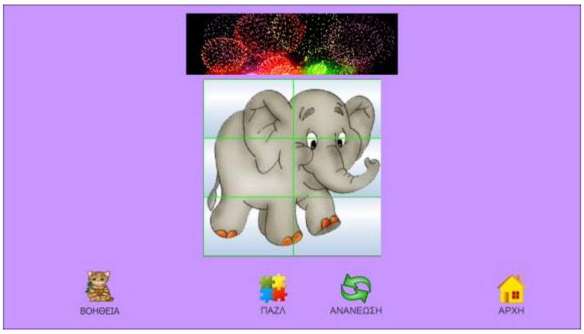

Figure 6. Rewarding the students when they solve a game

In all three games, students are rewarded with audiovisual media when they solve them. Specifically, when students manage to solve a game, a fireworks animation appears on the screen (Figure 6), accompanied by an audio reward. Our decision to include a fireworks animation aims to enhance the attractiveness and friendliness of PhysGramming, as these factors contribute to the effectiveness of educational software in achieving their learning goals (McManis & Gunnewig, 2012). International literature highlights the value of immediate reward, which encourages young children to increase their efforts to achieve their goals (Shoukry et al., 2015) and increases the chances for students to stay focused on what they are doing (Peijnenborgh et al., 2016; Richter et al., 2015). In addition, it fosters friendly competition among users (Montola et al., 2009) and enhances their self-confidence (Bleumers et al., 2012) and their acceptance by third parties (Richter et al., 2015).

The assessment tool

The relevant assessment tool we propose focuses on each one of the computational thinking concepts we aim to cultivate (Kanaki & Kalogiannakis, 2019). For each concept, we examine qualitative and quantitative factors (Cohen et al., 2002) that could lead us to conclusions about its cultivation (Table 1).

Table 1. Methods of collecting data

Skill		Methods of collecting data	
		Quantitative	Qualitative
Algorithmic thinking		Log files	Personal interviews
Abstraction		Worksheets	Observation
Data collection		Log files	Observation
Data organisation		Log files	Observation
Data analysis	Identify misconceptions	Personal interviews	Observation
	Reconsider choices	Worksheets	Observation

Applying the proposed assessment tool in the classroom requires two instructional hours. Before applying it, the teacher should have taught the section under study. During the first instructional hour, students construct their own digital games through PhysGramming and then they play with them. For the second instructional hour, they complete worksheets that are part of the assessment tool and are personally interviewed by the researcher.

The detailed presentation of the assessment tool is not the subject of this paper. However, in order to present its philosophy, let's discuss the way algorithmic thinking is evaluated. The quantitative data are provided by PhysGramming itself, which is programmed to keep track of students' actions and depict them in log files. These files, that do not include sensitive personal data (Livingstone & Locatelli, 2012), give information about the students' ability to solve puzzles. The qualitative data are derived from personal interviews, in order to determine if students hatch out a plan to solve the puzzles or if they act randomly. In the second case, the whole process involves just luck and no algorithmic thinking. Quantitative and qualitative data are analysed together for each student, in order to determine whether algorithmic thinking was successfully practiced.

The methodology of the pilots

The pilots were conducted by the first author attuned to the ethical guidelines of educational research and were both followed by an assistant researcher - observer. The target group was 27 children: 15 first grade students (four girls and eleven boys) and 12 second grade students (seven girls and five boys). The subject of both pilots was the fauna of Crete, focusing on the animals' eating habits.

The pilots (one for each class) were implemented in the Information Technology laboratory of the school as part of the Study of the Environment course. In Greece, this course encompasses the study of physical and natural sciences. Each pilot lasted three instructional hours (each instructional hour lasts 45 minutes). Children sat in pairs at the workstations. The researcher gave brief instructions about the functionality of PhysGramming. Each child had one hour to create their games and play with them. When both children of a pair had completed their tasks, they could play their games together.

Each one of the three kinds of games created through PhysGramming targets to cultivate fundamental computational thinking skills and introduce object-oriented programming concepts in playful and engaging ways. Through puzzles, we intend to cultivate algorithmic thinking (Hsu & Wang, 2018). Through group games, we aim to exercise the children's ability to organise data. Matching games aim to empower the skill to identify and to designate the attributes of an object.

While preparing the pilots, the researchers integrated into PhysGramming pictures of animals that do not live in Crete. Children should collect only the appropriate pictures and ignore the irrelevant ones. In this way, their skill of collecting data is exercised.

One of the pictures integrated into PhysGramming, portrayed a crocodile. Not much time had passed since a crocodile, the so-called "Sifis", was spotted in a lake of Crete. However, this does not mean that crocodiles are part of the island's fauna. In fact, the students' ability of abstraction should lead them to that conclusion and thus they should not select the crocodile's image. It should be noted that while discussing the content of the lesson, no reference was made about the animals that live in Crete. Therefore, selecting the crocodile's picture or not, did not depend on understanding the content.

Regarding data analysis, we exercise the students' ability to point out mistakes. Thus, we provide the children screenshots in which command lines are constructed with mistakes deliberately made, which children have to point out.

RESULTS

The thorough examination and study of the obtained data revealed that the overwhelming majority of children successfully practiced the computational thinking competencies. Difficulties that children faced were detected with defining the eating habits of the animals. Moreover, few of the children faced difficulties within the context of data analysis, when designating wrong perceptions regarding the eating habits of the animals. Nevertheless, we suspect that these difficulties might result from the poor understanding of the content of the relevant topic. This hypothesis is about to be examined shortly in a research we plan to conduct. As regards to the rest of the computational thinking competencies, they were successfully practiced by all the members of the target group.

As far as the qualitative results of the pilots is concerned, the students tended to paint their own images rather than choosing the ones embedded into PhysGramming. In addition, the syntax of the command lines did not trouble any of the students. This confirms our research hypothesis that the best period for introducing object-oriented programming into education is at the first stages of schooling.

After conducting the pilots, recording students' perceptions and experiences was considered necessary before proceeding with larger-scale research. Through personal interviews, we attempted to capture the general feeling left in the classroom after the pilots. Interviews were semi-structured (Newcomer et al., 2015) and lasted approximately 10 minutes for each child. All 27 of the children that participated in the pilots were interviewed immediately after the interventions. The open-ended questions asked intended to cover two main points: (a) highlighting the problems that students might encounter during the proposed educational framework and (b) identifying its most attractive features. The above mentioned points were also the main pillars of the research protocol of the interviews. Their semi-structured nature allowed children to discuss their experiences regarding the educational activity (Longhurst, 2003).

The proposed educational approach proved to be warmly received by students. While interviewing students, we investigated aspects of the approach they liked or disliked. We received a vast majority of enthusiastic responses and no negative response. A very interesting response was; "I liked it because I had to think, to create and to improvise".

DISCUSSION

The rationale for our research arose from the limited literature on cultivating computational thinking in early elementary grades. In this paper, we present the idea of enhancing fundamental computational thinking concepts at early childhood ages, through a fruitful, creative and engaging educational framework. The most important characteristic of the proposed framework is that children turn into creators, according to the theory of constructivism, while participating in physical and natural science courses, in a way that provides familiarity with basic aspects of computational thinking, without a direct reference to them. Furthermore, it satisfies the self-reliant philosophy of digital natives, the contemporary educational trend to disseminate computational thinking and the need for encouraging technological culture.

Our research is of general interest to the ESERA community, especially to scholars that applaud developing computational thinking in the first grades of primary school. It also concerns educators, researchers and policymakers that opt in favor of the learning theory of constructivism, endorse student-centered education, advocate game-based learning and are ready to adopt educational approaches that transform students from passive consumers to active creators of new technologies.

The limitations of our research have to do with the small sample used. However, we believe that the results of this small-scale research are significant, as they confirm the ease with which the proposed educational framework is implemented in the classroom as well as the positive impact it can have on enhancing computational thinking.

ACKNOWLEDGEMENT

We are especially indebted to the Special Account of Research of the University of Crete, which financially supports our research effort, KA 4713, PsysGramming (Physical Science Programming): An innovative game-based educational framework for the development of computational thinking in early childhood education within the context of physical science study.

THE EXAMINATION OF QUESTIONING METHODS ON YOUNG CHILDREN'S CONCEPTUAL UNDERSTANDING OF ASTRONOMY

Sinem Güçhan-Özgül[1], Mesut Saçkes[1] and Berrin Akman[2]

[1]Balıkesir University, Balıkesir, Turkey

[2]Hacettepe University, Ankara, Turkey

This study aims to examine the coherency of children's responses to the sub-dimensions of the interview protocol, including different types of data collection modes (open-ended questions, modeling, and model selection) at different measurement times. The sample of the study consisted of 56 children (31 girls, 25 boys) aged between 60-72 months attending a kindergarten in a city center located in the northwestern part of Turkey. The 3 classes of 56 children are randomly assigned to the groups (Experiment [n:15], Control [n:20], Placebo: [n:21]). Inquiry-based play activities (12 activities for six weeks) designed for developing young children's conceptual understanding of astronomy are implemented in the experiment group. The curriculum-based astronomy activities were designed and implemented by the teacher of the placebo group, and there was no intervention in the control group. Data collection tools of this study were Earth and Day-Night Concepts Interview Protocol and Earth-2 test. "Earth and Day-Night Concepts Interview Protocol" consists of three parts, such as answering questions with verbal expressions, creating models, and making selections among models. Earth-2 enables children to choose the representations (2D) of their conceptual understandings on the shape of Earth and the day/night cycle. The coherency of children's responses was examined using Intra-Class Correlation Coefficients. The results demonstrated that the consistency of children's responses was weak for the shape of the Earth part of the interview protocol. On the other hand, the consistency of children's responses to the day and night concepts part of the interview protocol varied according to the measurement times.

Keywords: Conceptual understanding, Early childhood education, Science education

INTRODUCTION

Children tend to explore and discover everything around them with their natural and inborn curiosity (Mantzicopoulos et al., 2008) and desire to learn (Akman, Üstün, & Güler, 2003; Eshach & Fried, 2005; French, 2004; Gelman & Brenneman, 2004; Saçkes, Trundle, Bell, & O'Connell, 2011; Tu, 2006). The amount and diversity of children's knowledge in the first years of their lives increases surprisingly; especially children between the ages of two and seven can learn thousands of words, counting and reasoning, reading other people's feelings and thoughts, and develop concepts and phenomena related to biology, physics, and astronomy as well (Gelman, 2005). Young children have a passion for Earth, celestial bodies, and space (Kallery, 2011; Özsoy, 2012; Saçkes, Smith, & Trundle, 2016). Therefore, children are curious about the physical properties of the Earth and other planets, the cycles of the moon and the sun, and the day and night cycle, which in turn supports them to make observations, ask questions and produce explanations.

In the last 40 years, there has been a remarkable increase in the study of early childhood children's reasoning and conceptual understanding within their own development and learning patterns. The conceptual understanding of young children on astronomy has become one of the most investigated subjects recently. Pioneering studies of Vosniadou and Brewer (1992,1994) on children's conceptual understandings about the shape of Earth and the day-night cycle indicated that children might have three distinct mental models regarding these scientific phenomena. These mental models are; (1) Initial model, (2) Synthetic model, and (3) Scientific model. These models serve as frameworks underlining children's conceptual understandings about the physical properties of Earth and day-night phenomena. Initial models are derived from daily observations and show no interaction with scientific knowledge. On the other hand, synthetic models are blended with everyday experiences and cultural/ instructional information but still away from scientific knowledge. Synthetic mental models are defined as consistent and durable conceptual understandings within themselves. Scientific models consist of understandings aligning with scientific explanations.

The works of Vosniadou and Brewer (1992, 1994) have been criticized and challenged by researchers. One aspect of these criticisms focuses on the consistency of children's responses and suggests that children might not have a consistent conceptual understanding regarding scientific phenomena. While Vosniadou and Brewer (1992, 1994) assume that children use coherent mental structures based on their interpretations of daily observations and/or beliefs, the other theory proposed by diSessa (1983) advocates fragmented pieces of knowledge that derive from everyday experiences, are weakly organized and should be discussed within the coordination agents. From this point of view, children are thought as "theory-free"- have no strongly held opinions while they reflect their conceptual understanding of astronomy, i.e., the shape of the Earth (Panagiotaki, Nobes, & Banerjee, 2006). The other challenging aspect derives from the works of Vosniadou and Brewer is the methodological considerations. Two opponent theories about the conceptual understanding of children on astronomy concepts have used different methods to reveal children's ideas. These methods differ from each other in terms of questioning types and the tools used (Hannust & Kikas, 2012; Kampeza, 2006; Siegal, Butterworth, and Newcombe, 2004; Straatemeier, van der Maas, Jansen, 2008; Valanides et al., 2000). Thus, different probing ways produce conflicting results regarding the verbal explanations, drawings, 2D, and 3D structures of tasks of the interview protocols. Vosniadou and Brewer's (1992; 1994) interview protocols about the shape of the Earth and the day-night cycle comprise of open-ended questions and drawing tasks. Likewise, Hayes, Goodhew, Heit, and Gillan (2003), and Hannust and Kikas (2012) have used Vosniadou and Brewer's form with only a few alterations. The findings of these studies that use underline the coherent mental structures of children assessed instead of a collection of fragmented facts. Proponents of 'fragmented knowledge' assume that children's representations of the Earth (drawing pictures, making models) might make their knowledge look like limited or they might have coherent mental models (Nobes and Panagiotaki, 2009; Panagiotaki, Nobes & Banerjee, 2006; Siegal et al., 2004). Moreover, the recent critics underline the inadequacy of open and generative questions that are challenging and confusing to reveal children's scientific knowledge about the matter (Frede et al., 2011; Nobes and Panagiotaki, 2009). On the contrary, the studies challenging with the mental model account put the importance of the recognition of child forward and use selection tasks (making selection from a set of models or pictures) and forced-choice tests (Frede et al., 2011; Nobes, Martin, and Panagiotaki, 2005; Panagiotaki, Nobes, and Banerjee, 2006; Straatemeier et al., 2008). These two-opponent views interfere with each other regarding the methods used to identify children's answers, whether scientific or naïve. Besides these methodological issues, recent studies have also investigated the effect of an instructional intervention on conceptual change and even the coherence of children's answers to different probing methods (Hannust and Kikas, 2007; Hayes et al., 2003).

From this point forth, this study takes the different point of views and questioning methods using open and forced-choice questions and model selection tasks regarding the intervention effect. The present study aims to examine the coherency of children's responses to the sub-dimensions of the interview protocol targeting children's conceptual understandings of the shape of the Earth and day-night cycle at different measurement times.

METHOD

This study is designed as a pre-test post-test quasi-experimental design within the embedded experimental mixed method, which might aim to embed both qualitative and quantitative data within the qualitative interpretation.

Participants

The sample of the study consisted of 56 children (31 girls, 25 boys) aged between 60-72 months attending the kindergarten in a city center located in the northwestern part of Turkey. The 3 classes of 56 children are randomly assigned to the groups (Experiment [n:15], Control [n:20], Placebo: [n:21]).

Instruments

Data collection tools of this study were Earth and Day-Night Concepts Interview Protocol (Saçkes, 2015) and Earth-2 test (Straatemier et al., 2008). "Earth and Day-Night Concepts Interview Protocol" consists of three parts, such as answering questions with verbal expressions, creating models, and making selections among models created by researchers. Besides, Earth-2 enables children to choose the representations (2d) of their conceptual understandings on the shape of Earth and the day/night cycle. This protocol allows for gathering different types of data to reveal children's conceptual understandings on Earth and the day-night cycle.

Data Analysis, Categorization and Coding

Children's responses to the interview protocol were coded by the researchers within the framework of mental models presented in the literature on the shape of the Earth and the day-night cycle. Responses were analyzed by coding as 0 (initial), 1 (synthetic), and 2 (scientific). This coding is based on the scientific/non-scientific nature of the mental models that children have, the use of daily observations, or the effect of acculturation. The coherencies of children's responses were examined using Intra-Class Correlation Coefficients within SPSS version 24.

Intervention Procedure

In the present study, inquiry-based teaching is used as a suitable method to teach children the nature of science and scientific concepts since this method enables children to involve in practical activities, meaningful discussions, and requiring active participation of learners. Inquiry-based activities are integrated activities that might be comprised of play, science, drama, and the other domains of early childhood curriculum and directly target to develop young children's conceptual understanding of astronomy, especially the shape of Earth and day-night cycle phenomenon.

Inquiry-based play activities (12 activities for six weeks) designed for developing young children's conceptual understanding of astronomy are implemented in the experiment group. The curriculum-based science activities deal with astronomy designed by the teacher of the placebo group are implemented in the placebo, and there was no intervention in the control group.

RESULTS

The consistency of the responses of the interview protocol to the sub-dimensions of the Earth's shape concepts can be interpreted as very weak (ICC_{PRE} = .017, ICC_{POST} = .277, ICC_{FOLLOW} = .277) (Cicchetti, 1994). The consistency of the responses to the sub-dimensions related to the day and night concepts of the interview protocol (ICC_{PRE} = .134, ICC_{POST} = .507, ICC_{FOLLOW} = .634) varies according to the measurement times. These results indicate that the responses of children to the questions related to the day and night formation were moderately compatible in the post-test and that children produced well-matched responses in the follow-up test.

Table 1. Consistency of Responses to Interview Protocol Sub-Dimensions (Whole Group).

		Pre-test	Post-test	Follow-up test
The shape of Earth	**Whole group (N=56)**	ICC_{PRE} (p= .402)	ICC_{POST} (p=.001)	ICC_{FOLLOW} (p= .001)
		.017 (-.121-.189)	*.277* (.113-.452)	*.277* (.112-.452)
Day-night cycle		ICC_{PRE} (p=.046)	ICC_{POST} (p= .001)	ICC_{FOLLOW} (p= .001)
		.134 (-.021-.313)	*.507* (.350-.651)	*.634* (.498- .750)

*ICC: Intraclass Correlation Coefficency (%95 Confidence Interval)

It is seen that there is no consistency in the responses of children when the whole group are considered. However, Table 2. shows that the consistency of the answers given by the experimental group children to the questions and tasks related to the day and night increases over the course of three measurement occasions. The consistency in children's responses has started to increase immediately after inquiry-based play activities and continue to increase in the follow-up test ($ICC_{PRE} = .195 < ICC_{POST} = .567 < ICC_{FOLLOW} = .729$). For the control group, there was a poor agreement between the sub-dimensions of interview protocol, whereas in the placebo group there is a partial but non-gradual increase in the follow-up test ($ICC_{PRE} = .283 > ICC_{POST} = .253 < ICC_{FOLLOW} = .610$).

Table 2. Consistency of Responses to Interview Protocol Sub-Dimensions (Within Group)

		Pre-test	Post-test	Follow-up test
The shape of Earth	Experiment	ICC$_{PRE}$ (p=.197)	ICC$_{POST}$ (p=.681)	ICC$_{FOLLOW}$ (p= .094)
		.129 (-.150-.498)	-*.079* (-.288-.276)	*.207* (-.091-.565)
	Control	ICC$_{PRE}$ (p=.618)	ICC$_{POST}$ (p=.352)	ICC$_{FOLLOW}$ (p= .451)
		-*.045* (-.243-.257)	*.045* (-.180-.359)	*.010* (-.205-.321)
	Placebo	ICC$_{PRE}$ (p=.645)	ICC$_{POST}$ (p=.061)	ICC$_{FOLLOW}$ (p= .300)
		-*.053* (-.244-.239)	*.205*(-.050-.504)	*.064* (-.162-.369)
Day-night cycle	Experiment	ICC$_{PRE}$ (p= .107)	ICC$_{POST}$ (p=.001)	ICC$_{FOLLOW}$ (p= .001)
		.195 (-.100-.555)	*.567* (.264-.807)	*.729* (.485-.889)
	Control	ICC$_{PRE}$ (p= .513)	ICC$_{POST}$ (p=.001)	ICC$_{FOLLOW}$ (p= .176)
		-*.010* (-.219-.297)	*.419* (.143-.681)	*.122* (-.122-.436)
	Placebo	ICC$_{PRE}$ (p= .018)	ICC$_{POST}$ (p=.029)	ICC$_{FOLLOW}$ (p= .001)
		.283 (.018-.571)	*.253* (-.009-.546)	*.610* (.369-.800)

*ICC: Intrarclass Correlation Coefficency (%95 Confidence Interval)

DISCUSSION

The findings of this study obviously indicate that different probing modes may produce different results. In a similar study, it was observed that forced-choice questions provide more accurate answers than open-ended questions, and open questions frequently produced responses assigned to initial and synthetic models (Panagiotaki et al., 2006). In a study by Siegal et al. (2004), a multidimensional interview protocol was used to examine the understanding of preschoolers on the concepts of astronomy, and the findings of this study showed that the questions that were easily understood and directly addressed produced more consistent and meaningful answers than the open-ended productive questions. Likewise, Panagiotaki, Nobes, and Potton (2009) adapted confusing and vague questions into more direct and clear ones, by the way, they elicited more accurate answers indicate children's mental models as scientific rather than naïve synthetic.

The methods used for discovering children's mental models about the scientific phenomena might generate different results conflicting with each other. The results of these studies suggest that poor compliance between the sub-dimensions of interview protocol presented in table 2 may be due to method effects. Children might undergo short-term conceptual changes that eventually produce consistent answers to different modes of data collection (drawing, model building, and open / closed-ended questions) (Blown & Bryce, 2006). Hannust and Kikas

(2012) also conclude that even 4th-grade students can produce scientific answers cannot express their knowledge by using other mediums like drawings or making a model.

Another aim of this study deals with the change of consistency among responses to sub-dimensions according to different measurement times. The present study explains that children generate more accurate and consistent answers, especially about the day-night cycle phenomenon as they get knowledge and have experience with it. Inquiry-based activities as an intervention program may explain the increase in consistent responses to different types of questioning methods in the experimental group. The studies examine the conceptual change, and the consistency of assessment methods have similar results show that children provide more coherent and scientifically acceptable answers in interviews as they get older and become informed about the phenomena (Bryce and Blown, 2013; Frede et al., 2011; Hannust and Kikas, 2010; Hayes et al., 2003; Nobes, Martin and Panagiotaki, 2005).

The overall findings of the present study suggest that different probing modes may cause children to produce inconsistent responses and as children's understandings about the scientific concepts and phenomena develop, children provide consistent answers to varying types of data collection tools.

CASE STUDIES OF COLLABORATIVE MODEL-BASED REASONING FOR CONCEPTUAL CHANGE IN PRESCHOOL CHILDREN

Eleni Sakellaridi[1], Spyros Kollas[2]
[1]National and Kapodistrian University of Athens, Athens, Greece
[2] National and Kapodistrian University of Athens, Athens, Greece

Contemporary multi-dimensional approaches conceptualize the notion of conceptual change as a slow and gradual affair that requires not only the restructuring of students' intuitive theories, but also the restructuring of their modes of learning, the creation of metaconceptual awareness and intentionality. Towards this goal many researchers emphasize the importance of model based reasoning and argumentation, as instructional practices that provide a fruitful combination of dissonance with knowledge building strategies, and also crucial understandings about the nature of science. Whereas such means have been proved successful in secondary education, there is a debate about their effectiveness among preadolescent students, due to developmental constraints. In our study, we investigated whether a collaborative model-based problem-solving learning environment could facilitate preschool children's conceptual change regarding the phenomenon of day and night cycle. Key features of the learning environment were: a) the use of narrating and theatrical play parts, inspired by the tale of the Little Prince, aiming to meaningfully engage preschool children, b) the construction and manipulation of play dough models by the children as means to help them make their implicit ideas overt and explain the phenomenon of day and night cycle, c) collaborative discourse and argumentative reasoning processes among students in order to examine and juxtapose each other's models, and d) a collaborative problem-solving task that incorporated the fact, that the day and night cycle phenomenon takes place on another planet, data that could be anomalous for the geocentric intuitive conceptions. Regarding the implications of a learning environment with such characteristics to three groups of preschool children, the results show important aspects of intentional conceptual change, including reasoned change in children's geocentric models towards heliocentric representations. We argue that these changes were the outcome of a deep engagement process, where children's implicit ideas were gradually transformed into reasoned views.

Keywords: Conceptual Change, Model-based reasoning, Pre-school Education

THEORETICAL BACKGROUND

Conceptual change (CC) has become a common conception of meaningful learning, treating learning as an intentional, dynamic, and constructive process (Duit & Treagust, 2012). Contemporary CC approaches denote a gradual and multi-dimensional learning process, rather than a sudden and radical restructuring of knowledge (Vosniadou, 2003), overcoming the individualistic and radical construvistic perspectives of the early 80's. Framework theory suggests that CC includes not only the restructuring of student's intuitive ideas and the creation of new ontologies. It also signifies considerable metacognitive, epistemic and representational abilities that allow learners to be aware of their ideas, relate them to the scientific ones, notice the discrepancy between them, engage in hypothesis testing, and proceed with conceptual change as reasoned change (Vosniadou & Skopeliti, 2014). A central challenge for contemporary CC approaches is how to simultaneously promote conceptual understanding as well as growth in reasoning, epistemic cognition and interest about science (Duit & Treagust, 2012). To this end, new science education standards highlight the importance of students' participation in first-hand experiences that reflect communally recognized scientific practices (Kidn & Osborne, 2017).

In search of instructional practices

Model-based reasoning and collaborative problem-solving tasks are considered significant means of developing not only learners' conceptual understanding, but also their epistemic believes and appreciation of science, reflecting core scientific practices. Nersessian (2008) argues that model-based reasoning is fundamentally related to conceptual innovation and change, mediating scientists reasoning to the new representations. Lehrer and Schauble (2015) also argue that modeling is the most defining practice of science and they suggest conceiving other practices in relation to this foundational one, whereas Osborne (2010) suggests that collaborative and argumentative practices reflect the social construction of scientific knowledge.

It is well documented that model-based reasoning and collaborative problem-solving environments can foster CC, providing a fruitful combination of cognitive dissonance with knowledge building strategies (Vosniadou, 2003). In educational settings, modeling transforms implicit physical knowledge into an explicitly coded external model, making it available for examination, questioning, revision, and further theorizing in either an individual base or a group discussion (Vosniadou, 2013). Therefore, it is argued that it could enable learners become aware of their beliefs and the presuppositions that define their reasoning.

Arguments about problem-solving suggest that it could help students be purposeful and planful, thus caltivating intentional learning. Hatano and Inagaki (2003) suggest, that alongside collaborative, argumentative or discourse practices, problem-solving environments ensure that students understand the need to fundamentally revise their believes, instead of engaging in local repairs. And furthermore, that they spend a considerable amount of time and effort in order to engage in the conscious and deliberate belief revision required for CC (Vosniadou, 2003). Argumentative practice is, moreover, suggested to enable learners to transform their personal beliefs into reasoned views, learning gradually to transfer this way of thinking beyond the specific dialogical contexts (Osborne, 2010).

Whereas such means have been proved successful in secondary education, there is a debate about their effectiveness among preadolescent students, due to developmental constraints. Research in cognitive developmental phycology (Pintrich & Sinatra, 2003) suggests that the cognitive abilities that are required for CC are not formed in preschool children. Previous research (Kuhn & Weinstock, 2002; Kyriakopoulou & Vosniadou, 2014) suggests that preschool students lack the cognitive flexibility and the epistemological sophistication to engage in hypothesis testing. The literature is inconclusive on how and when students' reasoning capabilities develop. A subset of scholars argues that they develop through adolescence, while another strand of researchers suggests that even preadolescent children are capable of making evidence-based inferences (Osborne, 2010).

In our study, we investigate whether such a learning environment of collaborative model-based problem-solving could facilitate preschool children's CC processes regarding the phenomenon of day and night cycle. Adopting Vosniadou's approach about the CC processes, we also investigate the characteristics of any possible changes in children's perceptions and representations, i.e. if can they be described as intrinsically motivated and reasoned changes.

METHODOLOGY

The research procedure

Considering the call for inclusive children-centered research methodologies for early childhood (Fleer & Robbins, 2003), the current study used a story, inspired by the tale of the Little Prince, in order to set a friendly and appealing environment to meaningfully engage preschool children in the problem-solving and modeling procedure. The story was adapted in a theatrical play, so that the children and the researcher would be actively participating in it. In the context of this play the children and the interviewer followed the Little Prince through his journey from Earth to his planet and were asked to address specific questions and tasks regarding the phenomenon of day and night cycle.

The research was designed as a semi - structured procedure, taking place in three stages:

(a) In the first stage the goal was to investigate children's ideas about the phenomenon of day and night cycle. Kids were asked to use play-dough in order to create models of the Earth, the Sun, the Moon and other celestial objects. Alongside the modelling, kids were asked a set of questions that were based on the questionnaire of Vosniadou and Brewer (1992 & 1994), in order to explain the phenomenon The questions were addressed, at first, to each kid individually.

Our hypothesis was that children would express multiple representations of the phenomenon, but would be committed to their ontological presupposition when answering to open ended generative questions Vosniadou & Brewer 1992; Vosniadou & Brewer, 1994; Vosniadou & Skopeliti, 2017).

(b) On the second stage our purpose was to engage kids into collaborative and argumentative discourses. We asked them to present their models to the team, and notice if their models and explanations were different. In order to challenge them deeper into collaborative model-based reasoning we asked them to try to make a joint decision about the most plausible and fruitful representation of the phenomenon. The aim was to provoke argumentation amongst different models, so that the children would examine their beliefs in comparison to the different models presented and question each other's explanatory adequacy.

At this phase we investigated the way that kids would deal with data that confront their ontological presuppositions. Based on previous research (Chinn & Brewer 1993; Vosniadou & Skopeliti 2017) our hypothesis was that they would ignore or reject the confronting data.

(c) The third phase included/implicated the kids into a problem-solving task, derived from the emerging/set by the story data that day and night cycle takes place not only on Earth, but also on another planet (here on the Little Prince's planet). This data could be anomalous for the geocentric intuitive conceptions that many preschoolers hold, thus resulting to cognitive dissonance. The kids were asked to engage in model-based reasoning in order to find a solution to their problem. This took place first individually, then as a collaborative and argumentative process.

Based on (Hatano & Inagaki, 2003) we hypothesized that the problem would introduce anomalous data that would urge kids to re-examine their own beliefs and test new hypothesis on the grounds of the most fruitful, reasonable and plausible solution.

The sample

Three teams of preschool children participated in the aforementioned process. The 1st and the 2nd team consisted of three children (three girls and three boys correspondingly), while the 3rd team of two children (two girls). All children were chosen by the school director of a private kindergarten school in Athens and were in the same class. The researcher had no previous familiarization with the sample.

The method of analysis

The 'interviews' were videotaped and analysed with a qualitive method of context analysis (Erickson, 2012). More analytically, the videos were split in episodes in accordance to the three stages of the research procedure. Our focus was on any possible changes on children's perceptions and representations through these stages and the parameters that seemed to triggered them. Moreover, we investigate whether these changes follow the patterns of reasoned change or compliance.

For this reason, each episode was analysed with respect to: (a) the students' ideas about the shape of the Earth, their ontological beliefs and their explanations of day and night phenomenon, (b) the students' reactions when confronting the new data emerging either by their peers or the story and the kind of data that provoke a problem-solving procedure and/or an intrinsically motivated argumentation (i.e. in which circumstances do they reject the data, when do they ignore them and when do they get involved in a process of 'negotiating'/re-examining their perceptions), (c) the role and use of models through the process of the argumentation (i.e. do they use them only as means of making their beliefs explicit and communicating or additionally as means of revising their own beliefs, making 'inventing' ways of explaining a phenomenon and testing this hypothesis).

RESULTS

The students' ideas expressed in the three phases of the research are summarized in Table 1. As shown at the first column, in the first phase of the research where students individually expressed and modeled their ideas about the shape of the Earth and the way the day and night cycle phenomenon occurs, half of the participating kids initially created the model of the spherical Earth and attributed the phenomenon to the rotation of the Earth around its axis in a sun-centered system (scientific view). Two children (K2 and K3) created models of the flattened sphere, where the Earth seems spherical, but humans only live at the top, and the day and night phenomenon occurs due to the movements of the Sun and the Moon respectively (when the night comes, the Moon comes in front of the Sun). The Sun and Moon motions also 'create' the phenomenon in the models of K4 and K5, where the celestial bodies move vertically up and down the intuitive flat-earth model of the children.

As we can see in the second column, the initial representations of the children did not change during the second phase of the research, where the kids were exhorted to participate in a process of argumentation regarding the different representations and explanations presented. On the contrary, in the process they rejected or even ignored the ideas of their peers, which confirms our second hypothesis and replicates the results of Chinn & Brewer (1993) and Vosniadou & Skopeliti (2017). In addition, at this stage, children needed to be externally mobilized to engage in the dialogue. Usually the researcher asked questions and tried to provoke an argumentation, though the conversation seemed not to have any flow.

In the third phase of the research process, where children were involved in a collaborative problem-solving process, conceptual development was observed in four of the eight students. In particular, all children with initially geocentric ideas revised them in favor of the sun-centric ones. These data corroborate the third research hypothesis and are consistent with the literature of Hatano & Inagaki (2003). It seems that the problem raised at this stage did indeed bring anomalous data that caused cognitive dissonance among students with geocentric perceptions. At this stage, the students were acting with significantly greater autonomy and appeared to be internally motivated. As part of the problem-solving process, the students consciously reorganized their representations in their quest for a model that would be most plausible and fruitful for the data emerged (explain that phenomenon of day and night cycle takes place both on our planet and on others).

	1st Stage	2nd Stage	3rd Stage
Childrens' concepts about the day/ night cycle	4 kids **(K1, K6, K7, K8):** • <u>**Earth shape:**</u> **Spherical,** • <u>**Solar system:**</u> **Heliocentric,** • <u>**Explanation of day and night cycle:**</u> **Rotating Earth around axis** 2 kids **(K2, K3):**	**No conceptual change among students.**	**Students do not modify the shape of the Earth.** 6 kids **(K1, K4, K5, K6, K7, K8) in order to solve the problem of the appearance of the phenomenon on another planet, create cooperatively solar**

	• **Earth shape:** **Flattened sphere,** • **Solar system:** **Geocentric,** • **Explanation of day and night cycle:** The Sun and the Moon move vertically up and down 2 kids **(K4, K5):** • **Earth shape:** **Flat,** • **Solar system:** **Geocentric,** • **Explanation of day and night cycle:** When the night comes, the Moon comes in front of the Sun		**systems where the effect is due to the rotation of each planet around its axis.** 2 kids **(K2, K3) create a solar system so that the Sun can illuminate all the planets, but they still explain the phenomenon by putting in turns the Moon in front of the Sun to create the night and inversely for the day.**
The role and use of models	**They use the models in order to make their ideas explicit and to be able to explain them**	**They use the models in order to explain their ideas to each other and compare them**	**They use models to evaluate the explanatory power of their model under the light of the new data, to make new hypothesis and testify them**
Students' reactions when confronting the new data		**They engage into the argumentation process** exhorted **by the researcher (external mobilization).** **They ignore and / or reject new data arising from their peers' arguments.**	**They engage in intense dialogue and deal with cases and new data brought about by internal mobilization.** They re-examine and make **evolve their representations** consciously**, by accepting and incorporating new data into their thinking.**

Table 1. Students' ideas and how they use modelling in order to respond to new data in argumentation and problem-solving processes.

Two episodes

Two episodes presented below are illustrating the dynamics of student dialogue and reasoning. The first episode occurs during the second phase of the research process and is a typical case of data rejection, as presented to the team. In this group, as mentioned above, two of the three children (K5: George and K4: Paul) interpreted the phenomenon with vertical movements of the Sun and the Moon over a flat Earth. The third child (K6: John) constructed a solar-centric system in which the phenomenon of day-night rotation was explained as the rotation of the spherical Earth around its axis.

Episode 1: Juxtaposing models and ideas

Researcher: What do you think about John's idea?... Have you ever heard that the earth rotates?

George: Yes! I have a globe- puzzle game! You make it round, then you put the basis that holds it, then the axis.. And then you can rotate it!

R: A ok! So you have seen it.

John: If it weren't so...

Paul: ... Here (he shows one side of his model) it would be forever day and on the other side ...

John and Paul: Forever night!

John: Yes.

Paul: But on my model as well… When the sun is here it doesn't shine on the other side!

Episode 2: Problem Solving

On the contrary, this episode presents the dynamics of the process of the argumentation that took place in the third phase of the research process, as an outcome of the emerging by the story anomalous data. As shown, the discussion became more intense and the kids seemed to experiment more freely with their models in order to find a more plausible and fruitful explanation.

On this part, a dialogue taking place between John and Paul is presented, in which John's arguments result in Paul's reasoned change.

John: How long would it take for the sun to go to all the other planets? How long would it take to go shine to all of them?

Paul: Then it wouldn‘t leave Earth.

John: But then, on the other planets will there only be night? And we, on the Planet of Little Prince, won't we be able to play?

Paul: There should be day as well…

John: So? Why do you say that the Sun won't shine on them? I mean, on your (model) the Prince is here, on his planet, and the sun is above Earth. How will it get there to shine?

Researcher: What's your solution? Where is your sun?

John: In the center.

Paul: A ok! So the sun shines everywhere at the same time!

CONCLUSION

In the context of collaborative model-based problem-solving along with storytelling and theatrical play, we witnessed the gradual transformation of children's implicit ideas into reasoned views. Children treated their as well other's ideas as hypotheses that could be tested, shared, argued and changed through the use of self-constructed models. The results show important aspects of intentional CC, including reasoned change in children's geocentric models towards heliocentric representations. We argue that the story was an important factor, creating a safe as well as engaging environment, with narrating spaces between research tasks, and most importantly, providing reasons for the preschool children to construct their models, juxtapose and argue about their representations. The construction and manipulation of models clearly supported children in a metacognitive manner, and made it possible for different positions to be elaborated, compared and contrasted. Without the ability to see and manipulate each other's ideas, as incorporated to the models, such an intense and lasting argumentative reasoning process wouldn't be possible among children of such young age.

Our results support the notion that intentional CC could be greatly supported and facilitated by schooling even in young ages. The limitations of the current study include the small sample and the fact that idiosyncratic factors may have had an impact on the presented results. However, we believe that these case studies show the potential of preschool children to fully engage in tasks that reflect scientific practices, where reasoning is understood as a problem-solving process via which one arrives at justified beliefs about natural phenomena. After all, as Driver et al. (2000) highlight, the process of enculturation into science comes about in a very similar way to the way a foreign language is learned—through its use.

COGNITIVE STYLE AND MOTIVATION AND LEARNING IN INQUIRY BASED EARLY-YEARS SCIENCE ACTIVITIES

Maria Kallery[1], Angelos Sofianidis[1], Popi Pationioti[2], Kaliopi Tsialma[3], Xristina Katsiana[2]
[1]Aristotle University of Thessaloniki, Greece
[2]Pre-primary Education, Thessaloniki, Greece
[3]Primary Education, Thessaloniki, Greece

Differences in children's motivation for science can be explained by the theory of "systemizing " and "empathizing" brains. Researchers claim that people with "systemizing " cognitive style are more engaged in science and more motivated to do science than those with "empathizing". They propose a suitable formulation of themes and didactic approaches to motivate children with an "empathizing" cognitive style. The aim of this work is to investigate how preschool and early-primary school children react according to their cognitive style in activities with specific characteristics. The approach of the activities was structured inquiry having as main features the guided by specific questions of the teacher building of knowledge through experiments and investigations, problem solving situations, forming coherent arguments, drawing conclusions and reflection. In this context children also had the freedom to test their own ideas that emerged spontaneously. The results showed large percentages of the highest levels of engagement/involvement which are signs of motivation that can be observed and recorded, and high success rates in children's learning outcomes for all types of cognitive style. The findings indicate that such type of activities and approach may be appropriate for triggering motivation and learning in science of young children with all types of brain.

Keywords: cognitive style, structured inquiry, motivation in science

INTRODUCTION

Previous studies that looked at different factors that influence the motivation and learning of young children in science have come to different conclusions. One of the most prevalent views was that boys have greater interest and more motivation to learn science than girls have (e.g. Alexander, Johnson & Kelley, 2012). In other studies the results varied according to the type of teaching and the instructional context in which science was taught. For example, kindergarteners who participated in a Scientific Literacy program based on a conceptually coherent sequence of integrated science inquiry and literacy activities, regardless of sex, had greater motivation for science than children who had only the regular science experience. (e.g. Patrick, Mantzicopoulos & Samarapungavan, 2009). Indeed, research on the relationship of different factors and science learning is inconclusive and asks for a change of paradigm.

The researchers argue that differences in children's motivation for science can be explained by the Empathizing-Systemizing (E-S) theory (Baron-Cohen, 2009). "Empathizing (E) (the drive to identify another person's emotions and thoughts and to respond to these with an appropriate emotion) is held to be generally stronger in females, whilst systemizing (the drive to analyze, explore and construct a system) is held to be generally stronger in males" (Auyeung et al., 2009, p. 1). Researchers claim that, regardless of gender, people with Systemizing cognitive style are more engaged in science and motivated to do science than those with Empathizing cognitive style. They suggested that people with an empathizing or a systemizing cognitive style need different approaches to science because, due to their brain types, they are not similarly motivated in this field of education. In order to motivate empathizing children for science, they suggest to appropriately formulating context, themes as well as didactic approaches (Zeyer et al., 2012).

Recent studies of science activities in an inquiry-based context with topics from physics and astronomy have shown great interest and at the same time very good learning outcomes in boys and girls of pre-school age (e.g. Kallery, 2011; Kallery, 2015). The approach of the activities was structured inquiry having as main features the guided by the teacher's specific questions building of knowledge through experiments and investigations, problem solving situations, forming coherent arguments, drawing conclusions and reflection. In this context children also had the freedom to test their own ideas that emerged spontaneously. Through these, they discovered and realized additional relationships between the different variables involved in the activity. Work in the classroom included collaboration in small multiage groups (Kallery & Loupidou, 2016) as well as whole-class discussions. The pictures presented in Figure 1 are characteristic of the work in the classrooms where children experimented. In this figure, in the first row on the left, the children guided by the teacher's questions study the conservation of mass. The next two pictures show children working in small groups investigating conservation of mass of pliable materials and of fluids. In the second row, on the left, the children work on the concept "the air takes the shape of the container into which we place it" and on the right they are testing one of their own ideas and try to find out if the air "does the same thing as the water does". They had the spontaneous idea to fill a balloon with water and then empty it and fill it with air. The testing of this idea helped them comprehend similarities in the behavior and characteristics of liquids and gasses.

Figure 1. Structured inquiry activities: Experimentation in real classroom settings

In the present study we investigated whether activities with the above characteristics affect differently the motivation and learning in science of children with different cognitive styles. But motivation cannot be observed. However, there are different signs of motivation which can be observed and recorded, such as: engagement/involvement, (which are closely linked to academic achievement), interest, which creates motivation and guarantees the engagement/involvement of a person in content-specific activities, persistence and satisfaction (O'Keefe, Horberg & Plante, 2017). In this paper, we study the engagement/involvement of the children in the activities and their learning outcomes. This allows us to diagnose whether children with empathizing cognitive style exhibit a lower degree of engagement/involvement than those with systemizing cognitive style (as supported in literature). For this, we implemented 5 conceptually coherent modular inquiry activities with the above approach and characteristics in preschool and early-primary school. Our study includes: a) Identifying the empathizing and systemizing quotients of every child and b) Investigating the level of engagement/involvement of each child in the activities and its cognitive achievements.

METHODOLOGY

Identification of the empathizing and systemizing quotients: Questionnaire

The empathizing and systemizing quotients were determined by analysis of data collected by specially formulated and validated by Auyeung et al. (2009) questionnaire completed by the parents of the children. The questionnaire included 55 questions a sample of which is presented in Figure 2. The questionnaire was adapted by our team to the context of our study. Its reliability was calculated giving a high Cronbach's alpha (for E:0.83, for S:0.81). The study involved 47 children aged 4-7 years attending public kindergarten and primary school. The statistical analysis of the questionnaires identified 5 types of brains: Extreme Empathizers (EE), Empathizers (E), Balanced (B), Systemizers (S) and Extreme Systemizers (ES).

Level of engagement/involvement and cognitive achievements: Classroom observations/recordings

The collection of data from the classroom was done by systematically observing and recording the reactions of the children by teachers based on a specific observation tool and instructions for use. Teachers recorded on the special observation sheets the level of engagement/involvement of children on a five-level scale (Leuven scale) and the indications that justified their evaluations and decisions. On this scale the highest level of engagement/involvement is scored 5 (see Table 1). The recordings based on this tool allowed us to quantify the data for the purpose of their statistical analysis and the possibility of correlations of the brain type of each child with the signs of engagement/involvement. At the same time, the learning outcomes of all children were recorded during the planned systematic evaluation of each activity. The teachers who implemented the activities of our study had many years of experience in implementing inquiry-based science activities as well as many years of experience in observing and recording in the real classroom and participating in collaborative action research for the development and implementation of inquiry-based activities (Kallery, 2017).

Table 1. The Leuven scale of active engagement in learning

Level1	Level 2	Level 3	Level 4	Level 5
Extremely low: The child shows hardly any activity	**Low:** The child shows some degree of activity which is often interrupted	**Moderate:** The child is busy the whole time, but without real concentration	**High:** There are clear signs of involvement, but these are not always present to their full extend	**Extremely high:** During the observation of learning the child is continually engaged in the activity and completely absorbed in it

Please complete by ticking the appropriate box for each statement

		Definitely Agree	Slightly Agree	Slightly Disagree	Definitely Disagree
1.	My child likes to look after other people.				
2.	My child often doesn't understand why some things upset other people so much.				
3.	My child doesn't mind if things in the house are not in their proper place.				
4.	My child would not cry or get upset if a character in a film died.				
5.	My child enjoys arranging things precisely (e.g. flowers, books, music collections).				
6.	My child is quick to notice when people are joking.				
7.	My child enjoys cutting up worms, or pulling the legs off insects.				
8.	My child is interested in the different members of a specific animal category (e.g. dinosaurs, insects, etc.).				
9.	My child has stolen something they wanted from their sibling or friend.				
10.	My child is interested in different types of vehicles (e.g. types of trains, cars, planes, etc.).				
11.	My child does not spend large amounts of time lining things up in a particular order (e.g. toy soldiers, animals, cars).				
12.	If they had to build a Lego or Meccano model, my child would follow an instruction sheet rather than "ploughing straight in".				

Figure 2. Sample of questions included in the questionnaire completed by the parents

Analysis of recordings and results

For statistical analysis purposes, each type of brain was assigned a number from a five-point Likert-type scale. According to the literature, students with systemizing brains have a greater tendency to engage in science activities than those with empathizing. Therefore, ES was assigned to number 5, S to 4, B to 3, E to 2 and EE to 1.

Also, the results of the assessment of the children's learning outcomes gave us the opportunity to see the relationship between learning outcomes and the type of cognitive style for each child separately and for the whole sample. For the assessment of children's learning outcomes, we used concept cartoons. All children were assessed each of them individually. The assessment was carried out during the planned systematic evaluation and was recorded by the teachers. For the analysis of children's answers to the assessment task we assigned value 1 to the answers that were considered scientifically acceptable for the age of the children and were satisfying the aim of the activity, and value 0 for the non-acceptable ones (range of values from 0 to 1) .

The statistical analysis of the teachers' recordings showed high percentages of the highest levels of engagement/involvement and high success rates in activity assessments for all types of children's brain. Samples of the results are shown in Figures 3 and 4. Figure 3 presents the results from the activity 'Conservation of mass' which is considered one of the most difficult concepts for young children to understand. In Figure 4 the results from the Activity 'Floating and sinking' of solid bodies, which is an equally difficult activity, are presented.

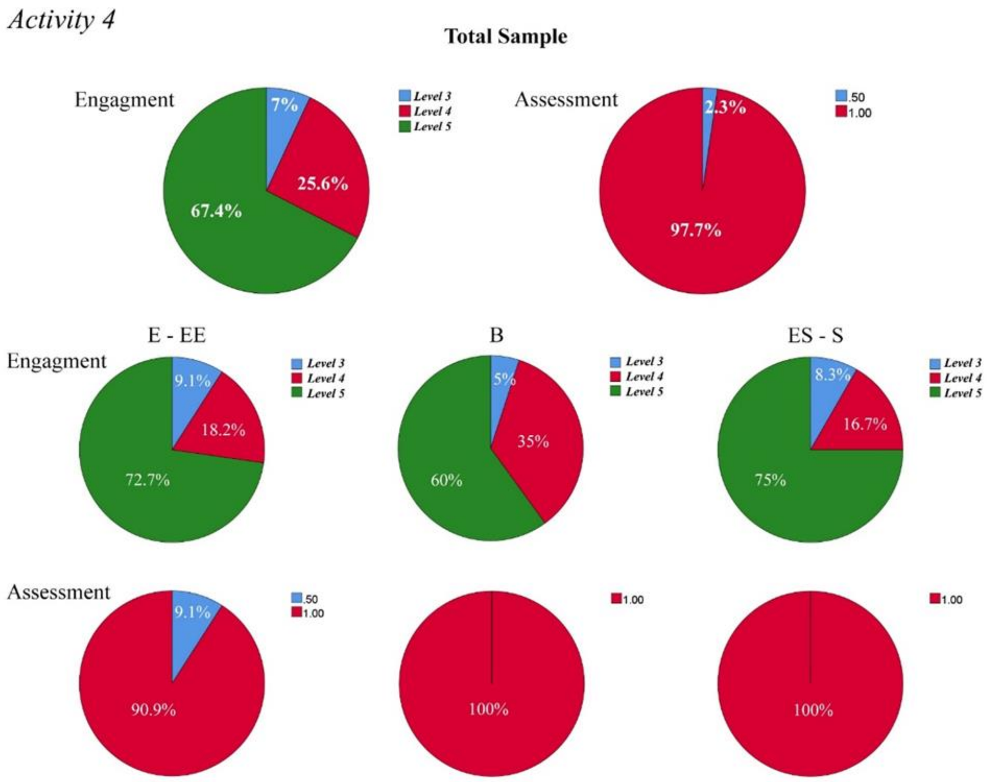

Figure 3. Results from the activity 'Conservation of mass'. Percentages for each level of engagement (values ranging from 1 to 5) and for learning outcomes (values ranging from 0 to 1) across the sample and per brain type.

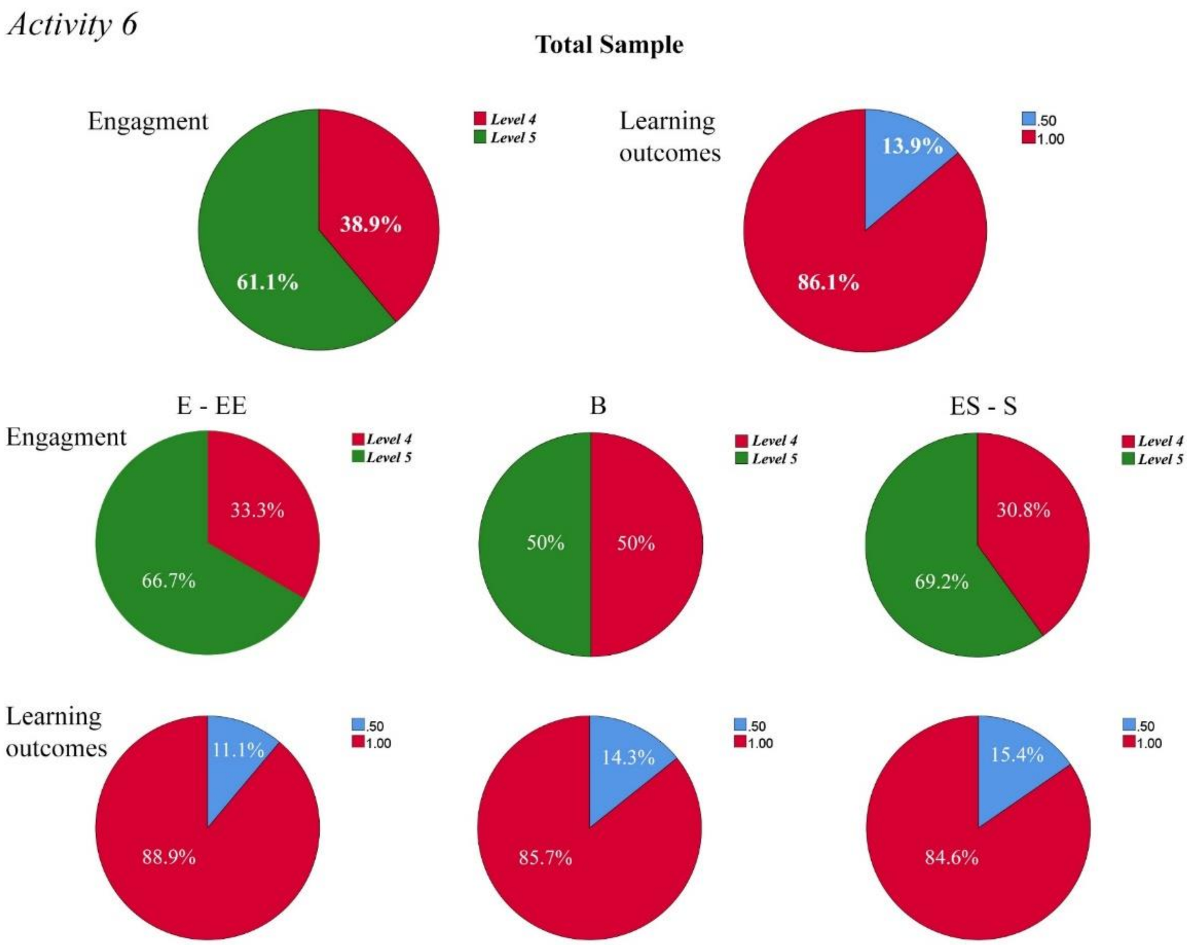

Figure 4. Results from the Activity 'Floating and Sinking' of solid bodies. Percentages for each level of engagement (values ranging from 1 to 5) and for learning outcomes (values ranging from 0 to 1) across the sample and per brain type.

Calculation of the Pearson rho coefficient to examine any association of the brain type with the level of engagement/involvement of children and with their learning outcomes showed no statistically significant correlation (indicative values of Pearson rho: 0.023 for learning, -0.092 for engagement).

CONCLUSIONS

The results of the descriptive statistics coupled with the fact that there is no correlation between the brain type and level of engagement/involvement and brain type and learning outcomes lead us to the conclusion that the inquiry activities of our study with the specific characteristics and approach can lead to high levels of engagement/involvement and similar learning outcomes for all types of pupils' cognitive style. These findings are inconsistent with the assumption that children with an empathizing cognitive style should have a lower degree of engagement in science than children with a systemizing cognitive style and create perspectives that such activities may be appropriate for triggering motivation and learning in science of young children with all types of brain.

YOUNG CHILDREN AND PERSONIFYING REASONING

Marida Ergazaki, Aggeliki Dimitrakopoulou,
Alexandra Spai and Dimitra Nousi
University of Patras, Patras, Greece

Personifying reasoning is reasoning about less familiar living things by applying knowledge about humans. This paper reports on a case study addressing the questions of (a) whether young children use personifying reasoning to predict the properties and behaviours or reactions of living things about which they don't know much, and (b) whether they actually use it in a controlled manner or not. Our informants were 360 conveniently selected preschoolers (age 4-6), attending public kindergartens in several areas of Patras-Greece. Children's reasoning was traced through individual, semi-structured 15-20-minute interviews performed with the protocol of Inagaki and Hatano (1991). All questions require predictions and justifications about a person and another living thing, which is a grasshopper or a tulip. Half children were asked about a person and a grasshopper, while the other half about a person and a tulip. The tape-recorded interviews were transcribed and coded with 'NVivo'. We coded children's responses as personifying or not, by taking into account children's predictions and justifications the way Inagaki and Hatano (1991) did. Children appeared to use personifying reasoning quite often. Our findings are thoroughly discussed in the paper.

Keywords: Early childhood education, Preschool Education, Reasoning

introduction

Young children are very interested in the biological world. By the time they become kindergarten pupils, they already have their own ideas about living organisms and the ways they function or interact with each other (Ergazaki, 2018). Research has shown that young children do hold ideas about growth and life cycles (Rosengren et al., 1991; Shepardson, 2002); habitat, food relationships, and decomposition (Ergazaki & Andriotou, 2010; Leach et al., 1996); internal body structure (Prokop et al., 2006; Reiss & Tunnicliffe, 2001); germs and illness (Ergazaki et al., 2010; Solomon & Cassimatis, 1999); reproduction and inheritance (Zogza & Christopoulou, 2005; Ergazaki et al., 2014; Solomon et al., 1996); evolution (Evans, 2001; Legare et al., 2013). These intuitive ideas may be considered as the body of children's 'naive biology'. The latter is also known as 'naive biological theory' since its core includes reasoning devices that allow children to predict or explain things within the biological world (Inagaki & Hatano, 2002).

One of these reasoning devices allows children to predict the properties and behaviours or reactions of living organisms about which they don't really know much, by applying knowledge they have about humans. This kind of reasoning is known as 'personifying reasoning', 'person analogy' or personification', and it has been suggested that the more the target organism resembles humans, the more children tend to mobilize it (Inagaki & Hatano, 2002). An example of predictive personification, which is cited in Inagaki and Hatano (2002) and provided by an almost 6-year-old boy, is the following: *'We cannot keep a rabbit forever* *small. Because like me, if I were a rabbit, I would be five years old and become bigger and bigger'*.

Most of the literature on personifying reasoning is concerned with young children's predictions about the properties and behaviours or reactions of the target organisms, to ascertain whether these are similar to the ones about humans (Inagaki & Sugiyama, 1988; Tarlowsky, 2006). However, what seems to be important in order to identify personifying reasoning in children's responses is to highlight how they justify their predictions. In fact, it seems that making similar predictions about the properties and behaviours or reactions of humans and other non-human organisms does not necessarily derive from projecting human-related knowledge to them. This was taken into account by Inagaki and Hatano in a study they performed in 1991. Exploring the use of personifying reasoning in a more meaningful way (i.e. focusing on children's predictions and justifications as well), they reached the conclusions that (a) young children use personifying reasoning when making justified predictions about the behaviours or reactions of less familiar living things, and (b) they use it in a rather controlled manner (namely, just when it makes sense).

So, according to Inagaki and Hatano (1991), personifying reasoning appears to be a well spread, useful tool for the early understanding of the biological world. However, their study was performed with 40 six-year-old children in a non-western cultural context almost three decades ago. And since its conclusions are potentially important for early biology education, it seemed interesting to us to explore whether they could be crosschecked in a western context nowadays. Thus, our study addresses the questions of whether (a) young children use personifying reasoning to predict the behaviours or reactions of living organisms that are less familiar to them than humans, and (b) they use it in a controlled manner or not.

METHODS

The overview of the study

This is a case study that has to do with tracing young children's reasoning about the behaviours or reactions of non-human living things like a grasshopper or a tulip, to different types of novel situations. Our data were gathered through individual, semi-structured interviews and analyzed qualitatively and quantitatively.

The participants

The participants of the case study were 360 preschoolers (age 4-6), attending several public kindergartens. These were situated in semi-urban areas of Patras-Greece with low, medium, or high socio-economic status, and were selected due to the teachers' wish to facilitate our study. All children were already familiar with educational interactions, since they were kindergarten pupils for quite some time. Tracing their reasoning was performed through individual, semi-structured 15-20 minute-interviews, conducted by the authors, who had already met the children and gained their own assent for participating. The parents were also informed at the beginning of the study and no objections were raised

The interview protocol

The interview protocol was the one used by Inagaki and Hatano (1991). It includes open-ended questions requiring *both* predictions and justifications about the reaction of a person and the reaction of another living thing to novel situations. Each question was formulated first for a person and then for a grasshopper or a tulip. Half children were asked about a person and a grasshopper and the other half were asked about a person and a tulip. Everyone was asked six questions of three different types: one question per type in the first half of the interview, and one question per type in the second. Here we are concerned only with two of the three types of questions (in short, *'Qs'*): those that had to do with situations in which the reaction of a grasshopper or a tulip would be dissimilar from the reaction of a human being. More specifically:

- '*Qs of dissimilar/incompatible reactions'* (in short, 'incompatible-Qs'): The questions of this type ('Left behind', 'Left unfed/unwatered') concerned situations in which a person would react in ways (e.g. speak) that being projected to a grasshopper or a tulip would lead to implausible conclusions (Table 1).
- '*Qs of dissimilar/compatible reactions'* (in short, 'compatible-Qs'): The questions of this type ('Loosing a care-giver', 'Deprived of comfort') concerned situations in which a person would show mental reactions (feelings or thoughts) whereas a grasshopper or a tulip would not. However, this time, projecting a person's reaction to a grasshopper or a tulip would lead to conclusions that might seem plausible to young children (Table1).

Table 1. An overview of the two types of Qs about a grasshopper or a tulip (G/T-*Qs*).

Q-type	Q-title	Q-content (*)
Dissimilar/ incompatible reactions	Left behind	A woman buys a G/T. On her way home, she stops at a store with G in a cage/T in a pot. After shopping, she is about to leave without G/T. What do you think G/T will do? How come?
	Left unfed/unwatered	Some people have a G/T in cage/pot at their home. It is Sunday morning and nobody has fed/watered G/T because they're all sleeping. What do you think G/T will do? How come?
Dissimilar/compatible reactions	Loosing caregiver	Everyday a man takes care of a G/T. One day the man dies. Do you think that G/T will feel something? How come?
	Deprived of comfort	Some people have a G/T in a small cage/pot at their home. One day someone puts a large cage/pot next to the small. Do you think that G/T will think something? How come?

(*) person-Qs were similar and preceded G/T-Qs

The data analysis

The tape-recorded interviews were transcribed and prepared for coding with 'NVivo'. We coded children's responses as personifying (P) or non-personifying (N) by taking into account children's predictions and justifications the way Inagaki and Hatano (1991) did.

More specifically, when children provided human-like responses about a grasshopper or a tulip and they justified them (a) by appealing to humans, or (b) by using human-related logic or terms, their responses were coded as personifying (P). For instance:

- '*The grasshopper will cry because they haven't fed it. Without food, babies cry and grasshoppers cry'* (a);
- *'The grasshopper will feel sad that the caregiver died, like the child before'* (a);
- *'The tulip will water itself. It will go out to the watering can and drink before people wake up'* (b);
- *'The grasshopper will think of calling someone to unlock its cage so that it can move to the bigger one, to be more comfortable.'* (b).

On the other hand, when children (a) drew upon knowledge about a grasshopper or a tulip, or (b) did not follow the logic they followed about humans, or (c) did not come up with any reasoning strand at all, their responses were coded as non-personifying (N). For instance:

- *'A tulip will do nothing when the woman leaves the store, because flowers do not understand. If she leaves, the tulip will not realize that she left'* (a);
- *'The grasshopper cannot think about the larger cage. The grasshopper does not have the same voice, the same stomach, the same brain'* (a);
- *'The child will cry if she leaves, because the child will be afraid'* whereas *'The grasshopper won't cry'*(b);
- '*The child will feel sad if the man dies'* whereas *'The tulip will not feel anything'* (b); *'I don't know'* (c).

The coding was simultaneously performed by three of the authors and all cases of disagreement were discussed until reaching consensus. Moreover, we counted (a) the personifying responses for a grasshopper, for a tulip and in total, (b) the children who came up with such for a grasshopper, for a tulip and for both, and (c) the frequency of the possible 'individual response patterns' for the 2 Q-types (PP, PN, NP, NN). Each pattern is named with two letters: the first refers to a child's responses to the 'incompatible' Qs, whereas the second refers to a child's responses to the 'compatible' ones. So, the response pattern of a child was coded, e.g., as PP if they had provided at least one personifying response to the 'incompatible'-Qs *and* at least one personifying response to the 'compatible'-Qs. Similarly, the response pattern of a child was coded, e.g., as PN if the child had provided at least one personifying response to the 'incompatible'-Qs *and* none to the 'compatible'-Qs. The results of our analysis are presented below.

RESULTS

Children appeared to use personifying reasoning quite often. As shown in Table 2, the total number of personifying responses to both the 'incompatible' and 'compatible'-Qs was 795/1440; so, the total proportion of personifying responses to both Q-types was 0.55. Children gave personifying responses more often for a grasshopper and less often for a tulip. The total proportion of personifying responses for a grasshopper was 0.82 (594/724 responses), whereas the total proportion of personifying responses for a tulip was just 0.28 (201/716 responses). Moreover, children gave personifying responses more often to the 'compatible'-Qs and less often to the 'incompatible'-Qs (Table 2). The total proportion of personifying responses to the 'compatible'-Qs was 0.65 (466/720 responses), whereas the total proportion of personifying responses to the 'incompatible'-Qs was 0.46 (329/720 responses). Of course, the latter proportion, although lower than the former, is still rather high, which indicates that personifying reasoning seemed appealing to children regardless the type of the situation they are asked to reason about.

Table 2. Numbers and proportions of personifying responses.

	'Dissimilar/Incompatible Reactions'- Qs		'Dissimilar/Compatible Reactions'- Qs		Both Q-types	
	P-responses		P-responses		P-responses	
	Number	Proportion	Number	Proportion	Number	Proportion
Grasshopper*	284/362	0.78	310/362	0.86	594/724	0.82
Tulip*	45/358	0.10	156/358	0.40	201/716	0.28
Total*	329/720	0.46	466/720	0.65	795 /1440	0.55

(*) G: 181 children x2Qs per type; Tulip: 179 children x2Qs per type; Total: 360 children x2Qs per type

As shown in Table 3, there were more children with personifying responses to the 'compatible'-Qs (268/360) than to the 'incompatible' ones (194/360). In fact, 74.4% of the children gave at least one personifying response to the 'compatible'-Qs, whereas 53.9% of the children did so to the 'incompatible' ones (Table 3). Of course, the latter percentage, although lower than the former, is still rather high, which indicates once more that personifying reasoning seems appealing to children regardless the type of the situation they are asked to reason about. Finally, there were more children with personifying responses for a grasshopper than for a tulip. In the case of the 'compatible'-Qs, the difference (92.8% *vs.* 55.9%) was remarkable. However, in the case of the 'incompatible' ones (87.8% *vs.*19.5%) the difference was even bigger (Table 3).

Table 3. Numbers and percentages of children with personifying responses.

	'Dissimilar/Incompatible Reactions'- Qs		'Dissimilar/Compatible Reactions'- Qs	
	Children with P-responses		Children with P-responses	
	Number	Percentage	Number	Percentage
Grasshopper*	159/181 34 once / 125 twice	87.8%	168/181 26 once / 142 twice	92.8%
Tulip*	35/179 25 once / 10 twice	19.5%	100/179 44 once / 56 twice	55.9%
Total*	194/360 59 once / 135 twice	53.9%	268/360 70 once / 198 twice	74.4%

(*) G: 181 children x2Qs per type; Tulip: 179 children x2Qs per type; Total: 360 children x2Qs per type

As shown in Table 4 that concerns the individual response patterns, children gave personifying responses to both Q-types at the same time (PP), much more often than they did to the 'compatible'-Qs only (NP). More specifically, the percentage of children with the PP response pattern was 50.8%, whereas the percentage of those with the NP response pattern was less than half (23.6%). However, if we focus on the tulip, things seem quite different (Table 4). The percentage of children with the PP response pattern for the tulip in particular, was just 16.7%, whereas the percentage of those with the NP response pattern for the tulip was more than double (39.1%). Finally, the PN pattern, which indicates use of personifying reasoning to the 'incompatible'-Qs only, was rather rare since it was given by just 3% of the children in total. On the other hand, the NN pattern, which indicates the absence of personifying reasoning to both Q-types, was not very frequent either, since it was given by less than one forth of the children (22.5%) (Table 4).

Table 4. Children's individual response patterns.

	PP		PN		NP		NN	
Grasshopper	153/181	84.5%	6/181	3.3%	15/181	8.3%	28/181	15.5%
Tulip	30/179	16.7%	5/179	2.8%	70/179	39.1%	53/179	29.6%
Total	183/360	50.8%	11/360	3%	85/360	23.6%	81/360	22.5%

DISCUSSION

As already shown, the participants of this study used personifying reasoning quite a lot. In fact, it seems that they used it even more than the participants of Inagaki and Hatano (1991): the total proportions of personifying responses in the two studies were 0.55 and 0.36, respectively. Our participants used personifying reasoning more for a grasshopper (0.82) than for a tulip (0.28), just like those of Inagaki and Hatano (grasshopper: 0.44; tulip: 0.29). The lower frequency of personifying responses for a tulip in both studies might be attributed either to what Inagaki and Hatano call ‘similarity constraint’, or to children’s knowledge about plants. In other words, children may not be very keen on using personifying reasoning for a tulip, because it is not similar enough with humans or because they do hold plant knowledge that allows them to articulate non-personifying responses about it. Moreover, our participants used personifying reasoning more to the ‘compatible’-Qs (0.65) than to the ‘incompatible’ ones (0.46), similarly to the participants of Inagaki and Hatano (1991) (‘compatible’-Qs: 0.62; ‘incompatible’-Qs: 0,1). However, in our study personifying reasoning was quite popular to the ‘incompatible’-Qs as well: our total proportion of personifying responses to the ‘incompatible’-Qs was 0.46 whereas Inagaki’s and Hatano’s proportion was just 0.1.

Our participants’ tendency to use personifying reasoning to both Q-types was also indicated by the individual response patterns they gave. More specifically, they mainly gave the PP pattern unlike the participants of Inagaki and Hatano (1991) who mainly gave the NP pattern. In other words, the latter participants tended to use personifying reasoning just to the ‘compatible’-Qs, whereas ours tended to use it to both Q-types. In fact, 50.8% of our participants gave the PP pattern for both a grasshopper and a tulip, whereas less than half (23.6%) gave the PN pattern in total. So, the use of personifying reasoning in our study was not as selective as expected considering the findings of Inagaki and Hatano (1991). Of course, this is not true if we focus just on the tulip. Now the NP response pattern is given by 39.1% of the participants and gets dominant, whereas the PP response is given by less than half (16.7%). A possible account for this finding that indicates selective use of personifying reasoning *particularly* in the case of tulip has already been suggested above.

It should be noticed that quite often our participants avoided blind projections of human behaviours or reactions to a grasshopper or a tulip. What they did was trying to adjust the human reactions to the profile of the target entities in order to come up with more plausible predictions about them. For instance, according to their views, a child might cry to catch the attention of the adults and get fed, while a grasshopper might make noise by falling on the cage-rails or by flying near their ears; similarly, a child might call the police if their mother had left them accidentally in a store, whereas a grasshopper cannot make such a call so it might just try to leave the store and find the woman on its own.

Children’s attempts to adjust human reactions in ways that would lead them to more plausible predictions about other, non-human living things are actually remarkable, especially if one takes into account that children are exposed to an entertainment culture that is actually dominated by anthropomorphism. Most of the storybooks or the series that are addressed to young children are full of animals or even plants that look, feel, think, communicate and generally behave like human beings (Ganea et al., 2008; Ganea et al., 2014). Anthropomorphism may be considered as a major type of personification (Gallant, 1981), which does not seem to be quite useful to young children. In fact, it often manifests itself through teleological explanations (Tamir & Zohar, 1991) that biology education needs to challenge.

In sum, even if our results are not completely in line with those of Inagaki and Hatano (1991) since the use of personifying reasoning in our study does not seem to be as selective as expected, this reasoning device that lies at the core of children's 'naïve biology' still seems to be a flexible and thus potentially useful tool in children's attempt to reason about less familiar living things. Finally, we should not forget that it has been suggested (Hadjigeorgiou, 2016; Lindholm, 2018) that thinking about non-human living things by drawing on humans, may develop a lifelong friendship between children and the biological world and also nourish children's curiosity and joy of learning about it.

CHARACTERISTICS OF SCIENCE TEACHING IN PRESCHOOL

Jesper Sjöström[1] *and Ann-Christine Vallberg Roth*[2]
[1]Department of Natural Science, Mathematics and Society, Malmö University, Sweden
[2]Department of Childhood, Education and Society, Malmö University, Sweden

This paper focuses on characteristics of science teaching in preschool. Science in general is in focus, but a special interest is put on what may characterize chemistry teaching in preschool. The study is part of a much broader R&D programme where in total almost three hundred preschool teachers/managers collaborate with a researcher group to which we belong. The participants (N=177) were in the autumn 2018 asked to answer a question in an e-mail-questionnaire about their views on science/chemistry teaching in preschool. On average a participant answered with 30 words, but obviously there was a big span, from 1 to 444 words in a single answer. In the word material (consisting of about 5400 words in total) we looked for common and prominent words, words used only low-frequently or not at all, and other patterns. We identified eighteen words that were used about 30 times or more. Among these words are: experiment, water, animal, plant, nature, forest, explore, examine, phenomenon, and baking. Low frequently used words were categorized in seven categories, among them chemistry. The words atom, molecule and particle could not at all be found in the word material. More qualitatively we also looked for patterns/traces based on the three main Didaktik questions: Why? What? and How?. Statements from the preschool teachers/managers were categorized in seven categories. In the discussion and forthcoming studies we will relate science/chemistry teaching in preschool both to the recently revised curriculum for the Swedish preschool and to other content areas and more general theories and ideas on what may characterize teaching in preschool.

Keywords: Pre-school Education; Continuing Professional Development; Didaktik

A R&D PROGRAMME ABOUT TEACHING IN PRESCHOOL

During the last years there has, at least in Sweden, been a growing interest in exploring what characterizes teaching in preschool (e.g. Hedefalk, Almqvist & Lundqvist, 2015; Melker, Mellgren & Pramling Samuelsson, 2018; Pramling et al., 2019, Thulin & Jonsson, 2018; Vallberg Roth, 2018) and not at least science teaching (e.g. Broström, 2015; Andersson & Gullberg, 2014; Fridberg, Jonsson, Redfors & Thulin, 2019; Gomes & Fleer, 2018; Sjöström, 2018; Sundberg, Areljung & Ottander, 2019). In the latest version of the Swedish curriculum for preschool (SKOLFS 2018:50), the mission of teaching was enhanced. The curriculum also includes science as a content area and the present study focuses on what may characterize teaching in and about the natural sciences, including chemistry. One of the goals in the curriculum for preschool is to provide each child with the conditions to develop “an understanding of natural sciences, knowledge of plants and animals, and simple chemical processes and physical phenomena”.

The study described here is part of a much broader R&D programme, which is a collaborative initiative involving eight Swedish municipalities and the independent Institute for Innovation, Research and Development in School and Preschool (Ifous), as well as Malmö University. In total almost three hundred (300) preschool teachers/managers collaborate with a researcher group of six, to which we belong and one of us (Prof. Vallberg Roth) is leading. The programme started in the summer 2018 and will contiue for three years in total. The aim of the present study is to get a better understanding of what may characterise science teaching, including chemistry, in preschool.

RESEARCH METHOD AND DESIGN

In the beginning of the R&D programme, the participants were asked to answer an e-mail-questionnaire about their views mainly on teaching in preschool, generally and in some specific content areas, among them natural science. Here we report results from the question (in the e-mail-questionnaire) about what may characterize teaching in and about the natural sciences, including chemistry. The specific question was (our translation): "What may characterize teaching in natural sciences, including chemistry, in preschool?". The collected and analysed empirical material consists of about 5400 words from in total 177 respondents, of which 131 were preschool teachers and 46 preschool managers. Of the words about 4400 words were from the preschool teachers and about 1000 from the preschool managers. The number of words per participant were as follows: On average a participant answered with 30 words, but obviously there was a big span, from 1 to 444 words in a single answer. For more details, see: Sjöström, 2019a.

Below, the results will be presented, analysed and discussed in a similar way as presented in some recent articles on teaching in Swedish preschools (e.g. Vallberg Roth, 2018; Vallberg Roth, Holmberg, Löf & Stensson, 2019). The analysis of the material can methodologically be described in terms of abductive analysis (Peirce, 1903/1990; Tavory & Timmermans, 2014), alternating between theory-loaded empiricism and empirically loaded theory. The purpose of the analysis is to identify traces and patterns in the "word data" (see further: Silverman, 2011), relating to the aim of and questions posed by the research. In the word data for the question about science/chemistry (i.e., about 5400 words from in total 177 respondents), we looked for common (and prominent) words, words used only low-frequently or not at all. The frequency of prominent words was counted using the "Find"-function in Word.

We also looked for qualitative patterns. How words interact with and reinforce each other in their contexts was analysed. The analysis was built on both high- and low-frequency traces in a second and qualitatively oriented interpretive path. The word-frequency analysis can be viewed as offering stabilising support in the analysis of the distinctive traces. Quotations were selected for their clear exemplification of the traces in the material. More concretely, the analysis involves identifying traces in the material in relation to the research aim. The analysis can be described in terms of the following interpretive paths (see e.g. Rapley, 2011; Tavory & Timmermans, 2014): close reading; distinctive traces were identified; and distinctive traces in the third interpretive path were problematized in relation to earlier research and concepts.

The so called *Didaktik* questions serve as both a practical tool and as a basis for analytical questions. In the context of research, such questions focus on what (content), how (teaching actions), who/whom (actor/actors), where (space/place), when (time) and why (goal and motivation). The three main *Didaktik* questions, What?, How?, and Why? are in focus in this paper.

Abductive moments in the analysis can involve suddenly seeing an alternative, discovering a previously undiscovered possibility: "Reality is not simply 'what is here-and-now' […] but also includes what potentially can be achieved – and which in the moment merely reflects a vague possibility" (Peirce, 1903/1990, p. 31). In this study, concepts were tested in relation to traces in the material that were revealed as possibilities by the analysis. Furthermore, cohesive analysis was performed in light of *Didaktik* models, resulting in a conceptualising focus. In practice, empirically based and theory-based interpretive paths are typically intertwined.

RESULTS AND DISCUSSION

We identified eighteen words that were used about 30 times or more. These high-frequently words (translated from Swedish) are below presented in a "word cloud" (Figure 1). Together these words give us an idea of the most common understanding and views on what may characterize science teaching in preschool in Sweden in 2018. The most common and prominent word was "child". It was used about 140 times, meaning about 2,5% of the total amount of words. On second place was "experiment", which was used about 100 times. This word was the typical answer for what may characterize science/chemistry teaching in preschool. More than half of the respondents used that word explicitly. Actually it was also the only single word used in an answer by one preschool teacher and in some other cases it was the only content: "We have experiments" and "experiments, for example".

Figure 1. High-frequency words (translated from Swedish) in the answers on the question of what may characterize teaching of science, including chemistry, in preschool year 2018. The word cloud was made in Wordle.

As seen in the word cloud, other common words were for example: water, animal, plant, nature, forest, explore, examine, phenomenon, and baking. Another word was "happens", which is about that something is happening during for example an experiment. Except experiment and water, it is mainly "baking" that can easily be related to chemistry. One preschool teacher answered: "In chemistry it is usually experiments and baking that are included."

Ever since the start of the Swedish preschool at the end of the 19th century, "nature meetings" have been central (Ärlemalm-Hagsér & Sundberg, 2016). Since the national curriculum for the preschool was introduced in 1998, the focus has also been on environmental work. Chemical processes and physical phenomena were introduced in 2010, when revising the curriculum (Thulin & Gustavsson, 2017). Sundberg, Areljung, Due, Ottander and Tellgren (2016) have claimed that science in preschool is dominated by the following content: water, human body, compost, nature and forest. These words, except for human body and compost, were – as seen in Figure 1 – common in the answer on what may characterize science/chemistry in preschool. On the other hand human body was a common word in the answers on what may characterize health teaching in preschool (another question in the questionnaire) and compost on what may characterize teaching about sustainable development in preschool (also another question). Except on the question on what may characterize science in preschool, nature, water and material were also high-frequent in the answers on what may characterize teaching about sustainable development in preschool (Sjöström, 2019b).

Except the high-frequently used words, we also identified many words used with lower or low frequency or not at all. For example the words atom, molecule and particle could not be found in the word material. The low frequently used words were categorized in the following seven categories: scientific work; physics (with or without connections to mathematics, technology, metrology and/or astronomy); chemistry; biology (including both green biology and human biology); general science linked to everyday-life; environmental science (including sustainability issues); and science pedagogy/teaching methods in preschool.

More qualitatively, we also looked for patterns/traces based on the three main *Didaktik* questions: Why? What? and How?. Statements from the preschool teachers/managers were categorized in the following seven groups: Why science in preschool?; What characterizes science in preschool?; Prerequisites: subject knowledge of the preschool teachers and educational teaching material; What content?; What activities and how?; Other pedagogical ideas; and, finally: The nature of chemistry teaching in preschool. We have a lot of quotations connected to the seven groups (Sjöström, 2019a), but here we focus on chemistry in preschool. Previous research on chemistry in preschool is very limited (e.g. Adbo & Vidal Carulla, 2019; Fridberg, Jonsson, Redfors & Thulin, 2019; Hansson, Löfgren & Pendrill, 2014; Åkerblom, Součková & Pramling, 2019).

Chemistry in preschool

One interesting quotation about what may characterize chemistry in preschool is (our translation): "Chemistry is more difficult, usually it becomes experiments that becomes ‘happenings’ without any follow-up or anchoring”. One example of a “happening experiment” is the “how to make a volcano”-experiment, which is common on the Internet and also – at least previously – in Swedish methods books about experiments to be done in preschool and primary school. “Volcano” is mentioned six times in the word material. However, the purpose of that experiment is unclear and its value can be questioned (see further discussion in: Sjöström, 2019a).

The empirical material (the word material) can also be discussed and problematized in relation to the chemistry triplet (macro; submicro; symbolic/representations) (see e.g. Johnstone, 1993; Talanquer, 2011). Furthermore, the statements by the preschool teachers/managers can be compared to the ongoing international discussion on when (what age) and how to introduce the concepts of particles and molecules to children (e.g. Sjöström, 2012; Åkerblom, Součková & Pramling, 2019). In forthcoming analysis and studies we will also relate our results to previous studies on science teaching in preschool and to more general theories and discussion on teaching/*Didaktik* in preschool.

Science content in preschool

According to Klaar (2016; see also: Klaar & Öhman, 2014), there are the following three main content areas related to nature/science, in the Swedish preschool:

1. to promote children’s personal development and health by being outdoors,

2. to care for the natural environment, and

3. to learn about nature, both in terms of scientific phenomena and processes and through inquiry.

The first content area links to a healthy lifestyle and the second to sustainable development. Scientific phenomena, products and processes are mainly to be found in the third content area. At the same time, ”nature teaching” in preschool can also be about nature experiences and wonder in a broad sense (Hadzigeorgiou, 2001; Hadzigeorgiou & Schulz, 2014), as well as about how scientific knowledge relates to technology, health and environmental work.

“Nature” is mentioned five times in the revised curriculum for preschool in Sweden. It is about stimulating the children’s “interest in and knowledge of nature, society and technology”. Furthermore, the preschool shall provide each child with the conditions to develop “an understanding of relationships in nature and different cycles in nature, and how people, nature and society affect each other”. Except in the curriculum goal about “natural sciences”, which was quoted above, “science” is mentioned three more times in the curriculum. It is about providing each child with the conditions to develop an ability to explore and discuss science and technology, and about language and communication in relationship to mathematics, science and technology (SKOLFS 2018:50).

In Figure 2, we suggest a *Didaktik* model on “nature / science content” in preschool. The corner “Experience of nature in a broad sense” includes for instance the human body and natural phenomena. Read more about different types of *Didaktik* models in e.g.: Sjöström 2019c; Sjöström, 2019d; and Vallberg Roth, Holmberg, Löf & Stensson, 2019.

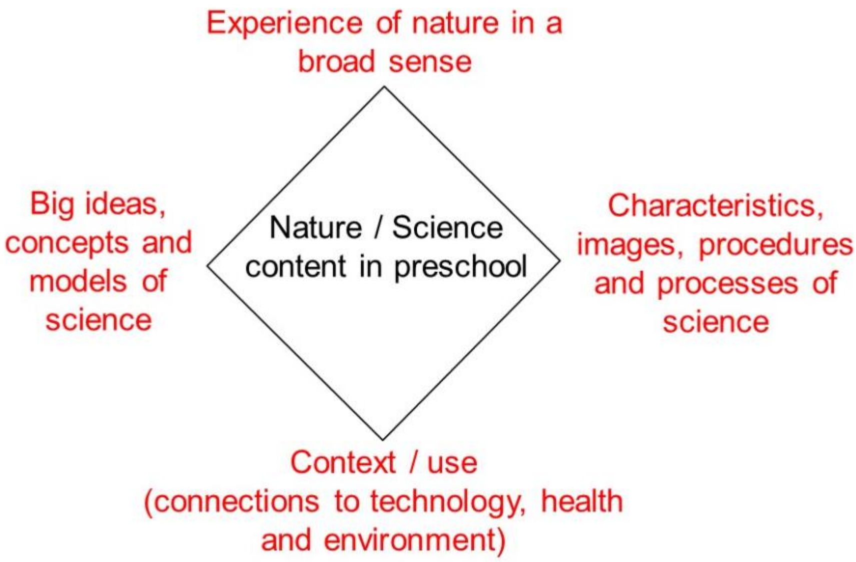

Figure 2. Didaktik model on nature / science content in preschool. The model is an English translation of a model in: Sjöström, 2019a.

In forthcoming scholarly work, based on the work presented here and related work, we will more in general discuss the concepts of *Didaktik* models and modelling in relation to preschool teaching praxis. Furthermore, we are interested in what happens when more general ideas about science teaching and *Bildung* (Sjöström, Frerichs, Zuin, & Eilks, 2017) are applied to a preschool context.

ACKNOWLEDGEMENT

We would like to thank eight Swedish municipalities (Eslöv, Enskede/Årsta/Vantörs SDF, Jönköping, Katrineholm, Skurup, Staffanstorp, Vallentuna, and Örebro) and Malmö University for financial support, and Ifous (the independent Institute for Innovation, Research and Development in School and Preschool) for coordinating the R&D programme, in which this research study is a part. We also would like to thank the other four authors of the research report *Vad kan känneteckna undervisning och sambedömning i förskola? Förskollärares och chefers/rektorers skriftliga beskrivningar år 2018* (Vallberg Roth et al., 2019) for their contributions in discussions about the results: Lecturer Sverker Aasa, Dr. Jan-Eric Ekberg, Dr. Ylva Holmberg, and PhD-student Catrin Stensson.

PART 16: STRAND 16

Science in the Primary School

Co-editors: *Federico Corni & Anna Spyrtou*

STRAND 16: INTRODUCTION

SCIENCE IN THE PRIMARY SCHOOL

In Strand 16, Science in the Primary School, 8 papers were included. Most of the studies come from the European Union (two from Greece, two from Ireland, two from Spain), while two papers are from Japan and Libanon groups. The theme common to all contributions is how specific teaching approaches can contribute to the acquisition of knowledge of modern (e.g., Nanoscale Science and Technology) and traditional scientific content (e.g., geology) by primary students and/or teachers.

Sarah Carroll, Veronica McCauley and Muriel Grenon (Ireland) investigated the effect of scientists on children's self-efficacy beliefs after participating in a hands-on informal science activity related to molecular biology. The intervention lasted for one hour, during which four pupils 11-12 years old got involved in the "Fantastic DNA" session. Changes to participants' self-efficacy beliefs were estimated via interviews, video observations and responses to a pre-post written questionnaire. All participants reported to feeling more confident on science after the intervention.

María-Antonia Manassero-Mas, Antoni J. Bennàssar Roig and Ángel Vázquez-Alonso (Spain) study deals with improving teacher training on epistemic aspects through games. To this aim, as the authors argue, games, such as with cubes and dices, offer an authentic analogy of scientific practices. The participants of the research were six Spanish teachers who prepared and implemented the cube game to their sixth-grade students, which involved about one hundred students. Taking into consideration the lack of resources and teachers' inadequate training concerning epistemic teaching and learning, the results seemed promising.

Eftychia Valanidou, Marida Ergazaki and Renia Gasparatou (Greece) examined whether having students practice in philosophy-inspired reasoning strategies may facilitate them in constructing the biological concepts of fish, amphibian, reptile, bird, and mammal. The learning environment that was designed consisted of seven teaching-learning activities with the aim 4th graders to engage in class-based groupings of vertebrates. Although, as the authors argue, the learning environment needs improvements, findings indicate that students made progress in grouping vertebrate animals in class-groups.

Naoki Komiya, Minami Yano, Kazuki Yamamoto, Ryohei Egusa, Shigenori Inagaki, Hiroshi Mizoguchi, Miki Namatame and Fusako Kusunoki (Japan) examined the reinforcement of knowledge about germination and plant growth. The writers developed a prototype system that supports learning using collaboration and full-body interaction. They applied it to a lesson at a primary school in Chiba, Japan, where multiple students learned about plant germination and growth conditions through quizzes and evaluated its effect. The results suggest that this system reinforces learners' knowledge of germination and plant growth conditions and that it is an effective tool for furthering students' learning.

Juan-Carlos Rivadulla-López, Susana García-Barros, María-Jesús Fuentes-Silveira and Cristina Martínez-Losada (Spain) put under inspection 671 activities on human nutrition included in year 6 primary education school texts in Spain and Portugal with the aim of examining the extent to which these activities promote scientific competency. According to the findings, both similarities and differences among the Spanish and Portuguese publishers were detected. For example, the Portuguese textbooks include more the abilities of describing explaining and justifying than their Spanish counterparts. The findings of the study could be exploited by schoolbook text writers and by teachers' trainers as well.

Pauline Abdouche[1], Assaad Yammine (Libanon) implemented project-based learning into teaching in order to introduce salient geology topics to 10 refugee grade 6 students and to study whether the project-based learning approach had an impact on the autonomy and motivation of the participants as well. The researchers acknowledge the challenge of the endeavor, given the special characteristics of the population on the one hand (the war situation in Syria) and the complexity of science topic on the other. However, findings were promising. The results showed that students motivation increased after the project was completed, though with fluctuations. Moreover, improvement in the acquisition of knowledge was evident.

George Peikos, Anna Spyrtou, Dimitris Pnevmatikos and Penelope Papadopoulou (Greece) deal with the inclusion of a modern topic such as Nanoscale Science and Technology (NST) to primary education. In particular, they study whether a six-unit pilot teaching approach about NST concepts (e.g. size), phenomena (e.g. superhydrophobicity) and applications (e.g. nanofiltration systems) addressed to 22 primary school students had an impact on students nano-related knowledge. Findings from the analysis of the pre-post questionnaire indicate the improvement of students' nanoliteracy.

Diana Bogusevschi, Odilla Finlayson and Gabriel-Miro Muntean (Ireland) analyze a Technology Enhanced Learning science, technology, engineering and maths (STEM) education case study, Earth Course, carried out in two primary schools in Dublin, Ireland. The authors focused on the assessment of learner motivation and affective state following the Earth Course case study. Most students found the Earth Course interesting and they would like to use similar lessons in other science classes. Students were extremely positive about the use of technology in the classroom, seeing it as a supporting tool for their teacher.

Federico Corni & Anna Spyrtou

'A SCIENTIST KNOWS WHAT S/HE'S DOING': EXPLORING THE EFFECT OF SCIENTIST-LED OUTREACH ON PRIMARY CHILDREN'S SCIENCE SELF-EFFICACY BELIEFS

Sarah Carroll[1], Veronica McCauley[2] and Muriel Grenon[1]
[1]Biochemistry, School of Natural Sciences, National University of Ireland Galway, Galway, Ireland.
[2]School of Education, College of Arts, Social Sciences and Celtic Studies, National University of Ireland Galway, Galway, Ireland.

Recent years have seen an increase in scientist-led hands-on science outreach events aiming to improve children's performance and engagement with science. Despite positive links with performance and motivation, the effect of scientists on children's science self-efficacy beliefs is currently unknown. Science self-efficacy can be influenced through four sources: mastery experience, vicarious experience, verbal persuasion and emotional state. Scientists may provide verbal persuasion to children participating in hands-on science events. This proceedings paper describes a case study embedded in a larger mixed-methods quasi-experimental study investigating the effect of scientists on children's science self-efficacy beliefs after participating in a hands-on science event on molecular biology. This case study analysis explored four children's experiences of the scientist-led event and how it affected their science self-efficacy. Several sources of data were collected, including pre- and post-intervention questionnaire results, post-intervention interviews and recorded observations of the hands-on session. Findings indicated that children perceived the scientist facilitators to be credibly competent in science. However, the true potential effects of verbal persuasion from scientists remains unclear. Scientist facilitators may increase children's science self-efficacy in skills related to the session through the provision of a helpful and supportive environment. These findings will be further investigated through the analysis of the larger quasi-experimental study.

Keywords: Self-efficacy, Informal Learning, Primary School

SCIENCE SELF-EFFICACY AND SCIENTISTS IN OUTREACH

Science self-efficacy (SSE) can be described as the confidence an individual has in completing science-related tasks. SSE is positively linked to academic performance, motivation and engagement with science (Pajares, 2015). Self-efficacy in general can be influenced by four determinants, often referred to as 'sources': mastery experience, vicarious experience, verbal persuasion and emotional state. These four sources have been empirically shown to be associated with self-efficacy beliefs for several different school subjects, including mathematics and science (Britner & Pajares, 2006; Joët, Usher, & Bressoux, 2011; Usher & Pajares, 2008; Webb-Williams, 2017). Whilst mastery experience and emotion state stem from oneself, vicarious experience and verbal persuasion are provided by others. Vicarious experience originates from observing others successfully completing specific tasks and verbal persuasion is the influence of others expressing belief in an individual's abilities in certain tasks (Bandura, 1997). The provision of these sources by teachers, peers and family members is positively correlated with student's SSE beliefs (Stake, 2006). Scientists may be ideal candidates for the provision of verbal persuasion in SSE, as verbal persuasion is most effective when the performer perceives the encourager as credibly competent in the task at hand (Bandura, 1997). Yet, there has not been any published studies investigating the effect of scientists in hands-on informal science activities on student's SSE beliefs. Consequently, despite the increasing prevalence of scientists in informal science activities (Jeffers, Safferman, & Safferman, 2004; The Stem Education Review Group, 2016), there is currently no best practice specifically for scientist facilitators on increasing children's SSE beliefs. To explore the effect of scientist facilitators on children's SSE beliefs, this study was underpinned by the following research questions (RQs) and hypotheses (H_n).

RQ1: Do children perceive the scientist facilitators to be credibly competent in science? *H_1: Children perceive the scientist facilitators from this intervention to be competent scientists.*

RQ2: How are children's SSE beliefs affected after participation in one scientist-led hands-on outreach session? *H_2: Children's SSE beliefs are increased after participation in this hands-on science session.*

RQ3: How do scientists facilitators delivering hands-on outreach affect children's SSE beliefs? *H_3: Scientists increase children's SSE beliefs through the provision of verbal persuasion.*

METHODS

Study Design - a case study embedded in a quasi-experimental study

To answer these research questions, a quasi-experimental study was conducted (Figure 1). Participants in the treatment group (N=106) had their SSE beliefs assessed before and after participation in a scientist-led hands-on science session. Pre-/post-test changes in questionnaire responses were compared to participants from the control group (N=50), who did not participate in the intervention (Figure 1). This proceedings paper will describe a case study from the treatment group that was carried out as a first step towards answering the questions from the larger study as case studies can serve well as a complementary method to experimental studies (Yin, 2009).

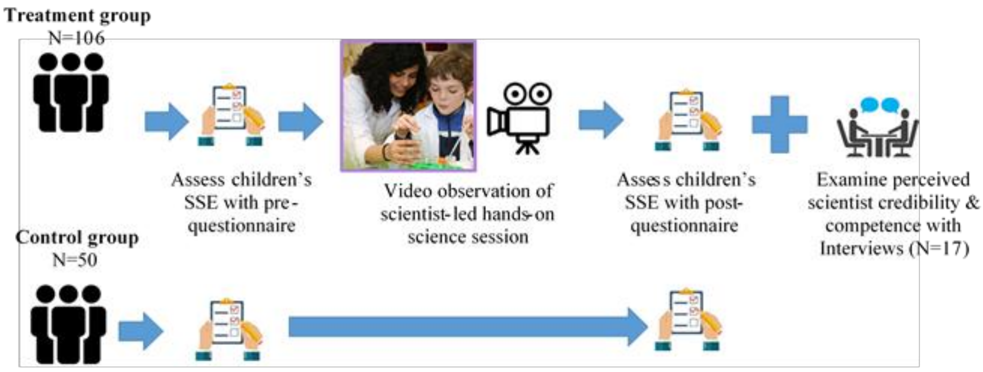

Figure 1. Pre-/post- quasi-experimental study design.

Data collection

A mixed methods approach to data collection was used to allow for the collection of a "…richer and stronger array of evidence than can be accomplished by any single method alone" (Yin, 2009). Six sources of data were collected: documentation, archival records, interviews, survey instruments, direct observations and participant-observation (Table 1). The interview schedule asked participants what happened during the session, whether participation in the session affected different aspects of their science confidence, and their perception of the scientist facilitator at their group.

Table 1. Sources of data collection in the case study.

Type of evidence	Data collected
Documentation	Description of the intervention
Archival records	Demographic data about the participant's school (the setting)
Interviews	Semi-structured interviews with participants after intervention
Survey instrument	Pre-intervention and post-intervention surveys completed by the participants
Participant-observation	Post-intervention survey completed by scientist facilitators
Direct observations	Recorded observations of the children's behaviours and interaction with others

The survey instrument used was the Irish Science Self-Efficacy Children's Questionnaire (IS-SEC-Q (Carroll et al., 2020). It comprises 5 scales (66 items): (i) General Academic Self-Efficacy, (ii) Performance-Related SSE, (iii) Knowledge-Specific SSE, (iv) Sources of SSE and (v) Task-Specific SSE. The Sources of SSE scale has four subscales, each approximating participant's exposure to the four sources of SSE and includes scientists as providers of vicarious experience and verbal persuasion (Carroll et al 2020). The post-test version has an additional 6th scale with items assessing participant's perception of their scientist facilitators. All items are answered using a 7-point Likert-like scale.

Immediately after the intervention, the scientist facilitators completed a short survey asking them to note any interesting interactions between themselves and the children and to note any child that was either particularly confident or withdrew from the session. For the video observations one video camera recorded a wide-angle shot of the classroom. Each group also had a small dictaphone to record the dialogue at the table.

The intervention

The intervention in this case study is a one-hour session on molecular biology called 'Fantastic DNA' and is delivered by the Irish science outreach and education programme Cell EXPLORERS (www.cellexplorers.com) to primary classrooms. After an introductory presentation on cells and DNA, pupils (8-12 years old) extract DNA from a banana in small groups of six. Each group is led by a scientist facilitator who demonstrates each step to the children, who then repeat it individually themselves. Two key steps in the experimental protocol will be discussed in this paper: 1) when pupils create a funnel from filter paper and filtrate a mixture of banana and saline and 2) when they use a pipette to add 1 ml of liquid soap to the resulting filtrate.

The participating school

The participating school was a primary school, with mixed-sex pupils (i.e. boys and girls). It was also a Gaelscoil, which means that all areas of the curriculum (including science) are taught through Irish. There are 8 classes (i.e. grades) in Irish primary schools. Sixth class is the final year and pupils are typically between 11-12 years old. The participating school had two sixth classes, each taught by a different teacher (one male and one female teacher). Each class had approximately 25 pupils, which is within the average range for primary classes in Ireland.

Participant details

Four participants were selected for the case study analysis: Oliver, Sarah, Owen and Lily (Table 2). They were selected based on their response variation in their post-test questionnaire to the pre-test questionnaire for the item ‘How confident are you that you could Learn Science?’. At least one participant was selected for each of these possibilities: increase, decrease or no change in their response score for the ‘learn science’ item. Participants were selected to come from the same school, received the intervention on the same day and to have an even number of boys and girls.

Table 2. Participant details in the case study. Learn science score variation refers to the changes in participant’s responses to the item ‘how confident are you that you could learn science’ between their pre-test questionnaire and post-test questionnaire.

Pseudonym	Variation in ‘Learn Science’	Gender	Age	Class	Scientist facilitator
Oliver	Increase	Male	12	1	Bethany
Sarah	Decrease	Female	12	1	Susan
Owen	Decrease	Male	12	2	Susan
Lily	None	Female	11	2	Bethany

Participant-observer details: the scientist facilitators

The scientist facilitators acted as participant-observers; they were guiding the children in the experiment during the session and took note of the children’s behaviour and interactions. Three scientist facilitators featured in this case study: Bethany, Susan and Evelyn (Table 3). Bethany was the scientist that guided Oliver and Lily in their experiment and Susan guided Sarah and Owen (Table 2). Evelyn acted as ‘Team Leader’. She supervised the intervention and sometimes offered support to other scientists, interacting with the children in their group in this way. All scientist facilitators completed the same training prior to the intervention.

Table 3. Details of the scientist facilitators (participant-observers). ‘Undergraduate’ course refers to the course they were studying at the time of the intervention. ‘Years of experience’ refers to the years spent volunteering with the outreach program.

Pseudonym	Role	Age	Gender	Undergraduate Course	Years of experience
Evelyn	Team Leader	21	Female	Microbiology	3
Bethany	Facilitator	19	Female	Biomedical science	1
Susan	Facilitator	21	Female	Biomedical science	2

DATA ANALYSIS

Quantitative analysis

Participant’s (N=4) responses to pre-test and post-test versions of the IS-SEC-Q were input directly into SPSS version 24. Some items were reverse-coded due to their negative wording.

Qualitative analysis

Interviews, video and audio recordings were transcribed verbatim. NVivo was used as a data analytical tool and transcripts were imported as internal sources (Figure 2). Steps in the qualitative data analysis were similar to those used in 'selective coding'(Cohen, Manion, & Morrison, 2007).

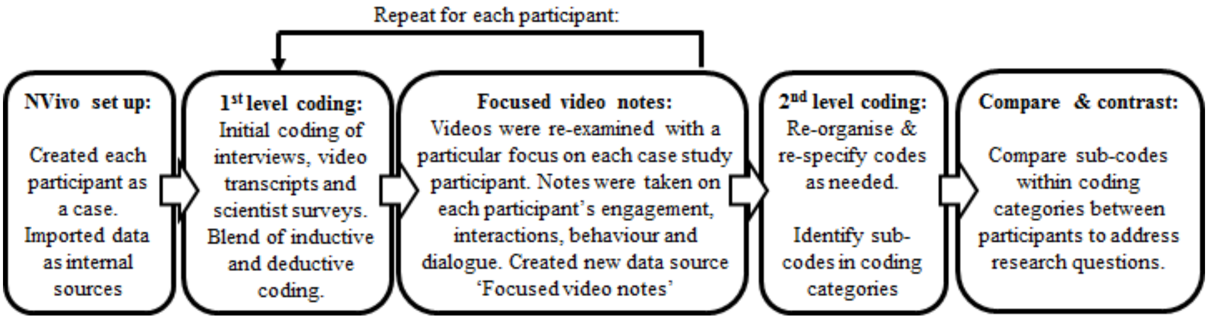

Figure 2. Steps in the qualitative data analysis.

First-level coding was guided by self-efficacy theory, current literature and the research questions. Data sources were reviewed to look for references to (i) the four sources of self-efficacy (mastery experience, vicarious experience, verbal persuasion and emotional state), (ii) interactions between the scientists and the children, (iii) interactions between the children and their peers at the group, (iv) engagement during the session and (v) descriptions of the scientists. These codes formed the 'core categories' (Cohen et al., 2007). In addition to the transcribed video and audio recordings, 'focused video notes' were also created, by re-examining the recordings with a sole focus on the actions and experiences of each participant. The second-level coding involved "…relating categories at the level of the dimensions identified" (Cohen et al., 2007, p. 562). Finally, a comparative analysis of participants looked for convergent and divergent findings to the research questions.

RESULTS

The 4 participants perceived the scientists to be competent, friendly & helpful

Verbal persuasion is most effective when the performer perceives the individual providing the praise to be credibly competent in the task at hand (Bandura, 1997). Therefore, before investigating whether the scientist facilitators affected participant's SSE beliefs, it was important to ascertain whether they perceived the scientists to be credibly competent. Nearly all the participants rated their scientists positively across the five items in the 'perceived competence of scientist' scale in the IS-SEC-Q (Figure 3). They agreed that their scientist facilitators were friendly, clever, well trained, encouraged them in the activities and felt that they got on well with them. Their perceptions of the scientists were further explored in the interviews. The core category 'descriptions of scientists' was divided into three sub-codes (Table 4). The first two sub-codes, 'competent in science' and 'friendly and nice' strongly complement participant's responses to the scale in the IS-SEC-Q (Figure 3). This indicates that participants perceived the scientists to be credibly competent, which makes them good potential candidates to act as providers of verbal persuasion. The third sub-code "helpful & supportive" was unexpected and came through strongly in the interviews. Both Lily and Sarah emphasised that their scientist facilitator helped them through explaining concepts and tasks in a simple and supportive manner.

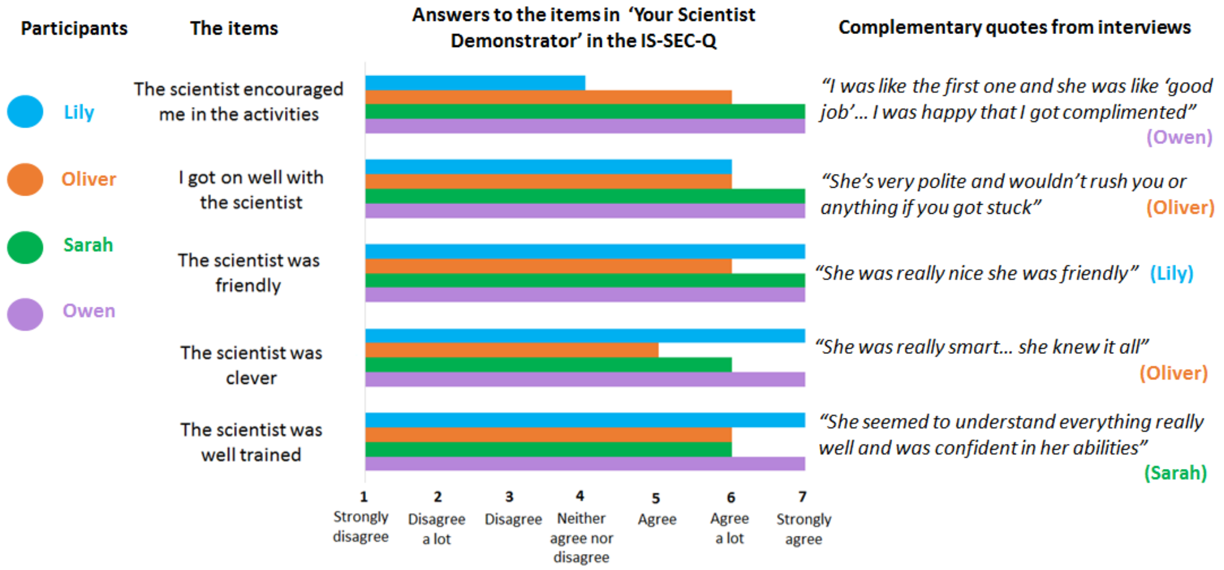

Figure 3. Case study Participant's perceptions of the competence and friendliness of their scientist facilitator. Each participant's answers to the five items (left) in the scale are presented (middle) combined with corroborating quotes from the interview (right).

Table 4. Case study participant's descriptions of the scientist facilitators from interviews. Tabulated are sub-codes and exemplifying quotes from the 'Scientist description' core category of the interview analysis.

Subcode	Exemplifying quotes
Competent in science	*"understand everything really well"* (Sarah) *"she was really smart"* (Lily) *"she knew her stuff"* (Oliver)
Friendly & Nice	*"really nice"* (Sarah) *"really friendly"* (Lily) *"very polite"* (Oliver) *"nice"* (Owen)
Helpful & Supportive	*"she just like explained everything really slowly and carefully so we could understand it"* (Sarah) *"when things are hard she can explain stuff in an easy way"* (Lily) *"she wouldn't rush you or anything"* (Oliver)

Participation did not greatly change the 4 participant's self-efficacy to 'Learn Science'

Changes to case study participant's SSE beliefs were explored through a combination of their responses in the IS-SEC-Q, their interviews and how their video observations. As participants were selected for this case study based on their pre-/post-intervention changes to the item 'How confident are you that you could learn science?', this was the first SSE variable that was examined. Although only one out of the 4 selected participants (Oliver) had an increase in their "Learn Science" score (Tables 2 and 5), all participants reported to feeling more confident in science after the intervention in the interviews (below).

Lily said, "*I've always wanted to do science…it boosted my confidence even more to do it*". Lily postulates that the reason her questionnaire changes did not reflect this increase is due to her low efficacy in maths (i.e. mathematics). Lily marked herself at a 1 (Terribly) in maths at both pre- and post-test. She explained that because she sees maths as such an important aspect of science, even though she felt more confident in science after the intervention, it was not enough to overcome her perceived shortcomings in maths.

"I marked myself the same because I'm not that confident with doing like the maths in science and stuff but em I think I was pretty good at the science" (Lily)

Table 5. Pre- and post-test responses from 4 case study participants for 3 SSE items in the IS-SEC-Q. Variables are assessed by single items in the IS-SEC-Q.

SSE variable	Lily		Owen		Sarah		Oliver	
	Pre	Post	Pre	Post	Pre	Post	Pre	Post
Learn Science	5.00	5.00	5.00	4.00	6.00	5.00	5.00	6.00
Filter a mixture	6.00	7.00	5.00	3.00	4.00	7.00	5.00	6.00
Pipette 1 ml of liquid	4.00	7.00	3.00	3.00	7.00	7.00	3.00	6.00

Sarah also said that the session increased her science self-efficacy, *"I think just doing one* [of the sessions] *made me feel a lot more confident"*. In fact, it was her second time doing the session as she had done it previously with a youth group outside of school. Sarah suggested that her questionnaire indicated a decrease instead of an increase because she over-estimated her confidence in the pre-test questionnaire and then did not perform as she predicted she would.

"…I was a bit more confident in my abilities than I was actually able to do so then I just kinda did more accurately the second time after I did it" (Sarah)

Owen could not explain why his questionnaire did not indicate an increase in his science confidence, despite feeling more confident after the intervention.

"I felt good that I did it, well I've never really done science before so when I done that I kinda felt good that I did the DNA extraction" (Owen)

Intervention did increase case study children's self-efficacy to perform related skills

Whilst an increase in SSE is not much indicated by the changes in responses to the item 'Learn Science', it is reflected in participants responses to the items pertaining to the specific skills that they performed during the interview: filtering a mixture and pipetting 1 ml of liquid (Table 4). Lily, Oliver and Sarah reported an increase in their self-efficacy to perform at least two of these skills. This increase in self-efficacy in these skills was also corroborated by their responses in interviews and how they were observed to perform the skills in the videos.

For example, Lily reported a +1 increase in her self-efficacy to filter a mixture successfully (Table 4). When asked about it in her interview she said that she felt more confident in filtering a mixture, even though she *"…needed help doing the funnel*". This was supported by her focused video notes, as it was observed that Lily did in fact struggle with creating the funnel with the filter paper. Once her scientist facilitator gave her some further guidance and praised her on completing it, Lily proceeded to filter the mixture with no further struggle. According to his questionnaire, Owen's self-efficacy in these skills was not increased (Table 4). From his questionnaire, he seemed to have become less confident about filtering a mixture (-2, from 'well' to 'not well') and his efficacy about using a pipette remained low (at 3, 'not well'). In his interview Owen describes how he struggled with the filtration step, that he "*…wasn't really good at it"* and "*was struggling a small bit but then got the hang of it*". This combined with his questionnaire would suggest that he had struggled considerably at this step. However, in the video he appeared to complete this step with ease, needing no additional guidance and did so at a rate equal to his peers.

Case study participants received little verbal persuasion from scientists

Only two of the four case study participants, Lily and Owen, reported changes to their perceived levels of verbal persuasion from scientists in the questionnaire after the intervention (Figure 4A and 4B).

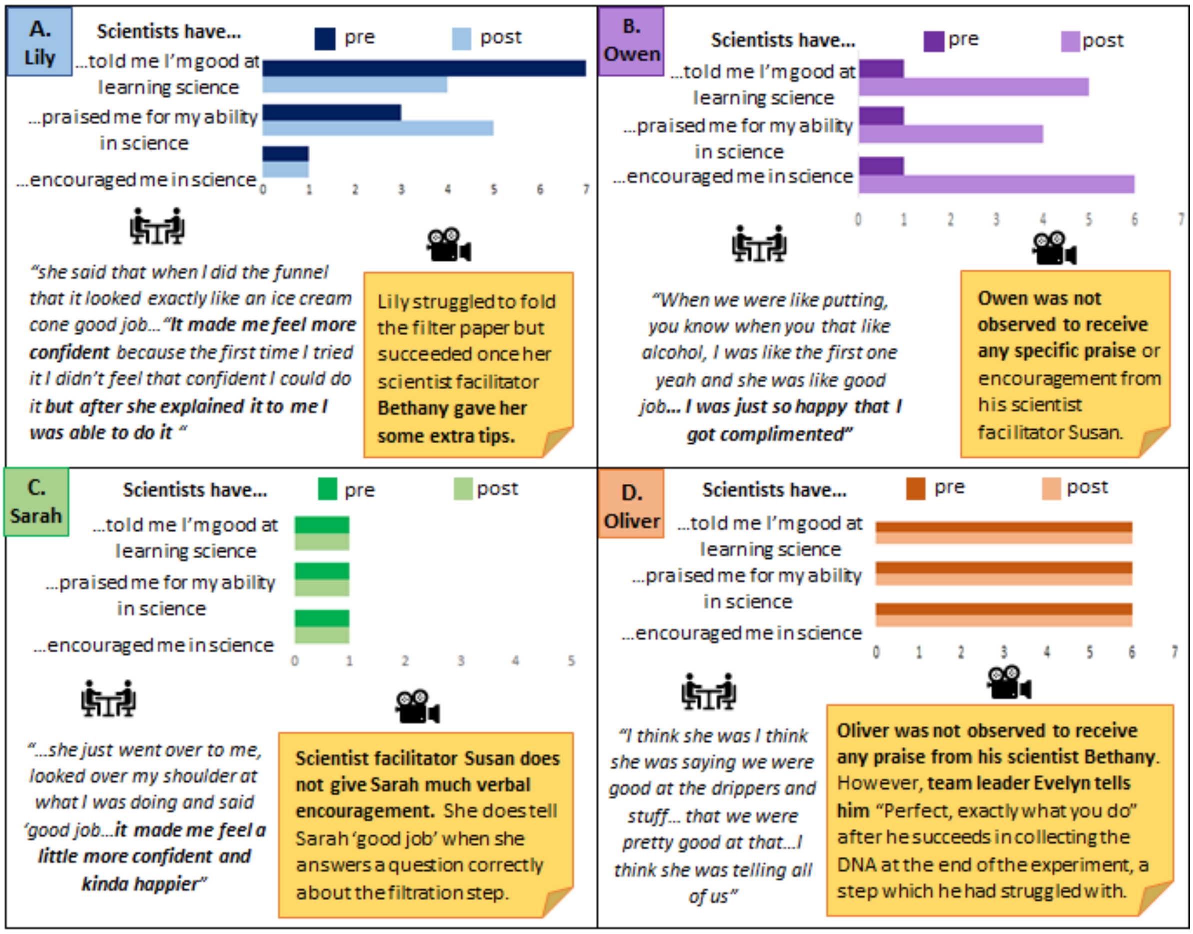

Figure 4. Verbal persuasion from the scientist facilitator. Each panel has a bar chart illustrating each participant's pre-/post-test scores to the three items assessing verbal persuasion from scientists from the IS-SEC-Q, an exemplifying quote in their interviews and excerpts from the videos notes ascertaining whether verbal persuasion from scientists was observed in their recorded session. The x-axis for each bar chart denotes the response range in the 7-point Likert scale used. Each point was labelled as follows (1-7): strongly disagree, disagree a lot, disagree, neither agree nor disagree, agree, agree a lot, strongly agree).

Three items in the IS-SEC-Q assess verbal persuasion from scientists: 'scientists have told me I'm good at learning science', 'scientists have praised me for my ability in science' and 'scientists have encouraged me in science'. Owen reported an increase in all three items (Figure 4B), which was corroborated by his interview. However, Owen was not observed in his video to receive any specific verbal persuasion from his scientist facilitator Susan. It is possible that it was not picked up by the recording device. Lily did receive additional advice and encouragement from her scientist facilitator Bethany (Figure 4A). Lily struggled to correctly fold her filter paper into a funnel before Bethany gave her extra instruction. Once Lily has successfully folded the filter paper, Bethany praised her for making it look like an ice-cream cone, which is how she initially described it. Lily felt that this made her feel more confident about the step (Figure 4A). Neither Oliver nor Sarah were observed to receive specific praise from their scientist facilitator compared to Lily and Owen, nor was this indicated by their questionnaire results (Figure 4C and 4D). However, they both talk about at least one event where their scientist did praise them. For Sarah, the praise was specific to her (4C), whereas Oliver recounted that his scientist facilitator Susan gave general praise to everyone *"I think she was telling all of us"* (Figure 4D). Surprisingly, Oliver did not mention the specific praise he was observed to receive from Team Leader Evelyn. This may be because he was asked about praise he received from his scientist facilitator, and he viewed the two roles differently.

CONCLUSIONS & FUTURE DIRECTIONS

This proceedings paper presents a case study analysis on how scientists delivering hands-on outreach interventions affect upper primary pupil's science self-efficacy beliefs. As a first exploration of related research questions, four participants were selected for analysis. Interviews and responses from the 'perceived scientist competence' scale and descriptions from the interviews supported the hypothesis that participants considered the scientists to be competent in science (RQ1). Although participation in the intervention did not seem to induce great changes to the four children's overall science self-efficacy, all of them reported an increase to their self-efficacy through either the IS-SEC-Q or their interviews in performing the specific skills related to the session: filtering a mixture and pipetting 1 ml of liquid. This supports that children's SSE beliefs are increased after participation in a hands-on science session but are mostly limited to skills practiced during the session (RQ2).

The effect of the scientist facilitators on children's SSE beliefs was explored (RQ3). It was hypothesized the scientists would incur positive changes to children's SSE beliefs through the provision of verbal persuasion. Although the participants perceived the scientist facilitators to be credibly competent, they reported to receiving little verbal persuasion from them during the intervention. It was confirmed through the video analysis that their scientist facilitators did not provide much (if any) verbal praise. Therefore, the hypothesis that the scientist facilitators induces an increase in SSE through verbal persuasion could not be fully examined in this case study. However, three participants (Lily, Owen and Sarah) recounted in interviews that the small amount of verbal persuasion that they recalled in receiving (whether it was observed to occur or not) induced a positive effect, either increased happiness or confidence. This suggests that there could be a relationship between the level of verbal persuasion provided by the scientist facilitator and the amount perceived by the child participant. Therefore, to address RQ3, a future direction of this study will be to attribute a level of verbal persuasion provided by each scientist facilitator and explore its perceived impact for each participant, through a triangulation of IS-SEC-Q responses, interviews and observations.

An unexpected outcome of this case study was the emergence of being 'helpful and supportive' as a strong sub-code in the analysis of children's descriptions of the scientists. By explaining concepts clearly and simply, in a manner that remains informal yet structured, scientists may indirectly contribute to participant's increased SSE through the creation of a positive and supportive atmosphere, thus mediating participants mastery experience. This additional characteristic of the scientist facilitators could provide an alternative explanation to verbal persuasion for how they may have facilitated participant's increase self-efficacy to perform the skills of the session.

Finally, the four participants constituting this case study are part of a larger sample in a quasi-experimental study. Future work will ascertain whether the experiences of these four participants are applicable to a larger cohort and will guide the further investigation of how scientist facilitators delivering hands-on outreach can affect children's SSE beliefs. In particular, the future analysis of the pre- and post-test questionnaires from the quasi-experimental group of 156 participants (N=106 in treatment group, N=50 in control group) will investigate whether there are any statistically significant changes to participant's SSE strengths and sources. Additional analysis of session videos and participant interviews will allow a more comprehensive understanding of the potential role of scientist facilitators in forming children's SSE beliefs in hands-on science sessions. This will be the first step in recommending best practice for scientists in outreach.

ACKNOWLEDGEMENTS

The authors thank the primary pupils, teachers and scientist facilitators for their participation in this study. MG's research group is linked to the activities of Cell EXPLORERS, an educational outreach programme funded by the Science Foundation Ireland strategic Discover awards 16DP4123 and 18DP5772. SC's PhD is funded by a College of Science scholarship. The funders had no role in study, design, data collection and analysis or decision to publish. This research had ethical approval granted by the NUI Galway research ethics committee, reference 17-NOV-02.

A SERIOUS GAME TO TEACH EPISTEMIC KNOWLEDGE: THE PLEASURE OF LEARNING TO THINK AND ACT LIKE A SCIENTIST

María-Antonia Manassero-Mas[1]*, Antoni J. Bennàssar Roig*[1] *and Ángel Vázquez-Alonso*[1]
[1]University of the Balearic Islands, Palma, Spain

Scientific literacy is a perennial objective of science education to adequately prepare all citizens to live in a sustainable world increasingly permeated by science and technology. A component of literacy involves epistemic learning on how science and technology work and how scientists think and act to validate scientific knowledge. Teaching and learning this innovative metacognitive component of literacy is difficult, and especially for primary teachers and students. This paper aims to innovate the initial science training of primary teachers through their involvement in developing and applying some teaching materials with the format of cooperative serious games to teach students an aspect of epistemic knowledge. To this aim, games offer an authentic analogy of the scientific practices, as they replicate complex science epistemological tenets and their cooperative and competitive social aspects that authentically simulate the actual arguments, cooperation and competition among scientists (as sociology of science has posited) and are flexible enough to allow access and evolutionary adaptation to teachers and students. This way, games allow actually training teachers to teach students complex epistemic aspects about thinking and acting like scientists. A real experience to teach students argumentation based on evidence of knowledge validation through a simple serious game with cubes and dices is presented. The results show primary teachers' satisfaction and students' motivation and interest after playing the cubes. The materials and some students' productions (observations, arguments and justifications) will be presented. Finally, the positive results encouraged the teachers to continue their science epistemic by deepening the complexity of the game.

Keywords: epistemic knowledge, primary teacher training, evidence-based argumentation

INTRODUCTION

Science literacy is the perennial objective of science education, which has currently focused on changing the traditional approach of "science for scientists" to a new inclusive "science for all" to adequately prepare citizens for everyday life in a sustainable world increasingly permeated by science and technology (S&T) (Millar, 2006). Besides the cognitive knowledge (traditional S&T concepts, facts, principles, and processes that dominate all textbooks), the key innovative component of science literacy is the knowledge "about" science, which is often called nature of science or epistemic knowledge, as it deals with how science and scientists work to validate their knowledge or intervene in society. Epistemic knowledge involves a set of complex, multifaceted, interdisciplinary, evolving, and changing meta-knowledge about scientific (and technological) practices, which refers to functioning, methods, values, scientific community, science, technology, relationships with society, etc. drawn from history, philosophy and sociology of science (and other disciplines) when they analyse scientific and technological practices (Lederman, 2007; NGSS, 2013; Vázquez & Manassero, 2012).

Teaching and learning epistemic knowledge copes with many difficulties and constitutes a pending innovation in school science. On the methodological hand, recent research suggests that the most effective teaching approaches must involve both explicit and meta-cognitive reflection activities for students (Abd-el-Khalick & Akerson, 2009; Deng, Chen, Tsai & Chai, 2011; García-Carmona, Vázquez & Manassero, 2011; Lederman, 2007). On the other hand, the lack of teacher training and appropriate educational resources for teaching epistemic knowledge contents are the greatest practical hindrances. For instance, Li and Tsai (2013) analysed 31 investigations (2000-2011) based on science digital games and showed that any game addressed the learning of epistemic knowledge topics.

Serious games for epistemic learning

Hence, this communication aims to fill in these gaps by trying an exemplary serious game of cubes as a teaching resource for students learning and teacher training, because games offer an authentic analogy of scientific practices and allow addressing complex epistemic aspects by emulating scientists' behaviour and thinking skills. Hattie's (2009) meta-analysis on visible learning assigns to interactive games and videos a good mean effect size (0.50 and 0.52) on learning and they justify the game's good impact on learning. Furthermore, several studies suggest that serious games are also effective to produce behavioural, cognitive and meta-cognitive changes and convey educational advantages: students do not usually need prior knowledge to play, the contents can be flexibly designed to fit students' needs (age, level, subject, etc.) and their activities can be planned for cooperative learning (McGonigal, 2011).

The use of games as teaching resource addresses those difficulties, especially in primary science education, as playing the game explicitly enhances teachers training and develops students' motivation and interest to learn that contribute to overcome the difficulties. Educational games deploy an authentic analogy of scientific practices that explicitly simulates cooperation and competition among scientists when researching and replicates some scientific epistemic tenets. Further, game design is flexible enough to allow developmental adaptation to students' grade and needs. Overall, games allow teaching students complex epistemic aspects about actually thinking and acting like scientists (Gee, 2007).

The rationale for trying the cube game stems from the ability to address the former difficulties and adding the primary science education context (training elementary teachers and teaching elementary students), a less frequent context of studies on teaching epistemic knowledge.

Teacher training and student learning: development of scientific (critical) thinking

Research points out another important drawback of effective teaching of epistemic topics: teachers do not usually have an adequate training. Thus, this study also deals with improving teacher training on epistemic through games, which is twofold: on the one hand, teachers' pedagogic appropriation of the games, as an innovative resource to teach epistemic knowledge; on the other hand, the development of teachers' scientific (critical) thinking skills to help students' reflective learning activities. This aims unfolds around the following ideas:

- Scientific knowledge assumes order and consistency in the natural systems.
- Scientific research uses a variety of methods.
- Scientific knowledge is based on empirical evidence.
- Scientific knowledge is open to review based on new evidence (change).

- The laws, mechanisms, models and scientific theories explain natural phenomena.

The development of critical (scientific) thinking skills in primary teachers and students involves actively practising these skills, which are relevant for both epistemic science education and everyday life. Some of these thinking skills may be the following:

- Asking questions and defining problems
- Analysing and interpreting data
- Building explanations and designing solutions
- Participating in evidence-based argumentation
- Developing and using models
- Planning and conducting research
- Obtaining, evaluating and communicating information

Thus, a real experience to train teachers in teaching students some epistemic knowledge through a serious game of cube is presented. The game grants students the scientist's role and introduces the scientific method as a generic protocol for problem solving, which has different components: reflective, interactive and cooperative. The objective is to provide opportunities to generate ideas and models, as this is the best way to stimulate students' creative and argumentative thinking to behave like a scientist. The general research question here is: is a serious cube game an appropriate tool to effectively teach epistemic contents in primary science?

METHODOLOGY

Instruments

The criteria for choosing the cube game were that it should explicitly address a topic on epistemic knowledge and allow students' cooperative and reflective thinking (like scientists) about elaborating learning (Vázquez & Manassero, 2012). Some authors were tracked, searching for games that fulfil the former inclusion criteria through puzzles, cubes, scenarios, dice, cards, etc., and digital games were purposefully overlooked as most of them do not meet these conditions (Vázquez & Manassero, 2017).

A simple cube (a dice with each face numbered 1 – 6 or with words) ware selected for the activity on training teachers and teaching students epistemic topics; one face of the cube is hidden from the students, as the aim of cube activity is to predict the content of the concealed face based on the observations and regularities identified in the visible faces. Students work in small groups to respond to the question: what is on the hidden side of the cube? Along the search for answers, students are gently introduced to the main aspects of practices carried out by scientists to validate knowledge (Figure 1).

Students' activities try to discover, verify and argue about the regularities observed through group discussion, solving objections and anomalies, making a prediction about the content of the hidden face of the cube, and verifying that the prediction is compatible with the observations. Only answers that are accompanied by some reasoning about evidence are allowed. The main advantage of this game is that the designs of the observable data on the visible faces can be adapted to various levels of difficulty to adjust to students' needs; for instance, a verbal cube was used in one group as a second activity (figure 1).

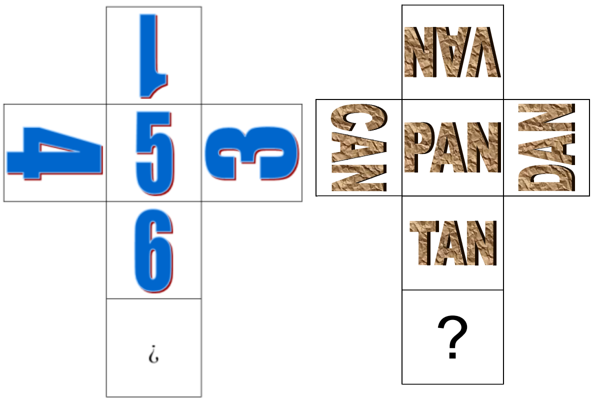

Figure 1. Two exemplary cubes used by students to predict the content of the face with the question mark. A traditional dice with the (1-6) numbers and a verbal cube with letters on its faces.

Procedure

The teachers prepare the lesson plan for the cube game, adapt its epistemic knowledge contents to teaching their groups of students, lead the teaching within the classroom, collect the students' reflections and arguments through organizers and help the students to draw conclusions about the epistemic knowledge involved.

The students observe the cube, look for evidence and reason about the evidence to reach conclusions based on valid reasoning about the accepted evidence. The general learning objectives for teaching the cube game to the students are the following: to practice/engage in accountable and constructive discussion with each other, share content understanding, build understanding on each other's observational data, drive each other to address misconceptions and misinterpretations, and encourage and model the skills of scientific inquiry that characterise scientific practice, such as thinking and argumentation, curiosity, scepticism, and openness to new ideas and data. At the beginning of the activity, the main difficulty was to curb the students' impulsiveness to give a quick response to the number on the hidden face, as everyone knew it, because they were familiar with the numbered dice, which are frequently used in Spain. The teacher insists on the task being to look for data and logical interpretations of data that lead arguably to a valid prediction about the number on the hidden face.

To complete teacher training on epistemic knowledge, the teachers share their experiences on teaching about the cube in a final joint session, to reflect on and analyse the activities carried out and the results achieved by their students.

The students try to respond to the initial question by developing some individual, whole-class and small-group activities, such as exploring the cube, writing down the observed data, looking for evidence, reasoning about data and evidence, proposing hypotheses and explanations, elaborating and discussing explanations supporting the data, reaching and arguing conclusions. A final whole-class activity may discuss all the answers to agree on some conclusions.

Participants

Six Spanish teachers (3 men) prepared and applied the cube game to their 6th grade (12-year-olds) students, which involved about one hundred students. None of the teachers held a major in Science, yet they all taught the subject Science to their students. The rationale of the implementation stems from the development of the Spanish Primary Science school curriculum content Block #1 (the activity of scientists), where the cube activity can be infused.

RESULTS

The first product of teacher training was teachers' design of the teaching-learning sequence (TLS) following the didactic model of the 7E's (elicit, engage, explore, explain, elaborate, evaluate and extend) to apply within the classroom; teachers' tasks involve the adaptation of the dice game lesson plan, the contents and the pedagogy to their students. The most important elements of the TLS on cubes include the general description, the learning standards, the relations of the game with the curriculum contents, the logical connection between evidence, scientific explanation, and theoretical models, and the students' activities.

The students respond initially to questions (How do scientists work? How would you describe a scientific investigation?) and develop some individual, group-class and small-group activities, such as exploring the cube, writing down the observed data, proposing explanations, elaborating and discussing explanations and supporting data, and arguing conclusions. In a final group-class activity, all the answers are discussed to reach a final conclusion.

The justification and general description of the sequence follows: science differs from other forms of knowledge through the use of empirical standards, logical arguments, and scepticism, as scientists struggle for the best possible explanation of things in the natural world. In the first part of the activity, the teacher uses a dice (a cube numbered 1-6) to engage the students in answering the question (what is on the concealed face?) The students propose explanations based on their observations. Optionally, the teacher may present a second cube and asks the students to propose an explanation of what is on the hidden face from the available evidence.

The objectives and learning standards related to epistemic topics of this TLS on the dice are the following:

- To identify issues that can be answered through scientific research
- To design and carry out a scientific research
- To collect, analyse and interpret data using appropriate tools and techniques
- To develop descriptions, explanations, predictions and models using evidence
- To think critically and logically to establish relationships between evidence and explanations
- To recognize and analyse alternative explanations and predictions
- To communicate scientific procedures and explanations.

The dice game relates to the following topics of Block 1 of Spanish Primary Education Science curriculum contents: scientific explanations emphasize evidence, develop logically consistent arguments and conclusions, and use scientific principles, models, and theories. The most important scientific literacy competence developed in this TLS is the logical connection between evidence, explanations and conclusions.

Table 1. Development of the teaching-learning sequence about the cubes, structured according to the didactic model of de 7E's (elicit, engage, explore, explain, elaborate, evaluate and extend).

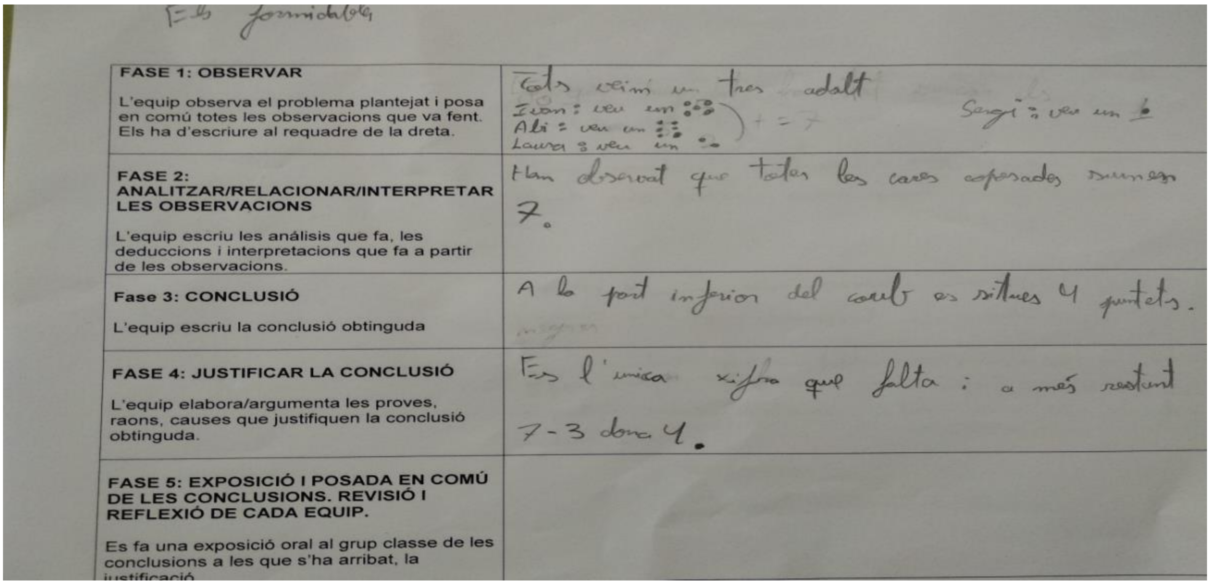
Time (min)	ACTIVITIES (Student / Teacher)	Methodology / organization	Resources
15	ENGAGEMENT Introduction-motivation Respond (write on the blackboard) / How do scientists work?	Whole class group	Verbal
15	ELICIT Previous knowledge Respond (write on the blackboard) / How would you describe a scientific investigation?	Whole class group	Verbal
	Development activities		
5	EXPLAIN/EXPLORE Content Explore dice to answer the question / What is on the bottom face of the dice?	Students in groups of 4	Dice, organizers
10	EXPLAIN/EXPLORE Procedures Write down observed data of dice / Supervise	Students in groups of 4	Dice, organizers
15	EXPLAIN/EXPLORE Attitudes Each student proposes explanations / Supervise The group elaborates its list of explanations / Regulates discussions	Students in groups of 4	Dice, organizers
50	ELABORATE Consolidation Each group presents data, explanations and argues its answer / Differentiates evidence-based explanations from non-based ones Ask and listen / Answer and explanations	Whole class	Dice, organizers
	EVALUATION Students' writings on organizer sheets Students' contributions (oral)	Whole class	
	EXTEND Transfer to verbal cube activity		Verbal cube, organizers
	TEACHER'S REFLECTION ON THE TEACHING PRACTICE (obstacles, facilitators, incidents, etc. the teacher completes pedagogical content knowledge questionnaires)		

Additional questions worth being asked to students may include the following:

- What questions do you have about the cube?
- What do we mean by evidence?
- How do you think an explanation based on evidence is different from other explanations?
- How is your investigation of the cube similar to a scientific investigation?
- May different scientific investigations require different approaches?

Students' observations about the dice will likely include many of the following:

- The numbers are black.
- The dice has five exposed sides.
- The dice has six sides.
- The exposed sides have the numbers 1, 3, 4, 5, and 6.
- The numbers on opposite sides add up to 7.
- The even-numbered sides are shaded.
- The odd-numbered sides are not shaded…



FASE 1: OBSERVAR L'equip observa el problema plantejat i posa en comú totes les observacions que va fent. Els ha d'escriure al requadre de la dreta.	Tots veiem un tres adalt Izan: veu un Abi: veu un Laura: veu un Sergi: veu un
FASE 2: ANALITZAR/RELACIONAR/INTERPRETAR LES OBSERVACIONS L'equip escriu les anàlisis que fa, les deduccions i interpretacions que fa a partir de les observacions.	Hem observat que totes les cares oposades sumen 7.
Fase 3: CONCLUSIÓ L'equip escriu la conclusió obtinguda	A la part inferior del cub es situen 4 puntets.
FASE 4: JUSTIFICAR LA CONCLUSIÓ L'equip elabora/argumenta les proves, raons, causes que justifiquen la conclusió obtinguda.	És l'única xifra que falta: a més restant 7-3 dona 4.
FASE 5: EXPOSICIÓ I POSADA EN COMÚ DE LES CONCLUSIONS. REVISIÓ I REFLEXIÓ DE CADA EQUIP. Es fa una exposició oral al grup classe de les conclusions a les que s'ha arribat, la justificació	

The organizer of Figure 2 contains some comments of a group of students, who reasoned this way on the data recorded on their organizer to find their answer:

Phase 1. Observe. “We all see a 3 above; Izan sees a 5; Abi sees a six; Laura sees a 2; Sergi sees a 1.” (The dice faces are represented by dots on the organizer, because the students' working dice was a classic black-dot dice).

Phase 2. Interpret the observations. “We have observed that all the opposite sides add up to 7"

Phase 3. Conclusion. "There must be 4 dots in the bottom face of the dice."

Phase 4. Justification. It is the only number that is missing, and also if you subtract 7 – 3, you get 4.

Figure 2. Two small groups of students playing with dice and the organizer at the table; the left group observes a numbered dice and the second group is using a verbal cube.

Some students’ verbal contributions and discussions during activities were recorded by teachers. Two exemplary excerpts of these discussions follow: the first excerpt accounts for the (synthetized) argumentative flow within a small cooperative group:

Group 5

- ✓ S1: “The numbers on the opposite sides of the dice are even and odd ...

- ✓ S2: And on top (on the upper face), we have a 2 ...
- ✓ S3: And on the left side, we have a 4 and a 6, which are even numbers, and on the right of the odd numbers are number 3 and number 1 …
- ✓ S4: … mmm… that means that on the bottom, there must be an odd number, and when discarding the known numbers, it has to be 5. The number of the invisible face is 5."

The second excerpt shows a boy's oral account to the class; his Spanish speech is particularly relevant for its simplicity, precision, clarity, coherence, language quality and eloquence.

> Group 4. A boy's speech accounting for the argumentation of his cooperative group to the whole class:
>
> "The parallel faces of the cube always add up to 7. You can check that number 3, which is on this side, plus the 4, which is on the opposite side, add up to 7; further, you can add the 2, which is on this side, plus the 5, which is in the other side, also add up to 7. If you have the 6 on top and subtract it from 7, you get 1, so number 1 is on the bottom."

To complete the primary teacher training on epistemic knowledge, the teachers shared their experiences on the application of the teaching-learning sequence about dice in a reflective joint session, where the teachers assessed the activities and the results achieved by their students. All the teachers were satisfied with the experience, as these two excerpts show:

- T2. "I must mention that working on credible activities of the same style/level we face at specific moments and situations in daily life is one of the things I have found most stimulating and interesting."
- T5. "The experience as a whole ... I found it very positive, as it has shown the value of little, simple activities that can be much more useful tools than they seem at first sight."

The researchers asked the teacher to agree on drawing much more specific conclusions from the experience on teaching the TLS on dice to their students. The teachers' conclusions reflect some students' behaviours that teachers unexpectedly found good enough to be emphasized:

- The students spontaneously accepted all opinions, in spite of being corrected or discarded later on.
- The students did not fight or quarrel to impose their personal views; rather, they accepted and tried to reach a consensus in spite of having quite different ideas.
- The students tried to change and adjust their views to the facts, especially when new evidence arose through the cooperative exchanges and argumentations.
- Students' initial acritical high impulsivity to use the first idea springing to mind was progressively reduced by increasing reflectivity on the evidence.

All in all, teachers' conclusions reveal a progressive awareness and action on self-regulation and meta-cognition processes that contributed to increase the students' self-control throughout their cooperative work along the cube activities.

DISCUSSION AND CONCLUSIONS

The innovative experience of teacher training and student learning about epistemic knowledge presented herein should be contextualized bearing in mind that it was the first innovative step toward including epistemic knowledge in science education of the primary teachers, who do not have specific training in science and much less in epistemic topics. Given that the main difficulty with epistemic knowledge is the lack of resources and teachers' lack of training and their reluctance to teach it, the satisfaction of teachers and students with the simple dice activity developed in the classroom shows that the aims of this study for teachers' training and students' learning were met. Teachers considered the experience with a serious dice game effective to teach epistemic contents and they appreciated the merits of the game: its flexibility to adapt to different topics and students' interests, needs and age, thus fostering students' motivation and interest in playing to learn complex topics (Abd-el-Khalick & Akerson, 2009).

Further, the experience of dice is deliberately simple to allow the teachers to achieve a balanced and calm training on these innovative and complex epistemic issues, so that they can sustainably increase the complexity of their future professional development on epistemic issues, through the experience of more complex games. In fact, the teachers expressed satisfaction and were encouraged to extend the teaching of epistemic contents through new games for the next step of training (Vázquez-Alonso & Manassero-Mas, 2017).

Further, playing dice games manifestly promotes transversal skills for general competences, namely, scientific and critical thinking skills, such as asking (and answering) questions, seeking data, making decisions, creating hypotheses, predicting outcomes, sharing ideas, arguing on evidence, discussing results, and communicating conclusions (NGSS, 2013).

As games contribute to overcome the complexities of epistemic knowledge by means of analogical simplification, they may display a limited image of scientific practices, and it might be argued that games do not perfectly represent the original epistemic content in scientific practice. However, the satisfaction and rationale of this study go beyond the relative limitation of their representativeness; first, the power of games for making complex epistemic knowledge accessible to teachers and students widely compensates these caveats; second, gamification allows teachers and students to draw on key epistemic knowledge for developing a relevant approach to scientific thinking, which is key for competent science literacy; third, the games make the epistemic content affordable, useful and practical to encourage novice teachers and challenge students. Thus, when considering the generation of students' motivation and participation in gamified learning, and teachers' satisfaction and confidence to maintain the epistemic contents in their classroom, the counterbalance to the potential imperfection of games is quite positive. Thus, teachers' and students' engagement with games may set up an inflection point for the omission tradition for epistemic teaching, as most literature reflects (Abd-el-Khalick & Akerson, 2009; Deng et al. 2011; García-Carmona et al. 2011; Lederman, 2007).

All in all, the originality of this study is its sustainability, as it allows systematically self-development of different games that can satisfy multiple adaptations to teach different epistemic topics at different educational levels without external help or previous knowledge. This feature also helps the teachers to deepen their training on these resources, which may encourage them to keep teaching these topics with confidence and excitement (Vázquez-Alonso & Manassero-Mas, 2017, 2018).

USING PHILOSOPHY-INSPIRED CATEGORIZATION STRATEGIES TO DESIGN A LEARNING ENVIRONMENT ABOUT BIOLOGICAL CLASSIFICATION: A CASE STUDY WITH 4TH GRADERS

Eftychia Valanidou, Marida Ergazaki and Renia Gasparatou
University of Patras, Patras, Greece

This paper reports on the second case study that has been performed in the first cycle of a design research, which aims at designing a learning environment about biological classification by drawing on philosophical theories of 'concept formation' or 'categorization'. Philosophy can provide theories that suggest different mechanisms of categorization. Family resemblance-inspired theories suggest that we categorize by relying on examples of the concept or on lists of the examples' shared features. Moreover, classical theory suggests that we categorize by articulating concepts' definitions. Considering the above theories, we developed a three-part, learning environment that aims at supporting primary school students in constructing the biological concepts of fish, amphibian, reptile, bird, and mammal, and in enhancing their categorization skills. The first version of the learning environment consists of seven teaching-learning activities that encourage students to use different types of reasoning in order to categorize vertebrate animals into their biological classes. Students are expected to collaborate in small groups in order to classify vertebrate animals into their classes, by (a) observing different examples of each vertebrate class, (b) making lists of the features the members of each class share ('shared features lists'), (c) deducing some key features of each class from the corresponding 'shared features list', and (d) using these key features to articulate definition-like reasoning strands about vertebrates. Analyzing the pre/post responses of the 21 conveniently selected 4th graders who took part in this case study, showed an improvement in their reasoning about the target biological concepts. The results are thoroughly discussed in the paper.

Keywords: Conceptual understanding, science education, reasoning

INTRODUCTION

Organizing human experience into mental categories (that is, concepts like chair, insect, etc.), allows us to store information efficiently, as well as to have theories about the world and reason with them (Ergazaki, Gasparatou, & Valanidou, 2015; Gelman & Meyer, 2011). In everyday life, people seem to categorize in many different ways, depending on the task they deal with (Murphy, 2002). When it comes to biology education however, it is important to familiarize children with *biologically* informed classifications of concepts like plants or animals (Ergazaki, Gasparatou, & Valanidou, 2018).

Biology education research then, is significantly concerned with the ways children classify living things (Allen, 2015; Anderson, Ellis, & Jones, 2014; Martinez-Losada, Garcia-Barros,

& Garrido, 2014; Papadopoulou & Athanasiou, 2015; Patrick et al., 2013; Prokop, Tolarovičová, Camerik, & Peterková, 2010; Rybska, Tunnicliffe, & Sajkowska, 2014; Tao, 2016), as well as with designing learning environments to help them shift to biological classifications in particular (Koliopoulos, Gouskou, & Arapaki 2012; Kos, Šuperger, & Jerman, 2015; Lorenzi, Labrell, Ronchi, Tatano, & Perucchini, 2013; Marulcu, 2014; Randler, 2009; Ronchi, Labrell, Lorenzi, Tatano, & Perucchini, 2012; So & Ching, 2015). Research shows that children have rather naive ideas about animals and their groupings (Marulcu, 2014), and that these ideas are rather resistant to teaching (Kattmann, 2001). For example, children tend to classify bats as birds, dolphins as fish (Natadze, 1963), and sea turtles and crocodiles as amphibians, even after biology instruction (Yen, Yao, & Chiu, 2004).

Since typical biology teaching does not always seem to work adequately, we thought it would be interesting to design an alternative learning environment by drawing on general theories of concept formation. Philosophy can provide us with such theories and suggest different reasoning strategies that may be involved in categorization (Gasparatou & Ergazaki, 2016). More specifically, classical theory claims that we categorize individual fish, for instance, under the concept fish, by articulating a fish definition. Family resemblance-inspired theories on the other hand, imply that we categorize individual fish under the concept fish, by exploring different examples of fish and intuitively grasping common fish-features.

Thus, our study addresses the question of whether it is feasible to use these philosophical theories in order to design a learning environment that could facilitate primary school students in constructing the biological concepts of fish, amphibian, reptile, bird, and mammal. In this paper, we are concerned with evaluating the first version of our philosophy-inspired learning environment by identifying students' ideas before and after taking part in it. So, the research question here is: 'How do primary school students of 4th grade reason about the biological concepts of fish, amphibian, reptile, bird, and mammal, before and after their participation in the first version of our philosophy-inspired learning environment?'. More specifically, 'do they group vertebrate animals in class-groups?', 'how do they justify their groupings?', and 'how they use the quantifiers 'all' or 'some' when reasoning about specific features of vertebrates classes?'.

METHODS

The overview of the study

This paper reports on the second case study of the first research cycle of a design research (Akker, Gravenmeijer, McKenney, & Nieveen, 2006) that aims at designing a philosophy-inspired learning environment about the classes of vertebrate animals. The learning environment is addressed to primary school students, and in this particular case study we implemented and evaluated its first version with fourth graders. The implementation was carried out with three, 1-1.5 hour sessions in three consecutive school days. Before and after implementing our learning environment, we performed a pre/post test, using an open-ended questionnaire that students had to fill in individually. The questionnaire was first piloted with students of similar profile with that of our participants, and the feedback was used for elaborating the initial phrasing and format of the items.

The participants

The participants of the case study were 21 4th graders (12 girls/9 boys, age 9-10), attending a public school in a semi-urban area of Patras with medium/high socio-economic status. Students were selected conveniently: their teacher volunteered to facilitate our study. According to her, students were familiar with group-work, as well as with some basics about animals. Before carrying out the pre-test, the first author visited children's class to meet them, inform them about the study, and ask for their own assent to participate.

The learning environment

Having in mind the mechanisms of concept formation suggested by relevant philosophical theories such as the family resemblance inspired theories or the classical theory (Gasparatou & Ergazaki, 2016; Murphy, 2002), we designed the first version of a constructivist learning environment. This consists of seven teaching-learning activities that aim at actively engaging students in class-based groupings of vertebrates. Using the strategies suggested by the family resemblance inspired theories, students were encouraged to think about vertebrates (a) by comparing new items with examples of each vertebrate class (*session 1*), and (b) by making lists of family resemblances for each vertebrate class *(session 2)*. Then, using the strategies that *classical theory* implies, children were encouraged (c) to make inferences about which of these resemblances are more usual and/or important for each vertebrate class (*session 2*), and (d) deduce the classes' 'key features' in order to differentiate between them (*session 3*). In sum, children had the chance to employ different categorization strategies throughout the sessions, like philosophers suggest we do in everyday life.

In more detail, the participants were divided into five mixed-level groups of 3-6 members and collaborated in all three sessions. In s*ession 1* (activity 1.1) students worked on a scenario about five small suitcases, each corresponding to one vertebrate class. Presumably, suitcases fell open, and the cards that were inside them fell off and got mixed; only two cards per suitcase remained in place. Each suitcase was assigned to one peer-group. Students were shown one by one the cards that fell off all the suitcases, and were asked to compare them to the two cards still inside their group's suitcase, in order to decide whether each card belonged to their suitcase and why.

In *session 2,* suitcases were assigned to different peer-groups, this time along with a *'features' list'* of the corresponding class. Students now had to identify how many members of the class had these features, by using the options *'all', 'some',* or *'none' (activity 2.1).* Then *(activity 2.2),* peer-groups exchanged suitcases again, were given 'animal-cards', 'features-cards' and *'all'*-/*'some'*-/*'none'*-cards, and they were asked to use them for creating *true* phrases about the depicted animals (e.g. *'some mammals fly'*; '*no bird has gills'*). Finally, they were presented with new animal cards and had to recognize which card belongs to which suitcase once more, but this time *not* by '*comparing to the class's examples'* like before*,* but by using *'features' lists' (activity 2.3).*

In *session 3,* students were asked to compare the lists of the five vertebrate classes and reject the features these lists had in common. Thus, they came up with the *'key features'* of each class *(activity 3.1).* Then *(activity 3.2)* students were asked to play a 'guessing' game. They were given lists of key or non-key features of unidentified animals and asked to guess to which vertebrate class these animals belonged. Finally, they were asked to create 'suitcase-tags' by articulating definition-like reasoning strands (e.g. *'If it has fur and is breastfed when young, it is a mammal'*), that could help put the cards back in place in case of another accident *(activity 3.3)*.

The pre/post questionnaire

The pre/post questionnaire included six open-ended items. Here we will present just three. The first two aimed at exploring how students' vertebrate groups may differ from the biological ones and why. Both these items relied on a scenario about a five-hall museum, with two animal exhibits of the same vertebrate class in each hall (hall 1: fox, squirrel; hall 2: eagle, sparrow; hall 3: snake, lizard; hall 4: frog, toad; hall 5: sea bream, sole). Someone supposedly donated sixteen new animal exhibits (bear, tiger, koala, dolphin, whale, bat, peacock, ostrich, penguin, crocodile, salamander, ray, seahorse, shark, swordfish and eel) to the museum. Students, having pictures of the animals at their disposal, were asked to distribute all new exhibits to the five halls (item 1) and justify *why* they chose to configure the halls as they did (item 2). Item 3 was designed to test students' ability to distinguish between features that characterize *all* the members of a vertebrate class from features that characterize only *some*. Students were given 10 propositions, two per vertebrate class, and they had to fill them in with a suitable quantifier (*'all'* or *'some')*. For instance, *'...... reptiles have scales'*, *'...... mammals lay eggs'* and so forth.

The analytic procedure

Students' responses to the items of the pre/post questionnaire were coded in *NVivo* as follows. Item 1 responses about the configuration of the museum halls with the new exhibits, were coded according to whether each hall was configured as a *'class-hall'* or not. So, we created an 'NVivo-attribute' per hall, we gave it the 'values' *'class-hall configuration: yes'* or *'class-hall configuration: no'* and we coded accordingly. In order for the first 'value' to be attributed to a response, students should have configured the hall by displaying in it (a) *all* the new exhibits that belong to the same class with the two already there, and (b) *no*ne that belongs to a different class. Responses that did not meet these two requirements *at the same time*, were given the value *'class-hall configuration: no'*.

Item 2 responses about *why* students chose to configure each hall as they did, were coded as *'naive', 'transitional'* and *'informed*'. Responses that justified the configuration of the museum-halls by appealing to the animals' class (e.g. '*They should go together because this will be the bird room')* and/or the class's key features (e.g. *'They are put here because they all have gills'*), were coded as *'informed'*. Responses that did not appeal to anything of the above were coded as *'naive' (e.g. 'They go together because they fly').* Finally, responses with *both* an *'informed' and* a *'naive'* part, were coded as *'transitional' (e.g. 'I've put them together because they give birth to babies and they breastfeed them)*.

Item 3 responses were coded with regard to how many propositions per vertebrate class were filled in with the appropriate quantifier *('all' or 'some')*. So, we created an 'NVivo-attribute' for each vertebrate class which we called *'correct quantifier'* (in short *'CQ'*), and since children had to fill in *two* 'same class'-propositions, we gave the attribute the three 'values' *'CQ_0', 'CQ_1', 'CQ_2',* and we coded accordingly. The coding of all items' responses was performed independently by two of the authors with a satisfactory agreement.

RESULTS

Configuration of the museum halls - Item 1

Analyzing students' pre/post responses about how they would configure the five museum halls by distributing the new animal exhibits to them showed that they made progress. In the post-test, the number of students who came up with *'class-halls'* (*'class-hall configuration: yes'* or *'CHC_yes'* in short) was always higher than in the pre-test; and so the number of students who did not come up with *'class-halls'* (*'class-hall configuration: no'* or *'CHC_no')* was always lower than in the pre-test (Figure 1).

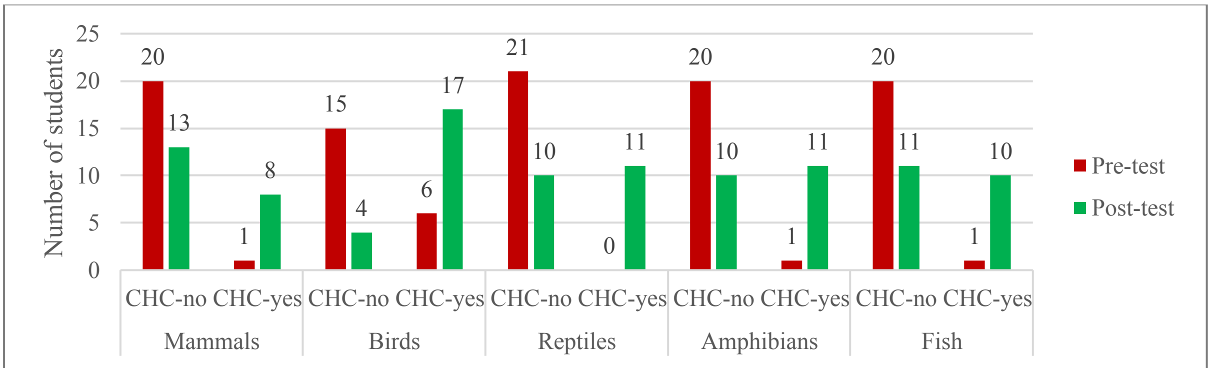

Figure 1. Class-hall ('CHC_yes') and non class-hall ('CHC_no') configurations - Item 1

More specifically, in the case of birds, the number of students with *'CHC_yes'* in the post-test (17/21) was much higher than the number of students with *'CHC_yes'* in the pre-test (6/21) (Figure 1). The results about mammals, reptiles, amphibians and fish were slightly different. The number of students with *'CHC_yes'* in the post-test was once more higher than the number of students with *'CHC_yes'* in the pre-test (mammals: 8/21 *vs.* 1/21, reptiles: 11/21 *vs.* 0/21, amphibians: 11/21 *vs.* 1/21, fish: 10/21 *vs.* 1/21); however, the number of students with *'CHC_no'* in the post-test, despite being reduced, it still remained rather high (mammals: 13/21, reptiles: 10/21, amphibians: 10/21, fish: 11/21) (Figure 1). Misclassifications revealed in non-class configurations of the halls concern whales (misclassified as fish), sharks (misclassified as mammals), penguins (misclassified as fish).

Justifications about the configuration of the museum halls - Item 2

The analysis of students' pre/post justifications about how they would configure the museum halls by distributing the new animal exhibits, showed progress as well. In the post-test, only a few students with class-hall configurations provided 'naïve' justifications for what they did (mammals: 0/8, birds: 3/17, reptiles: 2/11, amphibians: 3/11, fish: 3/10), whereas most of them provided *'informed' and 'transitional'* justifications (mammals: 8/8, birds: 14/17, reptiles: 9/11, amphibians: 8/11, fish: 7/10) (Figure 2). For instance, students configured 'hall 2' by distributing all the new bird-exhibits and none non-bird-exhibit to it *'because this is the group of birds'* ('informed' post-response); '*because they are all birds and because they all have wings'* ('transitional' pre-response); '*because they can fly'* ('naïve' pre-response).

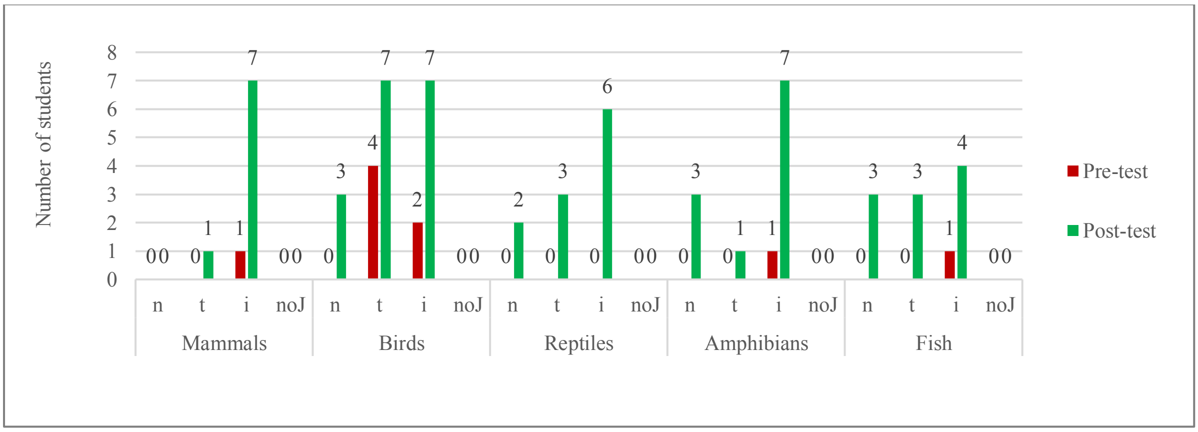

Figure 2. Justifying class-hall configurations ('CHC_yes') - Item 2

Moreover, all students with non-class-configurations (*'CHC_no')* in the post-test, gave much more *'informed'* and *'transitional'* justifications than *'naive'* ones: mammals: 13/13 vs 0/13; birds: 3/4 vs 1/4; reptiles: 7/10 vs 2/10; amphibians: 6/10 vs 1/10; fish: 8/11 vs 3/11) (Figure 3). The common mistake in *'CHC_no'* post-responses was including all the members of a class in the class hall together with a non-member, or, in some cases, leaving just one member of the class out of the hall. However, when they tried to justify their decisions, they would use 'informed' justifications. For instance, students configured 'hall 5' including the ray, the seahorse, the shark, the swordfish, the eel *and the dolphin* '*because these are the fish group'*. In other words, they did draw on the class of the animals in order to group them together, even though they had the misconception that dolphins are fish.

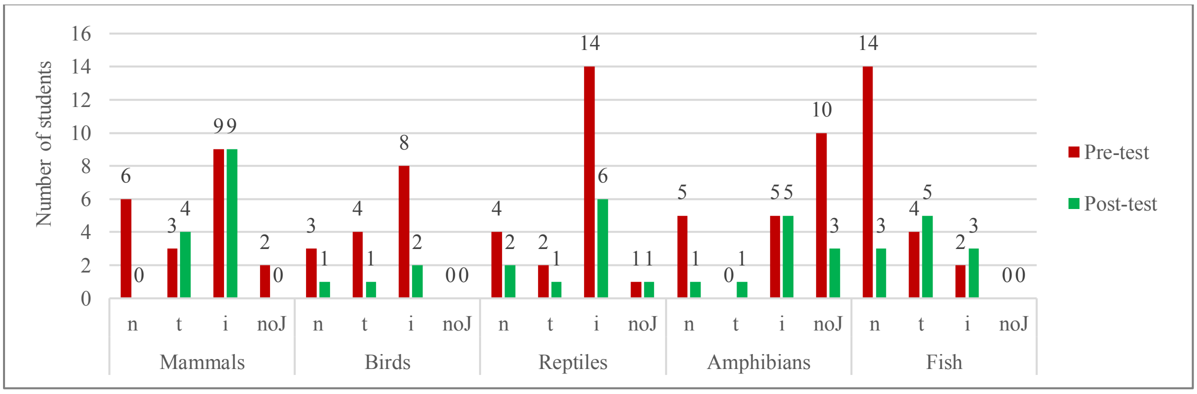

Figure 3. Justifying non class-hall configurations ('CHC_no') - Item 2

Use of the quantifiers 'all' and 'some'- Item 3

The analysis of students' pre/post-use of the quantifiers *'all'* or *'some'* with regard to the members of vertebrate classes, indicates progress as well (Figure 4).

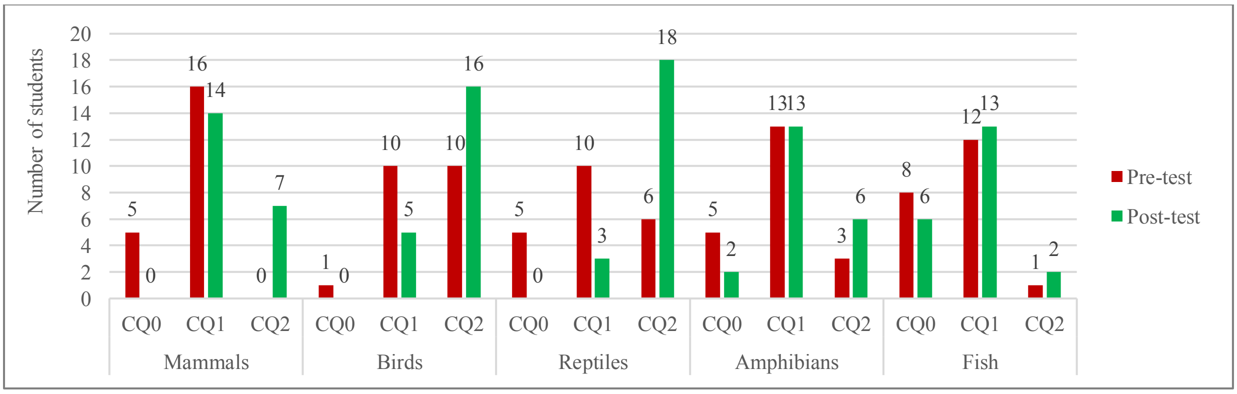

Figure 4. Use of the quantifiers 'all' and 'some' - Item 3

In the case of reptiles, the number of students who used the appropriate quantifier in *both* propositions *('CQ_2)*, increased quite remarkably in the post-test (18/21 *vs.* 6/21). In the case of mammals as well as in the case of birds, the number of students who used the appropriate quantifier in *both* propositions (*'CQ_2')* increased significantly (mammals: 7/21 *vs.* 0/21; birds: 16/21 *vs.* 10/21). On the other hand, in the case of amphibians, the number of '*CQ_2'* post-responses increased slightly (6/21 *vs.* 3/21), whereas fish seemed to trouble students even more: only two students used the appropriate quantifier in both propositions in the post-test (*'CQ_2'*: 2/21 *vs.* 1/19) (Figure 4).

DISCUSSION

According to the results, students made progress in grouping vertebrate animals in *class*-groups. After the implementation of the learning environment, class-groupings within the five-hall museum scenario became much more frequent. However, many students did not configure all their halls as class-halls. When justifying their configurations, most students in the post-test provided *'informed'* or *'transitional'* justifications, whereas only a few provided *'naïve'*. More interestingly, even children who came up with non class-groupings mostly provided *'informed'* or *'transitional'* justifications; that is, they appealed to the animals' class and/or the class' key features. So, even though they did not come up with *fully* class-configured halls, their justifications may indicate that they *did* wish to do so but they missed the correct information about specific animals. For example, they may have added one or two mammals in the hall they identified as the *fish* hall, because they did not know they were mammals; or they may have left one or two mammals out of the hall that they did identify as the *mammal* hall, just for the same reason. In other words, it seems that children grasped the overall idea of using biology-informed categorization strategies that involve class identifications or 'key-features' justifications, but they were unable to perform it adequately yet. Finally, students also improved their use of specific quantifiers (*'all', 'some'*) when reasoning about vertebrates classes. In the case of reptiles, mammals and birds, the number of students who used the appropriate quantifier in *both* propositions, increased quite remarkably. In the case of amphibians and fish, there was a slight increase, but results seemed less promising.

In sum, the first version of our learning environment worked quite well, not only with 5th graders as reported elsewhere (Valanidou, Ergazaki, & Gasparatou, 2019), but with 4th graders, too. It seems however, that there is still room for improvement. So, since the rationale of having students practice philosophy-inspired reasoning strategies in order to categorize seemed to pay off, we are considering extending our learning environment with more educational activities that could further promote students' understanding of biological classification.

REINFORCEMENT OF KNOWLEDGE ABOUT GERMINATION AND PLANT GROWTH: A CASE STUDY OF A LEARNING SUPPORT SYSTEM BASED ON FULL-BODY INTERACTION AND COLLABORATION

Through experiential learning, students not only obtain knowledge but also acquire the ability to solve problems; the former is necessary for the latter to be effective. However, most teaching relies on passive methods of learning, which has a negative effect on both student motivation and learning itself. Active learning methods can improve the impact of experiential learning. To this end, in this study we develop a prototype system that supports learning using collaboration and full-body interaction. We then apply it to a lesson at a primary school in Chiba, Japan, where multiple students learn about plant germination and growth conditions through quizzes and evaluate its effect. Our evaluation suggests that this system reinforces learners' knowledge of germination and plant growth conditions and that it is an effective tool for furthering students' learning.

Keywords: Active Learning, Collaboration, Primary School

INTRODUCTION

Experiential learning is vital to science education (Kolb & Kolb, 2005; Uitto & Nordström, 2017). For example, garden-based learning can help students acquire both knowledge and problem-solving skills (Robinson & Zajicek, 2005). To develop the latter, students must first identify problems through their own experiences. However, it is difficult to determine a problem simply through experience with no knowledge. Therefore, student learning is furthered when students first obtain any necessary knowledge and then deepen their understanding through hands-on experience (Rickinson, 2004).

Current approaches to teaching knowledge before experiential learning rely on watching videos and providing explanations: both of these methods involve explaining concepts to all students at once (Palmárová & Lovászová, 2012). However, since these are both passive methods, differences in student motivation result in differences in learning (Nicol, 2010). This may decrease the impact of experiential learning and must be addressed to ensure this tool's effectiveness. As one of the support methods, there is a learning support system for teaching knowledge before experiential learning (Fuse et al., 2003). This system reproduces the learning location on a computer. Students simulate experiential learning on a computer. Thereby, students learn the knowledge for experiential learning. However, in this system, since students use different computers, it is difficult to reduce the difference in student motivation. In addition, there is a problem that operation is difficult for students who have never used a computer.

Student discuss and learn effectively through collaboration with multiple people (Grabinger & Dunlap, 1995). Research shows that learning improves when body movement is incorporated into lessons (Norris et al., 2015). Therefore, we develop a prototype system that supports learning using collaboration and full-body interaction. We expect this system will help learners acquire knowledge actively and effectively.

In this paper, we describe developed learning support system using collaboration and full-body interaction and evaluate this system. In this system, students learn about germination conditions and plant growth condition. In order to evaluate this system's promotion of collaboration and full-body interaction, we conduced follow-up questionnaire. We also conducted the same tests before and after the system experience to evaluate improvement in knowledge of germination and plant growth conditions.

METHODS

Experiential Learning Model

Our model allows multiple students to simultaneously learn about germination and plant growth conditions using full-body interaction and collaboration. Figure 1 shows the system setup; it is comprised of two screens (one on the wall and the other on the ground), two projectors, a Kinect sensor, and a control PC. Three learners collaborate and discuss quiz questions about germination and growth conditions and answer using body movements. The system displays areas for answering each question and a plant seed or seedling on the wall screen. The floor screen, meanwhile, shows nine answer choices. Participants select three germination conditions (sunlight, water, moderate temperature) for seeds displayed on the wall screen from nine choices on the floor screen.

This system enables learning using bodily movements and collaboration by including an answer selection function to the floor screen through the use of a Kinect sensor. Kinect sensors acquire human skeleton coordinates as three-dimensional coordinates (Alabbasi et al., 2015). When the user stands on his or her choice of answer on the floor screen, the sensor obtains his or her position and compares it with the position of the answer choice and displays the user's response on the wall screen. If the user moves back and forth, new answers will display on the wall screen.

To foster collaborative learning, quiz answers are shared among participants. Nine answer choices are displayed on the floor screen in a 3x3 grid. Each participant selects one answer from three choices in a 1x3 grid. If each participant choices are correct, the quiz is correct. That is, participants need to collaborate, discuss, and find three correct answers to the quiz. Also, participants had time to discuss the quiz correct answers before answering the quiz.

When participants decide on their answers and step on the response, the wall screen displays whether students' answers are correct or incorrect. When all answers are correct, the seed image of the wall screen changes to the germinated seed image. When studying growth conditions, the seedling image changes the grown plant image. In the case of an incorrect answer, participants try again until they answer correctly. Visually presenting the answer, whether correct or incorrect, allows participants to feel a sense of accomplishment and to better remember their mistakes.

Figure 2. Lesson participants

Case Study

Participants

The participants were 45 sixth-grade students at Yamazaki Primary School in Chiba, Japan. We targeted all sixth-grade students at Yamazaki Primary School. We consulted with primary school and received permission, and we conducted an evaluation experiment. The evaluation experiment took place on October 12, 2018.

Study methods

First, we divided participants into 15 groups of three. Next, the participants experienced the developed system one group at a time. Students first took a quiz about germination conditions of a carrot. If they answered correctly, they had another quiz about carrot growth conditions.

We evaluated this system using a test and questionnaire. Participants answered the same six-question test before and after experiencing the system. Questions 1 to 3 asked about plant germination conditions and Questions 4 to 6 asked about plant growth conditions. Students were asked to select three out of nine choices: the same as those displayed in the experiential learning system. Students then received one point per correct choice. This allowed us to evaluate changes in knowledge.

We also created a questionnaire about the developed system based on the social presence module, a GEQ (Game Experience Questionnaire) that measures engagement in the game experience (De Kort et al., 2007; IJsselsteijn et al., 2013) (Table 5). We examined participants' involvement in psychological and behavioral games from three perspectives: psychological involvement-empathy, psychological involvement-negative feeling, and behavioral involvement.

The psychological involvement-empathy section included the following eight items: "I empathized with my friends," "During the quiz, I felt connected to my friends," "I found it enjoyable to do the quiz with my friends," "When I had fun, I think my friends also had fun," "When my friends seemed to have fun, I also had fun," "Taking the quiz together influenced my friends' feelings," and "My friends' emotions influenced my feelings," "I admired my friends." The psychological involvement-negative feelings section included the following three items: "This quiz game is fun," "I got angry with my friends," and "I was glad if my friends made mistakes or couldn't answer." The behavioral involvement measurement included the following six items: "During the quiz, I moved based on my friends' opinions," "During the quiz, my friends moved based on my opinions," "During the quiz, my friends paid close attention to me," "During the quiz, I paid close attention to my friends," "During the quiz, my friends' opinions influenced my movements," and "During the quiz, my opinion influenced my friends' movements." Answers were graded using a five-step Likert scale.

RESULTS

Tables 1 and 2 show the mean, median, and mode test scores of the quizzes conducted before and after our experiential learning activity. Tables 3 and 4 show the distribution of scores before and after the activity. Using a sign test, we investigated the bias between the number of participants whose score improved and the number of participants whose score decreased. We found a significant difference for both germination and plant growth conditions.

Tables 3 show participant responses to our questionnaire. We classify participants' replies into positive responses ("strongly agree," or "agree") and neutral or negative responses ("no strong opinion," "disagree," or "strongly disagree"). We then analyzed the differences between the number of positive, neutral, and negative replies for each item using a 1x2 Fisher's exact test.

All eight items of the psychological involvement-empathy section show more positive than neutral or negative responses. There is a significant difference between the number of positive responses and neutral or negative responses. This indicates that empathy occurred during social game play.

All three items of the psychological involvement-negative feelings section show more neutral or negative answers than positive answers. There is a significant difference between the number of neutral or negative responses and positive responses. This indicates that participants have no negative feelings toward one another during social game play.

Finally, all size items in the behavioral involvement section show more positive responses than neutral or negative responses. There is a significant difference between the number of positive responses and neutral or negative responses. This indicates that all participants showed active behavioral involvement during social game play.

CONCLUSION

In this study, we developed a learning support system based on full-body interaction and collaboration and evaluated it using a case study. Participants learned germination and plant growth conditions using this system. We evaluated this system using follow-up questionnaire and tests about germination and plant growth conditions. As results of follow-up questionnaire, we confirmed that participants experienced this system using collaboration and body movements. As results of tests about germination and plant growth conditions, we confirmed that Participants' scores improved before and after the system experience. This suggests that this system reinforces participants' knowledge of germination and plant growth conditions using collaboration and full-body interaction. We conducted this experiment for only sixth-grade students in primary school. In the future research, we will evaluate this system for other grade students in primary school.

ACKNOWLEDGMENTS

This research was supported by JSPS Grant-in-Aid for Scientific Research (B) Grant Number 17H02002. This evaluation experiment was supported by Yamazaki Primary School, Chiba.

SCIENTIFIC COMPETENCY AND HUMAN NUTRITION IN PRIMARY SCHOOL TEXTBOOK IN SPAIN AND PORTUGAL

Juan-Carlos Rivadulla-López[1], *Susana García-Barros*[1], *María-Jesús Fuentes-Silveira*[1] *and Cristina Martínez-Losada*[1]
[1]Universidade da Coruña, A Coruña, Spain

A total of 671 activities on human nutrition included in Primary education school texts in Spain and Portugal, produced by six different widely spread publishers, are analysed. The purpose of this paper is to learn to what extent these activities promote scientific competency. In order to collect the necessary data, an analysis dossier was elaborated, taking the abilities associated with scientific competencies determined by PISA 2015 (OECD 2016) as its reference. Furthermore, the basic cognitive abilities related to acquiring scientific knowledge which were identified in the activities are also added. Four types of ability were defined to undertake this analysis, and their respective sub-categories were likewise established. The findings show that chiefly basic cognitive abilities (type I) were included in both countries. On the other hand, the Portuguese textbooks, in their activities, include a greater number of specific abilities requiring scientific literacy (types II, III and IV)) than the Spanish, although they focus on those that are less demanding in terms of cognitive requirements. Besides, the activities of both publishers mostly promote one type of abilities. Schoolbook text writers ought to take these findings into account so as to be able to improve their texts. Moreover, these data are a wake-up call to those in charge of teacher training, as such training should enable teachers to have the capacity to select those activities aligning the most with the guidelines for scientific competency.

Keywords: Primary School, Scientific Competences, International Studies in Education.

INTRODUCTION

Furthering scientific competency is crucial to young people's education and training, as they will find themselves facing situations and issues stemming from the globalised high-tech world they live in (Pedrinaci, 2012). In this sense, the latest report from PISA (OECD, 2016) defines scientific literacy as the ability to interact with socio-scientific issues and Science itself as a reflective citizen. Furthering such skills entails acquiring knowledge, skills or attitudes (OECD, 2002) i.e., specific competencies requiring scientific literacy: explaining phenomena scientifically; assessing and designing scientific enquiring; interpreting data and evidence scientifically (OECD, 2016). It is also common to foster other basic cognitive abilities related to acquiring specific basic contents - identifying features, comparing...

Likewise, research has emphasised the relevance of applying different abilities to both personally and socially relevant contexts (Blanco & Lupión, 2015). In addition, science knowledge must be useful//serve//allow to explain scientific phenomena as well as promote a responsible behavior (Cañal, García-Carmona & Cruz-Guzmán, 2016). In this sense, a topic of special importance is human nutrition (en inglés probablemente se pondría al revés). Such a topic is included repeatedly across throughout compulsory education, highlighting the importance of addressing its study from an early age (Alburquerque, Pontes & Osório, 2013). Therefore, the study of human nutrition shall contribute, among other aspects, to the development of nourishment competency (Cabello, España & Blanco, 2016). Developing this competency goes beyond the academic knowledge and enters the personal and social needs of the citizenship (Rivadulla, García & Martínez, 2017).

Furthering scientific competency hinges on how teachers promote it in their classrooms (Blanco-López, España-Ramos, González-García & Franco-Mariscal, 2015; Lupión-Cobos, López-Castilla & Blanco-López, 2017) and on the quality of the teaching materials they use. In this respect, schoolbook texts are the most commonly used material among teachers in Spain and Portugal (Rivadulla, García & Martínez, 2017), as well as internationally (Yun & Park, 2018). In this regard, teachers trust and use textbooks to plan their lessons and their experimental activities in the classroom. Likewise, textbooks are the most convenient source of information for students to read and complete their school tasks (Enero Upahi, Ramnarain & Saheed Ishola, 2018).

On the other hand, research has consistently demonstrated how science textbooks tend to dictate - to a great extent - the content to be taught (including the activities to be developed as well as the discourse finally delivered in most science classrooms) (Abd-El-Khalick, Myers, Summers, Brunner, Waight, Wahbeh, Zeineddin & Belarmino, 2017). It has also been shown that in recent decades an array of activities labeled as inquiry, exploring and/or research tasks have been incorporated to textbooks, although they remain scarce (Yang, Liu & Liu, 2019).

So it is that this paper endeavours to find out to what extent Primary education textbooks from Spain and Portugal promote acquiring scientific competency amongst pupils. The analysis is focused on the activities included in those books, since scientific competency is shown by action (Sanmartí & Márquez, 2017). To narrow down our study, the issue of human nutrition was chosen, which facilitates explaining facts/phenomena in an integral way as well as making justified decisions with regard to personal behaviour (Rivadulla et al., 2017).

METHODOLOGY

The activities about human nutrition included in year 6 textbooks (11-12 years) pertaining to three widely used publishers in Primary Education in Spain– Anaya, Santillana and SM (henceforth referred to as A, B and C respectively) – and in Portugal were considered –Areal Editores; Porto Editora y Lisboa Editora (D, E and F respectively). 671 activities were analysed: 226 taken from the Spanish publishers and 445 from the Portuguese ones.

A dossier taking four types of ability into account was elaborated, based on what is taken into consideration in our introduction. Three of them (II, II and IV) are related to scientific competency (OECD, 2016), and another one is related to basic cognitive abilities (I). For each one of them, relevant sub-categories were established:

- Type I: basic cognitive abilities (identifying features, establishing relationships, comparing/ordering and defining or conceptualising what something is).

- Type II: abilities related to using knowledge in specific (describing what is happening, explaining phenomena scientifically and justifying by means of theories why it is happening).
- Type III: abilities related to assessing and designing scientific research (observing, searching for information from different sources, putting forth hypothesis and designing strategies performing experiments to obtain data).
- Type IV: abilities associated with interpreting data and evidence in a scientific manner (analysing data, reaching evidence-based conclusions, arguing in favour or against them).

In table 1 some examples of activities from different publishers associated to each ability are presented.

Table 1. Examples of activities associated to the different abilities.

	Abilities	Activity examples
Type I	Identifying features	Identify and locate the main organs involved in carrying out the life functions in the human body (Spanish publisher). Among the following variety of foods, select those ones that could be part of a healthy menu for your lunchtime... (Portuguese publisher).
	Establishing relationships	Match different daily life practices with an appropriate functioning of the body... (Spanish publisher). Establish relationships between the numbers contained in the diagram (showing the main functions of nutrients) and the following terms: lipids, carbohydrates, proteins… (Portuguese publisher).
	Comparing / Ordering	What is the difference between urine and sweat? What do they have in common? (Spanish publisher). Put in order the words in the sentences so that you describe chronologically the phenomena that take place in the oral cavity… (Portuguese publisher).
	Defining	Define the following terms: a) blood circulation; b) excretion (Spanish publisher). What is a healthy food? (Portuguese publisher).
Type II	Describing facts/phenomena	Describe the main characteristics of two systems involved in nutrition (Spanish publisher). What are the additional benefits of the product referred in the text *(vegetables)*? (Portuguese Publisher).
	Explaining	Tell the reason why during systole, blood does not flow backward from the ventricle to the atrium (Spanish publisher). What would happen to nutrition if any of these systems failed? A) excretory system; b) respiratory system (Portuguese publisher).
	Justifying	Why is it better to breathe through the nose than through the mouth? (Spanish publisher). When we run, we breathe faster than when we are still. Why does this happen? (Portuguese publisher).
Type III	Observing	Observe the diagram and write down a brief summary of the factors that have an influence on our health (Spanish publisher). Observe attentively the label from a soft drink and answer the following questions… (Portuguese publisher).
	Searching for information	Using ICTs, search how much air lungs can hold (Spanish publisher). Search information about how many children in Portugal are overweight… (Portuguese Publisher).
	Designing evidence	No examples in Spanish publishers' textbooks have been found. Using a spirometer, we can know how much air can be hold in our lungs. Build a spirometer using a bowl, a water bottle and a piece of hose (see photo). How much water was drained when you blew into the bottle? (Portuguese publisher).
	Experimenting	Researching. Building a model of a lung (Spanish publisher). Which food contains starch? Carry out the following experiment... (Portuguese publisher).
T	Analysing data	Read the following document and explain what a transfusion is (Spanish Publisher).

		Record in a table the results from measuring the pulsations. Explain how pulsations change throughout the experiment (Portuguese publisher).
	Elaborating conclusions	Evaluate the table elaborated by your classmate to check it agrees with the requirements of a healthy diet (Spanish Publisher). Taking into account what you know about nutrition and circulation, explain why we obtained those results (Portuguese publisher).
	Arguing	Imagine you are participating in a television debate about the convenience of having emergency services for all citizens. Prepare your arguments and discuss them in classroom (Spanish publisher). Write down three reasons you would give a smoker to quit (Portuguese Publisher).

FINDINGS

Our findings show that, in Spain, Type I abilities predominate in the activities provided by all the publishers (82.3%), the second most common abilities being Type II (39.8%). In Portugal Type I abilities prevail (60.4%) and II (57.3%), yet in a more balanced way, though there is a certain difference between the publishers, as D and F promote Type I abilities (70.1% and 60.3% respectively) to a larger extent, whereas E promotes Type II activities (62.9%). Type III and IV abilities are used to a lesser degree, being slightly more numerous in Portugal (30.1% and 29% respectively) than in Spain (2.7% and 14.6%). In connection with these two abilities, there are hardly any differences between the publishers in Spain, whereas Type IV abilities are more frequently found in Portugal in publisher l D (53.3%) (Table 2).

More specifically, identifying features is the most frequently found Type I abilities in both countries (60.2% in Spain versus 39.6% in Portugal). As far as Type II abilities are concerned, differences between Spain and Portugal clearly noted. The Portuguese publishers especially promote *describing* (41.3%), whereas the Spanish ones, exception for publisher A, further the three Type II abilities in a more balanced way. Within the Type III abilities, *observing* (20.9%) prevails in Portugal as opposed to *searching for information* (4.7%), whereas both abilities are virtually equal in Spain (10.6% y 10.2% respectively). *Designing evidences* and *experimenting* are scarcely included in the activities found in both countries. Within the Type IV abilities, *analysing information* is the most usual one, especially in Portugal (24.3% versus 9.3% in Spain), and in texts by publisher D in particular. *Elaborating conclusions* and *arguing* represent rarely promoted abilities, the latter being found somewhat more often in Spain (5.3%) than in Portugal (0.9%).

* % of activities including some ability of that Type

When analysing each activity individually, we observed that all publishers, either Spanish or Portuguese, tend to address just one type of ability per activity (figure 1). The number of activities where two types of abilities are worked on is clearly inferior. In this case, there are differences between the Spanish and the Portuguese textbooks, having detected this sort of activities to a greater extent in the former (between 20% and 30.9%) than in the latter (between 13.5% and 27.1%). On the contrary, Portuguese publishers include more activities where three types of abilities are covered (between 17.5% and 27.1%) compared to the Spanish ones (between 4.9% and 10.5%). Publishers that incorporate activities involving the use of the four types of abilities are a minority in both countries (5.3% in total in Spain and 6.7% in Portugal).

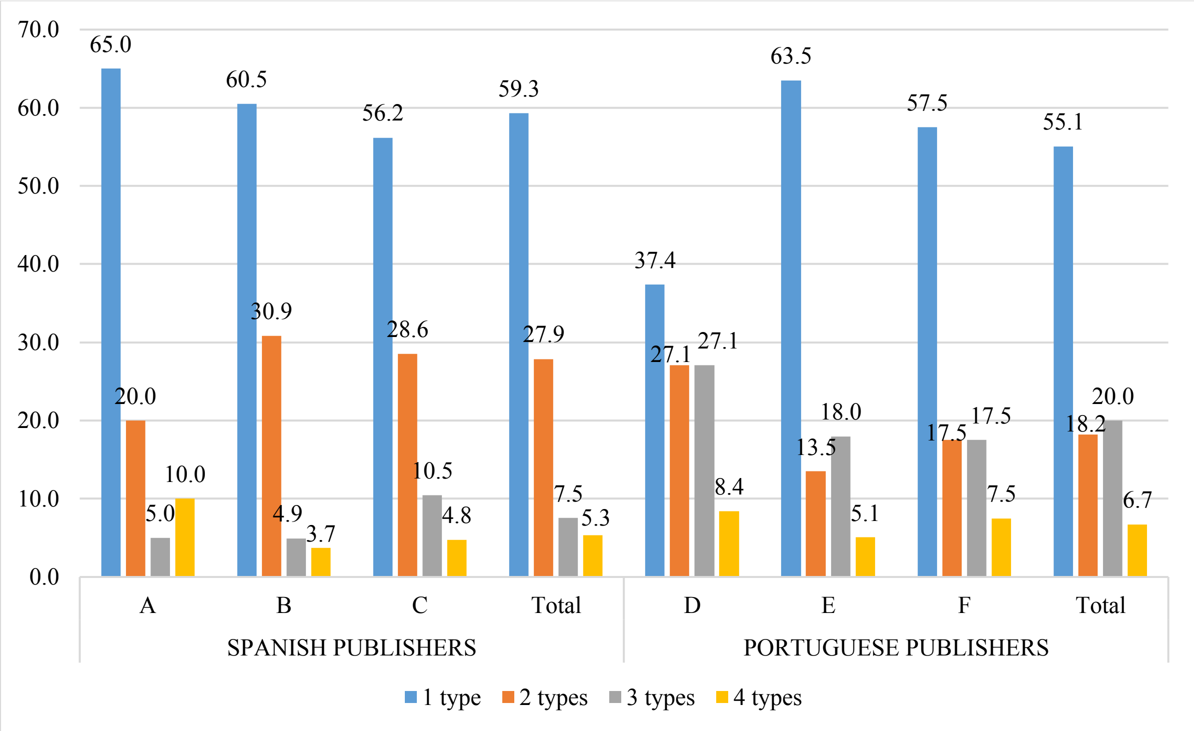

Figure 1. Percentage (%) of activities found in books by publishers where one or more types of skill are dealt with.

CONCLUSIONS

The publishers from Spain and Portugal promote different types of ability through the activities in their textbooks, where not only similarities but also differences are detected. The publishers from both countries, and the Spanish ones in particular, mainly further basic cognitive abilities in their activities, i.e. Type I, related to scientific knowledge itself. The Portuguese ones include more Type II, III and IV abilities (associated with scientific competencies) in their activities than their Spanish counterparts, Spain, although the Type III and IV ones are less seldom practised. The publishers from both countries tend to further those abilities found in each Type which are less demanding from a cognitive point of view, and the Portuguese ones more so than the Spanish.

In general, most of the activities from the publishers from both countries promote just one type of ability. Activities involving two or three types of abilities are less frequent and very few activities address all the four types of abilities.

Despite the differences between the two countries, a deficit is noted, in both countries, in the field of furthering the abilities related to assessing and designing scientific enquiry as well as to interpreting data and evidence scientifically, whereas acquiring scientific knowledge and using it to explain phenomena scientifically is favoured. These data constitute a wake-up call to textbook authors, as well as to those in charge of teacher training, since they are the people responsible for deciding what types of activity children are to do in order to achieve solid scientific training as early as Primary School.

THE PROJECT-BASED LEARNING: IMPACT ON LEARNING OF GEOLOGY BY SYRIAN REFUGEE GRADE 6 STUDENTS

Pauline Abdouche[1], *Assaad Yammine*[2]
[1] Lebanese University-Faculty of Pedagogy, Beirut, Lebanon,
[2] Lebanese University-Faculty of Pedagogy, Beirut, Lebanon,

The war in Syria has an impact on the entire population in general and especially on young people. Indeed, young Syrian refugees who have experienced the war are in a state of trauma that hinders their normal development, be it physical, emotional, behavioral or even at school level (concentration problems and/or learning, school delays due to long stays in refugee camps ...).

Geology is, therefore, a difficult field to address for both students and teachers. In order to familiarize primary school students (grade 6) with this theme, we have set up and realized a pedagogical project at the "Janah" educational center that deals with Syrian refugee students enrolled in public schools in Lebanon.

Working geology with refugee students has been a challenge for us given the double complexity of the topic on one hand and the population concerned on the other. We integrated project-based learning (PBL) into teaching in order to introduce grade 6 students to some basics in geology. We also sought by this approach to develop the motivation and autonomy of these students. Several tests were conducted before and after our intervention in order to study the effect of project-based learning on the motivation, autonomy, and success of the students. The results show that the PBL develops students' motivation and involves them more in learning situations while starting from their interests and promoting their cognitive engagement. In addition, PBL promotes their autonomy, awakens their sense of responsibility by integrating them into teams where they collaborate and communicate in order to solve problems or achieve a product. Our work has also shown a marked improvement in the acquisition of knowledge.

Keywords: Project-based learning, Primary school, Motivation

1- INTRODUCTION

Education today must aim to develop the communication and interpersonal skills of the students by submitting them to team work that promotes cooperation and collaboration between different members of the same team. In order to meet these needs and requirements and to achieve what education advocates for developing in students, different teaching methodologies are implemented. Among these promising methodologies, we particularly distinguish the project based learning (PBL). This approach puts students in situations of choice based on their interests, communication, teamwork, unsupervised work time and responsibility. Throughout the stages of the realization of the project, the pupil acquires knowledge, know-how and well-being. He then masters new knowledge and new attitudes (Belagra et al., 2014). As a result, the student becomes an actor of his / her learning, which consequently promotes the development of his / her autonomy. In addition, this approach allows more students to access learning and thus develop their potential in order to take charge, in the future, of the roles they have in society, whether in relation narrow with citizenship, work, family, learning, etc. (Gregoire et al., 1998, 2001). Indeed, for Huber (2005), "by developing analytical skills and a methodology of action, the young person will use his skills in his professional project and in his life project. This pedagogy then enables the young person to develop skills and knowledge that help him to structure and organize the situations he will face in his future life.

The war in Syria has an impact on the entire population in general and on young people who are between 12 and 14 years old. Young Syrian refugees experienced the war. Therefore, they are in a state of trauma that hinders their normal development, whether physical (sleep disorders, eating disorders ...), emotional (anxiety, dependencies ...), behavioral (hyper vigilance, irritability ...) or at school level (problems of concentration and / or learning, school delays related to long stays in refugee camps ...). All this influences the psychological development of the child and, consequently, his level of learning. "The personal and psychosocial responses that each refugee child draws from his memories and experience do not go away when he walks through the door of the school. He brings with him this emotional and social baggage and educators must take this into account. (Meyers M. 1993, cited in Azdouz 2003). As a result, these students find themselves behind school and - when they are re-enrolled in public schools in Lebanon - have to deal with a demotion at a class level or at a level that does not correspond to them. This causes a loss of interest and motivation for any activity and causes a feeling of rejection and failure at home.

The teaching of geology is confronted with several obstacles that hinder the acquisition of learning in this theme, whether at the epistemological, didactic, ideological, etc ... and which present difficulties for both students and teachers. This science is an important part of French and Lebanese school programs in the different school cycles. It is also very useful at the cultural level, because it explains most of the natural phenomena that occur around us, on the surface of the earth and at the level of deeper layers. Students find many difficulties and become demotivated and disinterested during geology lessons because this knowledge is not included in their daily lives and represent for them something virtual. This leaves a negative impact on their academic achievement. The use of new pedagogical approaches is thus necessary.

Working geology with refugee students is a challenge for us given the dual complexity of the topic on the one hand and the population concerned on the other. Our job is to integrate PBL into the teaching of geology. In order to introduce grade 6 students, going to the complementary cycle, to the geology part, and to familiarize them with these future learning. We also seek by this approach to develop motivation and autonomy of the student to acquire learning objectives in this part. This leads us to ask ourselves: Can PBL develop the autonomy and motivation of refugee students and, subsequently, ensure that they acquire better learning objectives in geology? The results of our research will identify, verify and confirm to what extent the PBL contributes and leads to the development of motivation and autonomy, as well as to the appropriation of the notions of geology by refugee students. This will promote the integration of project pedagogy into the systems and schools that deal with pupils requiring specific support.

2- METHODOLOGY

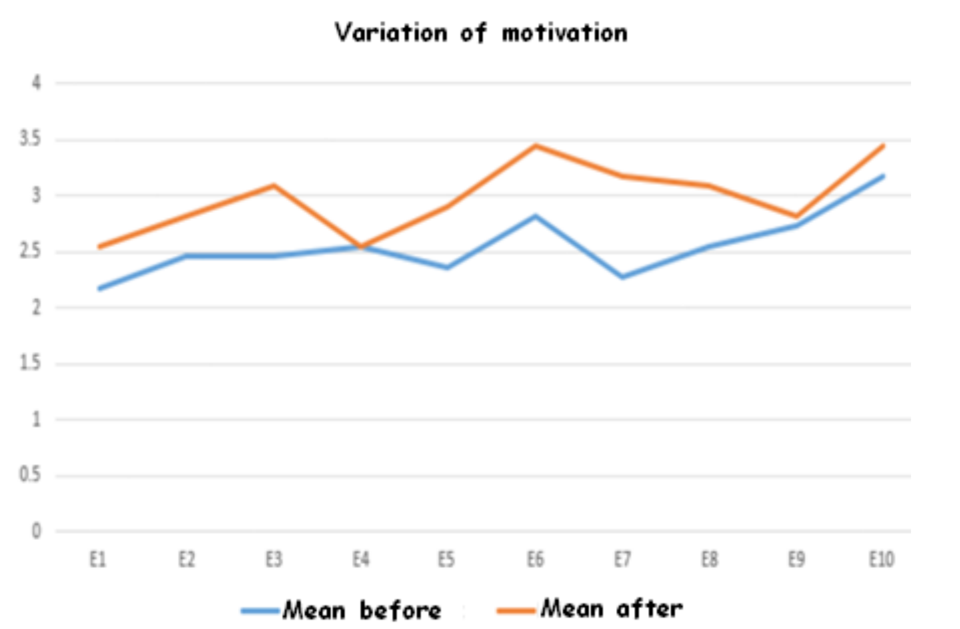
Our research aims to study the impact of project pedagogy on the motivation and autonomy of refugee students on the one hand and the acquisition of learning objectives in geology on the other hand. Our study was supported by the French organization "Semeurs d'avenir". This NGO is part of the IECD (European Institute of Coordination and Development) organization which supports the educational project that supports children and young people who come from vulnerable families (Lebanese and refugees). The educational center Janah, in which we work, is associated with the organization "Semeurs d'avenir". This center is interested in Syrian refugee students. It welcomes immigrant students who are enrolled in public schools and helps them to overcome the obstacles they face, on the one hand psychologically and socially and on the other hand, at the educational level. The sample consists of ten students of grade 6 class (three boys and seven girls), belonging to the same age group (12-14 years). Two hours a week are devoted to design, implement and evaluate the project, during the summer period (July-August 2018). Data collection was done through tests of knowledge, motivation and autonomy (one test at the beginning of the project and a second at the end).

3- RESULTS AND DISCUSSION

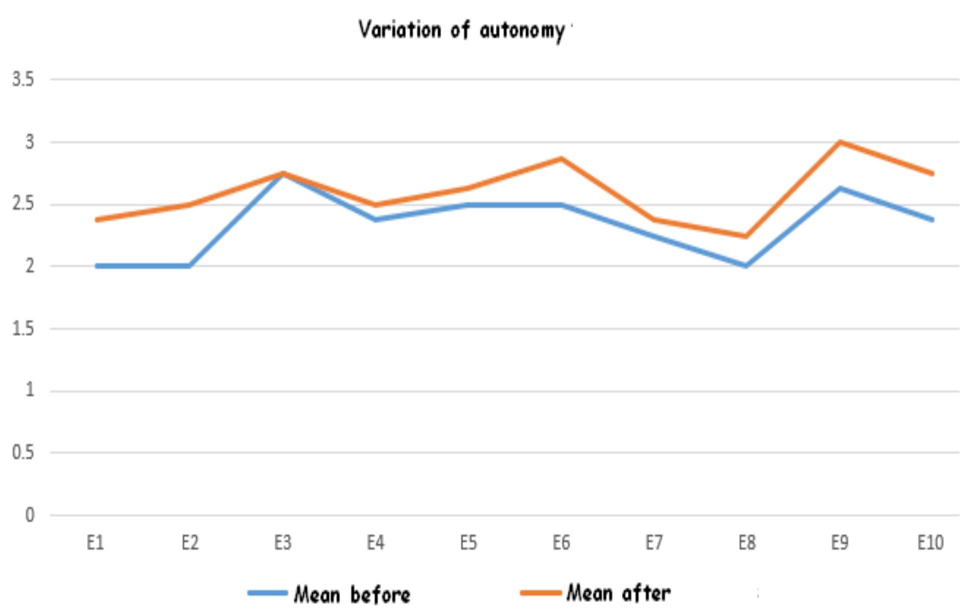
Our research enabled us to put 10 refugee students of the EB6 class, in a situation of introduction to geology through project pedagogy. Students were invited to work together and conduct research to learn and acquire the concepts, design a final product, the result of their learning and introduce it to others.

3.1- Analysis of test results assessing motivation and autonomy before and after the intervention of the PBL:

The particularity of our work is in testing the impact of project pedagogy on refugee students with psychological, social and academic difficulties. Indeed, the project pedagogy has stimulated the motivation of Syrian refugee students who have overall academic difficulties, to learn geology, considered one of the most rigid, difficult and incomprehensible topics for students and teachers, while promoting their autonomy. Comparing the results also allowed us to reveal the change in our students' motivation (graph 1) and autonomy (graph 2).



Graph 1: Variation in means of student motivation before and after application of PBL.



Graph 2: Mean Change in the autonomy of the students before and after the implementation of PBL.

Graphs 1 and 2, above, show that the average motivation and autonomy of the majority of students has increased after the application of PBL. But this increase is not the same for all students.

PBL seems to have a positive impact on the motivation and autonomy of refugee students. This impact seems to be associated with other factors to be defined.

3.2- Analysis of achievement test scores:

Graph 3: Variation of average marks of students in the achievement tests before and after the application of the PBL.

Graph 3 above shows a variation of the averages of the different tests done with the pupils, before and after the implementation of the project. We observe a significant increase of the average of 6.5 / 20 in the 1st prerequisite test carried out before the application of the project, to reach approximately 17/20 at the 3rd test level, final test carried out at the end of the project for test the notions acquired by the students.

This shows that the PBL approach has favored the acquisition of the notions of geology in refugee students.

Our results on motivation are consistent with the work of Genest and Pellaton (2012), where student motivation increased after the project was completed, but this increase was subject to fluctuations. It is raised at the beginning of the apprenticeship, and then drops in the middle of the project, so that it increases again during the implementation of the final product. Talbi et al. (2007) did not notice a development at the level of autonomy, which is contrary to our results. In fact, we had an increase in the level of autonomy itself that this increase was low. Our results also showed a clear improvement in knowledge following the implementation of project pedagogy. From the results obtained, we note that project pedagogy has a positive impact on the acquisition of targeted learning in geology. This is manifested by the remarkable increase in student marks in knowledge tests. These results are consistent with those of Lebrun (2002) who claims that PBL allows students to acquire knowledge better. Similarly Huber (2005) states that the student is mobilized during the implementation of the project, and that the resolution of problems encountered during this realization will promote the production and mobilization of new skills and knowledge. We were also able to confirm this statement thanks to the recovered results of the notes and the public presentation of the final product. Despite all the limitations we faced in carrying out our project, we find that this approach has greatly influenced the motivation of refugee students who have enough difficulties at school level than at the psychological level. It has stimulated and stimulated their desires and interests towards the theme while giving them the chance to take the initiative in their work and to be autonomous. This active role of the students, their cognitive engagement and responsibility, make the learning sound and help to memorize it in the long term, because the students have not just studied notions that are passed on to them but they have even learned and deeply understood these notions. They played their true role, the role of the "learner".

A TEACHING APPROACH ABOUT NANOSCALE SCIENCE AND TECHNOLOGY CONTENT: EVALUATION OF PRIMARY SCHOOL STUDENTS' LEARNING

George Peikos, Anna Spyrtou, Dimitris Pnevmatikos and Penelope Papadopoulou
University of Western Macedonia, Florina, Greece

Many researchers support the need for incorporating Nanoscale Science and Technology (NST) concepts in all levels of education. However, the related research in primary school is in its infancy. In this paper, we present a pilot teaching approach about NST content addressing to primary students (6th grade). The teaching approach included three components of NST: concepts, phenomena and applications. Our research aimed to investigate to what extent did students improve their ideas concerning the NST content after the implementation of the teaching approach. The data were collected via pre and post written questionnaires and analyzed qualitatively in order to create levels of understanding for primary students' ideas. The Wilcoxon test showed that students improved their conceptualization of the term nanotechnology, the concept of size and the lotus effect.

Keywords: primary school, conceptual understanding, science education

INTRODUCTION

Nanoscale Science and Technology (NST) is an interdisciplinary research field focusing on the manipulation of matter as well as on the exploitation of the unique materials' properties, in the nanoscale (1-100 nm) (Lin, Wu, Cho & Chen, 2015). The incorporation of NST concepts in all levels of education is supported by many researchers (Blonder & Sakhnini, 2016; Manou, Spyrtou, Hatzikraniotis & Kariotoglou, 2018; Stevens, Sutherland & Krajcik, 2009). Since students already use NST products, the need to develop a new aspect of their science and technological literacy, called nanoliteracy, has emerged (Laherto, 2010; Manou et al., 2018). School science curricula are focused on a macro or/and atomic scale to explain abstract concepts such as density (Wiser & Smith, 2008). However, in order to explain phenomena and applications such as superhydrophobic textiles, there is a need to use the nanoscale. This intermediate gap (the neglection of nanoscale between macro and atomic-scale) deprives students form the development of an explanatory model consistent to the scientific view about the non-observable causes that explain how a phenomenon works (Vosniadou, 2013). Moreover, the interdisciplinary nature of NST, the "mysterious" phenomena and the related applications have the potential to increase students' interest towards NST carriers. It is argued that elementary students may constitute the future workforce to be occupied in nano-related fields (Lin et al. 2015).

In this paper, we present a pilot teaching approach about NST topic as well as its impact on students' learning. The research question was the following: To what extent did primary students improve their ideas concerning NST concepts and phenomena after the implementation of the approach?

METHOD

Participants

The participants were 22 primary school students (aged 11-12), attending an urban public primary school.

The units of the teaching approach

In the teaching approach, we introduced five essential concepts qualitatively: (i) Size, (ii) Tools, (iii) NST Applications, (iv) Size-dependent Properties-Lotus effect, and (v) Models (Blonder & Sakhnini, 2016; Manou et al., 2018; Stevens et al., 2009). The teaching approach aimed to enhance students' understanding of how nanoworld affects macroworld. The cycles and the branches of Figure 1 represent the essential concepts and the specific content respectively that were included in the teaching approach. For example, in the case of the "NST Applications", we comprised in the approach the hydrophobic surfaces e.g. self-cleaning textiles and the nano-filter water purification systems.

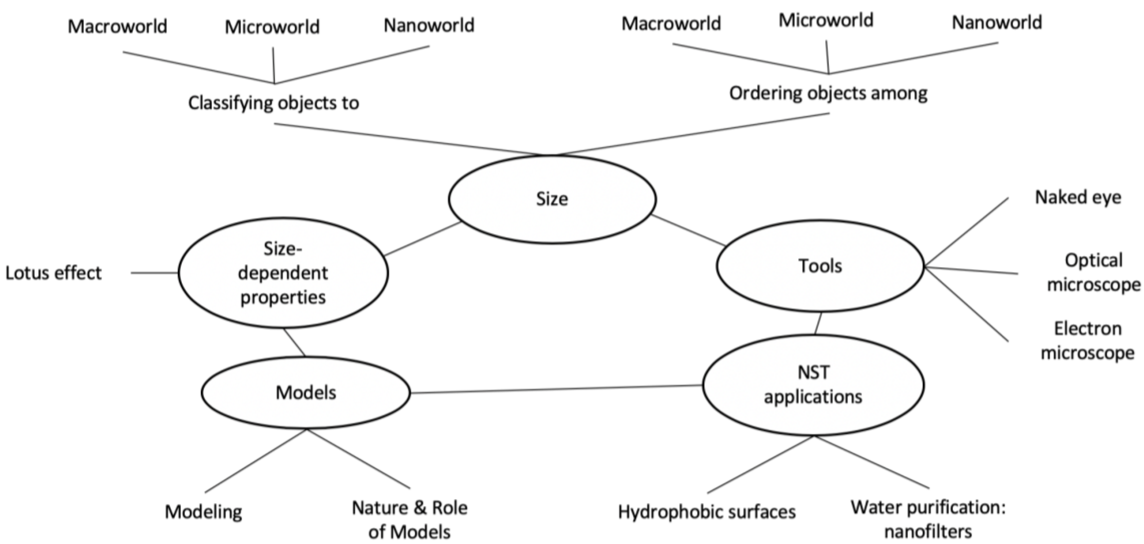

Figure 1. The essential concepts of the teaching approach.

We designed six units of two-hours duration each, in a way that that the five essential concepts were gradually introduced. The activities that were included were inspired by related literature in non-formal education settings (e.g. Filipponi & Sutherland, 2009) and corresponding online resources such as presented in nisenet.org. Table 1 presents the units of the approach and the intended learning outcomes.

Table 1. The units of the teaching approach and the intended learning outcomes.

The units of the teaching approach	Intended learning outcomes *Students will be able to*:
1. Macroworld 2. Microworld 3. Nanoworld	(a) Classify various sizes objects into the macro, micro and nanoworld based on the observation tool (naked eye, optical microscope, electron microscope), and (b) order macro, micro and nanoworld objects based on the qualitative criterion "which object is part of the other or fits into the other". (Essential Concepts: Size, Tools, Models).
4. The case of viral infection	Describe how nanoworld affects the macroworld in the case of viral infection using concepts as virus, cells, the human body. (Essential Concepts: Size, Tools, Models).
5. The Lotus effect	(a) Explain the phenomenon using the concept of leaf's nanostructure (nanobumps) or the hydrophobicity, and (b) recognise commercial products that mimic the lotus effect. (Essential Concepts: Size, Tools, Size-dependent Properties, NST Applications, Models).
6. Water purification using nano-filters	(a) Explain the filtration mechanism using the concept of the nanopore, and (b) recognise how NST contributes to the solution of the potable water shortage problem. (Essential Concepts: Size, Tools, NST Applications, Models).

The first unit included inquiry-based activities about macroworld, namely the human-world. Specifically, students collected small visible objects from the schoolyard, which they compared them according to their size. Also, they created models of the collected objects using playdoh and presented them into the class. Then, the teacher introduced aspects about the nature and role of models (e.g. the models focus on specific aspects of the objects) (Schwarz et al., 2009) and the students reflected about their designs. It is pointed out that a scaffolding instruction about the nature and role of models was adopted (Zoupidis, Pnevmatikos, Spyrtou, & Kariotoglou, 2016). So, in each unit, new aspects were introduced, or reflective discussions were conducted. Afterwards, the students placed their models in the first part of a classification poster, which was named "macroworld" (Figure 2, left part). In the end, they discussed the observation tool of the macroworld objects, namely the naked eye.

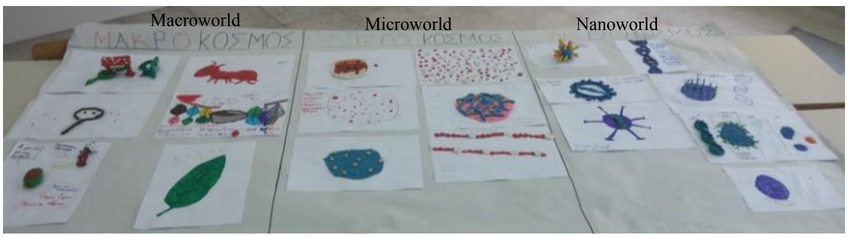

Figure 2. Classification poster created by the students.

In the second unit, the inadequacy of the naked eye for seeing an object smaller than a strand of hair triggered discussions that oriented towards microworld. Students studied onion cells and red blood cells using optical microscopes (Figure 3), guided by appropriate worksheets. They also searched for information about them within printed recourses, and they created models of onion cells, their nucleus and the red blood cells. Then the models were placed on the second part of the classification poster, the microworld (Figure 2, middle part). The optical microscope was established as a criterion for classifying objects to the category of the microworld. Moreover, the criterion "which object is part of the other or fits into the other" was introduced for ordering objects of the microworld; for instance, "the cell's nucleus is smaller than the cell because it is part of the cell".

Figure 3. Students handle the optical microscope.

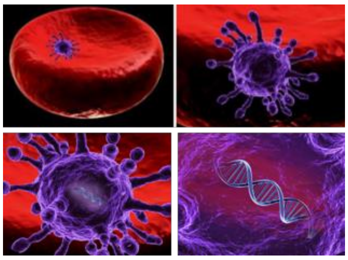

Figure 4. Print screen of the educational software.

The transition to the nanoworld happened similarly, as in the second unit. Namely, the inadequacy of the optical microscope for observing objects smaller than the cell's nuclei served as the entryway to nanoworld. The electron microscope was introduced via educational software (created by the researchers) which demonstrated its basic features. Students using this software "handled" an electron microscope to study models of a virus and DNA (Figure 4). They collected additional information by supplementary videos, and they created models of the above objects. Moreover, the electron microscope was used as a criterion for classifying objects to the category of the nanoworld. The same criterion with the second unit (which object is part of the other or fits into the other) was discussed for ordering the nanoworld objects by their size. The students created models of the nanoworld objects, and they placed them into the third part of the poster (Figure 2, right part).

The fourth unit included viral infection. The viral infection is considered to be relevant and meaningful to students' life (Delgado, Stevens, Shin, & Krajcik, 2015). We selected viral infection as a context to assign students to apply their knowledge about size, identifying the interaction of the three worlds as well. The students collected additional information by videos and printed images and created models in order to represent how the nanoword (a virus) affects the microworld (the cells) and the macroworld (the human body) in the case of viral infection.

In unit five, students were engaged in experimental activities about the lotus effect. They were assigned to pour some water droplets on the surface of four materials and to record the shape and behavior of the droplets (Figure 5). The materials were natural or artificial hydrophobic (cabbage leaf and textile respectively) and natural or artificial hydrophilic materials (lettuce leaf and textile respectively), Students collected information concerning the nanostructure of the lotus leaf's surface by videos and a poster. In addition, they were informed about several related commercial applications that mimic the lotus effect, such as athletic shoes. In the end, they created their models to describe this phenomenon.

Figure 5. Experimental activity for the lotus effect.

Figure 6. Experimental activity for the filtration.

The final sixth unit was about the contribution of nanotechnology to water purification. Students were motivated by a related video that demonstrated the problem and the consequent health issues arising from the contaminant water. Students were engaged in experimental activities trying to purify water using filters with a different pore size (Figure 6). Moreover, they collected information from videos about the nanostructure of the nanofilters. The last learning task was the creation of models that represented the water purification process by nanofilters.

Data collection tool

A written pre-post questionnaire was used to evaluate students' learning. The design of the first four items was based on suggestions of NST related literature (e.g. Castellini et al. 2007; Delgado, 2009; Delgado et al., 2015; Magana, Brophy, & Bryan, 2012), and the fifth item was designed by the researchers (Table 2). A pilot questionnaire was tested in a small number of primary school students (Peikos et al. 2017).

Table 2. The items of the questionnaire.

1. A student read on the internet the term nanotechnology and wondered what it means. How would you explain to him/her what is nanotechnology?
2. Name the smallest object you think that exists.
3. Classify the following objects to the boxes based on their size (ant, soccer ball, onion cell, red blood cell, human, DNA, virus, cell's nucleus). Explain your reasoning for each box. 4. Order the following objects from the biggest to the smallest: onion cell, DNA, the grain of salt, soccer ball, virus, cell's nucleus.
5. Two brothers washed some cabbage leaves for the salad and noticed that the water on the leaves beads up forming spherical droplets. Why do you think this happened? 

Data analysis

Based on both inductive and deductive qualitative methods, students' answers were grouped in categories and then were classified hierarchically in levels of understanding (Ls) from irrelevant and non-answers to more sophisticated (coded from L0 to L3), in respect to the expected learning outcomes. Specifically, concerning Items 1 and 5 (Table 2), the coding was inductive since no categories were retrieved from the literature. Regarding the Items 2, 3, and 4 the coding was both deductive and inductive as we retrieved categories from the literature that were modified and enriched (Delgado, 2009; Delgado et al., 2015; Magana et al. 2012). Following a deductive approach, new categories emerged to include data that did not fit the categories that were retrieved from the literature. The first author of this paper coded all the students' answers. Then two independent researchers, with experience in science education, coded the sum of the material too. The inter-rater agreement was high (Cohen's kappa > .80). All differences were settled by discussion. Table 3 presents the levels of understanding for each item.

Table 3. Coding rubric: The levels of understanding (Ls) per Item.

Items	L3	L2	L1	L0
I1: Meaning of NST	Nanoliteracy terms, e.g. nanoscopic objects, electron microscope	Terms concerning small size, microworld or optical microscope	No nanoliteracy terms or consider nanotechnology in anthropocentric terms	Do not know statements
I2: The smallest object	Nano or atomic world objects	Microworld objects	Macroworld object	Generalities/do not know statements
I3: Classification	Correct observation tool (OT) for the macro, micro and nanoworld objects and correct classification	Correct OT for the macro, micro and nanoworld objects and one mistake in classification	Correct OT for the macro, micro and nanoworld objects and two mistakes in classification	One or more mistakes in OT or more than two mistakes in classification
I4: Ordering	Correct ordering of macro, micro, nanoworld objects	Correct ordering of macro and microworld objects	Correct ordering of macroworld objects	Wrong ordering of macroworld objects
I5: Lotus effect	Reasoning based on the leaf's surface nanostructure (nanobumps) or the hydrophobicity	Reasoning based on the invisible features of the leaf (no reference to the nanostructure)	Reasoning based on perceptual based features of the leaf, e.g. the leaf is hard	Generalities/not know statements

RESULTS

Table 4 presents the percentage of primary students' answers in the Ls based on the pre-post questionnaire. Before the instruction, most of the students' answers were grouped in L0 or L1, while after that, most of their answers were moved in L2 and L3. A Wilcoxon test was used to examine whether, after the instruction, students increased their nanoliteracy significantly.

Table 4. Pre-post students' answers percentage (%) for each level of understanding.

	L0		L1		L2		L3	
Items	**Pre**	**Post**	**Pre**	**Post**	**Pre**	**Post**	**Pre**	**Post**
I1: Meaning of NST	27.3	0	31.8	13.6	36.4	22.7	4.5	63.6
I2: The smallest object	4.5	0	31.8	9.1	40.9	4.5	22.7	86.4
I3: Classification	100	18.2	0	18.2	0	31.8	0	31.8
I4: Ordering	59.1	18.2	18.2	4.5	9.1	0	13.6	77.3
I5: Lotus effect	77.3	9.1	18.2	9.1	4.5	9.1	0	72.7

Figure 7 displays the mean of students' score (0-3) based on the pre and post questionnaire and the corresponding standard error (SE) of the mean. The difference in the pre-post results was statistically significant for all the items (all *z* scores of the Wilcoxon test were greater than 3.11 and all the *p*s < 0.05).

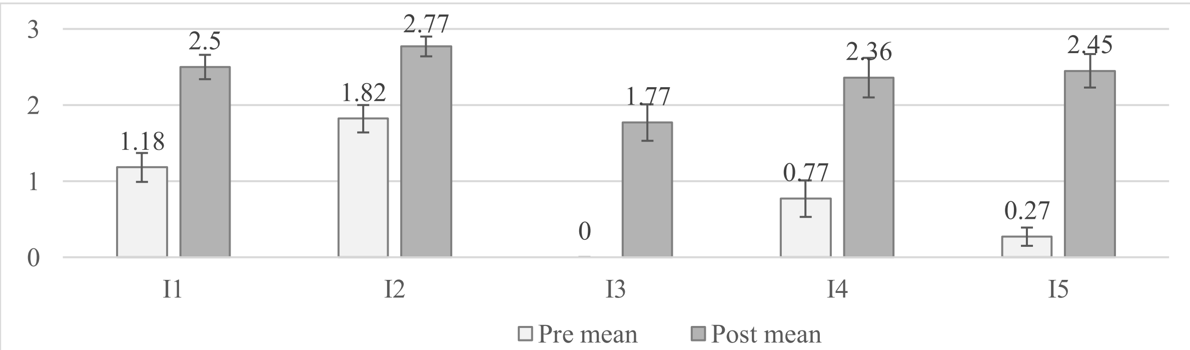

Figure 7. Mean and SE for the pre-post scores of the student's answers.

Concerning the "Meaning of NST" (Item 1) before the implementation of the teaching approach, most of the responses were categorized in L2 and L1. Indicative answers were *"There are some scientists who study small objects"* (L2) and, *"I think it is a technology for dwarfs"* (L1). After the intervention, most of the answers included nanoliteracy terms and were coded as L3. For example, a student mentioned *"Nanotechnology concerns nanoworld objects like a virus and the DNA. We can see these objects only with the electron microscope"*.

As regards "The smallest object" (Item 2), in the initial assessment, the highest percentage of the answers comprised microworld objects (L2), e.g. a cell and macroworld objects (L1), e.g. an ant. Interestingly, 22.7% of the students mentioned nanoworld objects e.g. *"a virus"* or subatomic particles e.g. *"electrons"*. In the post-assessment, most of the students' responses were coded as L3 since they included nanoworld objects such as *"the DNA"*.

Concerning the "Classification" (Item 3) before the instruction, no one student could classify all the objects correctly in the boxes by implementing the criterion of the corresponding observation tool, so all responses were categorized in the L0. After the instruction, 31,8 % of the students succeeded in categorizing all the objects according to the observation tools (L3). The same percentage of students made a single mistake in object categorization (L2).

As far as the "Ordering" in the pre-assessment most of the students ordered the macroworld objects (L0) inappropriately. However, in the post-assessment, a significant percentage of students succeeded in ordering all the macro, micro and nanoworld objects (L3) correctly. For example, a student responded *"soccer ball > grain of salt > onion's cell > cell's nucleus > virus > DNA"*.

Regarding the "Lotus effect" before the educational intervention, most of the students provided general answers or "do not know" statements (L0) while a small percentage expressed perceptual based explanations (L1). For instance, a student mentioned, *"Because the cabbage has a little gluey surface"*. After the implementation, a significant percentage of students explained the phenomenon using terms of nanoliteracy (L3). An indicative answer was *"Cabbage leaves have very small things on its surface which are called nanobumps. Nanobumps don't allow the water to break up and enter the leaf. Leaves that absorb or break up the droplets are called hydrophilic, while these which don't absorb and don't break up the droplets are called hydrophobic"*.

CONCLUSION

As expected, the teaching approach supported students to improve their nanoliteracy.

As regards the meaning of the term nanotechnology, results show that before the implementation, a significant percentage of students thought that nanotechnology concerns something small. One possible explanation for this finding is that the prefix "nano" is a Greek word which means "small" or "dwarf". Greek children in their everyday communication use this prefix. In literature, we find similar examples of people trying to approach the term nanotechnology etymologically (Waldron et al. 2006). After the educational intervention, most of the students used terms of nanoliteracy such as the electron microscope and the nanoworld objects. Among the five NST essential concepts (Figure 1), we found that "Tools" and "Size" were the dominant concepts that the students used to describe this new field. We argue that this finding is attributed to the content of the teaching approach since these concepts were evident in all the units of the intervention (Table 1).

The content of the "Size" is associated with the awareness of landmark objects of the three words, the skill of classification and the ordering from the biggest to the smallest. Results indicate that students achieved significant gains regarding the particular content. Before the implementation, most of the students referred to the non-visible objects as the smallest objects they could think of. The highest percentage of the answers regarded microworld objects and a small percentage included nanoworld or atomic world objects. Similar findings have been reported in previous studies (Castellini et al. 2007, Waldron et al. 2006). We argue that this knowledge may originate from the school textbooks that include units about non-visible objects such as the cells. After the intervention, students enriched their knowledge mentioning nanoscale objects (DNA, virus). Also, they improved their ordering and classification skills. However, the most challenging item after the intervention seems to be the classification of objects into macro micro and nanoworld. For the particular item, we identified that approximately only the 1/3 of the students' answers were coded as L3 after the intervention. In contrast, concerning all the other items, approximately the 2/3 of the students' responses were categorized in L3. This finding indicates the need to refine our approach regarding the development of students' classification criteria.

For the "Size Dependent Properties" aspect, we introduced the Lotus effect. Before the implementation of the teaching approach, most students either could not explain the phenomenon, or they explained the phenomenon using terms related to the macroscale physical features of the leaf. This finding is aligned with literature concerning the explanation of counter-intuitive phenomena (Vosniadou 2014). For instance, phenomena related to the particulate nature of matter are explained based on students' visual everyday experience (Wiser & Smith, 2008). After the implementation, most of the students described the Lotus effect using the newly acquired category of nanosize, and in terms of the leaf's nanostructure or the hydrophobicity.

Next step of this research is to refine the educational approach and to implement it in a larger number of primary school students. Moreover, we aim to enrich the data collection process by pre and post semi-structured interviews (Cohen, Manion, & Morrison, 2007) in order to provide in-depth qualitative data concerning students learning of the NST concepts.

ACKNOWLEDGEMENT

This research is co-financed by Greece and the European Union (European Social Fund- ESF) through the Operational Programme «Human Resources Development, Education and Lifelong Learning» in the context of the project "Strengthening Human Resources Research Potential via Doctorate Research" (MIS-5000432), implemented by the State Scholarships Foundation (IKY).

HORIZON 2020 NEWTON PROJECT EARTH COURSE: LEARNER MOTIVATION CASE STUDY IN STEM EDUCATION TECHNOLOGY ENHANCED LEARNING

Diana Bogusevschi[1], Odilla Finlayson[2] and Gabriel-Miro Muntean[2]
[1]Dundalk Institute of Technology, Dundalk, Ireland
[2]Dublin City University, Dublin, Ireland

This paper presents a Technology Enhanced Learning science, technology, engineering and maths (STEM) education case study, Earth Course, carried out in two primary schools in Dublin, Ireland as part of the European Horizon 2020 NEWTON Project. The presented Earth Course provides learners with educational content on the following main topics: Biosphere, Geosphere, Astronomy and Physics using digital applications developed as part of the NEWTON Project, employing technology enhanced learning (TEL) solutions. Two 5th classes participated in each school. One of the classes in each school interacted with the NEWTON approach as an introductory tool, with 30 boys in one school and 30 girls in the other school. The second class in each school used NEWTON lessons as a revision tool following the usual instruction by their teacher, with 30 boys in the first school and 27 girls in the second. This paper is focused on the assessment of learner motivation and affective state following the Earth Course case study. Most students found the Earth Course interesting and they would like to use similar lessons in other science classes. Students were extremely positive about the use of technology in the classroom, seeing it as a supporting tool for their teacher.

Keywords: Technology Enhanced Learning, STEM education, Technology in education and Training, Primary School

INTRODUCTION AND BACKGROUND

Technology Enhanced Learning (TEL) is one of the proposed solutions to enhance learners' engagement with STEM subjects, particularly when reduced interest in these subjects has been observed recently (Henriksen, 2016). Beneficial impacts of TEL have been noted in various research papers, such as (Ibáñez, Serio, Villarán, & Kloos, 2014), where Augmented Reality (AR) was evaluated in terms of its benefits on knowledge acquisition and improving learners' flow state when employed in teaching of Electromagnetism in a secondary school and was associated with very positive results. AR was also demonstrated as a valuable teaching tool in (Yipa, Wonga, Yicka, Chanb, & Wong, 2019) when used as support for teaching complex threading tasks.

Virtual Reality (VR) teaching environments were investigated in (Ruppa, et al., 2019). The authors showed that the increased sense of immersion provided by this technology improved learner experience and interest in the taught subjects as well as being beneficial to students' learning outcomes. VR technology was also employed in (Akbulut, Catal, & Yıldız, 2018) for software engineering teaching, where experimental group students exhibited higher knowledge gain compared to the control group, which employed traditional methods. In (Ak & Kutlu, 2017) it was shown that even 2D game-based learning environments improved university students' knowledge gain and were perceived by students as more valuable compared to the traditional approach. Virtual Laboratories were employed in conjunction with traditional-based methods in (Daineko, Dmitriyev, & Ipalakova, 2017) for teaching physics in universities, exhibiting significant enhancement of learning outcome and learning experience.

This paper presents the results of a primary school Horizon 2020 NEWTON Project STEM case study, *Earth Course*, where various technologies were used in a set of lessons in two schools, one girls only and one boys only. First, a description of the NEWTON Project is presented. This is followed by the overview of the *Earth Course* case study set-up, educational applications employed, its participants and assessment procedure which was focused on participating students' motivation and affective state. This is then completed by the results obtained during the evaluation and case-study conclusions

Horizon 2020 NEWTON Project

Horizon 2020 NEWTON Project has the objective of increasing learner quality of experience and learner engagement at the same time maintaining or increasing the learning outcomes in STEM subjects. It is focused on all levels of education, starting with primary level when learners are more open to new approaches, followed by secondary and tertiary institutions.

In order to achieve its objective, NEWTON project employs a variety of TEL approaches and various pedagogies, including **multimedia** and **multiple sensorial media** (Bi, et al., 2018), (Bi, Silva, Ghinea, & Muntean, 2018), (Bi, Zou, Maddi, Rozinaj, & Gabriel-Miro Muntean, 2019), **personalisation**, Virtual Labs (VL) (Lynch & Ghergulescu, 2018), (Ghergulescu, Moldovan, Muntean, & Muntean, 2019), (Ghergulescu, Zhao, Muntean, & Muntean, 2019), **gamification** (Lynch, et al., 2018), (Zhao, Muntean, & Muntean, Enhancing Students Learning Experience in Software Development by Employing Gamification,, 2019), **fabrication labs** (Togou, et al., 2018), (Togou, Lorenzo, Cornetta, & Muntean, 2019), **AR** and **VR** (Bogusevschi, et al., 2018), (Bogusevschi, Muntean, & Muntean, Earth Course: Knowledge Acquisition in Technology Enhanced Learning STEM Education in Primary School, 2019), **problem-based**, **game-based** and **self-directed learning** (El Mawas, et al., 2018), (Zhao, Bogusevschi, & Muntean, 2018), (Ghergulescu, Moldovan, Muntean, & Muntean, Interactive Personalised STEM Virtual Lab Based on Self-Directed Learning and Self-Efficacy, 2019).

All NEWTON Technologies and its Gamification Portal are embedded on the **NEWTON TEL P**latform (NEWTELP)[1] (Bogusevschi D. , Muntean, Gorji, & Muntean, 2018), which hosts all NEWTON project educational applications and technologies as well as its assessment procedure. NEWTELP can be used by teachers, for creating and personalising courses as well as evaluating knowledge gain and affective state following TEL approach lessons, and by students, for interacting with the educational content.

EARTH COURSE

The *Earth Course* case study was set up to assess the effect of NEWTON technologies, such as Virtual environments, including VLs, game-based learning, gamification and of the

[1] Developed by SIVECO, Bucharest, Romania (siveco.ro)

NEWTON Project platform, NEWTELP, on primary school learners' motivation and affective state, knowledge gain and usability of NEWTELP as well as of individual technologies and pedagogical approaches. Table 6 provides an overview of the topics within the *Earth Course* and specific applications within each topic (Bogusevschi, et al., 2018), (Bogusevschi D. , Muntean, Gorji, & Muntean, 2018), (Zhao, Bogusevschi, & Muntean, Improving Future STEM Education with an Innovative Learning Management System and Technology-Enhanced Learning Materials, 2018), (Bogusevschi, Muntean, & Muntean, Earth Course: Knowledge Acquisition in Technology Enhanced Learning STEM Education in Primary School, 2019), (Bogusevschi & Muntean, Water Cycle in Nature – An innovative Virtual Reality and Virtual Lab: Improving Learning Experience of Primary School Students, 2019). It also includes the main technology used and a brief description of the learner activities within each application. Applications *Wildlife*, *Sea-Life* and *Water Cycle in Nature* were developed by NEWTON consortium partner SIVECO, Romania. *Final Frontier* was developed by consortium partner National College of Ireland (NCI). *Geography* application was developed by consortium partner Slovak University of technology in Bratislava, Slovakia (STUBA).

Table 6 *Earth Course* Case Study Applications

Topic	Application	Technology	Description
Biosphere	Wildlife I Wildlife II[1]	VR, VL, gamification	Learners explore a nature environment collecting gas-cans in a forest and finding terrestrial animals, which are then explored in a VL. Quick quizzes are provided in order to reach the bonus level.
	Sea-life I[1] Sea-Life II[1]	VR, VL, gamification	Learners explore a nature environment collecting star-fish in an ocean and finding aquatic animals, which are then explored in a VL. Quick quizzes are provided in order to reach the bonus level.
Geosphere	Geography[2]	AR, VR	Learners need to familiarise with digital educational content focused on UK and the Republic of Ireland where images of monuments with enabled AR/VR functionality are provided. A Virtual Map is then employed for assessing learners' geographical knowledges.
Astronomy	Final Frontier I[3]	Gamification game-based learning	Game with an avatar on a spaceship which focuses on Rocky Planets, allowing for an exploration of virtual planets, where learners need to collect meteorites and answer quizzes.
	Final Frontier II[3]	Virtual library	Virtual library that exists on the spaceship and provides educational information about the giant Gas Planets and the Rocky planets.
Physics	Water Cycle in Nature[1]	VR, VL	Learners explore a virtual nature environment learning about phenomena participating in precipitation formation and a VL which exhibits relevant physics experiments in a laboratory setting.

The focus of this paper is on students' motivation and affective state with the main research question: What is the impact of NEWTON Technologies and platform on learners' motivation and affective state?

Set-up: Participants and Evaluation Procedure

The *Earth Course* case study was carried out in two single sex primary schools, St. Patrick's Boys National School (BNS) and Corpus Christi Girls National School (GNS) in Dublin, Ireland and it meets all ethics requirements. Two 5th class groups participated in each school with learners of 10-11 years of age. Classes A and A' in St. Patrick's BNS and Corpus Christi GNS respectively employed the NEWTON approach as an introductory tool to a topic. Classes B and B' were initially presented the educational content by their usual teacher in a teacher centred approach, following which, 4 to 10 weeks later they interacted with the NEWTON applications to review the previously presented content.

The NEWTON Project Pedagogical Assessment Committee (PAC) Toolkit (Montandon, et al., June 2018) was used to evaluate the intervention, whereby at the beginning of the intervention, two questionnaires were completed by learners - Demographics and Affective State/Motivation Pre questionnaires. Following the completion of the 8 NEWTON learning sessions, learners filled out the Affective State/Motivation Post questionnaire in order to determine students' motivation toward STEM and their engagement following interaction with TEL solutions. Interviews and focus groups were also conducted with learners and teachers, in order to obtain a more informal account of their experience during NEWTON lessons, ensuring that any aspects which might have been missed in the questionnaires were addressed.

EVALUATION OF CASE STUDY IMPLEMENTATION

Following completion of the *Earth Course*, during focus groups and interviews, the majority of learners reported being very engaged in the NEWTON lessons. It was reported quite strongly that they perceived NEWTON as a very useful supporting tool for the teacher. This was especially notable during the focus group, where students reported being very excited about the classes where the content was provided by both the teacher and reinforced by the NEWTON approach. Students reported enjoying the TEL approach together with the teacher for support and direction.

From the data in the Motivation/Affective State Post questionnaires, it can be noted that the majority of students were interested in the relevant subjects, where around 60% of learners in classes B and B' were very or extremely interested (65% of boys and 60% of girls), with an even higher percentage in classes A and A' (85% of boys and 70% of girls). While the majority of all the students responded that they were somewhat or very engaged, the female students responded more positively (90% of girls and 70% of boys). Only one girl in class A' reported boredom.

The implementation of the technology in introducing the topic was considered more favourably by participating students compared to its use as a revision tool (with over 80% of learners in classes A and A' indicating the NEWTON lessons were extremely interesting, and 53% of boys' class B and just over 62% of girls' class B' responding similarly). The students' preference to the use of technology in STEM subjects remains quite stable compared to before the *Earth Course* case study as assessed in the Pre Motivation/Affective State questionnaire, with 85% of boys in class A wanting to use more technology (compared to 92% in the questionnaire prior study), 76% of boys' in class B (compared to 77% prior study), compared to 72% (with 74% prior study) and 64% (with 60% prior study) of girls respectively.

When enquiring on students' preference toward computer-based and teacher-based learning, the majority of students stated that they prefer computer-based teaching: 96% of boys in class A and 76% of boys in class B, compared to 82% of girls in class A' and 62% of girls in class B'. However, it has to be noted that when further discussing this matter during interviews, students noted that they were really positive about computer-based teaching when it is supported by their teacher. They really emphasised that it was very important for them to have the support and the leadership of their usual teacher during TEL lessons.

Following the Post Motivation/Affective State questionnaire, comments obtained from girls include: "I like NEWTON very much […] thank you so much for teaching me about the Earth space and nature" and "I loved learning with NEWTON [,] it was really fun and interesting" in class A'; "I think I preferred doing the game [,] it made it more interesting" and "I enjoyed learning" in class B'. Boys' answers included: "I really enjoyed NEWTON and hope to continue with it in 6th Class" and "I liked the animation" in class A; "Good" and "Games are more fun" in class B. Girls were considerably more detailed in their feedback provided in the Post questionnaires. During interviews and focus groups, both genders were very open to provide their comments and reactions to the novel NEWTON Project TEL solutions.

CONCLUSION

This paper presents the findings of a EU Horizon 2020-funded NEWTON Project case study carried out in two primary schools in Dublin, Ireland, one a boys only school and one a girls only school. Two 5th classes participated in each school, one class assigned as the experimental group employing NEWTON technologies as introduction to a topic and the other class was employing NEWTON technologies a revision to a topic which was previously presented to students by their usual teacher in a classic approach lesson. Students' affective state was evaluated following the TEL NEWTON lessons, exhibiting excellent results. It was shown that the experimental classes employing NEWTON as an introduction tool benefited slightly more in terms of affective state, compared to the revision classes, even though the revision classes benefited more in terms of knowledge gain, as seen in (Bogusevschi, Muntean, & Muntean, Earth Course: Knowledge Acquisition in Technology Enhanced Learning STEM Education in Primary School, 2019). However overall, following NEWTON approach lessons, all groups of students presented increase in motivation, satisfaction and interest in STEM subjects.

Further analysis of the data will probe the learning gains presented by the technologies and the comparison of uses in the different class groups (Bogusevschi, Muntean, & Muntean, Earth Course: Knowledge Acquisition in Technology Enhanced Learning STEM Education in Primary School, 2019). Interview data from teachers will be used to support data analysis (Bogusevschi, Maddi, & Muntean, Teachers' Impact and Feedback Related to Technology Enhanced Learning in STEM Education in Primary and Secondary Schools, 2019). Following the extremely positive outcome of this NEWTON Project case study, access to the NEWTON Project platform, NEWTELP, and to the previously employed *Earth Course* educational content and assessment procedure was provided to both schools for future use in classes both for in-class and after-school activities, as identified more suitable by school teachers.

ACKNOWLEDGEMENT

This research is supported by the NEWTON project (http://www.newtonproject.eu/) funded under the European Union's Horizon 2020 Research and Innovation programme, Grant Agreement no. 688503. The support of the Science Foundation Ireland (SFI) Research Centres Programme Grant Numbers 12/RC/2289 (Insight) and 16/SP/3804 (ENABLE) if gratefully acknowledged.

PART 17: STRAND 17

Science Teaching at the University Level

Co-editors: *Jenaro Guisasola & Paula Heron*

CONTENTS

STRAND 17: INTRODUCTION

INTRODUCTION: TRANSFORMING UNIVERSITY-LEVEL SCIENCE EDUCATION

During the last few decades there have been significant changes in society and in the environment that have driven changes in the teaching of science at all educational levels, including higher education (NRC 2015). New demands in science education frequently challenge the efficacy of traditional teaching at the university level. The scientific community needs to change science and technology teaching to make it effective and relevant to a diverse university student population. The new social needs are very different from those in the past, when the main objective of science education was to train a small number of students to become future scientists. Scientific-technological education at the university level now needs to support and train a diverse student population where the actual use of knowledge, not just memorization, is increasingly important (Report European Commission 2013). Science education research shows that it is necessary to change university instruction in a way that changes the way students think about science, about solving scientific problems, and allows them to practice the scientific skills of the scientific-technical community. (Hake 1998, McDermott 2001).

The "Science Teaching at the University Level" strand (strand 17) focuses on the relationship between research in science education and teaching and learning in higher education. The nine articles that make up strand 17 of the ESERA Conference Proceedings e-book illustrate that inquiry-based teaching is fundamental to the process of university education. The studies are based on data collected with different tools such as questionnaires, surveys and interviews. The results are mainly focused on learning problems, related to conceptual understanding and scientific practices in a wide range of aspects, such as cognitive, affective, and social. The research presented includes the analysis of teaching processes with various purposes. Two articles deal with analyzing the attitudes, behaviors and interests of students towards "Responsible Research" in scientific research (Elster) and on the benefits and challenges of technology-enhanced learning (Roche). Another article focuses on evaluating the results of an educational action focused on proposing authentic research to students in the form of research works (Hougaard and Nielsen). Two articles analyze the improvement of learning evaluation formats considering aspects that range from structural factors, psychological and physical resources, study behavior, study motivation and study performance (B. Paczulla et al.), to evaluation criteria in study program and competences (Flodin and Davidson). Four other articles analyze the conceptual learning and/or scientific skills of students in traditional teaching in lectures (Zuazagoitia et al; Praprotnik and Torkar), in the laboratory (Poensgen and Reiners) and in problem solving (Woitkowski).

The collection of articles included in this section shows the need to investigate science teaching processes using a variety of methodological approaches and in different contexts. The combination of complementary methodological tools and types of analysis can support a systematic analysis of science education practices with the aim of reforming learning and teaching. The "Science Teaching at the University Level" strand was defined for the first time in the 2015 Conference and has remained as a strand in the following congresses in 2017, 2019 and, in the next 2021. The number of contributions has been growing with 16 oral communications in 2015, 25 in 2017 and 34 in 2017. However, the number of studies submitted for the e-book ESERA Conference Proceedings is a low proportion of those submitted.

Consequently, the number selected for the e-book is low. In 2015, 4 papers were published, 8 in 2017 and 9 in 2019. However, research in science education is increasing at the university level, as shown by the large increase in research published in high-impact journals. Thus, it will be necessary to disseminate and share the results of the e-book proceedings with the community of university professors. Having a specific strand on teaching and learning problems at the university is necessary for the discussion and dissemination of advances in science teaching at the university.

STARBIOS2 - ENGAGING WITH RESPONSIBLE RESEARCH THROUGH SCIENCE EDUCATION

Doris Elster
Institute of Science Education, University of Bremen, Bremen, Germany

The purpose of this theoretical paper is to present and discuss a strategy to implement the concept of Responsible Research and Innovation (RRI) in the Faculty Biology and Chemistry at the University Bremen using science education as a promoter of this process. The project is part of STARBIOS2 (Structural Transformation to Attain Responsible Biosciences), a European project funded in the HORIZON 2020 program Science With And For Society (Swafs) (see http://starbios2.eu). It aims to implement Action Plans to promote RRI in partner institutions of six European countries. Based on the experiences a model and guidelines has been elaborated to facilitate the implementation of RRI in other research institutions.
The University of Bremen is one of the 12 partners of STARBIOS2. The Bremen team develops, conducts and evaluates an Action Plan with Science Education as a trigger for the structural transformation process. The Action Plan aims in the performing of a series of educational building blocks with the goal of raising the awareness of RRI issues. The vision is to implement RRI in the future concept of the Faculty of Biology and Chemistry.

Keywords: Responsible Research, Higher Education, European project

CONTEXT AND RELEVANCE TO SCIENCE EDUCATION

STARBIOS2 – Structural Transformation to Attain Responsible Biosciences - is a European project that has received funding from the Framework Programme HORIZON 2020 (coordinator: Universitá di Roma Tor Vergata, Italy). The goal of STARBIOS2 is to raise the awareness of Responsible Research and Innovation (RRI) and to better align research to the needs of the society. Therefore, structural transformation processes in six European research institutions (in Bulgaria, Germany, Italy, Poland, Slovenia, and United Kingdom) and three non-European entities (in Brazil, South Africa, and United States), all active in the field of biosciences, are initiated and tailored in respect to their culture, rules and procedures. The processes are focussing on the five RRI key issues: Public Engagement, Gender, Education, Open Access, and Ethics (Colizzi et al., 2019).

The University Bremen is a member of the STARBIOS2 consortium. The goal is to raise the awareness of RRI by conducting a transformation process in regard to RRI issues in the Faculty of Biology and Chemistry (one of the 12 faculties of the University Bremen). This process is triggered by the Institute of Science Education with the goal to provide future researchers and teachers with new capacities for attracting children and youth to science and technology (Elster et al., 2016; 2019a,b).

THEORETICAL FRAME

Responsible Research and Innovation (RRI) represents a contemporary view of the connection between science and society. The goal is to create a shared understanding of the appropriate roles of those who have a stake in the processes and products of science and technology, scientists as well as educators and the general public. It is estimated that a shared understanding and mutual trust will lead to safe and effective systems, processes and products of innovation. RRI can be defined as 'a transparent, interactive process by which societal actors and innovators become mutually responsive to each other with a view to the (ethical) acceptability, sustainability and societal desirability of the innovative process and its marketable products (in order to allow a proper embedding of scientific and technological advances in our society)' (Sutcliffe, 2011:19).

In the Horizon 2020 framework RRI is built on the following key dimensions (Von Schomberg & Von Schomberg, 2013):

- *Societal Engagement* and *technology transfer* focus on the promotion of the engagement of all societal actors in the R&I process;
- *Gender* aims at favouring gender equality within research institutions as well as in the Research and Innovation (R&I) content;
- *Science Education* aims to provide future researchers with news capacities for attracting children and youth to science and technology;
- *Open Access* focuses on making research and innovation transparent and accessible through making Open Access a reality; and
- *Ethics* aims in ensuring high quality research results and ethical standards.

This framework of RRI allows research institutions to raise the awareness of current and future scenarios regarding the science and technology advances.

Enhancing Responsible Research in Biosciences

The European project STARBIOS2 aims to contribute to the advancement of the RRI strategy by fostering structural change in biosciences research institutions. The hope is to cope with one of the main risks for European research: its inadequate connection with society by changing the institutional culture, values and procedures in a holistic manner (STARBIOS2 Consortium, 2016; Colizzi et al., 2019).

To reach these goals the project comprises three steps:

In a first step, six European STARBIOS2 partners in Bulgaria, Germany, Italy, Poland, Slovenia, and United Kingdom develop, evaluate and implement six RRI Action Plans (APs) in their research institutions. The experiences about the APs' implementation form the base for the development of new practical knowledge. They are the starting points for the development of tailored APs Based in three non-European entities in Brazil, South Africa and United States.

In a second step, a complex learning process about the implementation of APs is initiated. That that allows the members of the partner institutes to learn from each other. Questions about supporting and hindering structures are reflected. The goal is a better understanding about the different possible ways of the implementation of RRI in biosciences research institutions.

In the third step, the outcome of the learning process results in the development of a sustainable model and a set of guidelines on RRI implementation, aimed at providing recommendations on how to deal with resistances to RRI in research institutions (Declich et al., 2019). As each community of the participating Higher Education Institutes is characterized by its own features, culture, languages, networks, communication means and power dynamics it is important to identify multiple RRI strategies tailored to each research institute (STARBIOS2 Consortium, 2016).

Science Education as a Trigger to Attain Responsible Research

The University of Bremen is a relatively young university with 12 faculties and about 20 000 students. Faculty Biology and Chemistry takes part in the STARBIOS2 project with the goal to develop a tailored AP for the implementation of a RRI mission statement. To reach this goal a whole-institute-approach based on a bottom up – top down is conducted. Therefore, af a Core Team of scientists and science educators as well as an Extended Team with important stakeholders of the faculty (dean, vice dean, member of the quality management) and representatives of the status groups students, doctoral students and researchers has been set up. A central goal is the initiation of a negotiation process of RRI issues (among stakeholders, researchers, students) and the inclusion of RRI in the future concept (mission statement) of the faculty.

To reach these goals a roadmap (fig.1) is set up (Elster et al., 2016; 2019a).

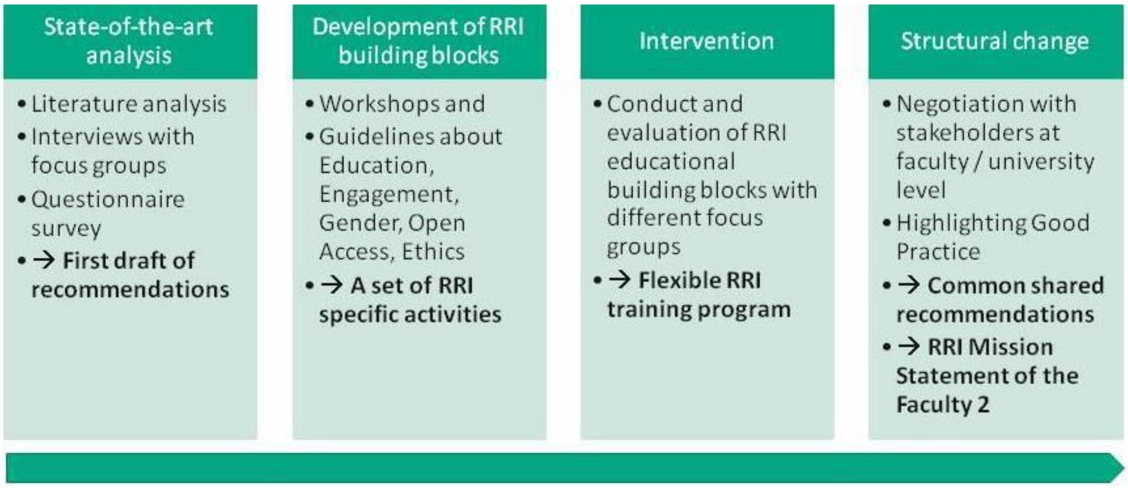

Figure 1. Roadmap for structural change at the University Bremen (Elster et al., 2016).

1) We started with a comprehensive **state-of-the-art analysis** of literature and research programmes. The findings of the analysis built the basis for the development of interview guidelines. The interviews were conducted with different focus group(s) (doctoral students, students, researchers, and/or educators; n=21). Based on the interview results a RRI questionnaire survey was conducted on-line at the faculty (n=163). From the findings of the interviews and the questionnaire survey criteria for the successful promotion of the specific RRI issues were deduced. The criteria formed the basis of a first draft of recommendations.
2) The development of **RRI specific educational building blocks** comprised the development of RRI modules and reflective activities in respect to the RRI keys. These building blocks (5) and reflective activities (6) were conducted and evaluated within the different focus groups or in the outreach lab Backstage Science (with school classes). They formed the base for the educational intervention.

3) The goal of the **RRI educational intervention** was the connection of the key-specific building blocks to a RRI training programme in accordance of the needs and the interest of the specific target group(s). The results contributed to a further development of the RRI recommendations and the RRI future concept of the faculty.
4) **For structural transformation and change** the goal was to foster sensitiveness and awareness in respect to RRI through dialogue with important stakeholder, offer of academic lectures, and transparency by a user-friendly website, good practice examples, and recommendations at the faculty level and at the university level.

EDUCATIONAL CONCEPTS TO PROMOTE RRI IN BREMEN

Science education has an important role to educate the future scientists and university students. What scientists do, how they work, innovate and make decisions are important subjects for contemporary science education. While science and technology develop, science education needs to renew itself and work along with the developments in science and technology. New developments and technologies are very often controversially discussed in society. Therefore, a useful model for the processes of **communication between researchers and the public** is needed. It forms the basis of educational and didactical interventions.

In the case of the University Bremen new educational models should trigger the raising of awareness of RRI issues and an inspiring and fruitful structural change regarding RRI issues. As a consequence, within the Starbios2 project new educational concepts are developed at the level of students' individual training by **RRI reflective activities**, **RRI modules** as inspiring practices, and **RRI in the curricula of academic programmes**.

A Communication Model between Researchers and the Public

Our communication model is based on the Common Ground Theory of Bromme (2000) and the Model for Communication about Biotechnology based on Ben France and John K. Gilbert (2006). In everyday communication, interaction partners encounter different perspectives. The question of how mutual comprehension arises in the case of different perspectives or knowledge especially in the expert and layman communication. The Common Ground Theory postulates that every act of communication presumes a common cognitive frame of reference between the partners of interaction called the common ground. All contributions to the process of mutual understanding serve to establish or ascertain and continually maintain this common ground (Bromme, 2000). 'Two people´s common ground is, in effect, the sum of their mutual, common, or joint knowledge, beliefs, and suppositions.' (Clark, 1996: 3)

Researchers in the field of biosciences face the challenge to persuade 'the public' of the rightness of their case, whilst 'the public' is trying to argue a scepticaly or even contrary case. A model that might be of use in any field where technological controversy takes place was set up by France and Gilbert (2006). They took the idea of a *communicating community*, defined as relatively coherent social group engaging in communication with itself. The authors differentiate in the *biotechnology communities* and the *public communities*. Each of the communities has a certain 'view' on biotechnology that is made up of four 'dimensions': their understanding of the nature of science and biotechnology; understanding of the key concepts and models used in biotechnology; perceptions of the nature of risk; and beliefs and attitudes about biotechnology.

Similar to Bromme´s definition of a 'common ground' (Bromme, 2000) France and Gilbert (2006) define a 'search room' as a virtual arena where the 'views' of the communities of scientists and the public communities are exchanged. 'Where there are elements of the views that are in common to the two, communication is possible. Where there is no commonality, the degrees of understanding reached must be used to construct a mutual understanding that may evolve into an agreement exchange.' (France & Gilbert, 2006: 2).

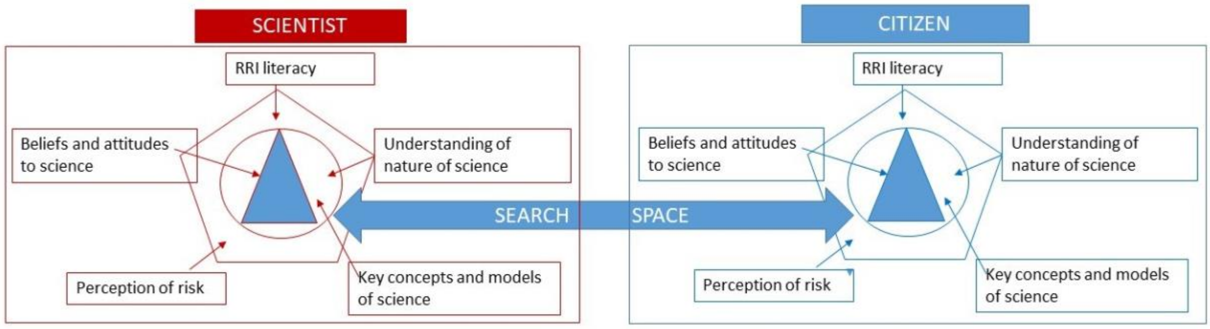

Fig. 2 The inclusive communication model for biosciences (Elster et al, 2019a)

Within our Starbios2 project in Bremen we have to expand this model in respect to the RRI issues. Firstly, we defined a *RRI literate researcher* is a person who 1) perceives sensibly to detect questions related to RRI issues related to societal engagement and technology transfer, gender, ethics, open access publications and science education; 2) who is willing to apply its knowledge of RRI issues; 3) who actively acts to disseminate RRI issues in the context of research and the research institution. Secondly, we expanded France and Gilbert´s four 'dimensions' by a fifth dimension, the RRI literacy. And thirdly, we extended the model which specifically focused on biotechnology to a more comprehensive view on biosciences. Our inclusive communication model is summarized in figure 2.

Promotion by RRI Reflective Activities

The promotion of critical thinking is considered one of the key issues of good scientific RRI education. Students and researchers should be encouraged to critically question about what is responsible and conscientious practice within their scientific domain. They should be aware of societal needs and that research is not oblivious towards societal values.

Reflexive capacities are crucial for understanding the role and responsibilities of research. Therefore, students and researchers should be aware of the interrelationship of their own research with other areas of science. The goal is to open the view to collaborate and coproduce knowledge with researchers as well as professionals outside their own fields and with interested citizens.

Within the Starbios2 project a series of reflective activities in respect to the societal engagement, contextualization of research, publication open access, gender in research, diversity team management, ethics in science communication are developed, tested and evaluated. They are summarized in the RRI toolbox at the local website (https://blogs.uni-bremen.de/starbiosbremenenglish/)

RRI Modules as Inspiring Practices

In the context of Starbios2 at University of Bremen the concept of raising awareness of RRI issues through RRI educational building blocks is based on the Citizen-SIP educational model. The model is based on Problem-based Learning (PBL) in socio-scientific contexts (SSC) and Inquiry-based Science Education (IBSE) with a specific focus on Citizenship Education (CE). Problem-based learning stands for self-determined and discovering learning, action-oriented teaching, interdisciplinary learning and self-evaluation. Participants learn to analyse a topic or question, to find and use suitable sources of information, and finally to compare, select and implement solutions. Socio-scientific issues (SSI) are open-ended, multifaceted social issues with conceptual links to science (Sadler, 2011). PBL in socio-scientific contexts in authentic research projects as ‘real-world scenarios’ offers powerful opportunities to develop critical thinking on the nature of science and its implications (Lederman et al., 2014). IBSE is an appropriate educational instrument to acquire process skills and an adequate view of the Nature of Science (Capps & Crawford, 2013) as well as a meaningful understanding in a societal context. Citizen Education takes into account the moral and social function of education at a socio-political level.

RRI in science education requires that students have creative thinking and problem solving skills. RRI deals with dilemmas and uncertain situations where students’ arguments are as important as the scientific facts. Examples of RRI modules developed at the University of Bremen are ‘Promotion of Risk Literacy in Regard to Nanotechnology’ (Eschweiler & Elster, 2018), ‘Wake up – Sensitisation of adolescents for the stem cell donation for leukaemia patients’ (Holzer & Elster, 2019), and ‘Biodiversity loss and climate change in the Wadden Sea’ (Müller & Elster, 2018). These modules are developed in doctoral and master studies in cooperation of scientists, science educators and teacher candidates. The modules are evaluated in in-service trainings, pre-service education and schools.

RRI in Curricula of the Bachelor´s and Master´s programmes

University students as nascent researchers should acquire knowledge and skills needed to work responsibly during their academic experiences. In their academic development, ideas and concepts of RRI should be fostered and developed throughout the formative process of education. Traditional academic hierarchies should be modified to enhance the voluntary participation and debate among the students. In an atmosphere of openness and trust, students should be encouraged to draw their own conclusions and provide valuable contributions to the debate.

The integration of research and teaching can provide valuable ways of enhancing student learning experiences. Nevertheless, the linking can be challenging and the understanding of a ‘research-based education’ and ‘research-informed teaching’ within and between disciplines is diverse. The ‘nexus’ of research and teaching is influenced by the departmental structural arrangements for organising research and teaching activities, and a potential gap in making connections between staff research outputs and students´ learning when this research is too far ahead of the undergraduate curriculum to be accessible to students (Jenkins, 2004). Graffiths (2004) and Healey (2005) distinguish five ‘Research-informed teaching’ approaches:

- Research-led (RL): Students learning “about” the research of others.
- Research-oriented (RO): Students learning about research processes.
- Research-based (RB): Students learning as researchers.
- Research-tutored (RT): Students learning through critiquing research.
- Scholarship of teaching and learning (STL): Enquiring and reflecting on teaching and learning.

In the bachelor’s biology programme and in the different master’s programmes at the Faculty Biology and Chemistry all five approaches of research-informed teaching are offered. They provide different avenues for RRI learning. Whereas during the bachelor’s programme different concepts, ideas, relevance and aims of research and RRI are discussed (RL and/or RO), the integration in research groups and writing of the bachelor theses offers the possibility of students learning as researcher (RB). That allows them to relate RRI processes in the own field and the role of responsibility in these processes. Especially within the associated modules ‘interdisciplinary key qualifications’ students learn about criteria for good research and ethical issues in scientific writing.

In the master’s programmes of biosciences students focus on the specific topics of their fields of research and research-tutored (RT) learning may be at the core. Science chats and master seminars allow doing and experiencing dialogical reflection on research and innovation (STL) and a perspective with the wider society.

RRI in the curricula of PhD programmes

Most of the reflective activities developed in Starbios2 projects are targeted to PhD students and young researchers. When doing more or less self-reliant research the application of RRI issues is important. The assessment of possible societal impacts of one´s own concrete research activities as well ethical issues of research receive increased importance. The goal is to propose adoptions to better align a research project with societal needs, values and expectations.

A good practice example at the University of Bremen is the Graduate School NanoCompetence – Research, Mediation, Design. This interdisciplinary graduate school combines the expertise of natural sciences and humanities, aiming at enlightening society about the applied aspects of nanotechnology. (https://www.nano.uni-bremen.de/)
Especially in the doctoral programme of Science Education RRI is reflected and RRI issues like socio-scientific issues and contexts, how to deal with gender and diversity as well as ethical questions are fields of investigation in doctoral studies (see e.g. Birkholz, 2019).

DISCUSSION – A NEW CHALLENGE FOR SCIENCE EDUCATION

Responsible Research and Innovation (RRI) represents a contemporary view of the connection between science and society. The goal is to create a shared understanding of the appropriate roles of those who have a stake in the processes and products of science and technology, scientists as well as educators and the general public. It is estimated that a shared understanding and mutual trust will lead to safe and effective systems, processes and products of innovation (Sutcliffe, 2011).

Especially the Biosciences have the responsibility to form links to the society. STARBIOS2 aims to cope with this risk of the loose connection of research and society, by promoting the increasing alignment of European research with the needs and values of society (Colizzi at al, 2019).

Science education has an important role to educate the future scientists. What scientists do, how they work, innovate and make decisions are important subjects for contemporary science education. While science and technology develop, science education needs to renew itself and work along with the developments in science and technology. New educational models should trigger an inspiring and fruitful structural transformation regarding RRI issues. RRI in science education requires that students have creative thinking and problem solving skills. RRI deals with dilemmas and uncertain situations where students' arguments are as much important as the scientific facts. Therefore integrating RRI in science education requires a change in teaching methods and strategies in the higher education sector.

This paper demonstrates a possible way of supporting and steering of a structural transforming process in the Faculty Biology and Chemistry. Science educators play an important role in this process by supporting communication and negotiation between different stakeholders as well as offering didactical models and materials for the implementation of RRI issues. Educational building blocks, reflective activities, RRI modules, and curricula enrichment for bachelor´s, master´s and doctoral programmes have been reflected and further developed. A on-line RRI toolbox tailored for Faculty´s needs has been set up. Based on formative evaluation of RRI activities, a broad literature analysis, interviews and a faculty-wide questionnaire survey the Booklet of Recommendations "Towards a Sustainable and Open Science – Enhancing Responsible Research and Innovation in the Biosciences at the University of Bremen" (Elster, Barendziak, & Birkholz, 2019b). It will now be discussed and negotiated. Together with the on-line RRI toolbox it will form the sustainable outcome of the four-year-long process of RRI structural transformation and development of a RRI mission statement tailored to the Faculty Biology and Chemistry.

ACKNOWLEDGEMENT

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 709517.

TECHNOLOGY-ENHANCED LEARNING SUPPORTING ENGAGEMENT, ASSESSMENT, AND REFLECTION IN HIGHER EDUCATION SCIENCE

Joseph Roche[1]
[1]*Trinity College Dublin, Ireland*

In this paper, the results of a study conducted in higher education science across three groups of early-career scientists in the same university—undergraduate students, masters students, and doctoral students—will be presented. All three groups were taking similar versions of a Science & Society module that focused on the roles and responsibilities of scientists. The students from these groups provided short continuous feedback before, during, and after each lecture in the module, and focus groups were conducted with the students at the end of each module. The main factors being considered were the benefits and challenges of technology-enhanced learning in regards to student engagement, assessment, and reflection. This work highlighted that while the benefits are numerous, the challenges can often vary depending on the students' current level of higher education science.

Keywords: Higher Education, Technology, Reflection.

INTRODUCTION

In this study, technology-enhanced learning was compared across three different stages of higher education science: undergraduate, masters, and doctoral level. There have long been concerns about the standard of teaching in higher education science (Sunal et al., 2001). One of the ways to address such concerns and raise these standards is to integrate technology into the learning experience with the view of supporting student creativity, innovation, engagement, assessment, and reflection (Johnson & Carruthers, 2006).

The guiding research question was:

"What are the benefits and challenges of technology-enhanced learning in higher education science?"

This was tackled by breaking down the work into two sub-questions:

1. "How do these benefits and challenges relate to engagement, assessment, and reflection?"

2. "How do they compare between students in undergraduate, masters, and doctoral level courses?"

Technology was used to support engagement in this study through the use of audience response systems and virtual learning environments. In higher education there has been growing emphasis on finding ways for students to engage in lectures using their own smart devices, such as tablets or smartphones (Stowell, 2015). This follows the gradual move away from outdated radio frequency transmitters ('clickers') towards software solutions that rely on smart devices (Kay & LeSage, 2009; Koppen & Langie, 2013). For this study, engagement was facilitated and evaluated across three levels of higher education science using contemporary audience response systems.

Both self-assessment and peer-assessment were supported through the Blackboard Learn virtual learning environment (Heaton-Shrestha, et. al., 2007). Students uploaded their assignments and then anonymously reviewed and graded their classmates' work. Technology can speed up the assessment process, which aligns with the recommendations of Brookfield (2015) who noted that when it comes to providing student feedback: "immediacy is valued by students and demonstrates your responsibleness, an important element of authenticity" (p. 192). While reflection is often used as a means of practice-based professional learning (Thompson, 2000), this process of self-assessing personal development can offer early-career scientists a way to better understand their own learning.

METHOD

This work began by carrying out literature reviews of the three chosen areas of technology-enhanced learning: engagement, assessment, and reflection. Student feedback from the undergraduate, masters, and doctoral level students was recorded using reflection questions before and after each lecture on a Science & Society module.

Before each lecture the students were asked to record their initial understanding of the concepts that were going to be covered in class. After the lecture, the students were asked to reflect on their understanding of the concept, if it had changed, as well as any aspects of the lecture that were significant to them.

One of the goals of the module was to help early-career scientists to "take responsibility for their own learning" (Hall, 1996, p. 112). The module was underpinned by a general framework of social constructivism (Hodson & Hodson, 1998), but with a focus on how values, perceptions of socioscientific issues, and ethics all play a role in creating a mutual understanding of the world around us (Arghode, Yalvac, & Liew, 2013).

The students engaged in the lectures using software called "Poll Everywhere" — an audience response system that facilitates democratic decision-making in audiences (Shon & Smith, 2011; Kappers & Cutler, 2015). The students were asked to anonymously and independently provide feedback on their learning following the recommendations of Hughes, Kooy, and Kanevsky (1997) and answered questions using their own smart devices (spare iPads were provided to students without access to a smart device of their own). This use of audience response systems is common for large-scale events such as public lectures and festivals (Roche, Cullen, & Ball, 2016; Roche, Stanley, & Davis, 2016).

Reflective practice was integrated into the module in terms of teaching (Brookfield, 1995) and the students' reflective writing assignments (Bolton, 2010). At each level (undergraduate, masters, doctoral) a representative subset of the students took part in a focus group to provide feedback on their experience of the technology-enhanced aspects of the module. The focus groups followed the protocol described in Roche et al., (2017).

DISCUSSION AND CONCLUSIONS

As was expected, when addressing the research questions, technology-enhanced learning in higher education science posed both benefits and challenges (Table 1). Engagement through mobile technology was found to be a beneficial method of facilitating safe, anonymous, whole-class discussions in real-time. This was especially useful in large classes, and was found to be especially meaningful for participants who did not feel confident speaking out in a lecture. Such students found seeing their contributions appear anonymously on the lecture screen empowering.

For some masters students, and a larger group of doctoral students, there was a feeling that digital engagement deprived them of the opportunity to actively engage in lectures. This could be due to the smaller class sizes at masters and doctoral level, growing confidence to engage at those levels, or an average age difference compared to the undergraduate students. All of these factors are worthy of further consideration and follow-up research.

As has been found elsewhere, self and peer-assessment worked best when the students and staff jointly determined the criteria and marking rubrics (Dochy, Segers, & Sluijsmans, 1999). This is particularly relevant as many universities move more towards e-learning, distance learning, blended learning, and flipped classroom approaches. It is becoming increasingly important to understand the strengths and weaknesses of these approaches for student learning at different stages of higher education science.

Using technology to support reflection was found to equip students with valuable tools to observe, gather information, analyse, and draw conclusions on their own learning and development. Given the challenges that early-career scientists are facing (Powell, 2016; Roche & Davis, 2017) such skills are more pertinent than ever. The students responded best to having a clear model to follow.

One of the biggest challenges to emerge was balancing the burden on students to be continuously providing feedback, which was reported as more of an issue for the masters and doctoral students. The students discussed this in similar terms to the reflection "burnout" referred to by Anderson (1992, p. 308). While the drawbacks of technology-enhanced learning are smaller than the number of benefits, they could become more pronounced if several types of technology-enhancements are combined. This multiplier effect also requires further investigation. This would help form a framework for technology-enhanced learning that is determined by the needs of the students at different levels of higher education science.

Table 1. Benefits and challenges of technology-enhanced learning in relation to student engagement, assessment, and reflection.

Type of Technology-	Benefits	Challenges

enhanced Learning		
Engagement through mobile technology	Anonymity Facilitates real-time whole class discussions Empowering for less confident students More suitable for large undergraduate classes	Reduces opportunities for oral discussion in small groups (especially for postgraduate students)
Self and peer-assessment	Gives more ownership and agency to students in their assessment Reduces burden on staff to provide formative feedback	Critiquing a classmate's work can be an uncomfortable experience for some students
Reflection	Facilitates faster personal insights for students on their learning Develops critical thinking skills	Risk of reflection burnout

SCAFFOLDING RESEARCH-LIKE LABORATORY PROJECTS FOR FIRST-YEAR STUDENTS

Rikke Frøhlich Hougaard[1] and Birgitte Lund Nielsen[2]
[1] ST Learning Lab, Aarhus University, Aarhus, Denmark
[2] ST Learning Lab, Aarhus University & VIA University College, Aarhus, Denmark

Research-based teaching is the cornerstone of university teaching. A central part of research-based teaching relates to students' work in inquiry-based projects where they make sense of and use research literature. Collaborative work with research methods and literature in the laboratory might be a key to develop students' sense of belonging to a specific academic field within the STEM disciplines. During the first years of studies, such teaching is however often challenged since novice students do not yet have the qualifications to work with an authentic research project. The present paper discusses findings from two first year courses in the study programs of chemistry and biotechnology, respectively. In both courses, students work with authentic research in the form of research papers and laboratory work with research-like activities. A comparison of the design of the two courses shows differences, e.g. in the extent of student autonomy, collaboration, feedback and peer-feedback. Students' learning experience, perceived learning outcomes and sense of belonging at the department were investigated with repeated questionnaires with open reflections and likert-scale questions. Based on these data possibilities and challenges related to designing research-like learning experiences for first-year students are discussed.

Keywords: Laboratory work in science, higher education, learning communities

INTRODUCTION

First-year university students' retention to the university and to the field of science and technology studies in particular is frequently discussed. Tinto (2017) suggests a focus on how to support students' persistence emphasizing a student perspective instead of an institutional perspective ('retention'). Understanding students' persistence can be approached by theories about intrinsic motivation referring to their experience of competence, autonomy and also relatedness (Ryan & Deci, 2017). 'Sense of belonging' referred to by Tinto (2017) as determinant for persistence is a complex construct with some similarity to 'relatedness'. It is dependent both on efficacy beliefs before entering the university and on students experience of being invited into a community of practice with peers and academics. Hence, there are reasons to believe, that being invited into collaboration about research, which can be seen as the core of the subject and its methods, might affect student persistence.

The present study involving cases from laboratory-intensive studies at the faculty of Science & Technology (ST) was inspired by the model of research-based education from Healey (2005) (figure 1) referring to both students' active involvement in research-processes and their work with research as content. Healey and Jenkins (2018) suggest that university students can be involved in research-like activities from an early stage in their studies: "..*given suitable support and encouragement many more students – and at an earlier stage in their courses – can be* *engaged in discovery activities than many staff initially think is possible ..*" (Healey & Jenkins 2018:54).

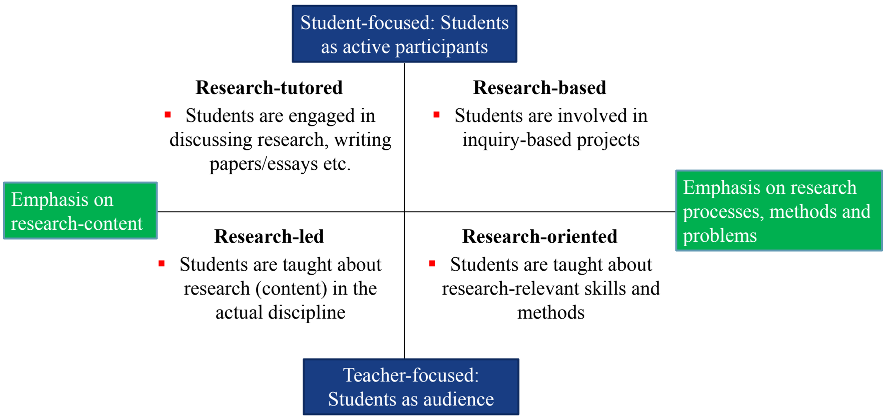

Figure 1. Research-based education (after Healy, 2005)

Healey and Jenkins (2018) discuss how to define 'undergraduate research' referring to this definition: "*..an inquiry or investigation conducted by an undergraduate student that makes an original intellectual or creative contribution to the discipline*" (Healey & Jenkins, 2018: 54). They suggest a broad understanding of the term "original contribution" and emphasize that you can speak about students' learning through research and inquiry even if the knowledge produced during the learning process is not necessarily new for the research society. This links to research in science education in particular about inquiry-based approaches such as IBSE (Inquiry based Science Education) and 5E (Engage, Explore, Explain, Elaborate, Evaluate). From technology education the so-called FITS model illustrates learning through design (Breukelen, Michels, Schure & de Vries, 2016) in iterative phases. The latter model inspired the phases used to represent the design of the two courses studied in here, namely 1) Preparation, 2) Experimental design, 3) Investigation, and 4) Report. Intentionally, these stages reflect the stages in an authentic research project.

In higher education the potential of transforming the traditional 'cookbook like laboratories' towards more inquiry-based approaches have been discussed in decades of research (Hofstein & Kind, 2012; Reid & Shah, 2007). Our previous work has evidenced how students' learning outcomes from laboratory teaching can be enhanced even with 'smaller' redesigns involving elements of 'guided inquiry' (Nielsen & Hougaard, 2018). This involves designing for learning both before, during and after a laboratory class, e.g. using pre-lab activities to make students engage with the content and methods, and scaffolding dialogue and critical reflection on data and methods during the activities in the laboratory (Nielsen & Hougaard, 2018).

In general academics believe strongly in the importance of research-based teaching with a direct link between research and teaching, but the term is not always used unambiguously (Robertson, 2007; Visser-Wijnveen et al., 2010). It can be used about transmission of research results to students, considering how the research performed at the local institution is integrated in the teaching or, alternatively, about challenging how students understand knowledge, knowledge-creation and research. However, there is no simple relationship between research productivity and teaching effectiveness of schools (Hattie & March, 1996; Brew 2001). How to frame students' work with research-based content and methods is basically a pedagogical question about: "*..attention to the design of the curriculum and how students learn*" (Healey & Jenkins, 2018).

At the faculty of Science & Technology at our university there is increasing emphasis on making students engage with research at early stages of the study programs. This has led to the development of several courses where first-year students work with primary research literature and laboratory work referring to this. The research presented here, refers to two specific courses "Introduction to Chemistry research" (ICR) and "Biotechnological project" (BTP). It is the purpose of both courses to give students an experience of working with research, but the designs of the courses are markedly different, as will be described below. In both courses, it was a challenge is to engage first-year students with complex research literature and research-like methods. The dilemma is that although it is difficult for the students, there are reasons to believe that a key to stimulating their persistence and sense of belonging at the university is indeed to scaffold them in collaborative work with research-like methods and content from cutting-edge research (Reid & Shah, 2007). This leads on to the following research questions.

Research questions

- How are the courses "Biotechnological project" (BTP) and "Introduction to Chemistry research" (ICR) designed and which activities do the students engaged in, during the phases of, 1) Preparation, 2) Experimental design, 3) Investigation, and 4) Report?
- What do the students emphasize as learning outcomes, possibilities and challenges after participating in one of the two courses?
- What characterizes the students' sense of belonging at the university in the beginning and after their second semester of study (including the BTP or ICR courses)?
- In which ways do the two courses contribute with a research-like experience for the students?

METHODS

The project operates implicitly with a design based research approach (Barab & Squire, 2004). The authors have been involved in suggesting minor elements in the course designs represented below in relation to the first research question. The findings from the present study are presented for the teachers to inform future redesign. The questions about perceived outcomes etc. were examined using a pre and post questionnaire with both likert-scale questions and essay questions for open reflections. The pre-questionnaire contained questions about the students' experiences from the first semester including questions about perceived outcomes from various teaching formats, their experience of mastering, and their expectations for the specific courses. Furthermore, there were items about sense of belonging (adapted from Trujillo & Tanner, 2014). These items were repeated in the post-questionnaire which also included questions about perceived outcomes, challenges as experienced by the students and experiences from working with cutting-edge research. Data analysis included frequency analyses and cross tabulations. Essay answers were analyzed using thematic analysis (Braun & Clarke, 2006). The pre-questionnaire was distributed to all students at a teaching session in the two courses in February 2019, with responses from 35 students from BTP and 34 from ICR.

Post-questionnaire was distributed (electronically) in May/June 2019 after the end of the course, and answered by 20 students from BTP and 26 from ICR (58% and 76%, respectively). A non-response analysis showed no systematic differences in answers in pre-questionnaire comparing respondents and missing answers from post-questionnaire.

RESULTS

In the following, the design of the two courses are illustrated (figure 2), and the perceived outcomes, challenges and possibilities are reported for the two cases one by one. Finally, the answers to the last two research questions are presented as a comparative analysis.

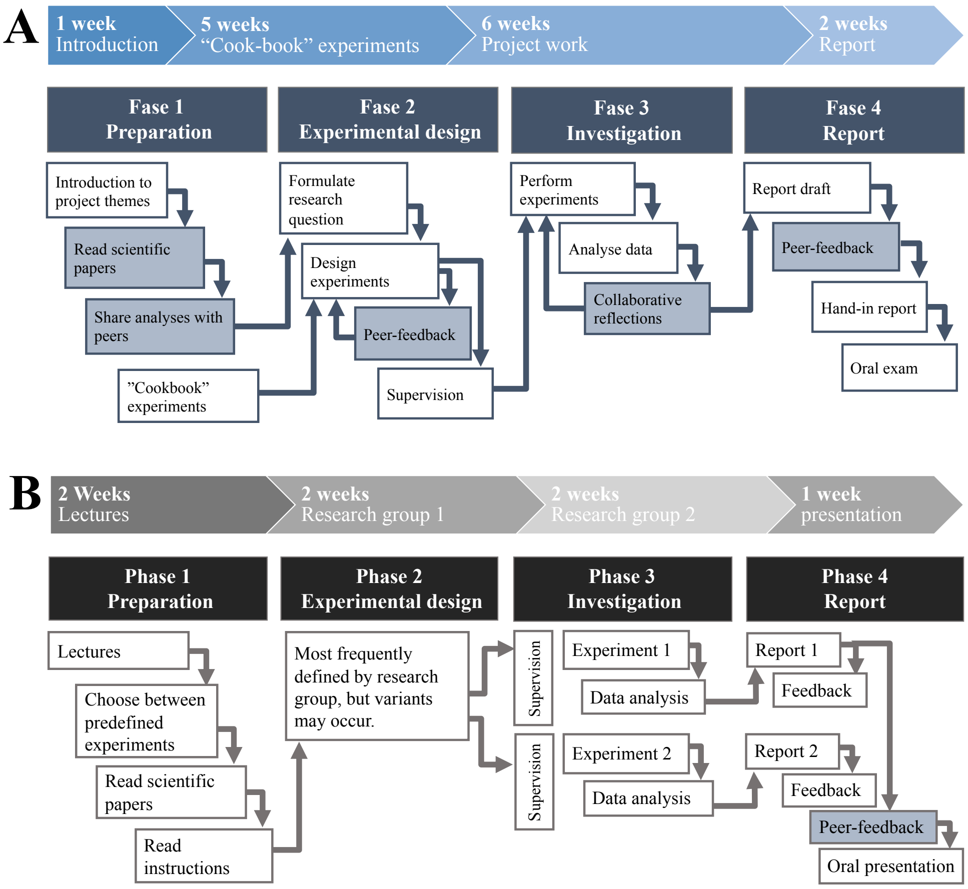

Figure 2. A schematic representation of students' tasks during the four phases of the redesigned courses: A) BTP B) ICR. Both courses account for 1/6 of the workload of the respective semester. Light blue boxes represent collaborative activities.

Design of the two courses

The BTP course (figure 2A) is offered at the second semester of the Biotechnology Engineering program. During a Preparation phase (phase 1) students attend introductory lectures and highly guided cookbook labs. In addition, they choose between different topic for their project and read one or a few research papers related to the topic. The topics ("Biosynthesis af Indigo",

”A cure for Phenylketonuria”, or”Development of antibiotic peptide”) are determined by the course lecturer. Common to all projects is that the students must clone and express a gene. During the Experimental Design phase (Phase 2) the students work in groups and autonomously decide which experiments to perform, and they make a project plan. After peer and teacher feedback, students adjust their plans and perform the planned experiments under guidance by teaching staff during the Investigation phase (Phase 3). At the end of the semester, in the Report phase (Phase 4), students hand-in a draft report for peer-feedback and subsequently a final report for assessment at the final exam. During all four phases of this design, emphasis has been put on scaffolding students´ inquiry and collaboration, e.g. via peer-feedback activities. Particular effort is put into the experimental design phase, where students work on designing the experimental setup.

The ICR course is offered at the second semester of the bachelor program in chemistry. The main intention with the course, as expressed by the course teacher is, that students gain experience with cutting-edge research in an authentic research laboratory and engage in collaboration with staff. The course is organized with a preparation phase (Phase 1) with a series of invited lectures about cutting-edge research at the department. The course coordinator assigns two experiments, offered by different research groups to groups of 2-4 students. The two student groups followed in this study performed the experiment ”Growing one-crystal topological insulators” or “Investigating protein structures at a biomaterial surface with femtosecond laser light”, respectively. In most cases, the experiment is predetermined by the research group and described in a cookbook-like manual. The students do not necessarily engage in any activities related to experimental design (Fase 2). During the investigation phase (Phase 3), the students work on two consecutive, but typically unrelated experiments, in two different research groups. Each experiment is reported in a lab report during the report phase (Phase 4). A collaborative task was designed for this phase, where students provide peer-feedback on a draft version on the oral presentation before a final presentation was assessed by the teacher.

Perceived outcomes, challenges and possibilities: BTP

In the post questionnaire 85% of the students reported a high or very high learning outcome from the BTP course as represented in figure 3. In both pre and post questionnaires, students were asked about their perceived learning outcomes from a broad range of teaching formats not restricted to this specific course. It can be seen in the representation in figure 3 that the majority (78 %) of students value the learning outcome from project work high or very high before the project work. In the post-questionnaire at the end of the second semester this number increases to 97 % (compare light blue columns with the dark blue).

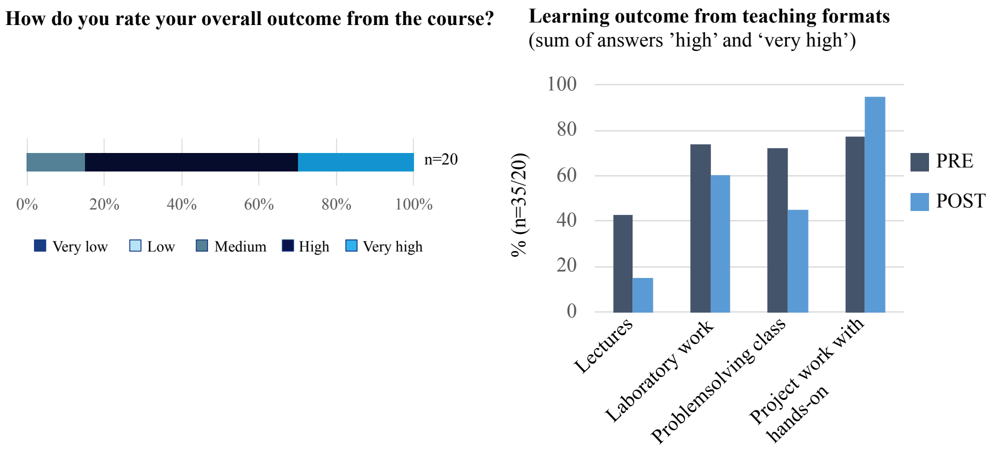

Figure 3. Learning outcomes from BTP (left) and learning outcomes from various teaching formats as expressed in the questionnaires before (pre) and after (post) project work (right).

In their reflections many of the students referred to the experience of autonomy in relation to their own project, and the influence on learning and motivation. They referred e.g. to being ”the master” of their project. Furthermore, there are indications that the students engaged in authentic inquiry process, but also that the guiding and scaffolding of both the experimental and writing tasks in Phases 1 and 2 were a good learning support.

- *"It has been really good to be in charge of the project ourselves and to have the freedom to investigate exactly what we find interesting"*
- *"The degree of autonomy made you think more about what we did and why we did it. You inquired into things in an entirely different way than you would usually do".*
- *"..that we had small assignments during the course (e.g. writing and giving feedback to peers on introduction and draft report). In this way you learned efficiently what you had to do, and what could be improved".*
- *".. in the beginning we had a manual, later on we had to design experiments with guidance from the teacher. I think this was really good and I learned a lot from having to figure out how things could be investigated in the lab"*

Challenges were identified, particularly relating to the use of research literature. The scaffolding of reading tasks was apparently not sufficient, and the perceived mastery of the theory low:

- *"There has not really been any theoretical "teaching". Therefore, theory has not been so in-depth and it is hard to answer questions regarding this in the exam".*

Perceived outcomes, challenges and possibilities: ICR

The majority (60%) of students attending the ICR course perceived their learning outcome as high or very high as evident from the representation in figure 4, left. In the open reflections the students particularly emphasized a perceived outcome relating to the experience of being in an authentic research laboratory and working in a research group (figure 4, right).

- *"The theory behind the project was nice to learn. It was a lot of fun to be part of a research group and learn how their daily routine works".*

- *"It has been exciting to see two different ways of working with chemistry..... And I have noticed how our auxiliary courses are more relevant than I thought"*

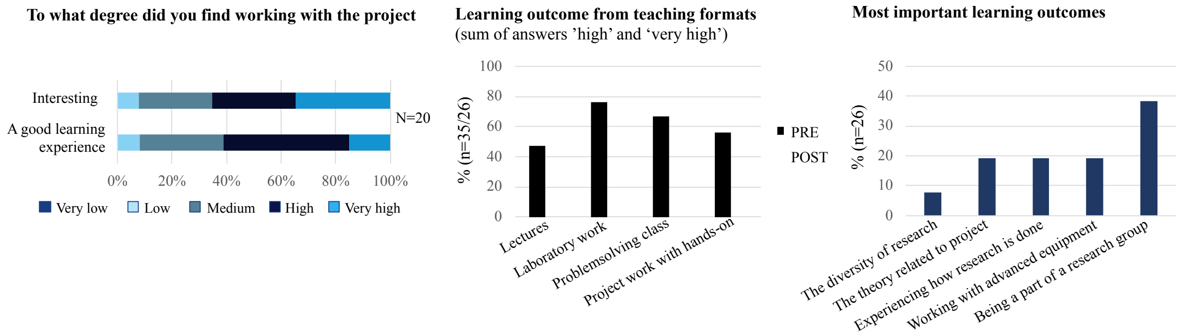

Figure 4. Learning outcomes from ICR (left) and learning outcomes from various teaching formats as expressed in the questionnaires before (pre) and after (post) project work (middle). Learning outcomes expressed in students' open reflections in the post-questionnaire where categorized and represented (right).

The challenges reported by the students mainly related to understanding the theory:

- *"It was difficult to understand the theory behind the experiments and do the data analysis because we do not understand what we are actually doing".*

It is interesting that these students apparently perceived the learning outcome from project work with hands-on lower than students from BTP before the project work. Additionally, in this course fewer students reported a high or very high outcome from project work in the post-questionnaire (grey) compared to the pre-course questionnaire (black).

The experience of mastering: Comparing before and after and across courses

The pre-questionnaires included questions asking students to what degree they expected to be able to perform specific tasks related to the project work, and the post-questionnaire correspondingly to what degree they experienced to be able to perform the tasks (figure 5).

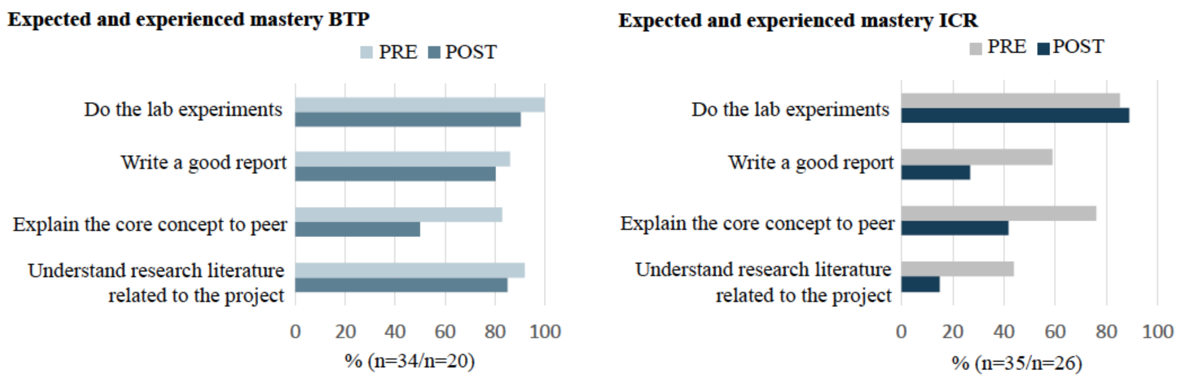

Figure 5. The expected and experienced mastery as reported before (pre) and after (post) project work in the BTP (left) and ICR (right). The figures represent the sum of the answers 'Agree' and 'Highly agree".

For BTP prior to the project work more than 80 % of the students stated that they agreed or highly agreed that they expected to be able to do the lab experiments, write a good report, explain core concepts, and understand research literature. After the course, 50% of the students agreed or highly agreed that they were able to explain core concepts, while 80% or more answered within these likert-categories for the remaining tasks. For ICR, the students' expected mastery before the project work was high relating to the experimental work and to explaining concepts (84 % and 76% respectively), whereas the numbers were lower (59 % and 44%) relating to writing a good report and understanding research literature. Interestingly, in this course the experienced mastery remained comparable to the expected only relating to performing the experimental work whereas the numbers for other tasks were halved.

A slight decrease in experienced mastery could be expected, as a decrease in student self-efficacy is typically during the first year of a university study (Tinto, 2017), but the difference between the two courses is remarkable. It is also noteworthy that although the experienced mastery in ICR is lower than the expected, the students rate their perceived outcome high (figure 4, left). The data presented in figure 5 emphasizes the finding above that in these courses it is a major challenge for students to read and understand research content and literature.

Sense of belonging: Comparing before and after and across courses

The students were asked about their feeling of belonging in their study program in pre- and post-questionnaires and the answers are represented in figure 6. One question addressed whether the students feel they have chosen the right study program (figure 6, upper part). For BTP a slightly higher percentage of students answered "agree" or "highly agree" after the course compared to before (90% compared to 72%) whereas for ICR these categories account for 80 % and 84% respectively, reflecting a minor decrease.

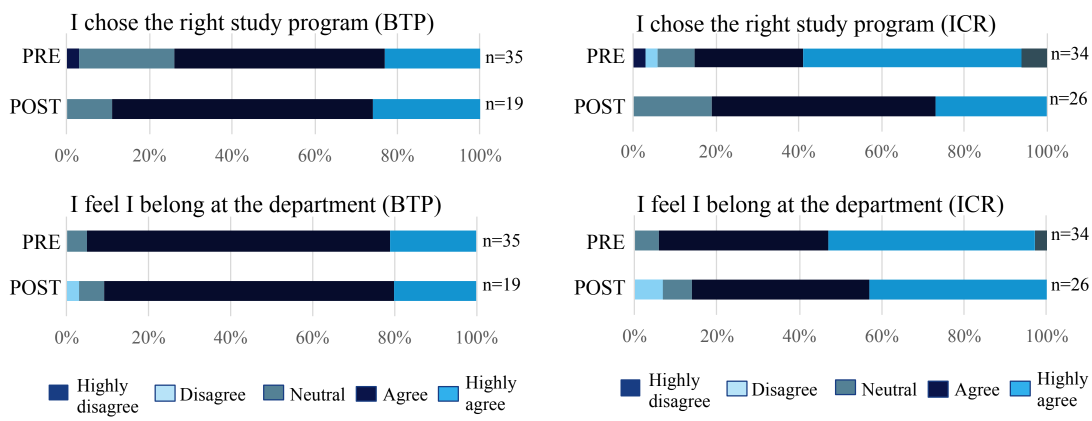

Figure 6. Sense of belonging before (pre) and after (post) project work in BTP (left) and ICR (right)

Another question addressed whether students' feel that they belong at the department (figure 6, lower part). Here 95% of students in BTP agree or highly agree in the post-questionnaire (91% pre). The corresponding numbers for ICR are comparable, namely 90% and 85%, respectively.

DISCUSSION

In the two courses BTP and ICR students have worked with research literature, guided experiments in the lab, data analysis and reports on data. The two courses were designed very differently, with e.g. more scaffolded possibilities for feedback and peer-feedback during BTP than ICR. Previous research has shown that scaffolding of the inquiry-based activities can be crucial (Hofstein & Kind, 2018; Nielsen & Hougaard, 2018), and the scaffolding of the collaborative activities appear to have been supportive according to the students' perceived learning outcomes, in particular at BTP. The students emphasize the progression through the course towards the more open inquiry approach. But students have also experienced some challenges. At both courses the students refer to a lack of support in working with the complex content. The students from ICR in particular emphasize the experience of working in a research group, e.g. working with the advanced equipment, as an important learning outcome. There are also indications of an authentic research experience including a growing understanding that research requires both creativity and persistence and that you do not always get the expected results. The students from ICR have experienced to master the tasks they were given in the laboratory, but they also reflect on how these tasks have been rather elementary, since they experienced that the procedure was predetermine similar to a (invisible) cookbook.

In what ways research-like?

The students' reflections on the two courses can be understood referring to motivation research (Ryan & Deci, 2017). The students from BTP have experienced and valued the autonomy that followed the first phase with guiding in the laboratory. These students have to a relatively high degree experienced to master the tasks associated with the project work, except for challenges in relation to perceived understanding of the theoretical content (including research literature). The students from ICR did not report the same experience of autonomy, but have experienced to master the relatively simple tasks they had in the research lab. In figure 7 the differences between how these two courses provided a research like experience for the students are illustrated with the green and yellow arrows in the model from Healey (2005).

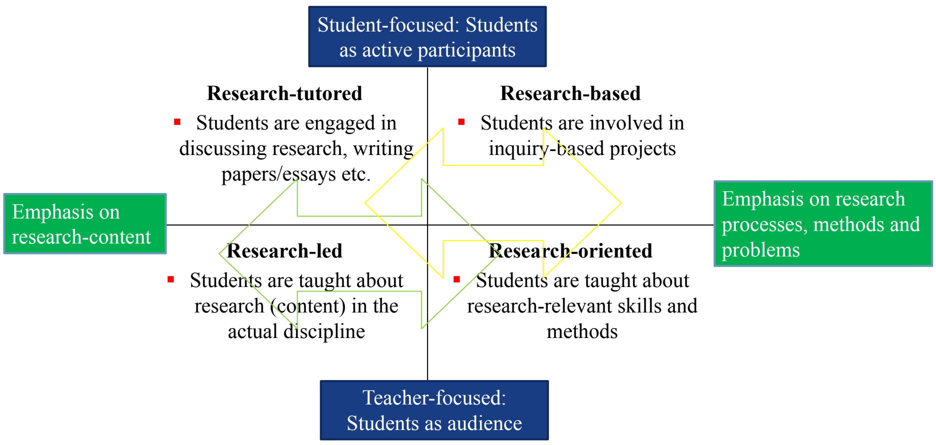

Figure 7. Using the model from Healey (2005), to compare the two courses.

A strength in the design of the BTP is that the students do their own inquiries in the laboratory. The students have to a relatively high degree an experience of mastering the task associated with completing a research-like project in the laboratory, even though they in reality worked in a teaching laboratory. Opposite to this, the students from ICR have been in authentic research laboratories. They value this, but have an experience of being audience to the real research, performing tasks of low complexity in the periphery of the research. They have however been introduced to the actual research in lectures and conversations with researchers and therefore the green arrow is mainly covering the lower field to the right in the model (figure 7).

Looking forward, one recommendation is to address the challenge about the complex theory when redesigning the courses. A first step could be to explicate, via dialogue with the students, that they are not expected to understand all details in the research papers at this stage of their studies. Scaffolding of the students work with research papers could involve pointing out certain elements they have to focus on, and gradually progress to help them learn how to read this genre of literature. This has for example been done with good results in several settings using the so-called C.R.E.A.T.E. approach (Hoskins et al., 2011), which focuses on scaffolding students understanding of the methods and the way data are represented.

DEVELOPMENT AND EVALUATION OF A CHEMISTRY TEST FOR HIGHER EDUCATION

Bianca Paczulla[1], Vanessa Fischer[1], Elke Sumfleth[1], Maik Walpuski[1]
[1]University of Duisburg-Essen, Essen, Germany

The persistently high dropout rates in chemistry study programs can be traced back to a number of performance related problems students face during study entry phase (Maaz et al., 2018; Heublein, 2014; Ulriksen, Madsen, & Holmegaard, 2010). In Germany, the dropout rate has been shown to be 45 % for first semester students in chemistry study programs at universities and 34 % for their counterparts at universities of applied sciences (UAS) in 2012/2013 (Heublein & Schmelzer, 2018). Previous research on academic achievement has mainly focused on chemistry study programs at universities. Due to several differences between students from universities and students from UAS (Middendorff et al., 2017), it is difficult to transfer the results to students from UAS.

One research goal of the project CASSIS (Chemistry, Social Sciences and Engineering: Study success and dropout) lies in identifying subject-specific reasons for students' dropout at universities and at UAS referring to Heublein's (2014) model of the dropout process in order to improve study conditions evidence based depending on students' specific characteristics and on specific qualification aims.

Hence, we focus on the individual study process characterized by structural factors, psychological and physical resources, study behaviour, study motivation and performance in the studies. To investigate students' performance, it is necessary to develop and to evaluate content knowledge tests that can be used not only at universities, but also at UAS. This paper describes the construction and evaluation of such a test on content knowledge for the subject chemistry.

Keywords: higher education, evaluation, STEM education

THEORETICAL BACKGROUND

German higher education institutions – comparison between universities and universities of applied sciences

After having completed secondary school, students can obtain the upper secondary degree (*Abitur*) or a restricted upper secondary degree (*Fachhochschulreife*) which are equivalent to ISCED3 and which both give access to tertiary education (van Ackeren, Klemm, & Kühn, 2015). In general, the *Abitur* allows for studies at all universities. The *Fachhochschulreife* allows for studies at universities of applied sciences (UAS) and certain studies at universities. Although these higher education institutions award comparable bachelor or master degrees or rather ISCED6 or ISCED7 (van Ackeren et al., 2015), they are different in a number of ways. For instance, UAS show not only a greater vocationally orientation than traditional universities but they also emphasize the applicability of knowledge (Schindler & Reimer, 2010). Furthermore, students from UAS differ from students from traditional universities (Middendorff et al., 2017). The majority of students from traditional universities (90.5 %) have obtained the *Abitur*, whereas there are only 59.6 % of students from UAS with the same degree. Therefore, there are more students skilled in vocational training on UAS (36 %) compared to traditional universities (14 %) (Maaz et al., 2018).

Research project CASSIS

CASSIS aims at investigating whether the significance of the factors in Heublein's (2014) model (Figure 1) of the dropout process differs between universities and UAS in regard of different study programs. In addition, the interaction between these factors will be investigated in a longitudinal study. This paper focusses solely on chemistry study programs. First year chemistry students from two universities and two UAS are surveyed for three semesters. To investigate their performance in the studies within this period, it is necessary to develop and to evaluate a chemistry content knowledge test, which can be applied at both types of higher education institutions. Furthermore, this chemistry content knowledge test needs to contain a variety of chemistry-specific topics that are taught in the first three semesters. The pilot study includes the development and the evaluation of this test which are central in this article.

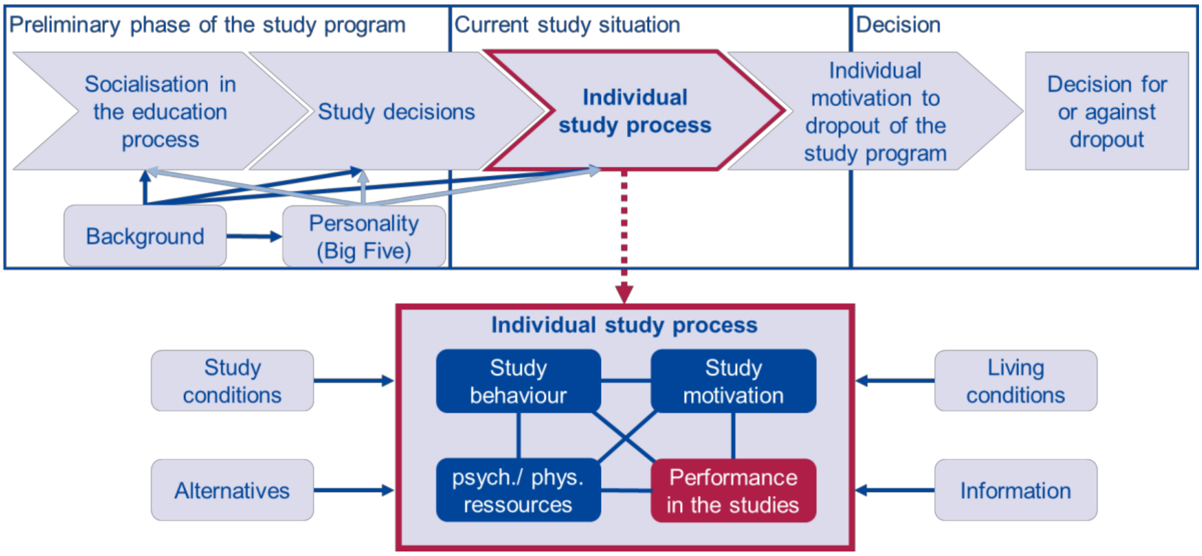

Figure 1 Model of the dropout process based on Heublein (2014).

METHOD AND SAMPLE

It is essential to check the test quality criteria of especially a new test instrument. The validity of a test is of particular importance and can only be given, if the test measures objectively and reliably (Moosbrugger & Kelava, 2012). The new test instrument shall not only measure students' chemistry content knowledge acquired during the first three semesters of their studies but also be suitable for the application at traditional universities and at UAS.

Regarding the content validity, it is first necessary to select relevant topics for the chemistry content knowledge test. In consideration of these topics, suitable items need to be chosen. Therefore, already existing and items can be used or new items can be developed, if it is necessary.

By comparing the curricula of the first, second, and third semester of chemistry study programs from two universities and two UAS, many relevant topics for the chemistry content knowledge test have been identified. All four chemistry study programs comprise courses in *General, Inorganic, Physical, Organic,* and *Analytical Chemistry*. To assess students' performance, overall tests for all courses are necessary. As a first step, the usability of already existing chemistry knowledge tests was checked. In a second step, these tests were modified and amended by additional items. All adapted tests were revised in a pilot study, while already empirically evaluated tests were not included in pilot study or only administered to new target groups.

Freyer, Asikainen, Hirvonen, & Sumfleth (2015) have developed a General Chemistry knowledge test that has been used at different universities including the University of Duisburg-Essen. We evaluated the applicability of the test at two UAS in winter semester 2017/2018 with positive results (Paczulla, Schüßler, Sumfleth, & Walpuski, 2018).

The research group ALSTER developed chemistry content knowledge tests for the disciplines *Inorganic, Physical, Organic,* and *Analytical Chemistry* that refer to the topics of the first two semesters (Averbeck, Hasselbrink, & Sumfleth, 2018; Dickmann, Rumann, & Opfermann, 2017). Within their research projects, these chemistry content knowledge tests were used at two universities. By comparing the topics in these tests with the identified relevant topics from the curricula, many existing items were selected for the new chemistry content knowledge test. Items covering the curriculum of the third semester were added with the support of local teaching staff. The chemistry content knowledge test contains 140 items and is divided into the four disciplines *Inorganic, Physical, Organic* and *Analytical Chemistry* (35 items for each discipline; each discipline contains 5 anchored items). All items are multiple-choice single-select items.

Students from University Duisburg-Essen have already taken chemistry content knowledge tests designed by Averbeck et al. (2018) and Dickmann et al. (2017). Thus, it was not necessary to involve students from this university again. Consequently, the investigation of the adapted test was carried out at one more university (*Uni*) and at two UAS at the beginning of summer semester 2018. Accordingly, students from the second (*2nd Sem*) and the fourth semester (*4th Sem*) participated in the study ($N_{total} = 179$, $n_{Uni} = 48$, $n_{UAS} = 131$; $n_{2nd\ Sem} = 81$, $n_{4th\ Sem} = 98$). Four test booklets were administered in a multi-matrix-design. The test booklets for students from the second and the fourth semester are identical. This makes it possible to examine, whether students from the fourth semester perform better than students from the second semester. Each student had 80 minutes to work on one test booklet.

The data of the chemistry content knowledge test is evaluated by using Winsteps® Rasch Measurement (Version 4.3.4) (Linacre, 2019). In particular with regard to objectivity and reliability of the test, the first step of the analysis focusses on the evaluation of the entire test regarding the Rasch model. By conducting a principal component analysis (PCAR), multidimensionality of the test was investigated.

RESULTS AND DISCUSSION

Due to low values for the item discrimination ($r < 0.2229$), five items were excluded from further data analysis. As shown in Table 1, there are good reliabilities for the whole sample and for the whole test. Furthermore, the person reliabilities for each higher education institution are good, whereas the item reliability for the single university is slightly below the desired value of .90 due to the small sample size (Linacre, 2018). As a result, person abilities can sufficiently be determined. Moreover, the item fit values show a satisfactory range ($0.75 \leq$ InfitMNSQ ≤ 1.35) providing evidence, that items fit the Rasch models. Regarding the entire sample, the whole test shows an adequate difficulty with the mean of item difficulty ($M_{Item\ difficulty} = 0.00$, SD = 1.06) being approximately equal with the mean of person abilities ($M_{Person\ abilities} = 0.08$, SD = 0.73). Consequently, not only the data fits the Rasch model well, but is also adequate for the focussed sample. Regarding students from UAS, it was possible to compare students' performance in the second and fourth semester. As expected, students from the fourth semester perform better than students from the second semester ($M_{Person\ abilities,\ UAS,\ 2nd\ Sem} = -0.33$, SD = 0.62; $M_{Person\ abilities,\ UAS,\ 4th\ Sem} = 0.27$, SD = 0.65; $t(129) = -5.28$, $p < .001$, $d_{Cohen} = 0.95$). Consequently, it is possible to measure the development of chemistry content knowledge during the study entry phase.

Table 1 Sample, reliabilities and fit-statistics estimated with Winsteps® Rasch Measurement (Version 4.3.4) (Linacre, 2019).

	Person			Item ($N_{Item,\ total}$ = 135)			
	Reliability	Separation	Abilities *M (SD)*	Reliability	Separation	Abilities *M (SD)*	Infit MNSQ (Range, *M*)
Total (N_{Person} = 179)	.86	2.51	0.08 (0.73)	.94	4.02	0.00 (1.06)	0.79 – 1.34 1.01
Uni (N_{Uni} = 48)	.81	2.04	0.54 (0.68)	.83	2.17	0.00 (1.37)	0.75 – 1.34 1.01
UAS (N_{UAS} = 131)	.85	2.35	-0.09 (0.69)	.92	3.29	0.00 (0.06)	0.78 – 1.35 1.01

Since the chemistry content knowledge test contains items from of the four disciplines *Inorganic, Physical, Organic* and *Analytical Chemistry*, multidimensionality of the entire test was investigated by conducting a principal component analysis of residuals. Due to the small sample size in comparison to the great number of items, the interpretation of the results (Table *2*) needs to be treated with caution (Linacre, 2018).

Table 2 Principal component analysis of residuals (PCAR) computed with Winsteps® Rasch Measurement (Version 4.3.4) (Linacre, 2019).

		Eigen-value	Observed percent-age of total variance	Observed percent-age of unexplained variance	Expected percentage of total variance
Total raw variance in observations		177.32	100.0 %		100.0 %
Raw variance explained by …	measures	42.32	23.9 %		23.5 %
	persons	16.45	9.3 %		9.2 %
	items	25.867	14.6 %		14.4 %
Raw unexplained variance (total)		135.00	76.1 %	100.0 %	76.5 %
Unexplained variance in…	1st contrast	4.40	2.5 %	3.3 %	
	2nd contrast	3.89	2.2 %	2.9 %	
	3rd contrast	3.51	2.0 %	2.6 %	
	4th contrast	3.22	1.8 %	2.4 %	
	5th contrast	3.21	1.8 %	2.4 %	

Due to the high number of items, it is possible that a random cluster of items is inter-correlated by accident (Linacre, 2018). Although the results (Table 2) seem to indicate several dimensions because of the great eigenvalues (< 2.0), the variance explained by the several contrasts (1.8 % to 2.5 %) are clearly below the variance explained by the item difficulties (14.6 %). Accordingly, the Rasch item difficulties of the unidimensional data explain more variance than a further dimension. This result suggests that the data structure is unidimensional. Furthermore, the disattenuated correlations between the person measures on the assumed cluster of items and the person measures on the other items (Table 3) indicate that the assumed cluster of items and the other items do not measure different things. Thus, the data structure is unidimensional.

Table 3 Approximate relationships between the person measures computed with Winsteps® Rasch Measurement (Version 4.3.4) (Linacre, 2019).

PCA Contrast	Item clusters	Pearson correlation	Disattenuated correlation	PCA Contrast	Item clusters	Pearson correlation	Disattenuated correlation
1	1 - 3	0.1867	0.4418	4	1 - 3	0.1612	0.2627
	1 - 2	0.7489	0.9593		1 - 2	0.5337	0.8399
	2 - 3	0.3008	0.7351		2 - 3	0.6272	0.8226
2	1 - 3	0.1614	0.2240	5	1 - 3	0.2857	0.4672
	1 - 2	0.6094	0.8126		1 - 2	0.6686	1.0000
	2 - 3	0.5775	0.7752		2 - 3	0.5730	0.7818
3	1 - 3	0.2327	0.3086				
	1 - 2	0.5141	0.7028				
	2 - 3	0.5723	0.7783				

Because of unidimensional data structure, the chemistry content knowledge test with its 135 items measures reliably one single construct. The Rasch models give evidence that it is suitable for estimating chemistry knowledge of students from universities and UAS. Linacre (2018) explains that test can be split into separate test instruments, if further dimensions are important and different enough to merit various measures. At this point, it should be mentioned that each item of the chemistry content knowledge test refers to one of the four disciplines *Inorganic, Physical, Organic* and *Analytical Chemistry*. Consequently and due to the results of the PCAR, it is allowed to divide the entire test into four tests concerning the four disciplines *Inorganic, Physical, Organic* and *Analytical Chemistry*.

For the main study, the tests for the four disciplines Inorganic, Physical, Organic and Analytical Chemistry need to be shortened. The shortened tests shall cover a wide range of topics of the related disciplines. Considering this intention, the item fit statistics and the results from Averbeck et al. (2018) and Dickmann et al. (2017), 20 items have been selected for each discipline (80 items in total).

OUTLOOK

The following main study has started at the beginning of winter semester 2018/2019. At the first measurement point (Table 4), 289 first year chemistry students from two universities and two UAS took part in the main study. In consideration of the curriculum at all participating higher education institutions, the tests in *General Chemistry, Physical Chemistry* and *Analytical Chemistry* have been applied to assess students' prior chemistry knowledge (Table *4*, MP 1) that students gained in secondary school. Besides students' school career, students' prior knowledge is a part of the socialisation in the education process of Heublein's (2014) model of the dropout process (Figure 1). Students' chemistry content knowledge as part of the performance at the studies (Figure 1) was surveyed at the beginning of summer semester 2019 (MP 2) and of winter semester 2019/2020 (MP 3). The last survey will take place at the beginning of summer semester 2020 (MP 4). In addition to students' content knowledge, further influencing factors from Heublein's (2014) model as study motivation, personality, background (e.g. socio-demographic background), study behaviour (e.g. self-evaluation, learning strategies) will be surveyed several times and investigated regarding their impact on study success in chemistry study programs.

CRITERIA-BASED ASSESSMENT OF KNOWLEDGE IN BIOLOGY IN HIGHER EDUCATION

Veronica Flodin[1] and Jessica Slove Davidson[2]
[1]Stockholm University, Department of Mathematics and Science Education, Stockholm, Sweden,
[2]Stockholm University, Department of Biology Education, Stockholm, Sweden

Assessment of knowledge is a key part of all programs. In higher education, the assessment process since 2006 also has had an ambition to be equivalent in Europe through a joint agreement in Bologna. Standards and guidelines for quality assurance are made, for example that criteria for and method of assessment are published in advance to enhance transparency. Course objectives are formulated as student-centered learning outcomes coupled with assessment criteria that describe what the learner is expected to do and to what level. At some Swedish universities, the reform was completed in 2007. A question is thus, how learning outcomes and assessment criteria are expressed in biology courses of today. All course plans and course documents from the academic year 2015/2016 in biology at one university have been collected and categorized according to type of assessment criteria. This study focuses qualitatively expressed assessment criteria, i.e. differences in quality are expressed with words. Three different categories were found. The quality of student answers are assessed as different levels of abilities, different levels of relational complexity or different levels of attributes. Possible knowledge taxonomies affecting the criteria are discussed as well as the lack of critical analysis of assessment practice in higher education courses. The influence of view of knowledge is highlighted and differences in preconditions for knowing in different sub disciplines. Consequences for teaching and learning and possible solutions are raised.

Keywords: biology, higher education, assessment criteria

INTRODUCTION

Assessment of knowledge is a key part of all programs. In the standards and guidelines for quality assurance in the European Higher Education Area (ESG, 2015), it states that "The criteria for and method of assessment as well as criteria for marking are published in advance; the assessment allows students to demonstrate the extent to which the intended learning have been achieved " (p.12). The Bologna process in Europe includes a shift of attention from what is taught to what the student is expected to know and is able to do at the end of the course or program, as well as being more explicit and transparent with assessment criteria.

However, Torrance (2007) describes how this transparency (and measurability) which is supposed to give rise to an absolute and equal treatment are increasingly time-consuming processes. Torrance (*ibid*) believes that the quest for transparency encourage an instrumental approach to learning and can further be characterized as "… a move from assessment *of* learning, through the currently popular idea of assessment *for* learning, to *assessment as learning*, where assessment procedures and practices come completely to dominate the learning experience, and 'criteria compliance' comes to replace 'learning"' (p. 282). Furthermore, it has been shown in studies by, for example, Orsmond and Merry (2013) that students may have different ease with or difficulties in understanding what the criteria actually mean.

In a school-level review, it was shown that new assessment systems take almost ten years to anchor among teachers (Lindberg, 2013). This development can be compared to the implementation of the Bologna process in Sweden, where the shift to completely new type of syllabus was transposed in less than a year, and university teachers would learn completely new ways of designing courses and examinations (Lindberg-Sand, 2012).

At a university in Sweden, the teachers in science subjects went from formulating course goals that mirrored the intentions of the teachers, to learning outcomes that should specify what the students were supposed to be able to do, if they passed the course. Further, before the Bologna process, the assessments at the science faculty were based on credits, or points, which corresponded to a three-graded scale: failed, passed, and passed with distinction. The new directions not only meant a restructuring of course material, but also included to write assessment criteria for a seven-graded scale: A, B, C, D E, Fx, F (where Fx and F corresponds to failed). The criteria would qualitatively describe how the different grades corresponded to the learning outcomes of the course.

Different kinds of supporting material were developed, in order to support the teachers in transforming their course plans and other course documents. This can also be seen internationally. For example, Moon (2006) has written texts about how to link learning outcomes with assessment criteria as well as examples of how to write them. In a narrow perspective, it is about changing verbs. Instead of a formulation where the student should 'know' (goal), the student should be able to 'distinguish', 'identify', 'compare' (learning outcome). Instead of getting 60% or 80% credits on a written exam, the student should get a written statement in beforehand about what kind of assessment criteria that should be met by the student.

However, how do you differentiate and formulate what the student should be able to do in seven different steps, for all the learning outcomes? As a teacher in science in higher education, you are an expert *within* your subject, but not especially equipped to reason *about* your subject. One way for the teacher to solve it, is to simply put an adjective in front of the content: sufficient insight into the subject, satisfactory, good.., very god… and excellent insight into the subject. So, what has actually happened? What do the assessment criteria look like today, some 10 years after the implementation of the Bologna process?

Aim and question

This study is part of a larger study that aims at developing knowledge of the assessment practice in higher education based on the experienced university teacher. The purpose of this study is to categorize the content of the assessment criteria in different courses in biology. The questions is: How are assessment criteria qualitatively expressed in courses in biology?

METHOD

All course plans and course documents from the academic year 2015/2016 in biology at a university in Sweden have been collected. The formulated assessment criteria have been categorized inspired by Sadler (2005). The assessment criteria were dived into three themes, A- non-qualitative grading criteria, B - qualitative grading criteria and C -different combination of activities.

This study focus on twelve course plans that have assessment criteria that are qualitative (B), which means that the assessment criteria are expressed with words, which describe levels of understanding.

The assessment criteria from the different courses in theme (B) are further categorized into sub-categories. In this presentation, examples of assessment criteria from different sub-categories are chosen in order to show differences between them. The assessment criteria sometimes involve a lot of text describing what criteria the student should meet for the specific grade in relation to all learning outcomes in the course. Text that has not been included in examples or citations are notated as brackets […].

RESULTS

How are assessment criteria qualitatively expressed in courses in biology? The assessment criteria were distributed into three different sub-categories 1) abilities, 2) relational complexity, 3) attributes. One example from course documents are shown for each category. The examples are then followed by a comment that show how the criteria has been read. Only grade E (passed, lowest grade) and grade A (excellent, highest grade) are shown as illustrations. The course example is introduced with a learning outcome, which is connected to the assessment criteria. This was not always the case. In some instances, the learning outcomes and assessment criteria were not obviously in relation to each other. The results are further interpreted and discussed in the next section.

1) The quality of student answers are assessed as different levels of *abilities*.

Course (1)

Example of learning outcome: *Compare and contrast different disciplinary approaches to social-ecological systems, and explain in what contexts they are more or less useful*.

Example of assessment criteria:
Grade A - *excellent insight and deep understanding of how the module concepts are related to research social-ecological systems. Excellence in analysis, assessment and synthesis in written and oral discussions*.
Grade E - *can recapitulate the contents of the course and define the basic concepts discussed in the different module components*.

Comment: The content concerns different abilities; define basic concepts compared to be able to relate to research and do analysis. There is a difference in what the student is supposed to know or do for the different grades. For the grade E the student should be able to ‘recapitulate’, ‘define’ the ‘basic concepts’ and the text does not even mention or require any analytical skills or any additional skills in discussing and explaining the module concepts . Grade A demands abilities like ‘analysis’, ‘synthesis’ and how concepts are ‘related to’ social-ecological systems.

2) The quality of student answers are assessed as different levels of *relational complexity*.

Course (2)

Example of learning outcome*: Explain basic concepts in molecular genetics; these include recombination, meiosis, replication, transcription and protein synthesis*.

Example of assessment criteria:
Grade A - *Can critically analyze different concepts in molecular genetics and put these into a larger context. Possess a full picture of the molecules that control different processes in molecular genetics and how these are interconnected*. […]
Grade E - *Explain basic concepts in molecular genetics without major misunderstandings. Can name a few important molecules and show acceptable understanding for how these control processes in molecular genetics*. […]

Comment: The content concerns knowing concepts and molecules, and doing that in a successively more complex way. For grade E, the student can 'name' basic concepts, 'name' a few molecules and show 'simple' or acceptable understanding of processes. In grade A, the higher level corresponds to 'critically analyze' different concepts and put into a 'larger context' 'integrated to a structure' (a full picture of the molecules) that are 'interconnected'.

3) The quality of student answers are assessed with different levels of *attributes* (adjectives).

Course (3)

Example of learning outcome: *Be able to utilize existing tools for taxonomic, systematic and ecological analysis of information such as are collected from scientific object collections and data collections.*

Example of assessment criteria:
Grade A - *Very well executed analyses and problem solving during the time allotted, conducted with a very high degree of autonomy and scientific maturity.* […]
Grade E - *Analyses executed. Some understanding of the problems presented and the theoretical background*. […]

Comment: The content concerns being able to do an analysis. The grade E corresponds to an analyses that is simply done and the student show 'some' understanding, a kind of 'sufficient' level. The grade A correspond to a 'very well executed analysis in a kind of 'excellent' manner. In this example, the content in the assessment criteria concerns the same ability, namely to perform an analysis, but it does not state what might be involved in a very well executed analysis (other than performed independently, on time and with maturity).

DISCUSSION

How are assessment criteria qualitatively expressed in courses in biology?

The principles of alignment and Blooms taxonomic pyramid guide course design and assessments as well as how the assessment criteria are formulated, in European higher education (see, for example, Kennedy, 2006, or Moon, 2006). The category 1) above (the quality of student answers are assessed as different levels of abilities), show clear traces of a "Bloomish" terminology, where the words describing the lowest and higher grades can be seen corresponding to the hierarchy of Blooms pyramid (Bloom, 1956). A possible knowledge taxonomy is therefore Bloom, where knowledge is fragmented into different distinct cognitive abilities, and where the ability to analyze is among the top cognitive abilities.

However, the underlying principles of higher education assessment have been used quite uncritically (Sadler, 2009). That which constitute the basis for a higher or lower grade can have several different interpretations, based on what view of knowledge and knowing one entails. The Bloomish perspective is about a view of knowledge where it can be fragmented into different distinct steps. The higher cognitive skills are also not part of the lower skills. For example, 'analysis' is not something that you may be more or less skilled at. Instead, the ability only emerges *after* other cognitive skills are in place.

An alternative approach is the SOLO taxonomy (Structure of the Observed Learning Outcome), which assess students' work in terms of increasing complexity. The model was once created by Biggs and Collis for schools (1989) and is now widely used internationally in higher education. The model starts with few aspects of the task at hand (uni-structural) towards a more relational and an integrated whole, and ends in multi-structural and generalized untaught applications. The category 2 in the result section above (the quality of student answers are assessed as different levels of relational complexity), can be seen as an example of this taxonomy. The understandings of molecular concepts increases in relational complexity, from a basic understanding to be able to put them in a larger context. In a study done by Chan, Tsui, Chan, and Hong (2002) they interpret student answers with SOLO taxonomy and compares to Blooms taxonomy. They see some application problems when applying SOLO and the ambiguities in interpreting for example what is' multi-structural'. They also state that Blooms taxonomy have "…a clearer division of categories that are mutually exclusive…" (p. 518). This also strengthen the view that we really need to examine more, what we mean are examples of quality of knowing (in biology). Questions to ask are for example, do we really have mutually exclusive abilities? Alternatively, what do multi-structural relations actually mean? Moreover, how do these different views of knowing affect the teaching and learning situation?

The last category in the results above, 3) different levels of an attribute, describes what the student is expected to do and to what level, but the level is described as 'very well' and it is unclear what that really entails. Since this is a study only of written material, it is possible that the actual teaching and learning activities makes it more clearly for the students on what is a good performance or a better performance. It is hard work to write what it means to know something good or better, and in time pressed schedules, it is easy to fall back to manuals and premade verbs. All three examples show at the same time a view of increasing quality going from some kind of "sufficient" basic performance (knowing "basic concepts"), to an "excellent", more complex, relational and analytic ability. The difference between the categories is how the abilities are shown: if being able to analyze is an ability that shows as a higher cognitive ability or can be graded and performed better or worse ("analyze performed, analyze performed very well”). If knowing concepts is an ability that may involve few concepts or may involve putting the concepts into a larger context and how processes are interconnected.

Biology is a university subject that, by its very nature, spans different perspectives, types of problems and approaches to solving them and various central conceptual contexts. One could therefore talk about different forms of knowledge (Hirst, 1974) even if it concerns one discipline (Flodin, 2015). Biology is about molecular processes, the functions of organelles, about cells and organs, and further about how ecological processes interact in different biomes. This means that biology encompasses very different conditions for teaching and learning and thus for assessment and what qualities of knowledge mean. Therefore what constitutes a knowledgeable student differ. It might be to know many definitions of concepts or a knowledgeable student can name many plants or use different tools for analysis.

Bloxham, den-Outer, Hudson and Price (2016) show how experienced teachers in the subject history vary greatly in their interpretation of assessment criteria and the authors believe that we must stop pretending that grading is consistent. Instead, we should be honest with the students and actively help them understand how assessment is a complex activity. The authors mean that if we can understand the roots of variation, what it is that allows teachers to vary in their assessment, then maybe that would help in identifying strategies to reduce variation or to understand if it is actually possible to reduce variation. Sadler (2009) argues that we need to see the assessment from a holistic perspective where teachers balance different aspects of the student's work that cannot be fully captured in specified criteria.

The student and the lecturer might need, together as far as possible, to conceptualize or make visible what constitutes examples of good quality of knowledge, or as Boud (2009) emphasizes, based on what kind of accepted standard the quality is formulated. We therefore need to highlight what kind of expertise different qualities mean. In this way, the teaching can be developed towards an increasing degree of transparency in how the discipline perceives qualities in the knowledge. This, in turn, could mean other didactic priorities and processes in teaching practice than, for example, alignment alone (compare to Sadler, 2009).

Absolute transparency and justice thus seem impossible to achieve and may not be what is central. Assessment criteria and the assessment processes can instead be developed into, not only a kind of functional checklist, but also to become part of developing the understanding of fundamental qualities of the knowledge at hand. Overall, studies show that assessment is a complex process and that we need to gain more knowledge about what happens in specific assessment situations.

CONCLUSIONS

How are assessment criteria qualitatively expressed in courses in biology?

This study show that it is important to question:

- the view of knowledge expressed in templates and other course supportive material
- the view of the assessment process as transparent
- what aspects of assessment need to be explicit and in what way?

The professional assessment is further not captured solely by means of assessment criteria.

[3]Department of Didactics of Experimental Sciences, University of Valencia, Valencia, Spain

From a socio-constructivist approach to the practice of teaching and learning, recognizing the different ways of reasoning of students is crucial when considering the objectives and contents of teaching. Solubility equilibrium offers a source of teaching-learning problems both at High School and University level. The dynamic concept of equilibrium, the relationship between solubility and the solubility product constant (Ksp) as well as the qualitative meanings of these magnitudes may be a cause for these problems. Teaching-learning of the Solubility Equilibrium (SE) phenomena has not been deeply researched from a pedagogical point of view, if compared with other chemistry subjects. In this sense, a questionnaire has been developed to evaluate students' ideas about solubility and Ksp concepts and to test the presence of teaching-learning problems. This research was carried out with a random sample of 243 students from the last course of different High Schools in Spain, and 97 students who were studying the first year of Physics at the University of the Basque Country. The questions used in this research were qualitative and focussed more on explanations than on obtaining a result by applying a formula. The results showed that some students have severe learning difficulties related to the qualitative solubility and Ksp concepts. This research offers information about the students′ understanding of SE, which could be useful in planning curriculum to facilitate the teaching-learning process.

Keywords: Chemistry Education, Secondary School, Higher Education, Solubility Product

INTRODUCTION

Solubility equilibrium and related concepts such as the dynamic nature of this equilibrium and the qualitative interpretation of the solubility product constant (Ksp) are fundamental to understand both heterogeneous equilibrium and some of its technical applications connected to everyday life. Indeed, this type of equilibrium takes place both in processes of industrial interest and in natural phenomena. So, we are in daily contact with compounds that dissolve in water to a greater or lesser extent. For example, sodium hydrogen carbonate, more known as baking soda, has been used as a home remedy for acid reflux for many years. In its dissolution process, a solubility equilibrium is established. Furthermore, sodium carbonate is obtained industrially from precipitation reactions, stalactites and stalagmites are produced by precipitation of calcium carbonate and caries appear when tooth enamel, hydroxyapatite, dissolves in acidic medium. Understanding these equilibriums becomes crucial in choosing some social decisions about chemistry and commercial products.

The most important concepts involving chemical equilibrium (acid-base, redox, solubility and complex formation) are found in the basic curriculum of introductory courses in chemistry, and are essential to understand key issues of our environment. In Spain, the basic curriculum of compulsory secondary education and bachelor of the Ministry of Education (Royal Decree 1105/2014) explicitly includes these concepts which are expanded in a phased progression of learning. Thus, the subject of Physics and Chemistry (ages 14-16) devotes a block to chemical reactions where contents such as substances, mixtures and aqueous solutions are developed. The evaluable Learning Standards of this subject determine that students should, among others, identify the solvent and the solute when analysing the composition of homogeneous mixtures of special interest. In the subject of Chemistry of High School (ages 16-18), within the block "Quantitative aspects of chemistry", students must work on contents related to solutions (ways of expressing concentration, preparation and colligative properties), heterogeneous equilibria and precipitation reactions. These contents are revisited in the first courses of science degrees so the most commonly used books of general chemistry (Chang 2008, Petrucci 2017) also include the equilibrium of solubility and its main characteristics (dynamic nature of equilibrium, Ksp, temperature effect on solubility, common ion or parallel reactions). Even so, research on chemical equilibrium has shown the persistence of general teaching-learning problems in secondary school and university (Quilez-Pardo 1995).

MODELS EXPLAINING SOLUBILITY AND SOLUBILITY PRODUCT CONCEPTS

Solubility equilibrium is usually explained in the context of compounds with a relatively low solubility, that is, compounds that dissociate only a little bit. In the development of the theoretical framework of Chemistry some concepts involved in this topic must be rigorously defined: the dissolution process of a salt in aqueous solution, the importance of stoichiometry, when a salt is sparingly soluble or practically insoluble, saturated solutions, etc. Knowing these items as prerequisites, students will be in a position to understand the existence of a dynamic equilibrium in a saturated solution in which the constant (Ksp) provides information about the equilibrium displacement.

The concept of solubility becomes necessary when appreciating the different easiness of substances to dissolve. IUPAC (Orange Book, 2019) defines it as "*The analytical composition of a saturated solution, expressed in terms of the proportion of a designated solute in a designated solvent, is the solubility of that solute. The solubility may be expressed as a concentration, molality, mole fraction, mole ratio, etc.*" According to IUPAC, in macroscopic qualitative terms, solubility is defined as the ability of a substance to be solved in another substance at a given temperature. Solubility product (Ksp), for its part, provides information about the extent of the direct reaction versus the inverse one and it is defined by IUPAC (Orange Book, 2019) as "*The product of the ion activities raised to appropriate powers of an ionic solute in its saturated solution expressed with due reference to the dissociation equilibria involved and the ions present*". According to this definition this magnitude provides a qualitative view about the equilibrium displacement towards the ions formation. In general terms, taking into account the stoichiometry, the higher the Ksp value, the more soluble the substance is.

IUPAC texts are written for and addressed to professionals, but students are far away from being experts in chemistry. Thus, in order to facilitate them to grasp the meaning of the concepts, making clear the different levels in which chemistry works becomes fundamental. In this sense, although the observable facts are described at a macroscopic level, is in the sub-microscopic level were the explanation to these facts is hidden. The symbolic level, in which drawings are transformed into letters and numbers, simplifies representations and allows students to understand the real meaning of mathematic calculations. Therefore, students must be able to establish appropriate connections between these three levels.

However, even though macroscopic, sub-microscopic and symbolic levels are fundamental prerequisites to understand the chemical concepts in general and the specific concepts of solubility and solubility product (Ksp) studied in this work in particular, students are generally asked to solve exercises about these concepts in a mathematic way. In general, two kinds of exercises exist: (i) starting from Ksp students must calculate the concentrations of cations and anions, then calculate the molar solubility of the compound and finally its solubility in other units or (ii) starting from the solubility of the compound they must calculate its Ksp. This way of working allows knowing the students' mathematic comprehension of the process, but offers little information about their understanding on solubility and Ksp concepts and its differentiation. In the next section, previous work on students' understanding of the relations between solubility and solubility equilibrium will be reviewed.

STUDENTS´ CONCEPTIONS OF SOLUBILITY AND SOLUBILITY EQUILIBRIUM CONSTANT

The review of previous research on teaching-learning problems about solubility and heterogeneous chemical equilibrium is limited to concepts included in the basic curriculum of introductory courses in chemistry (Quílez-Pardo & Solaz-Portolés, 1995; Banerjee, 1991; Voska & Heikkinen, 2000). In this sense, Ebenezer & Erickson (1996) conducted a phenomenographic study in which students' grade 11 responded to an interview consisting on different tasks and questions. Their objective was to elicit students' conceptions of solubility prior to formal instruction on solutions. The students' explanations allowed researchers to visualize their different ideas about the way a salt dissolves in a solvent. Some of them considered it as a physical transformation from solid to liquid, for others it was a chemical transformation of solute; another focused its explanation through the density of solute or the amount of space in solution stating that "*substances do not dissolve because they do not find sufficient space in the dissolving medium"*. Finally, other students thought the solubility was exclusively dependent on the size of solute or in some specific property of solute.

Other research studies also show that students have several misconceptions about chemical equilibrium at High School and University levels (Driel, 2002; Huddle & Pillay, 1996). Educational research on solubility equilibrium has shown evidence of poor learning achieved by High School students (HSS) (Onder, 2006; Cam 2013), but few studies have been developed at the university level (Raviolo, 2001). Most studies on students' ideas about the concept of equilibrium in solubility focus more on the ability to solve mathematical problems (Rahmi, 2017; Hawkes, 1998; Raviolo, 2001; Gunter, 2018) than on the description of students' visions of these concepts (Onder, 2006; Gorodetsky, 1985; Cam, 2013). Few research papers indicate in their conclusions how HHS in general present alternative ideas in all concepts related to equilibrium in solubility. In a more recent study, Setiowati *et al.* (2018) analysed the thinking of HSS about the concepts of solubility and solubility equilibrium. They found serious difficulties in the understanding of both concepts and detected different misconceptions expressed by many of them. This paper also shows the existence of students' problems to understand the concept of solubility equilibrium, especially because they ignore the law of neutrality of charge in solution and the concept of solubility.

Educational research on solubility equilibrium has shown evidence of poor learning achieved by HSS, but few studies have been developed at the university level. Raviolo (2001) highlights in his work that: *"Although students of general chemistry often correctly solve different kinds of numerical problems (in solubility equilibrium, for example, Ksp and solubility calculations), this alone does not guarantee a conceptual understanding of the phenomenon because of misconceptions that persist after instruction"*. According to this author, if we want University students (US) to develop an adequate conceptual understanding, their learning process should include as objectives the ability to offer explanations and descriptions at the macroscopic level (experiments), the sub-microscopic level (atoms, molecules, ions) and the symbolic level (symbols, formulas, equations) as well as the ability to establish appropriate connections between these three levels.

Research in science education has revealed the existence of many difficulties in the teaching and learning of the concepts related to solubility equilibrium. As shown, several studies have revealed students' difficulties in analysing the concept of solubility. Many of them analyse how students' mathematical resolution improves through new methodologies (Günter, 2018), but few studies are aimed at elucidating students' difficulties with solubility equilibrium concept. Usually, solubility equilibrium is considered an easy item when compared with other equilibriums (acid-base and redox), so the time spent on its study is usually shorter. Nevertheless, the research studies published about the topic and the teaching experience disagree with that conclusion. Thus, in this work we aim to answer the following research questions:

1. What do students of last year at High School and first year at University understand about the concepts of solubility and solubility product in introductory chemistry courses?
2. What conceptions and forms of reasoning do these students use in explaining solubility and solubility product concepts from a macroscopic level?

METHODS

In this research a transversal study involving a sample formed by 243 students chosen randomly from different Spanish last year High School (aged 18) and 97 studying an introductory course of chemistry during their first year of Physics degree at the University of the Basque Country has been done. A questionnaire comprising twelve conceptual free-response questions about solubility (four questions), equilibrium of solubility (two questions), factors influencing solubility (three questions) and relationship between solubility and solubility equilibrium constant (three questions) was designed. Both University and HSS studied the topic of solubility equilibrium before answering the questionnaire, which was filled out in exam situation. This work will be focused exclusively on two of those questions related to the qualitative aspects of solubility (named question Q1) and solubility equilibrium constant (named question Q2). The two questions start from a fictitious situation between two students who find a table with the solubility constant of several salts.

The students' answers were subjected to a rigorous phenomenological analysis. Phenomenology shows how the different ways of perceiving and understanding reality can be classified into different categories. In recent years, phenomenology, as a rigorous form of qualitative research has experienced a great development, especially in higher education (Tight, 2016), making use of the obtained results to elaborate new teaching approaches with the aim of improving students' learning. Phenomenography is a qualitative research approach which aims to investigate and describe the full range of ways in which people think about or experience a concept or phenomenon (Marton, 2015). It deals with how the range of ways of perceiving and understanding reality can be classified into a system of hierarchic categories of growing complexity. In our study, the range of conceptions of solubility and Ksp given by HSS and US is enclosed into a hierarchic series of descriptive categories, following the criteria of Marton and Booth (1997). Such categories were constructed based on students' responses themselves, and the system of categories was organised to reflect an increasing level of understanding about what solubility and Ksp are. The research group, made up of three people, examined all the answers separately, looking for a pattern in the response categories and selecting the most significant between them. Once the initial categories were established, the researchers met to discuss and review them until a consensus was reached on the final categories. The intrarater kappa Cohen reliability coefficient averaged 0.84 for the questions, indicating a very significant degree of agreement in the judges' criteria for applying the categories used to interpret the responses. Thus, the refined final definition of the system of categories used to analyse students' conceptions was obtained after an iterative process of comparison, discussion, and re-definition to consensus. When disagreement about a description category or the location of responses to a specific category appeared, it was resolved by just using evidence of students' understanding as a reference.

RESULTS

The results presented here are part of a study that aims to examine students' ideas about solubility and solubility equilibrium. This work deals exclusively with two questions (named Q1 and Q2) of the questionnaire that focus more on the qualitative aspects of solubility and solubility equilibrium constant, rather than on getting a result by using a mathematical formula. In this way, the objective of the questions was to obtain an in-depth knowledge of the students' thinking.

Q1. Explain the qualitative meaning of the concept of "solubility".

Q2. Explain the qualitative meaning of the concept of "solubility product".

In question Q1 students were asked for a qualitative definition of solubility. As mentioned above, a correct qualitative definition of solubility should explain that it offers a measurement of the ability of a substance to dissolve in another substance. The preliminary results of the study show that both, university and HSS tend to give only a quantitative definition of solubility; avoiding the qualitative answer they have been asked about. Less than 10% of students, in both cases, responded with a suitable qualitative definition of solubility (A category - i.e. *solubility offers a measure of the ability of a substance to dissolve in another substance*), and around 15% and 40% (HSS and US respectively) gave a proper quantitative definition of solubility (B category). A fairly high amount of students showed conceptual errors in their answers (C category). These types of errors can be categorized into subcategories in turn, and their origin is detected when the student:

- Defines the solubility as any concentration of the solution.
- Refers to any amount of solute dissolved in an amount of solvent / solution.
- Confuses solubility with concentration in qualitative terms: saturated, concentrated, diluted
- Confuses solubility with the amount of solute that dissolves (mass), without considering the total solution

- Defines the solubility in terms of the s of the Ksp formula. (The solubility has no value by itself)
- Confuses solubility with the physical dissolution process
- States that solubility is a property of the solvent

The other erroneous answers no classifiable into the previous ones were classified as inconsistent (D category). Finally, it is remarkable that 58,0% of HSS did not answer the question while only a 7.2% of US did not answer it. The results of the students' answers to the question Q1 are shown in percentages in table 1.

Table 1. Results for the Question Q1

Descriptive Category	High School % (N=243)	University % (N=97)
A.- Solubility offers a measure of the ability of a substance to dissolve in another substance. (Qualitative idea)	9.1%	5.2%
B.- Its measurement is obtained as the maximum amount of solute, which can be dissolved in a given volume at a given temperature. (Quantitative idea)	14.8%	40.2%
C.- Incorrect	12.8%	35.1%
D.- Inconsistent	5.3%	12.4%
No Answer	58.0%	7.2%

In question Q2 students were asked for a qualitative definition of Ksp. The results of our study show that, as occurred in the previous question, university and HSS tend to give only a quantitative definition of solubility product, avoiding the qualitative answer they have been asked about. It is remarkable that, less than 3% of students, both university and high school, answered the question in the correct way (A category). Therefore, most of the students were not able to offer a qualitative definition. On the contrary, some of them provided a correct quantitative (operative) definition (B category), which implies that for them Ksp basically has only a mathematical meaning. These students offered a correct operational definition of the solubility product formula based on the chemical reaction expressed as: A_aB_b (s) $\rightarrow aA^{+b} + bB^{-a}$, where the solubility product constant is expressed as: Ksp (A_aB_b) = $[A^{+b}]^a \cdot [B^{-a}]^b$. Apart from the categories mentioned above, several incorrect ways of interpreting the sense of the equilibrium constant were identified. C category groups those students who have a utilitarian idea of Ksp. For them the Ksp is a subsidiary constant and it has no value by itself. It is used to calculate the solubility or it is used to determine when a compound will precipitate. D Category includes explanations that limit the definition to affirm that Ksp is a constant, or just paraphrase the question. In category E, erroneous visions of solubility constant are grouped, for example, those students who confuse Ksp with Qsp (ion product). In this case, they focus on the mathematical expression of the constant as a function of the concentrations of the ions of the dissolved salt, but without making reference to the fundamental factor: it represents the concentration of these ions when the equilibrium has been reached. For other students Ksp is identified with the amount in mass (g) or with the concentration of the dissolved salt. Other different erroneous answers that do not fall into any of the previous classifications and do not have sufficient entity to generate their own category were classified like incoherent (F category). For example, High School student 34 maintains that *"Solubility is the process by which a solute is dissolved totally or partially by a solvent and the solubility product is the result obtained after the previous process"*. It should be noticed that 64.2% of HSS did not answer this question, while only 17.5% of US did not answer it. The results of the students' answers to the question Q2 are shown in percentages in table 2.

Table 2. Results for the Question Q2

Descriptive Category	High School % (N=243)	University % (N=97)
A.- Correct Qualitative definition of Ksp	2.5%	2.1%
B.- Correct Cuantitative definition of Ksp	0.8%	23.7%
C.- Utilitarian value	2.1%	22.7%
D.- Limit the definition to affirm that Ksp is a constant, or paraphrase the question	6.2%	7.2%
E.- Incorrect	24.3%	14.4%
F.- Incoherent	7.4%	12.4%
No Answer	64.2%	17.5%

CONCLUSIONS AND IMPLICATIONS

This study aims to evaluate students' ideas about the macroscopic meaning of the concepts of solubility and the solubility equilibrium constant (Ksp) in order to detect teaching-learning problems about these concepts. As stated in some evaluation proposals on conceptual knowledge about solubility equilibrium, in order to guarantee a conceptual understanding of this phenomenon, a diagnosis of difficulties related to solubility basic concepts is necessary (Raviolo 2001). In this sense, the research findings of this study have allowed to highlight some of the students original ideas related to the subject.

The results of this study show that, even after studying these topics during one or two years, students' ideas about them are far away of their scientific meaning. Notwithstanding, the results for US are significantly better. It is especially remarkable that more than a half of HSS were not able to answer the questions. In general, the ideas about the concept of solubility are more accurate than those of Ksp showing that solubility concept is better settled, as other works affirm (Setiowati, 2019). This is in some way logical because the concept of solubility is studied in previous years whilst HSS studied Ksp for the first time. It is important to emphasize the fact that most of the HSS could give neither the qualitative meaning of solubility nor that of Ksp. Several of them developed incorrect ideas, and only a few offered explanations fitting the qualitative scientific model. In contrast, US students offered well-established ideas about solubility and less elaborate ideas of Ksp.

We can affirm that, in general, students cannot give a meaningful explanation for the concept of Ksp and its usefulness to understand solubility equilibrium. Instead, they generate a wide spectrum of alternative conceptions such as considering both concepts being the same, confuse Ksp with the ion-product expression, Qsp, or focus only on the mathematical expression of the constant without making reference to the fact that it represents the concentration of these ions when the dissolution equilibrium has been reached. Other students identified Ksp with the amount in mass (g) or with the concentration of the dissolved salt and, finally, a significant percentage give meaningless explanations or no explanations at all.

As mentioned above, this analysis is a small part of a larger study that tries to determine students' learning problems related to the solubility equilibrium. Our research has provided meaningful insights into students understanding of this equilibrium. It is a fact that having a prior knowledge of the problems students must face in the study of these concepts can help to prevent possible mistakes by considering them into the teaching process. Using these findings, the objective of our future research will be to design teaching tasks related with them, useful to put students in situation of using scientific work strategies to enable them to grasp the meaning of these concepts and to establish its macroscopic, sub-microscopic and symbolic connections. It is suggested that research with the objective of designing teaching materials and subsequently implementing them with students is necessary to reduce the gap between the teaching of the concept of solubility, solubility constant and their understanding. A second phase of our research could take us to develop a teaching sequence design for introductory chemistry courses at secondary school and university taking into account the students' difficulties in order to improve the teaching-learning process.

ACKNOWLEDGEMENTS

We thank our colleagues from the Science, Technology and Mathematics Education Research Group (STEM-ERG) from the University of the Basque Country, who provided insight and expertise that greatly assisted the research, and for comments that greatly improved the manuscript.

SPECIES DIVERSITY AS A FACTOR IN THE DESIGN OF FOOD CHAINS

Luka Praprotnik[1] and Gregor Torkar[1]
[1]University of Ljubljana Faculty of Education, Ljubljana, Slovenia

This paper focuses on the importance of familiarity with the species diversity of ecosystems for the proper use of the food chain concept. The research objective was to explore if pre-service preschool and primary teachers can correctly name specific examples of food chains in Slovenian forests. The study included 170 students from the University of Ljubljana's Faculty of Education. The students had to list four examples of food chains and explain what a food chain is. The majority of students do not have as much difficulty understanding the concept of a food chain, but they have limited familiarity with species diversity and animal nutrition, which makes it difficult for them to adequately form food chain examples. A quarter of respondents did not offer a single correct example of a food chain in the forest. It turned out that some students find it difficult to understand the role of arrows in a food chain even after the end of the university basic biology course. The arrows were often missing or facing the wrong direction. Some students think fungi are primary producers in the food chain. Many students are not familiar with the nutrition of common forest species. Pre-service teachers' knowledge about forest species diversity is fundamental to facilitate their construction and understanding of a food web in an authentic, local context.

Keywords: food chain, knowledge, student

INTRODUCTION

In ecology, consumption sequences are illustrated with various diagrams, such as food chains and food webs. A food chain represents a linear sequence of organisms or the transfer of energy accumulated in food from a primary producer through a sequence of consumers, whereby each predator in the chain is also food for another organism (Chapin III, Matson, and Vitousek, 2011; Odum and Barrett, 2005). The species are related to each other as members of the chains, which are thus called food chains or trophic chains. Only about 10 to 20% of the energy is transferred to the higher trophic level from one chain member to another. Consequently, the number of chain members is limited to four or five (Odum and Barrett, 2005; Odum, 1989). The links between chain members are illustrated by arrows that indicate the direction of energy, conversions, and substance passing. Organisms are included as producers, consumers or decomposers. Food chains are not isolated from each other but are linked to food or trophic webs. In such systems, the relationships between organisms are not only linear, like in the chain, but developed in different directions (Tome, 2006).

Knowledge of food chains and food webs is a popular ecological topic in pedagogical research (e.g., Adeniyi, 1985; Allen, 2017; Eilam, 2012; Hogan, 2000; Leach et al., 1996; Wyner and Blatt, 2018). Allen (2017) reports that most five-year-olds can perceive key concepts related to food chains. However, several researchers report that students at all levels of education often struggle with understanding the complexity of food chains and food webs (Hogan, 2000; Eilam, 2012; Wyner and Blatt, 2018). Students confuse the two concepts, even though some had a proficient understanding of food web interactions, but were unable to connect school science understanding with the daily life activities (Wyner and Blatt, 2018). Griffiths and Grant (1985) reported that students understand the food web only as a set of more food chains. They have problems in understanding energy transfer in these systems and indirect influences between organisms (Hogan, 2000; Leach et al., 1996). They often do not perceive themselves as a part of the food chain or the web (Wyner and Blatt, 2018).

This article presents the findings of preliminary research, focusing on the importance of knowing the species diversity of ecosystems for the proper use of the concept of a food chain. A review of literature and articles did not yield any studies focusing on this aspect of the problem described. We were interested in whether pre-service preschool and primary teachers, who will teach children about ecological concepts such as food chain and species diversity, can correctly name specific examples of food chains in Slovenian forests.

Research questions (RQ)

(RQ1) How well do pre-service teachers understand the concept of food chains?

(RQ2) How well do pre-service teachers know the species diversity of forest in Slovenia?

RESEARCH METHOD AND DESIGN

The study included 170 students from the University of Ljubljana's Faculty of Education. Of these, 105 were students in the undergraduate program in preschool education enrolled in the course Primary Science, and fifty-five were students in the undergraduate program in primary education enrolled in the course Science and Biology. In addition, ten students in the undergraduate program were questioned about their understanding of an example of a food chain in the Slovenian forest.

The data were collected in the academic year 2016/17 and 2017/18. The knowledge test took place in February or. June 2017. We gave the students a written task: "Describe four examples of food chains in the Slovenian forest. Each example of a food chain should consist of at least three links (plant, herbivore, and carnivore) and should not be repeated between the chains." With this question, we wanted to check the understanding of the concept of the food chain and the knowledge of the species variety of forest organisms. We subsequently carried out ten in-depth interviews with students of the primary teacher study program who did not participate in the knowledge test. We asked them more in detail about the understanding of the presentation of the food chain (each student was shown an example of a food chain with three articles: pine → pine leaf caterpillar → cuckoo bird). We were interested in whether students know that the diagram shown is the food chain, why the plant is in the first place of the food chain, what the order of the organisms in the chain is, and what the arrows in the diagram represented.

Collected data were quantitatively processed. The data processing procedures used included descriptive statistics procedures. The frequencies (f) and percentages (f%) were calculated. The results are displayed graphically or tabularly. The data obtained through interviews were processed qualitatively.

FINDINGS

Preliminary results showed that only 11% of the students correctly cited four examples of food chains in the forest (Fig. 1). About a quarter of the respondents did not offer even one correct example of a chain. The students most often incorrectly defined plant taxa. Various plant parts, plant forms, or plants replaced by fungi and other heterotrophic organisms were cited. Students also lacked familiarity with the nutritional habits of individual groups of animals and, consequently, placed them in the wrong trophic levels. There was also a lack of understanding of the importance of arrows and their direction in the food chain. There was often no arrow or it pointed in the wrong direction, toward the primary producers. Among the errors, we also detected inadequate examples of organisms that cannot be found in forest ecosystems. Figure 2 explains students' most frequent misconceptions related to the food chain.

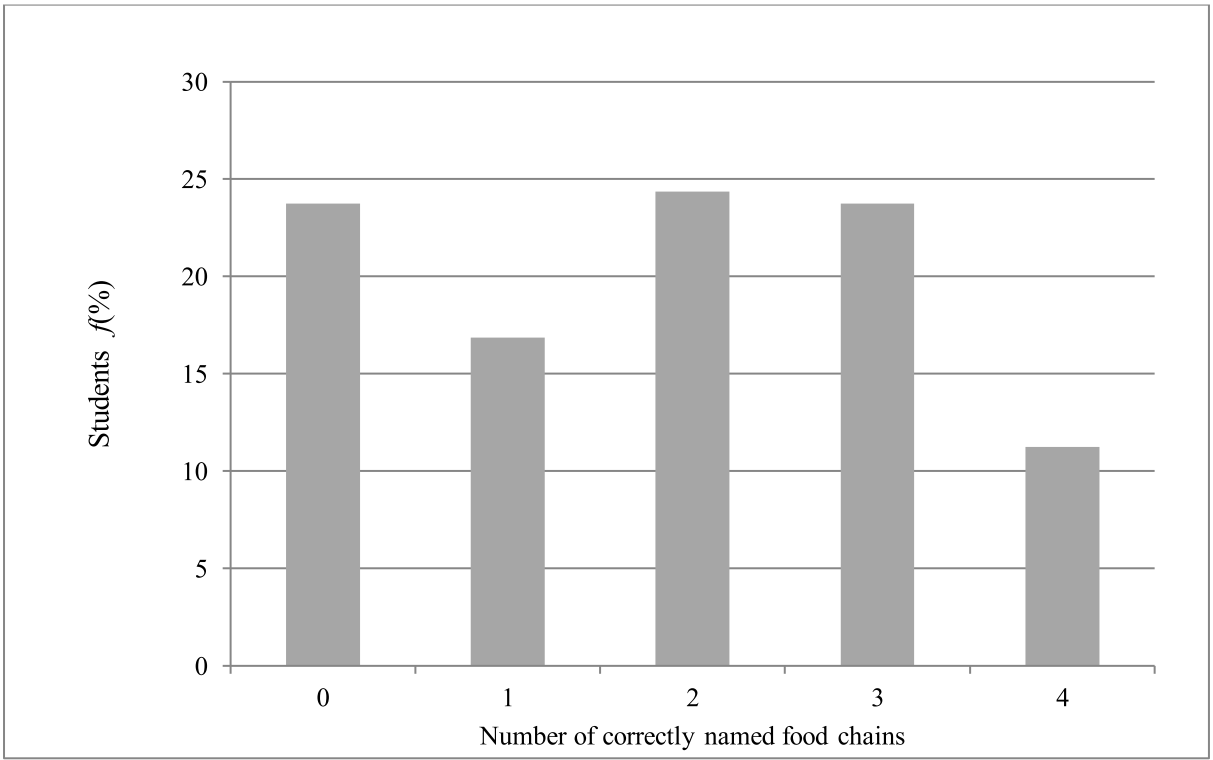

Figure 1: Frequency of students who correctly cited examples of the food chain.

Among the plants, the use of Spermatophyte samples was predominant (94.1%), and mammals (55.5%), birds (17.3%) and insects (16.4%) were among the groups of animals. The students listed twenty-four different types of plants. Plants with a total share of records exceeding 10% are grass, oak, and beech. The students listed forty-four different species of animals or groups of animals. Those most often cited in the food chains were foxes, squirrels, deer, and rabbits. Fungi were also mentioned in the food chains and were cited twenty-four times. Only in five out of twenty-four times fungi were properly placed in the food chain. Four different fungi or their groups were listed.

Table 1 & 2. List of ten most frequently mentioned species of plants and animals or their higher taxons.

Plant taxon	*f*	*f*(%)
grass	110	19.10
oak	71	12.33
beech	58	10.07
hazel	36	6.25
spruce	34	5.90
fern	29	5.03
clover	22	3.82
chestnut	13	2.26
raspberry	11	1.91
dandelion	10	1.74

Animal taxon	*f*	*f*(%)
fox	120	9.48
squirrel	110	8.69
roe deer	84	6.64
hare	83	6.56
wolf	63	4.98
bear	55	4.34
lynx	50	3.95
leaf louse	42	3.32
ladybird	40	3.16
mouse	40	3.16

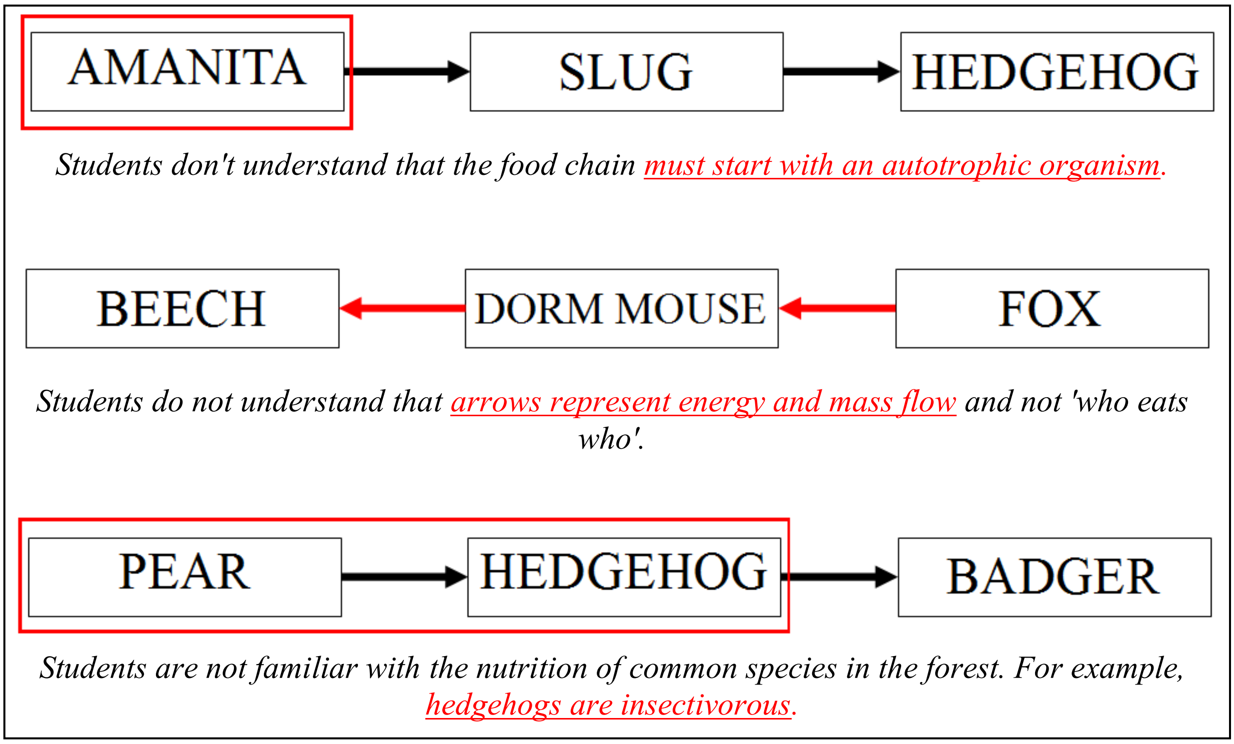

Figure 2. Examples of misconceptions about food chains.

DISCUSSION

The curriculum for preschool education expects that pre-school children learn about different natural ecosystems and relationships between organisms in ecosystems in the local environment. Among the global goals, it is stated that it is necessary to promote "experiences and learning about the living and non-living nature in its diversity, connection, constant change, and aesthetic dimensions" (Curriculum for preschool education, 1999, p. 38). Curriculum for elementary school, especially science and technology, natural sciences and biology, further develops concepts in ecology. The concepts of the food chain and food web are discussed for the first time in the fifth grade of elementary school, in the field of science and technology. Among the learning goals, it is stated that pupils need to be able to compose simple food chains and link them to the food web (Curriculum: primary education program Natural Sciences and Technology, 2011). In the first research question, we were therefore interested in whether pre-service preschool and primary teachers were properly trained in the interpretation of the concept of the food chain. From the results of the study, it can be seen that almost a quarter of respondents did not correctly compose food chains in the forest. The other three-quarters of the respondents correctly stated one, two, three or four examples of food chains in the forest.

Most of the students did not have difficulties in understanding the concept of a food chain, but they had more difficulty with knowing forest species diversity (the second research question) and animal nutrition. The students compensated for their unfamiliarity with species variety by using more general biological concepts, e.g. shrubs, trees, and undergrowth. They also referred to various plant parts (e.g., leaves, fruits) or classified fungi as primary producers. The limited number of species recorded in food chains also testifies to their limited knowledge of the diversity of tree species and other forest plants. They mostly mentioned spermatophytes, although many species of ferns and mosses can also be observed in Slovenian forests. Lack of knowledge of plants and the ability to determine plant species may reflect their lack of interest in plants and “plant blindness” (Wandersee and Schussler, 2001). Students also showed limited familiarity with animal species in the forest. Mammals predominated among species mentioned by students. They also lacked familiarity with the feeding habits of individual groups of animals, which is why they classified them incorrectly in trophic levels.

Only some of the pre-service teachers had difficulties with understanding concepts of trophic levels or the role of plants as primary producers in the food chain. Similarly, Eilam (2012) reports secondary school students to fail to regard plants as essential elements in the food chain. She reported that novice students’ definitions of food chains lacked basic ecological concepts like producers, the location of the decomposers or the function of organic matter in supplying matter as well as energy. In the present study, some students have difficulty understanding the role of arrows in the food chain – constructing food chains with missing arrows or reversely directed towards producers. It can be concluded that some students still do not understand what arrows actually illustrate. Students often explain the food chain primarily as relationships between organisms, where the predator eats prey and accordingly direct the arrows toward the primary producer. Similar problems with students’ understanding of energy transfer were reported in previous studies (Hogan, 2000; Leach et al., 1996). Wyner and Blatt (2019) report that the majority of interviewed teachers and students were unable to connect the food they eat with ecosystem food webs even though some had a proficient understanding of food web interactions, but were unable to connect school science understanding with the daily life activities. A similar conclusion can be made in the case of students' knowledge about forest species diversity which is fundamental to facilitate their construction and understanding of a food web in the authentic, local context. Only in this way, one can reasonably expect understanding and wider social support for the conservation and sustainable use of forests and other natural resources.

PRACTICAL PERFORMANCE ASSESSMENT OF EXPERIMENTAL COMPETENCE IN SCIENCE TEACHER EDUCATION LABORATORY CLASSES

Fabian Poensgen[1], Christiane S. Reiners[2]
[1,2] Universität zu Köln, Cologne, Germany

Laboratory classes are a key feature in chemistry studies at university level. They are meant to develop practical skills, process abilities, an awareness of the safety aspects of laboratory work and risk-assessment, acquisition of knowledge and understanding. At our home and other universities teacher trainees spend almost half of their contact time in laboratories, consuming lots of material and personal resources. Since the late 1970s some educators have seriously questioned both the effectiveness and the role of laboratory work. In order to judge the impact of lab classes, it is necessary to systematically assess the effects of laboratory instruction concerning student learning and growth.

We therefore developed an open inquiry, practical performance assessment to evaluate experimental competence of trainee chemistry teachers based on a deductively developed competence progression model. Therefore, students are confronted with an everyday object and asked to develop an experimental problem-solving-strategy. Data is collected by a written lab report, video- and audio-records via camera glasses and is qualitatively analysed to evaluate experimental competence regarding conceptual knowledge, process abilities, practical skills as well as the awareness of the safety and environmental aspects.

The results of a pilot study hints at a growth in a lot of aspects of conceptual knowledge, process abilities and foremost in practical skills. Nevertheless some problems persist which are similar to those found at school-level researches: Students seem to understand laboratory work primarily as a search for the 'correct' answer. Hence, many of them develop inquiry questions to which they already know the answer, do not generate falsifiable hypotheses, ignore unexpected observations and do not anticipate the risks of apparatus and chemicals properly.

Keywords: Laboratory Work in Science, Performance Assessment, Initial Teacher Education (Pre-service)

INTRODUCTION

Knowledge, abilities and skills concerning experiments are an important part of scientific literacy as "purpose of science education" (Bybee, McCrae, & Laurie, 2009), such as "scientific inquiry competence", "scientific inquiry", "inquiry skills" or "science practices" (Arnold, Boone, Kremer, & Mayer, 2018; Baur, 2018; Gehlen, 2016; Meier, 2016). Experimental competence is therefore addressed both in the development of curricula and international comparative studies (Gut & Mayer, 2018; Ministerium für Schule und Bildung des Landes Nordrhein-Westfalen [MSB], 2019; National Research Council [NRC], 2013), which underlines its importance among the necessary professional knowledge for chemistry teachers, too (Hartmann, Upmeier zu Belzen, Krüger, & Pant, 2015; Konferenz der Kultusminister

[KMK], 2014; Strübe, Tepner, & Sumfleth, 2017). Experimental competence is furthermore essential for safety aspects (KMK, 2014), to understand the empirical nature of science (Lederman, Abd-El-Khalick, Bell, & Schwartz, 2002) and last but not least for motivation (Becker & Hildebrandt, 2000).

Our responsibility as researchers in teacher education is the analysis of teachers' competences and their systematic development (Ferber, 2014; Rieß, 2012; Wellnitz, 2012). Laboratory classes can be regarded as a medium for instruction (Hofstein & Lunetta, 2004) to learn more about experiments but the success of this resource-intensive form of learning has hardly been studied for chemistry teacher education (Abd-El-Khalick et al., 2004; Berry, Mulhall, Gunstone, & Loughran, 1999; Hofstein & Lunetta, 2004; Kambach, 2018).

In order to learn more about the experimental competence of our students, we first compiled a model on the basis of existing models, designed an assessment that covers all relevant aspects and then developed a scoring system based on the model to evaluate students level of competence.

COMPETENCE MODEL

Experimental competence is regarded as an independently measurable competence construct (Bybee et al., 2009; Gut & Mayer, 2018) being both a possible outcome and a prerequisite for meaningful laboratory work (Abd-El-Khalick et al., 2004). In our project we understand experimental competence as a problem solving strategy (Gut & Mayer, 2018) and define it, inspired by the definition of competence by Weinert (2002), as:

> *individually utilisable conceptual knowledge, procedural abilities, practical skills, awareness of safety and environmental aspects, as well as personal motivation, willingness and creativity to use these problem-solving skills successfully and responsibly in variable situations by using experiments.*

Following this we compiled a model of experimental competence, based on extensive literature research by assigning all aspects found to the competence dimensions on three different levels, which was accomplished later by a fourth level: <I. This model was repeatedly tested in performance assessments and five times revised in an iterative-cyclical process. We are currently conducting an expert survey to validate the categorisation according to competence dimensions and the taxonomy of the levels. The current version of the model contains four aspects of ‘conceptual knowledge’, 15 of ‘procedural abilities’, five of ‘practical skills’, six of ‘awareness of safety and environment’ each on four levels and 6 of ‘personal competence’ on three levels. By the large extent of aspects we try to cover the competence construct as completely as possible, in order to avoid an underrepresentation of the actual scope of competence (Messick, 1995).

Conceptual knowledge is defined here as propositional or declarative knowledge of facts, concepts, principles (Shavelson & Ruiz-Primo, 1999), that is derived from what is mentioned by the participants in the assessment. Procedural abilities are defined as procedural knowledge (Gut & Mayer, 2018) and abilities that are needed to acquire empirical evidence (Mayer, 2007; Shavelson & Ruiz-Primo, 1999) and that are applied to a concrete problem or phenomenon given in the assessment. Practical skills are defined as actions controlled at the sensomotoric level (Emden, 2011) in the form of the exercise of scientific techniques at the practical level (Meier, 2016).

Each aspect is represented on four levels referring to the quality, problems are solved with: level <I: insufficient concerning demands of lab class, level I: sufficient, reproducing, level II: satisfactory, applying, level III: most complex, reflecting.

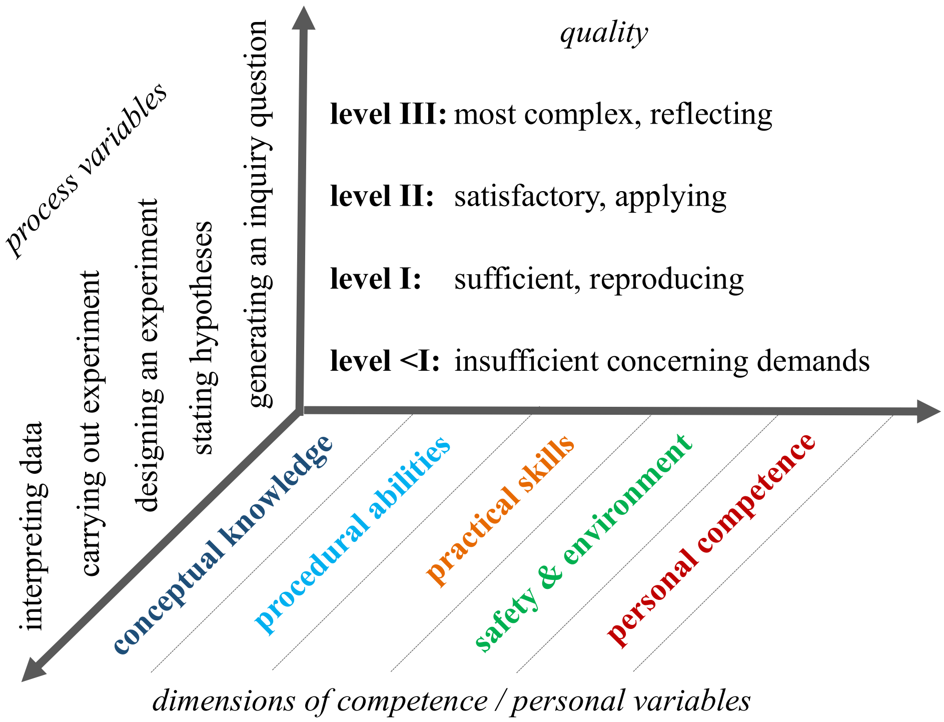

Figure 1. Model of experimental competence.

Although most aspects found in existing literature are regarded as process-orientated, the conceptual expertise determines the quality of the solution to the highest degree (Hammann, 2004; Vorholzer, 2015). Considering this, the differentiation in competence dimensions is not absolute, but rather analytical as was also shown in an expert rating. Nonetheless it is supposed to allow a more precise diagnosis and thus, in the long run, to support learners individually.

For example, the stating of hypotheses, though it requires a lot of knowledge, is considered as a procedural ability to gain evidence. On level one students utter assumptions concerning their inquiry question. On level two they are supposed to add reasons and mention relevant variables and on level three they have to explain their hypothese(s) theory-based.

Our competence model is used for self-assessment, as well as for external assessment, i.e. interpreting laboratory reports, video and audio data acquired from the performance assessments. In order to test the reliability of the competence model, Cronbach's Alpha was calculated for 203 self-assessments by chemistry-students before and after their first semester. A value of .940 was achieved for the entire construct and values between .692 and .906 for the individual competence dimensions.

PERFORMANCE ASSESSMENT

Assessing experimental competence is described as a need for science education research (Abd-El-Khalick et al., 2004; Gut & Mayer, 2018). There are many ways by which experimental competence has been tried to be measured such as paper and pencil test, computer-based simulation or performance assessment, of which the latter is considered the most adequate (Arndt, 2016; Arnold et al., 2018; Dickmann, 2016; Emden, 2011; Kambach, 2018; Schreiber, 2012; Shavelson & Ruiz-Primo, 1999). Ruiz-Primo & Shavelson (1996) define it as 'an assessment that provides students with laboratory equipment, poses a problem, and allows students to use these resources to generate a solution.' However, performance assessments are not undisputed, because they cause an enormous expenditure of costs and time, especially in evaluating data (Dickmann, Eickhorst, Theyßen, Neumann, & Schreiber, 2014). In addition, the results can vary greatly in relation to time and task (Gut & Mayer 2018), which can be also true for more standardised written tests (Dickmann, 2016). Since we did not find any studies on the development of experimental competence among university chemistry students, we decided to explore practical performance assessment in a qualitative setting in order to obtain first insights.

Based on our definition and model, competence is always related to specific problems and therefore needs to be assessed with specific tasks. These must be open (Bell & Banchi, 2008) and concerned to everyday life phenomena (Abd-El-Khalick et al., 2004). We developed an open practical performance assessment that enables students to create their own inquiry question (Fricke, 2018) and pursue an individually constructed experimental path, including the generation of hypotheses, experimental design and the evaluation of hypotheses. By doing so, participants have to search in a hypothesis space as well as in an experimental space according to Scientific Discovery as Daul Search [SDDS] (Klahr & Dunbar, 1988). Thus we try to examine as much as possible of what is understood as experimental competence.

So far two different tasks have been implemented, in which participants must develop ideas what to do with either mulled white wine after Christmas or with the remaining brine of pickled gherkins. In both cases they were asked to

1. generate an inquiry question,
2. state hypotheses,
3. design an experiment,
4. carry out an experiment and observe/measure and
5. analyse data and draw conclusions.

While students are familiar with these five process-steps, they are not with the phenomenon, which varies. Thus competence-irrelevant aspects of the task are minimized (Messick, 1995) and the complexity of the open setting reduced.

The assessment consists of three parts. After distribution of the task, participants have 15 minutes to prepare, 40 minutes to conduct and 15 minutes for postprocessing and writing a laboratory report. While working in laboratory, students are wearing camera glasses recording video and audio data. To ensure safety aspects and offer assistance when needed, they are accompanied by a lab assistant. The latter also asks given questions, such as 'Which hypotheses would you like to test regarding your inquiry question?' or 'which security aspects do you have to consider?' This standardises the assessment as a response format (Ruiz-Primo & Shavelson, 1996) to a certain degree by structuring, allowing comparability of different experimental approaches and reduces the extraneous cognitive load of participants (Reiners, 2017) just as the everyday life context does (Krell, 2018; Mayer, 2007; Ziemek, Keiner, & Mayer, 2005). But at the same time, we have to be careful not to suggest the impression of a uniform scientific method, which does not exist in such a way (Lederman et al., 2002). So far there is no evidence that the order of process in a scientific activity indicates a high or low level of experimental competence (Shavelson & Ruiz-Primo, 1999; Arndt, 2016; Meier, 2016; Gut & Mayer, 2018), so we do not expect any negative effects of this guidance.

EVALUATION

In each exam, data is collected by students' free verbal expressions, answers to the guided questions of the assistants, observable actions and written lab reports. This allows us to focus not only on a product, but also on more procedural abilities and manual skills (Gehlen, 2016; Schreiber, 2012), i.e. to consider experimental competence as comprehensively as possible. Nonetheless it remains a very complex, multilayered and highly inferent construct. All data are analysed according to Mayring (2014) through qualitative content analysis. Therefore, we first identify any event that might provide insight into the experimental competence of the participant and then attribute a category and level to each one.

So far, 43 examinations have taken place with 31 candidates. Except from one student who did a synthesis, all of them followed one of these three different problem-solving approaches, regardless whether the task was about pickled gherkins or on muled wine:

1. qualitative *analysis* of substances (especially ions contained),
2. measurement of quantity by *distillation* and
3. by *titration*.

These approaches can be regarded as experimental problem types similar to those stated by Metzger, Gut, Hild & Tardent (2014). Thus, to foster the reliability of evaluation we also differentiate between these three experimental approaches by using three different coding guidelines. These vary in the inductively derived anchor examples for each problem type but in one point also in the categories: in a titration stoichiometric calculation is an important aspect that does not occur with distillation or analysis.

Until now we have arranged a suitable guide for distillation with the help of assessments of a preliminary study. For example, if participants answer to the question about their hypothesis that alcohol can be separated from wine by heating it in a distillation apparatus, this is coded as level I. If this separation is explained to some extent by everyday experience it is coded as level II and as level III, if different boiling points of ethanol and water differ are explained on sub-microscopic level.

So far, six assessments of a different sample have been evaluated in detail by two intercoders with mostly acceptable reliabilities around 0.80 according to Holsti. The results are summarised in a grid, thus offering the opportunity to compare performance at different times (pre/post lab class or at different stages of their study), between students and with their self-evaluation.

FIRST RESULTS

Although only a few data have been systematically evaluated so far, the assessment format and competence model have been developed to such an extent that we can gain first insights into the experimental competence of pre-service chemistry teachers. Overall, an increase in experimental competence could be observed after lab classes and at later stages of studies, which mainly affected conceptual knowledge, process abilities and practical skills. However, it is hard to say whether these progressions are the outcome of the laboratory classes or of other influence. Similar to results found at school-level projects (Berry et al., 1999; Hofstein & Lunetta, 2004; Kambach, 2018; Meier, 2016) our study reveals particular deficiencies which have to be addressed in teacher education:

- Research questions and hypotheses are often constructed around specific experimental methods typically connected to the phenomenon, and thus mostly serve as a confirmation of students' pre-existing expectations ('confirmation bias' (Kambach, 2018)).
- Learners do not refer to their knowledge, even if they have it, when formulating hypotheses, analysing data and, above all, on security aspects.
- Thus hazards that may arise from materials and chemicals often cannot be anticipated or dismissed.
- Control-of-variables strategy is sometimes inadequate, rarely considered explicitly.
- Measurements are performed inaccurately, and observations and data are inadequately processed.
- Data are only evaluated according to expectations.
- Errors are rarely explained, procedural errors and limits of the experiment are only partially recognized, although they are sometimes corrected during performance.

CONCLUSION AND OUTLOOK

We will develop our model and assessment format further to achieve an even higher degree of validity and reliability. Therefore, we have started an expert survey on the gradation and categorisation of the competence model, will develop coding guidelines for the other two experimental problem types ('analysis' and 'titration') and test a third task beside 'wine' and 'brine'. Based on this, further strategies will be developed to examine more profoundly and quantitatively.

Our open assessment certainly poses high demands on our students (Kirschner, Sweller, & Clark, 2006). However, these are comparable to those in schools, where teachers have to design an inquiry question about an everyday life phenomenon relevant to their students and guide them through an exemplary ideal-typical experimental process (KMK, 2014; MSB, 2019; NRC, 2013). Therefore, teachers have to be experimentally competent to a high degree. In order to achieve this goal, our competence model and practical assessment give us the possibility to diagnose the competence level individually and differentiated, to work out which aspects need to be addressed more intensively in laboratory classes. Perhaps school-level interventions could serve this purpose, such as to open up experiment instructions (Bernholt, Walpuski, Parchmann, & Sumfleth, 2009), to train assistants more intensively (Fricke, 2018), to address control-of-variables strategy explicitly (Schwichow, Croker, Zimmerman, Höffler, & Härtig, 2016) as well as scientific methodology (Mannel, 2011; Reiners 2017), to offer further training (Telser, 2019), to foster cognitive activation (Platova, 2017) or to provide systematic feedback (Marschner, 2011).

SURVEYING UNIVERSITY STUDENTS' PROBLEM SOLVING SKILLS IN REALISTIC SETTINGS

David Woitkowski[1]

[1]*Paderborn University, Paderborn, Germany*

Solving problems in physics is one of the core learning objectives in physics education on all levels. In our study we analyze the problem solving skills of German first year university students. Here the typical problems are fairly mathematised and complex. For this we developed a new test instrument that mimics the appearance of a real problem sheet used in typical tutorials and that can be used at three test times during the first year. The students solve these problems and are interviewed about their solving process afterwards.

Based on these data, we are able to distinguish two groups of problem solvers which differ by their overall success but which also show significant differences in the used resources – content knowledge and problem schemes. The latter are of special interest because they are only rarely taught explicitly in those classes.

Keywords: Problem Solving; Diagnostic Tools; Higher Education

INTRODUCTION

Learning to solve physical problems is one of the core objectives in physics education on all levels. At German universities physics students typically attend frontal lectures laying out relevant content knowledge and additional tutorials where students get (typically fairly mathematised and complex) problems for homework which then are discussed (and probably graded) the week after. These tutorials and the discussed problems can thus be seen as a core learning opportunity when studying physics – both for factual knowledge and for problem solving skills. The efficacy of these classes in teaching problem solving skills is however relatively underresearched.

In our project we investigate the problem solving skills of first year students at a German university by using a setting very similar to the real-world situation of solving tutorial problems. In the analysis we concentrate on the overall success and on cognitive resources (physics knowledge and problem schemes) used. The findings could be used to improve the relevant classes and to help students to efficiently acquire problem solving skills.

THEORETICAL BACKGROUND

A problem in general is classically defined containing three features: an initial state (which is known), a goal state (which is to be reached) and a gap between them that has to be bridged (Maloney, 2011). Our study is based on the more specific problem definition by Smith (1991, p. 8): "A problem is any task that requires analysis and reasoning toward a goal (or 'solution'). This analysis and reasoning must be based on an understanding of the domain from which the task is drawn. A problem cannot be solved by recall, recognition, or reproduction […]. Whether or not a task is defined as a problem is not determined by how difficult or by how perplexing it is for the intended solver. 'Problem solving,' therefore, becomes the process by which a system generates an acceptable solution to such a problem." which accounts for problems that can be identified as knowledge based, i.e. that requires knowledge of the domain to be solved efficiently.

The process of solving such problems is often described as a series of steps without prescribing their order of execution (Dewey, 2002; Pólya, 1985). The contemporary model by Friege (2001; figure 1) describes the solving process of knowledge based problems in four steps: During the problem representation the solver generates a mental model of the posed situation (Savelsbergh, 1998).

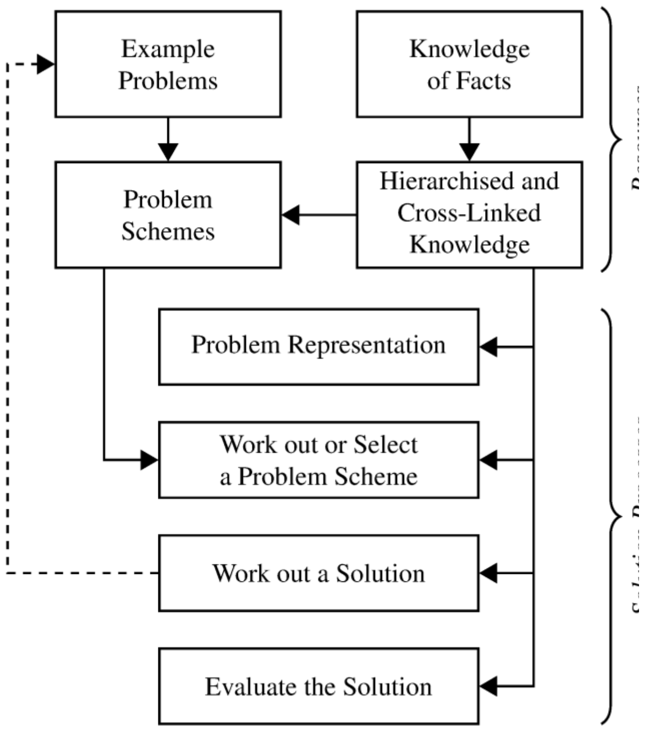

Figure 1: Model of knowledge based problem solving (Friege, 2001).

To find an approach, novices may use one or several strategies described in literature (Larkin, McDermott, Simon, & Simon, 1980). Experts however often just seem to know the right solution approach because of their expertise in the field and often show some kind of intuition which relies on a kind of specialised knowledge of typical problems and their solutions (VanLehn, 1989).

Based on this approach, the solver then works out the solution and probably evaluates it. After that evaluation – but in principle at any other point in the process – the problem solver might jump into another step to redo some of the work. Finally, the worked out solution might generate a new example problem and thus helps to solve other, similair problems.

For this process, the problem solver has to use two distinct cognitive resources: A hierarchised and cross-linked knowledge of the domain is essential for virtually all steps as it forms the cognitive basis for understanding the problem text, relating it to a mental model, and carrying out any further work that is based on any knowledge of facts or procedures within that domain. That content knowledge typically can be easily tested by paper-pencil-tests (like Woitkowski, Riese, & Reinhold, 2014).

The more interesting resource (at least in our context) are problem schemes which play a crucial role in finding a suitable solution approach. These can be considered the main source for experts expertise and intuition. The notion of problem schemes is based on the observation that novices sort given problems according to surface characteristics, while expert sort according to common structures of typical approaches and solution strategies Chi, Feltovich, and Glaser (1981). This can be interpreted as indications the existence of schemes (Friege & Lind, 2006), i. e. groups of problems based not on surface characteristics but on the underlying structure and working mechanisms. These Schemes are generated (i.e. learned) by aggregating several example problems' solutions and grouping them into problem classes by abstracting from interchangeable objects and identifying similar structures in each problem (Kolodner, 1983).

RESEARCH QUESTIONS

Out of the broader research interest of the project KEMΦ (Development of Competencies in Physics during the First Year at University), for this paper we concentrate on the problem solving skills of first year physics students at German universities. We will discuss the following two questions:

(1) In what way can more and less successful problem solvers be characterised?

(2) What resources are used for solving the problems, and to what extend can we find evidence for the use of problem schemes?

The results here may lead us in improving the students' learning of problem solving skills at universities.

METHOD

Sample and Times of Testing

The sample was recruited in the context of the KEMΦ content knowledge test, which is administered to physics students in their very first week at German universities. Those students were asked to participate in an additional study concerning their problem solving skills. In autumn 2017 eight students could be recruited this way. Two further tests were administered to the same group at the end of their first and their second semester.

A sample overview is shown in table 1. Six participants were enrolled as physics students, two to become physics secondary school teachers. The reported grades are comparable with the grades of the whole cohort. Two participants dropped out after the first time of testing.

Test Instrument

For this study, an interview guide and 3 problem sheets – one for each time of testing – where devised. Each sheet first contains a standard problem that is probably known to the students, and three mathematically or conceptually more advanced problems. Each sheet's problems can be solved with variations of the same scheme in the domain of classical mechanics (schemes from Chi et al., 1981; 1st: inclined launch and equations of motion; 2nd: balance of forces and

Table 1: Sample overview. Grades are given from 1 (best) till 6 (worst) as reported by the students. ToT is the time of testing the test persons took part in.

harmonic oscillation; 3rd: conservation of energy and momentum) within different outer contexts. This allows for a more detailed analysis on the cost of only covering few schemes.

The problem sheets are designed to match real exercise sheets from the students' physics lectures, both in outer appearance and in problem selection. To make the test situation further similar to the real world setting, students may use a calculator, books, lecture notes or the internet during the problem solving process as required.

The test persons first get an introduction into the method of thinking aloud and then solve the given problems this way. This typically takes about 60 to 90 minutes. The following 30-minute interview consists of 4 phases as in table 2.

Audio of both parts of the test is recorded and transcribed; written solutions are collected. For analysis, the interview and written solution were considered primarily, as the audio from the problem solving process is often rather difficult to understand and to follow without the more explicit explanations in the interview.

RESULTS

Characterisation of successful problem solvers

The interview data combined with the written solution give a coherent image of the success in solving the problems. We were able to generate five levels of success from the data: (A) difficulties with the problem representation, (B) no working solution approach, (C) partially working approach, (D) working approach with difficulties later on and (E) correct solution. Those categories correspond to specific steps of the model in figure 1. All 5 categories were found in the material.

Interesting here is that all four problem solutions by one test person at one time of testing either fall into the categories A, B and / or C or all four solutions fall into the more successful

Part 0	*Without looking at problem sheet or solutions* What was the overall topic of the problems? Give a specific account of the problem texts. (problem representation) Where there similarities between the problems? (surface or structural, problem schemes)
Part 1	*Without own solution* General approach to the problem sheet (order of solution, correspondence with real exercise sheets) Self assessed success (self-perception, recognition of in-/correct solutions) Sort problems by difficulty (difficulty generating problem characteristics, reflection of own skills)
Part 2	*Problems are discussed in the order they were solved* Comprehensibility of the problem (problems with representation or content knowledge) Solution approach (how approach was found, indicators for problem schemes) Difficulties with further solution (possible factors for giving up on problem, missing knowledge)
Part 3	Comparison to real exercise sheet (validity concerns, degree of realism)

Table 2: The four interview phases. For every given question its intention is given in brackets.

categories C, D and / or E. This can interpreted as an easy, albeit coherent way to differentiate two degrees of overall success when solving these problems.

The two test persons who dropped out of the study after the first test exhibited less success in solving the problems.

Used resources and problem schemes

Identifying problem schemes is more interpretative and was done in a two step procedure. First, indicators for the presence of a scheme are devised from literature as (1) problem scheme is explicitly named and explained (Larkin, 1983); (2) problem representation is very short or left out entirely (Simon & Simon, 1978); (3) students indicate routine or approaches being intuitively clear (Reinhold, Lind, & Friege, 1999; VanLehn, 1989); (4) the solution seems intuitively clear to the student (Chi, Glaser, & Rees, 1982) and typically (5) all solutions have at least a correct solution approach (Chi et al., 1982).

On this basis the students' performance on the whole test including the interview can be categorised by the degree of presence of problem schemes: (O) no indication for problem scheme; (P) first indication for developing problem scheme; (Q) during the test the scheme is developed to be successfully used at least at the last problem; (R) the solution approach part (algorithm) of the scheme is functionally available while the classification of problems is not fully able to decide when to use the scheme; (S) the problem scheme is fully developed from the beginning.

Here we see that in eight of the twenty tests the scheme was developed either at category R or S and those test persons had correct approaches to most or all of the problems. The case of students developing the scheme during the test only occurs in three cases. The other nine cases showed no scheme (category O or P).

Two interesting results are that students who exhibit successful problem solving most of the time also show strong indicators for the use of problem schemes. On the other hand, those who did not succeed in solving the problems also showed next to no indicators of problem schemes. Further, students who exhibits signs of problems with the needed content knowledge also show no signs of available problem schemes.

DISCUSSION AND CONCLUSION

This test format can be used to gain relevant information about students' problem solving abilities. When asked about the level of authenticity of these problems, the student indicated that these problem sheets where realistic in form but comparatively short (which was intended to keep required times manageable). Several of the problems where known as standard problems to the more successful students.

Although the problems and schemes differed between test times, we see an overarching difference between students who are successful and those who are not. Two main differences can be identified between these relatively stable groups: The less successful group was not able to choose appropriate knowledge for interpreting and approaching the problem. The more successful group mostly could use the appropriate problem scheme to quickly and safely find a suitable approach which may be interpreted as having more "routine".

These results can be seen as strong reasons to see problem schemes as a major factor when it comes to the ability to solve typical physics problems. However, the finding that about half of the students tested do not show signs of available problem schemes and must be regarded as very poor problem solvers – even after the first year of studying physics at university – must be considered problematic.

Concerning physics classes at university, this poses the question why some of the students successfully acquire these schemes and some do not. One element here might be a lack of content knowledge (which is used to generate these schemes by abstraction and grouping) but another might be a lack of practice (more example problems would give them more material to work on when generating those schemes). This poses the question how we can revise our lectures and tutorials to enable those less successful students to do that abstraction and grouping step which helps them generate usable problem schemes?

From theory, we would expect two strategies to be relevant when fostering the acquisition of problem schemes: First, students should discuss the solution to several problems in detail, and especially discuss the structure of their respective solution. This should enable the students to collect a larger reservoir of example problems. Secondly, students should discuss heuristics of the kind “when do we use this strategy or that approach” and be instructed to regard the deeper functional structure of a problem situation rather than surface characteristics. This might foster the classification of known example problems into categories which then might help generate problem schemes.

PART 18: STRAND 18

Methodological Issues in Science Education Research

Co-editors: *Shulamit Kapon & Marianne Odegaard*

CONTENTS

STRAND 18: INTRODUCTION

METHODOLOGICAL ISSUES IN SCIENCE EDUCATION RESEARCH ASPECTS OF EPISTEMOLOGY, ONTOLOGY AND AXIOLOGY.

The focus of the presentations in Strand 18 - Methodological Issues in Science Education Research - is not the generation of novel knowledge or insights in science education, but rather the processes by which this knowledge and insights are created, validated, evaluated, and disseminated. Papers in this strand can be situated in any context of science education research; the common ground is the focus on the research methods, and the discussion of aspects of epistemology, ontology and axiology.

The contributions to this year proceedings include five chapters that present and problematize a span of methodological issues in science education research. The first two chapters discuss instruments and surveys. Toma et al. problematize and question the validity of existing instruments for measuring students' attitudes in science education, by critical examination of their psychometric properties. Teo discusses the design and validation of a survey that aims to measure science teachers' views about students with special needs, the self-efficacy of these teachers about teaching students with special needs, and their familiarity with teaching practices appropriate for inclusive science classrooms. The next two chapters discuss innovative research methods in science education research. Bolte et al. show how eye tracking can be used to examine the applicability of Gestalt psychology principles to effective design of demonstration in chemistry. Espinoza et al. examine the applicability and efficiency of machine learning for automated content analysis that identifies different inquiry-based learning phases in transcriptions of authentic face-to-face discussions of students; and compare it to human coding. The last chapter focus on systematic methods for curriculum design. Kamphorst and Kersting argue that the combination of Design Based Research, and the Model of Educational Reconstruction provides a productive synergy that can guide effective curriculum design particularly in abstract areas such as modern physics.

A SYSTEMATIC REVIEW OF SCIENCE EDUCATION ATTITUDE INSTRUMENTS PSYCHOMETRIC PROPERTIES

Radu Bogdan Toma[1], Norman G. Lederman[2], Jesús Ángel Meneses Villagrá[1]

[1]University of Burgos, Burgos, Spain.
[2]Illinois Institute of Technology, Chicago, USA.

Following a systematic review procedure, the psychometric properties of science education attitude instruments (N = 62) retrieved from the WOS and SCOPUS database were in-depth analyzed. Findings reveal that attitude instruments published in science education between 2004 and 2018 years are generally lacking theoretically underpinnings and validity psychometric evidences, which calls into question the results obtained to date, demands a re-examination of the conclusions reached in this line of research, and highlights the need to improve practices in instrument validation.

Keywords: attitudes toward science, development and validation, instrument.

INTRODUCTION

One decade ago, Blalock et al.'s (2008) review warned about the lack of psychometric properties of the measurement instruments in science education published between 1935 and 2005. Since then, new approaches to improve student's interest in science have gained momentum, with an increase in research implementing and evaluating different educational interventions (NAE & NRC, 2014). Given the conceptual and methodological issues underpinning the instruments reviewed by Blalock et al.'s (2008), it is necessary to evaluate if the instruments designed in recent years have better psychometric evidence than the ones analysed previously.

For this reason, the purpose of this study is to identify and examine the psychometric properties of attitude toward science instruments developed and published between 2004 and 2018 to determine whether new science education efforts for improving students' attitudes towards science are being complemented by the development of valid and reliable quantitative questionnaires.

METHOD

A systematic psychometric review was conducted following the PRISMA statement for systematic reviews and meta-analysis (Liberati et al. 2009). Accordingly, studies were deemed relevant based on the following inclusion criteria: (a) instrument validation study, (b) instruments measuring attitudes, (c) quantitative instruments. Potentially relevant articles were identified in the Web of Science Core Collection (WOS) and Scopus database using the following search strategy: *attitud* OR view* OR opinion* OR image* OR motivation* AND scien* AND scale* OR instrument* OR measur* OR survey* OR questionnaire* OR tool* AND validat* OR develop* OR psychometric* OR properties OR evaluat**. A follow-up snowball technique was used by screening the reference list of eligible studies to include potentially relevant articles that were not retrieved using the search strategy. Search was restricted by the following filters: (a) articles, (b) written in English or Spanish, (c) indexed in the Education & Educational Research (in WOS) and Social Science categories (in Scopus), and (iv) published since 2004 to June 2018, that builds upon and updates Blalock et al.'s (2008) study. The psychometric properties reported in included studies were assessed using a checklist created *ad-hoc* for this study following recent recommendations as the ones from the Standards for Educational and Psychological Testing (AERA, APA & NCME, 2014). In this study, we report the results related to the theoretical framework adopted and the validity evidences reported in each reviewed study. The full-reference for the reviewed studies are included in the Appendix.

RESULTS

A total of 1327 records were retrieved, of which 1055 were excluded after applying search filters. Of the remaining 272 articles, 174 were excluded after reading title and abstracts for not meeting inclusion criteria. After removing duplicated records, searching for full articles copies, and examining the reference list of eligible articles, 61 studies reporting on the development and validation of 62 attitude instruments were retained for in-depth analyses.

Up to 30 of the 62 reviewed assessments (48.4%) were developed without a clear conceptualization of the attitude construct and thus were not guided by any theoretical framework. Of the remaining instruments referring to theory, it was used in a problematic way, like replacing theory constructs with other constructs without a rationale, or extracting factors representing two theoretically distinct factors under the same umbrella/factor (e.g. including in one factor items measuring interest, self-efficacy and outcome expectations).

Table 1. Descriptive statistics on validity psychometric evidences reported

Validity evidences	N	%
Content & face		
Expert panel	27	43.5
Target population	23	37.7
Not reported	23	37.1

Discriminant	13	21.0
Discriminative	30	48.4
Not reported	19	30.6

[a] EFA-CFA (Exploratory-confirmatory factor analysis); IRT (Items response theory).

In relation to validity, although all instruments were presented as valid tools for attitude measurement, for the most part this was only supported by the reporting of few validity psychometric properties. Thus, 36 of the 62 assessments (58.1%) were validated reporting less than three out of the nine total possible validity evidence, with five instruments reporting only one validity evidence. A closer examination of the validity results reported reveals that overall, test developers failed to provide consistent evidence for some fundamental types of validity psychometric properties (Table 1). Thus, in up to 23 of the 62 assessments (37.1%), evidence for content and face validity was inexistent, and for only 23 assessments (37.1%) the content validity was examined using interviews with the target population of study. As for criterion related validity, concurrent or predictive tests were missing in 49 of the 62 assessments (79%). The concurrent validity was examined for only three assessments (4.8%) and the predictive validity was assessed in only 10 out of the 62 analysed assessments (16.1%). In addition, information regarding hypothesis-testing construct-type of validity was rather limited. 39 of the 62 instruments (62.9%) were not tested for convergent validity, and the discriminant validity was not assessed in 49 assessments (79%). The ability of the proposed assessments to correctly discriminate between groups it should be able to discriminate (i.e. discriminative validity) was not reported for 32 of the 62 assessments (51.6%).

DISCUSSION

Results of this review reveal that methodologically strong and psychometrically sound attitude instruments in science education continue to be scarce and that most of Blalock et al.´s (2008) criticism are still relevant for newly developed science attitudes instruments. Among the reviewed instruments, most were of deficient quality according to current standards. While some instruments were rooted in a theory, no dominant framework of attitudes toward science informing the development and validation process was identified, and therefore many distinct factors hypothesized to be measuring attitudes toward science were reported in each study without justification. This lack of a clear conceptualization of what constitutes attitudes toward science led to instruments with inconsistent construct structure, with factors loadings not reflecting the intended construct, many cross loadings, or different factor structure in translated versions.

As for the validity evidences, most instruments were not subjected to enough psychometric analyses in order to be promoted as valid tools. Specifically, the lack of studies reporting on the convergent and discriminant validity of the proposed instruments is highly worrying. Considering that attitude is a multidimensional construct, these results are kind of problematic and the construct validity of many instruments remains unclear and calls into question the ability of most reviewed instruments to validly measure individuals' attitudes. Likewise, the lack of temporal stability evidence (i.e. test-retest validity) calls into question the ability of the analysed instruments to measure attitudes consistently and accurately in repeated administrations. Since these instruments could be used to track the development of students' attitudes and to examine interventions impact on the construct under study, the use of assessments lacking temporal stability evidence will lead to results which validity is unknown at best.

Several implications arise from these findings. First, a greater conceptualization of the attitude toward science construct is crucially required. Until then, it is advisable to abandon any attempt to further develop instruments based on existing ones and to avoid the use of instruments that do not have a theoretical framework. Second, instruments should be submitted to test-retest reliability evidence before being advocated and used in quasi-experimental time-series design or intervention studies with multiple longitudinal test data collection. Third, most reviewed instruments should be subjected to further empirical work to provide more validity evidences. Finally, it is worth considering the need for a re-examination of the assumptions reached in attitude toward science research derived from the use of these instruments.

In conclusion, the findings of this review study reveal that although a rather large body of attitude instruments was developed and published in the science education field in the last 14 years, the conceptual and methodological quality of most of them are below modern standards for educational and psychological testing. These results can be useful as it highlights those aspects that need improvement when developing and validating attitudes instruments in science education research.

DESIGN AND VALIDATION OF A TEACHER SURVEY ON SPECIAL NEEDS EDUCATION

Tang Wee Teo
National Institute of Education, Nanyang Technological University, Singapore, Singapore

Teachers are increasingly challenged in inclusive classrooms as more children are being diagnosed with special education needs (SEN). Teachers teaching disciplinary-based lessons in inclusive classrooms have to give conceptual, epistemic, and social considerations. Additionally, they have to adapt according to the needs of learners with SEN at the same time. However, inservice and preservice teacher preparation programmes rarely discuss the topic of SEN in science pedagogies and assessment. The science education research literature is not well-established in the area of special needs science education. This paper addresses the gap in the literature and teacher education programmes by designing and validating the Views and Practices in Special Needs Science Education (VPSeNSE) survey to measure: (a) teachers' views about students with SEN, (b) teachers' self-efficacy views in teaching students with SEN, and (c) science teaching practices in inclusive science classrooms. These constructs are important because teachers' views about their students and self-efficacy views have been reported to shape teaching practices. In this paper, I describe the design and validation process of VPSeNSE. Specifically, a literature search on teacher survey instruments related to special needs education was conducted and 51 papers were found. Survey item related to the three constructs were selected and compiled. Qualitative validation via interviews with one current primary (Grade 6) science teacher teaching in inclusive science classrooms, and a former primary science teacher who was recently seconded to lecture in primary science teacher education courses, were conducted. Based upon the qualitative validation process, the items were revised, deleted, or added. The final teacher survey comprised 35 items. The survey responses gathered from 108 Singapore science teachers were subjected to Rasch analysis and the results were reported here. The survey has been validated for our research purpose.

Keywords: design and validation, teacher survey, special needs science education

SCIENCE EDUCATION AND SPECIAL EDUCATION NEEDS

Students with special education needs[1] (SEN) are increasingly included in mainstream science classrooms and are expected to demonstrate academic proficiency on standardised assessments (McLeskey, Landers, Williamson, & Hoppey, 2012). Advocates for inclusive education have emphasised the importance of quality science experiences for *all* students including SEN students (Lederman, & Stefanich, 2004), even arguing that it is a moral imperative (McGinnis, 2003). Research have suggested that science lessons, when designed to accommodate students with special needs, can afford effective learning (McGinnis, 2013). While the inclusion of SEN students in regular classrooms confers many benefits in terms of socialization and curricular access (Baker, Wang, & Walberg, 1994), it presents challenges to teachers who may not be prepared to teach students with learning disabilities. Previous studies have reported on science

[1] Different terms have been used in the literature to refer to learners with diverse learning needs that can be emotional, cognitive, development, or physical. In this proposal, we use the term special education needs (SEN) for consistency.

teachers who feel unprepared to teach students with SEN and special education teachers feel unprepared to teach science (Irving, Nti, & Johnson, 2007; Norman, Caseau, & Stefenich, 1998). Teacher preparation and attitudes have been cited as the major factors contributing to the success or failure of students with disabilities in science learning (Elhoweris & Alsheikh, 2006; Jobe, Rust, & Brissie, 1996; Van Reusen, Shoho, & Barker, 2001). A mixed methods study conducted by Kahn and Lewis (2014) on 1,088 K-12 science teachers in the U.S. revealed that they received little formal training and felt unprepared to teach SEN students. Yet, a paucity of studies about special needs science education, especially about science teachers remains.

GOAL OF THIS PAPER

This paper reports on the design and validation of a teacher survey instrument that is used to measure the following three constructs: (a) teachers' views about students with SEN, (b) teachers' self-efficacy views about teaching students with SEN, and (c) science teaching practices in inclusive science classrooms. There is no specific programme or course about special needs science education in Singapore. There is also no survey instrument specifically for investigating teachers' views in the context of special needs science education. The survey reported in this study is used to conduct a baseline inaugural study of science teachers in Singapore so as to identify specific support for them to teach science in classrooms, which are all inclusive. As most teacher surveys focus on teachers' views about inclusiveness, which is the policy for Singapore education, they are not relevant to the context of the study. Hence, a new teacher survey was developed for this study with a disciplinary focus in SEN.

THEORETICAL CONSTRUCTS

The three theoretical constructs examined in the survey are: (a) teachers' views about students with SEN, (b) teachers' self-efficacy views in teaching students with SEN, and (c) science teaching practices in inclusive classrooms. These three constructs are being studied because it has been well-established in the literature that teachers' views about students will impact what they do in the classroom. Their successfulness in the classroom will in turn affect their self-efficacy views and then impact students' achievements (Goddard, Hoy, & Hoy, 2000).

METHODS

This research is part of a larger one year study involving a quantitative scan of science teachers' views about special needs science education and qualitative case study of three teachers to obtain a more in-depth view. The quantitative component of the research involves a survey design that entails: (1) literature review on the three theoretical constructs, (2) qualitative validation using interviews, and (3) Rasch analysis (Wright, 1993).

The design of the survey instrument began with a literature search on peer-reviewed journal articles related to surveys about teachers in special education needs. A total of 51 papers were found and all the theoretical constructs studied and survey items were compiled. Three theoretical constructs that were relevant to the goal of research were identified. Qualitative validation via interviews with one current primary (Grade 6) science teacher teaching in inclusive science classrooms, and a former primary science teacher who was recently seconded to lecture in primary science teacher education courses, were conducted. Based upon the qualitative validation process, the items were revised, deleted, or added. The final teacher survey comprised 35 items. The survey was administered to Singapore primary science teachers and the responses were analyzed using Rasch modeling.

In Singapore, science is taught only from Grades 3 (aged 9) onwards. As such, primary science teachers, who have had taught Grades 3-6 classes with at least one student with SEN (autism spectrum disorders, ADHD, intellectual disabilities, and learning disabilities), were recruited via email to complete the online survey. The email was sent to all Singapore public and independent primary schools. The survey could be completed within 20 minutes and teachers could access it via a webpage link or QR code. A total of 108 science teachers, who met the selection criteria, completed the survey. All institutional guidelines related to human ethics clearance had been obtained prior to the start of the study. Only responses from teachers who had submitted the consent forms were included in the analysis.

FINDINGS AND DISCUSSION

Fit statistics

The infit and outfit mean squares, *and* standardized residuals from the Rasch analysis outputs showed that no items appear misfitting. That means that no items were found to be confusing and not performing well in determining the teachers' responses. The results also showed that no persons were misfitting (i.e., no teachers were "misbehaving" on the survey).

Item and Person Reliability

Person and Item reliabilities were achieved. The values were at least 0.70 for all three constructs. This means that if the survey was readministered to another sample of the same size, the persons and items placement on the survey pathway would remain consistent.

Item Maps

Based on the Wright map on science teachers' views about students with SEN, the mean of the person "ability" is about 1 logit higher than the mean of the item "difficulty" (see Figure 1 in the Appendix). This means that most of the teachers found it easier to agree with the items in this construct. On the other hand, the Wright maps on science teachers' self-efficacy views in teaching students with SEN (see Figure 2 in the Appendix) and science teaching practices in inclusive science classrooms (see Figure 3 in the Appendix), showed that mean of the person "ability" is about 1 logit lower than the mean of the item "difficulty". This means that most of the teachers found it harder to agree with the items in these two constructs. Typically, instruments (e.g., cognitive tests) that are used to collect data about specific areas of competencies (e.g., analytic skills, computation skills) should ideally have the two means (person "ability" and item "difficulty") in close proximity. This means that the difficulty of the items matches the abilities of the participants taking the test. However, in our survey validation, the separation of the two means by approximately 1 logit is acceptable (i.e., not excessively positive or negative) as the instrument is intended to gather their explicit and implicit views about students with SEN and the types of adaptive teaching practices that use in their inclusive science classrooms.

IMPLICATIONS AND CONCLUSION

This paper has reported on the design and validation process of a survey instrument (available upon request) to investigate science teachers' views about students with SEN. The three constructs—namely, science teachers' views about students with SEN, science teachers' self-efficacy views in teaching students with SEN and science teaching practices in inclusive science classrooms—were included in the survey. The constructs and relevant items were qualitatively and quantitatively validated using interviews and Rasch modeling. Based on the Rasch analysis results, we conclude that the survey instrument has been validated. To date, we have translated and administered the survey to science teachers of similar demographics in Taiwan and South Korea. The instrument will be validated further and international comparisons based on the results will be reported elsewhere.

ACKNOWLEDGEMENT

This study was funded by Singapore Ministry of Education (MOE) under the Education Research Funding Programme (OER 25/17 TTW) and administered by National Institute of Education (NIE), Nanyang Technological University, Singapore. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author and do not necessarily reflect the views of the Singapore MOE and NIE.

DEMONSTRATION EXPERIMENTS IN THE CONTEXT OF COGNITIVE PSYCHOLOGY RESEARCH

Claus Bolte[1], Marten Hollauer[1], Rene Mückai[1] and Nadine Zöphel[1]
[1]Freie Universität Berlin, Germany

In this article, our project team examines the question: Under which conditions are students in a position to perceive presented experimental phenomena in such a way that these phenomena can best be used throughout the course of the learning process?

The theoretical inspiration for this research project came from the Gestalt psychology motivated research of Schmidkunz during the 1980s and 1990s. In addition to this, new cognitive psychology methods were adapted from the field of "eye tracking research." A total of 135 students from six classes grade 8 of two grammar schools took part in the study. The participants were divided into four groups, before each of which one of four different versions of a video documented experiment was played on a computer. While the students each observed their version of the experiment, the movements of their gaze and fixation were recorded. After the presentation of the experiment, the students were asked to complete a pre-structured laboratory report. The assessment of these reports and the results of the eye tracking analysis presented unexpected findings.

Keywords: Gestalt psychology laws, demonstration experiments, eye tracking analysis

THEORETICAL FRAMEWORK

The Gestalt psychology motivated works and recommendations from Schmidkunz for the presentation of chemistry-related demonstration experiments form the theoretical starting point for our project (Schmidkunz, 1983; 1990; 1991; 1992; 1997; 2007). In addition, we oriented ourselves on newer cognitive psychology works, especially in the field of eye-tracking research (Rayner, 1992; 1998; Havanki & VandenPlas, 2014). Studies using the eye-tracking method offer the prospect of shedding some light into the black box of the cognitive processing and perception of visual stimuli.

Works motivated by chemistry education and Gestalt psychology from Schmidkunz

In the 1980s, Schmidkunz had already proved that elements from Gestalt psychology theory could contribute to the explanation of chemistry-related learning processes with his case studies oriented on chemistry education (Wertheimer, 1985 [1925]; Fitzek, 2014). In the course of his studies, Schmidkunz dealt with various laws of Gestalt psychology; among others the law of continuity (2007; cf. Treatment 1), the law of figure-ground contrast (1991; cf. Treatment 2), and the law of symmetry (1992; cf. Treatment 4). The results of these studies suggest that disregarding the principles described in the Gestalt laws during the presentation of chemistry demonstration experiments leads to impaired learning success on the part of the pupils involved – at least in comparison to the learning of the pupils to whom the optimum possible experimental arrangement (here: Treatment 3) was presented (Schmidkunz, 1983; 1990; 1991; 1992; 1997; 2007).

Subject-specific teaching and cognitive psychology in eye tracking research

In the field of neuropsychology and cognitive psychology, studies are increasingly being conducted by means of the eye tracking method (Ravner, 1992; 1998; Auer et. al., 2005; Havanki & VandenPlas, 2014). With the help of special software and hardware, visual fixations are recorded in the millisecond range enabling the reconstruction and visualization of the corresponding movements of gaze. In this way, attention and concentration as well as perception processes can be quantitatively analyzed. This in turn allows conclusions to be drawn about the triggered cognitive processes and the learning of selected facts. For some time, eye tracking studies have found their way into more and more studies motivated by science education and specifically chemistry education (Sumfleth & Gnoyke, 1995; Gnoyke, 1997; Fäth, Watzka & Girwidz, 2013; Hofmann, 2011; Richtberg & Girwidz, 2013; Rohde et al., 2013; 2015).

RESEARCH QUESTIONS

Following the two research strains outlined above, our project group addressed the following research questions:

1. To what extent can the findings presented by Schmidkunz be replicated?

2. What causes for successful and/or unsuccessful chemistry-related learning can be derived from the results of our eye tracking analysis?

METHOD

To answer the research questions, we decided to plan and conduct an *experimentally designed study in the Treatment Control Group design*. The large number of case studies presented by Schmidkunz concerning the eight Gestalt psychology laws, as well as the large number of attached recommendations necessitated that we make a selection for the upcoming investigation. Our choice landed on the "law of the straight and continuous line" (Schmidkunz, 2007, 406; Treatment Group 1: Line), the "law of figure-ground contrast" (Schmidkunz & Büttner, 1991, 338; Treatment Group 2: Contrast), and the "law of symmetry" (Schmidkunz, 1992, 12; Treatment Group 4: Symmetry) as conciseness-governing factors in chemical experiments. The experimental design which avoided the violation of the three laws mentioned, and thus corresponded to the "state-of-the-art" didactic example of recommendable experimental practice, served as a control variant (control group: state of the art; see Fig. 1 and Image 4 in Fig. 4).

Fig. 2. Basic equipment setup of an eye tracking laboratory space

Fig. 3: Workspace in the eye tracking laboratory of the FU Berlin

We invited six school classes from year 8, accompanied by their teachers, to a project day in the student-laboratory of the Department of Chemistry Education at the FU Berlin. The project day was planned and executed by the members of this project group. From the classes that took part in the project day, four groups were formed by random sampling, each of which in turn was randomly assigned to one of the four experimental treatments (see Fig. 3).

First, the students were familiarized with the experimental setting of the eye tracking laboratory in the workspace of the Neuropsychology Department at the FU Berlin. Afterwards, one of the four taped chemistry experiments was shown on the computer. During the introduction, students were instructed to observe the experiment carefully in order to be able to complete a pre-structured lab report afterwards.

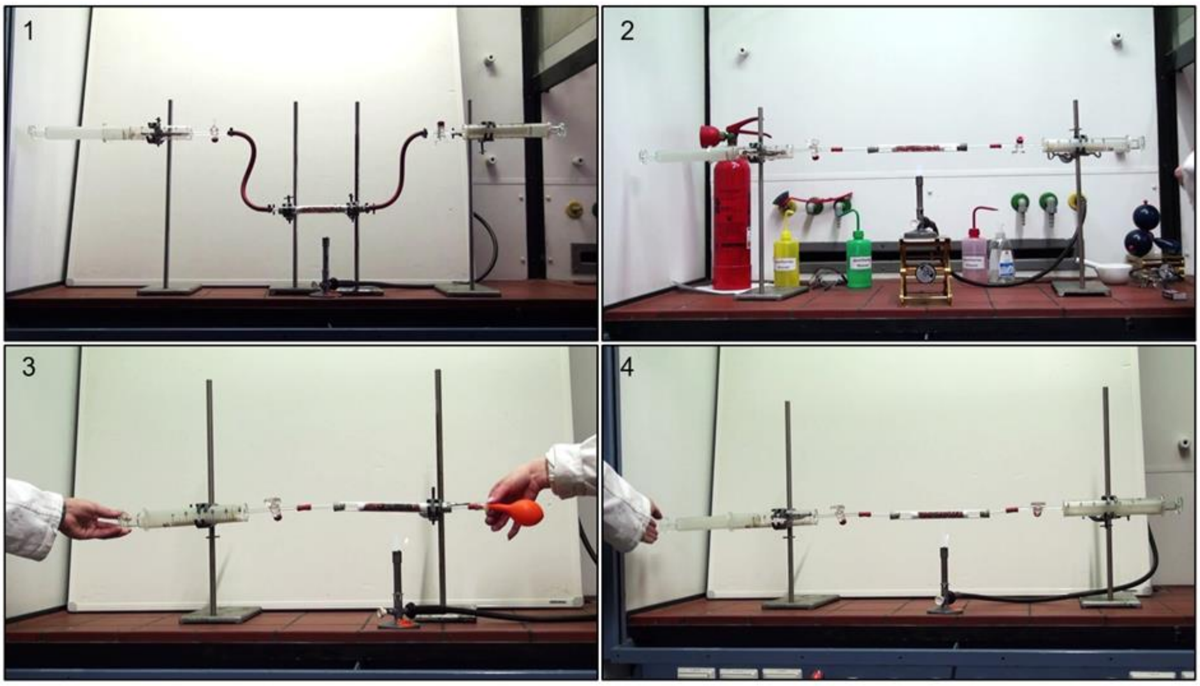

Figure 4. Four variants of the video-documented demonstration experiment. Image 1: Violation of the law of the continuous straight line (Treatment Group 1); Image 2: Violation of the figure-ground contrast law (Treatment Group 2); Image 3: Violation of the law of symmetry (Treatment Group 4); Image 4: "State of the Art" (Treatment Group 3, Control Group)

After being filled out by the test subjects, the lab reports were evaluated according to specially developed evaluation criteria. In the course of this grading process, cumulative and relative solution frequencies were calculated. As long as the necessary subsample size was reached, a group-specific statistical significance test was performed (Eid, Gollwitzer & Schmitt, 2015) and the obtained results were compared with those from the Schmidkunz studies.

In this regard, we expected (in agreement with Schmidkunz; see above) that the students which could recall the experimental procedure that followed the Gestalt laws (Treatment Group 3:

representing the Control Group), compared to the other three treatment groups would achieve the best comparable results with regard to recording (logging) the experiment. In addition, eye fixations and eye movements of the participants were recorded and analysed using eye tracking software and hardware during the four different sets of experiments (see Fig. 1 and 2).

Theory-compliant results from the analysed lab reports, as well as those which deviated from Schmidkunz's findings (contrary to our expectations), were examined and discussed in detail, using the eye tracking findings that we generated and analysed.

With regard to our eye tracking analyses, we expect statistically significant differences that indicate differences in perception and/or attention differences when considering the four different experimental demonstrations.

EMPIRICAL RESULTS

The sample of our study consisted of 135 pupils from year 8, which came out of six classes from two different schools. The students were assigned to the four experimental sub-samples (treatment groups) and distributed as follows: Treatment 1 (solid line): 34; Treatment 2 (basic figure contrast): 33; Treatment 3 (Control and "State of the Art" Group): 32; Treatment 4 (Symmetry): 36.

The results of the analysis of the pre-structured test protocols prepared by the students can be found in Table 1, differentiated according to the experimentally different sub-samples or settings. Selected findings from the eye tracking analysis – differentiated by treatment group– are summarized in Table 2.

Table 1: Results from the analyses of the pupils' completed pre-structured lab reports - differentiated according to treatment groups

INTERPRETATION

The performance-based findings from the Schmidkunz case studies could not be replicated in our investigation. This may be due to the varying experiment designs and evaluation processes as well as the different sample groups, but the termination of the testing process may also be to blame. These findings alone speak for the conducting of further experiments of this kind.

The results of the analyses related to content and learning growth, based on the pre-structured lab reports of the pupils, suggest that the pupils involved were evidently capable of compensating for didactic shortcomings in the presentation of the demonstration experiments. Contrary to expectations, the best results were not achieved by the treatment group to which the supposedly best trial demonstration was presented (see Table 1). Indeed, the findings of our eye tracking analyses (see Table 2) suggest that the planned violations of the principles of Gestalt psychology were not as attention-grabbing as the previous case studies of Schmidkunz from the 1980s and 1990s would have us assume.

CONCLUSION

Apart from the abovementioned limitations, the overall design of our study has proven itself. Although eye tracking studies are time consuming and demand much organization, the method offers many interesting, scientifically valid and subject-relevant insights into the learning of scientific facts. Therefore, further and even more systematic and nuanced studies should be undertaken promptly, while the study presented here should provide suggestions for such studies in order to gain in-depth and differentiated insights in this field.

ACKNOWLEDGEMENTS

A very special thank you goes out to Dr. Sascha Tamm (from the eye tracking laboratory in the Department of Neuropsychology at the Freie Universität Berlin) for his support throughout our survey and evaluation of the eye tracking data. We would also like to thank all the students who participated and their teachers who supported us during our tests. Furthermore, we sincerely thank Dr. Sabine Streller and Anke Ayyasky (from the Chemistry Education Department of the FU Berlin), for their support in the planning and implementation of the project days for the participating school classes.

AUTOMATIC CONTENT ANALYSIS IN COLLABORATIVE INQUIRY-BASED LEARNING

Catalina Espinoza[1], Joni Lämsä[2], Roberto Araya[1], Raija Hämäläinen[2], Abelino Jiménez[1], Raúl Gormaz[1], Jouni Viiri[3]

[1]Centre for Advanced Research in Education (CIAE) – University of Chile, Santiago, Chile

In the field of science education, content analysis is a popular way to analyse collaborative inquiry-based learning (CIBL) processes. However, content analysis is time-consuming when conducted by humans. In this paper, we introduce an automatic content analysis method to identify the different inquiry-based learning (IBL) phases from authentic student face-to-face discussions. We illustrate the potential of automatic content analysis by comparing the results of manual content analysis (conducted by humans) and automatic content analysis (conducted by computers). Both the manual and automatic content analyses were based on manual transcriptions of 11 groups' CIBL processes. Two researchers performed the manual content analysis, in which each utterance of the groups' discussions was coded to an IBL phase. First, an algorithm was trained with some of the manually coded utterances to prepare the automatic content analysis. Second, the researchers tested the ability of the algorithm to automatically code the utterances that were not used in the training. The algorithm was a linear support vector machine (SVM) classifier. Since the input of the SVM must be a numerical vector of constant size, we used a topic model to build a feature vector representation for each utterance. The correspondence of the manual and automatic content analyses was 52.9%. The precision of the classifier varied from 49% to 68%, depending on the IBL phase. We discuss issues to consider in the future when improving automatic content analysis methods. We also highlight the potential benefits of automatic content analysis from the viewpoint of science teachers and science education researchers.

Keywords: Collaborative learning; Inquiry-oriented learning; Quantitative methods

INTRODUCTION

In the field of science education, content analysis is a popular method for analysing collaborative inquiry-based learning (CIBL) processes (e.g., Lämsä et al., 2018, 2020; Wang et al., 2014). Typically, researchers have pre-defined codes, such as the phases of inquiry-based learning (IBL), on which the content analysis is based. Identification of different phases of IBL is needed when designing scaffolds for CIBL processes. For instance, previous research has shown that students need support, especially in the first phases of IBL (Lämsä et al., 2018; Wang et al., 2014). However, it is known that optimal scaffolding is context-specific, so there is a need to study CIBL processes in various contexts. Due to the vast human resources that content analysis of CIBL processes requires, in this study, we illustrate the potential of automatic content analysis for analysing CIBL processes. In the following, we briefly present how automatic content analysis has been applied in learning sciences so far.

Automatic content analysis in learning sciences

A major challenge in building a practical tool that supports teachers in the classroom is the need to analyse students' discussions in each group. Hence, we need novel methods to process and analyse massive amounts of data. This is not only time-consuming when performed by humans, but also requires the analysis of parallel speech produced in each group of students. Moreover, the analysis needs to be done in real time in order to be useful to the teacher. Furthermore, it is not straightforward to produce a robust diagnosis, as trained human raters must agree on coding. Specifically, in order to provide a robust analysis, it is necessary to have at least two raters and ensure sufficient inter-rater and intra-rater agreement.

So far, studies have investigated the potential for automatic content analysis in developing a better understanding of computer-mediated student–student interaction as well as teacher–student interaction. In the context of student–student interaction, Rosé et al. (2008) presented an overview of work on automatic analysis of computer-supported collaborative learning (CSCL) in which the authors stated, 'Our specific goal has been to extend and apply current text classification technology to CSCL, exploring which classification techniques are most effective for improving the performance on different types of coding dimensions used in the CSCL community.' They found that some discourse processes in educational psychology could be automatically detected in text messages at a level of agreement comparable to that between human coders. Dowell et al. (2018) also developed a group communication analysis by combining automated computational linguistic techniques with analyses of the sequential interactions of online group communications to detect emergent roles in group interactions.

Text analysis also allows the study of the effect of questions posed by the teacher. This is a subject of great importance in teaching practice and in the preparation of teachers. More than a century ago, Stevens (1912) emphasised the realisation of questions as a fundamental component in teacher training. Araya et al. (2018) analysed written responses to open-ended questions of students from various elementary school classes and built an automatic predictor of the length of the answers of each student based on the presence of keywords in the teacher's questions. Donnelly et al. (2017) used an automatic speech recognition (ASR) algorithm to automatically detect teachers' questions, and Caballero et al. (2017) used an ASR algorithm to automatically provide teachers with a visualisation of the structure of concepts present in their discourse in science classrooms. Araya et al. (2012) built an automatic classifier of estimations of teacher practices using ratings of a subset of transcriptions made by trained raters. The agreements between the automatic classifiers and the corresponding raters that were computed for transcriptions from an independent subset were better than the agreements between the human raters. More recently, Kelly et al. (2018) compared human coding and semi-automated computer coding of the authenticity of teacher questions. They concluded that the correlations were sufficiently high to provide a valuable complement to human coding in research efforts.

These examples show that automatic content analysis has been applied to the study of computer-mediated communication between students and teachers in CSCL classrooms. CSCL research could benefit from the opportunities afforded by technological and methodological development. So far, the results of automatic content analysis have been encouraging. In this paper, we apply automatic content analysis to authentic student face-to-face interactions taking place in computer-supported settings in order to identify the different IBL phases in students' discussions. We address the research question (RQ): How similar are the results of the proposed automatic and manual content analyses in a CIBL context?

METHODS

Our study was conducted in introductory university physics courses on thermodynamics at a Finnish university. The participants were divided into groups of five students at the beginning of the course. Here, we focus on face-to-face discussions as the groups solved problems collaboratively in a technology-enhanced learning environment with shared laptop computers. Eleven groups screen-captured and audio-recorded their group-work sessions. First, we manually transcribed these sessions as they solved an inquiry problem (on average, 180 utterances per group). The inquiry problem was a study of how the displacement of an atom in a two-dimensional gas depends on time. The groups had a Python programme that calculated the displacement of an atom with different values of the number of collisions and then plotted the atom's path. Based on the output of the Python programme, the groups inferred the relationship between the displacement and time.

Second, we conducted theory-driven content analysis (Neuendorf, 2002) in which two researchers coded the transcriptions based on the IBL framework presented by Pedaste et al. (2015), i.e., each utterance was coded to one of the IBL phases (orientation, conceptualisation, investigation, conclusion, and discussion). In the orientation phase, the students became familiar with the given assignment, its main variables, and technological resources (in this case, the Python programme). In the conceptualisation phase, the students identified the dependent and independent variables of the problems and proposed research questions or hypotheses. In the investigation phase, the students planned the data collection and collected, analysed, and interpreted the data. In the conclusion phase, the students drew conclusions and offered solutions to the research questions or hypotheses. In the discussion phase, the students could communicate and reflect on the process at the end of the inquiry or in relation to an IBL phase. The inter-rater agreement was 67.7%, and any disagreements were discussed and resolved.

After this manual content analysis, we performed automatic content analysis to identify the IBL phase from a given utterance. All the analysed transcriptions were written in Finnish. We approached this task as a text classification problem—finding a characterisation of utterances (vector representation) and building an automatic classifier. Figure 1 shows the four stages of the automatic content analysis that we conducted, describing the process for each stage and the corresponding input and output.

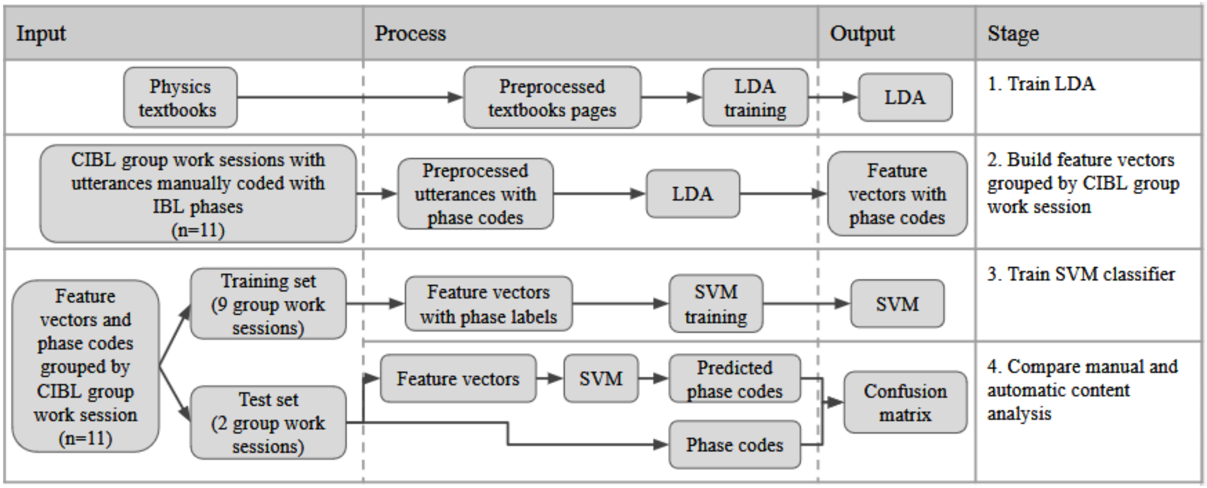

Figure 1. Stages for training and assessing the automatic content analysis.

Stage 1: Train an LDA

In order to build a characterisation of utterances, we trained a latent Dirichlet allocation (LDA) topic model (Blei et al., 2003). Topic models are statistical models that are used to find topics in large document collections in a wide range of applications, e.g., analysing historical documents, understanding scientific publications, or machine translation (Boyd-Graber et al., 2017; Dowell et al. 2018). The term *topic*—in the topic models context—is used to refer to groups of words that usually appear together in a document collection. The assumption behind topic models is that documents have a mixture of topics, and the words in a single document will depend on the topics that comprise the document. Applying a topic model to a large collection of documents allows the identification of topics and the description of documents in terms of the topics present in each document.

Table 1. Example of seven topics found by applying the LDA model to physics textbooks. These topics were common in the CIBL group-work sessions. For each topic, the top four words are shown.

Topic 8	Topic 13	Topic 17	Topic 19	Topic 27	Topic 33	Topic 39
[number]	v	=	so	T	?	[proportional to]
a	R	+	for example	l	a	measurement
b	voltage	R	same	o	how	increase
m	l	o	or	R	b	measure

Topic models need a large collection of documents to find topics that are formed by coherent groups of words. In learning sciences, there are usually learning materials available for different contexts, subjects, and languages. Our assumption was that we could use relevant topics from upper secondary school physics textbooks if we wanted to describe the discussions of undergraduate physics students. Thus, the first stage consisted of using 31 Finnish physics textbooks to train the LDA model. We trained the model to identify 60 topics, which allowed us to represent an utterance as a mixture of 60 topic proportions. Table 1 shows the words most relevant to seven of the topics. We have translated the words from Finnish to English. Topic

19 relates to words used in explanations. Topic 39 relates to words describing measurements. The other topics refer to numbers, units, name of variables and symbols.

Stage 2: Build feature vectors grouped by CIBL group-work session

In the second stage, we built a feature vector, or an enhanced representation of each utterance in the CIBL group-work sessions. The feature vector was used to train the automatic classifier in the next stage. Each utterance of the CIBL sessions was pre-processed (removing stopwords, symbols, and infrequent words). The LDA model was then used to obtain, for each utterance, a vector of 60 topic proportions. The output of this stage was a 182-dimensional feature vector representing each utterance: 60 components of the topic proportions for the utterance, 60 for the previous utterance, and 60 for the following utterance. The two additional dimensions corresponded to the number of words and the relative position of the utterance in the group-work session. It is important to note that each feature vector was related to the corresponding human-coded phase.

For the third and fourth stages, we grouped the feature vectors into two sets: a training set with the feature vectors from nine group-work sessions and a test set with the feature vectors from two group-work sessions. The training set would be the input for the third stage and the test set would be the input for the fourth stage.

Stage 3: Train the SVM classifier

In the third stage, we trained a linear support vector machine (SVM) classifier (Burges, 1998). SVMs are one of the most popular automatic classifiers (e.g., Araya et al., 2012; Rosé et al., 2008). The training of the SVM consisted of adjusting a function to optimise the number of utterances in the training set that were automatically coded to be the same as the manual code. By the end of Stage 3, a workflow had been created that allowed automatic coding of an utterance with an IBL phase. The following are examples of utterances coded with the SVM classifier:

> Yes, it was something like 20, approximately [the number of collisions $N = 300$ in the Python programme]. Then it was a little bit more than 30. Let's now try when it [N] is 500. I'll try a couple of times: 11, 15, 25, 21, 15 … [manual coding: investigation; automatic coding: investigation]
>
> ...
>
> Would someone else like to tap [run the Python programme]? [manual coding: discussion; automatic coding: orientation]

Stage 4: Compare the manual and automatic content analyses

In the fourth stage, we used the test set to compare the manual coding with the phase automatically assigned by the SVM (see the previous examples). The output of the fourth stage was a confusion matrix, i.e., a 5×5 matrix that summarises the number of utterances that were manually coded as the phase indicated by the row and automatically coded as the phase indicated by the column.

As the dataset was small, the results were highly dependent on the test set selected. To get a more robust estimation of the SVM classifier's errors, we independently ran the third and fourth stages while varying the input with all the possible combinations of nine and two group-work sessions in order to build the training and test sets. With 55 combinations in total, we obtained 55 confusion matrices. As different test sets had different numbers of utterances, each matrix was standardised to total 100. The output of the overall process was then an average confusion matrix of the 55 standardised matrices. This procedure allowed us to answer the RQ, as the confusion matrix described how well the IBL classifier was performing for each IBL phase.

Baseline

To test whether the classifier was gaining information from the text features, we defined two baselines that did not require the extraction of information from the utterances. The first baseline was a classifier that classified all the utterances as the more frequent phase. In this study, the discussion phase was the most frequent and represented 36.1% of the utterances in the CIBL sessions. The second baseline was a classifier that, in the first part of the sessions, classified the utterances as orientation, and, in the second part of the sessions, classified them as discussion. To define where in the transcription the baseline classifier should start to classify utterances as discussion, we used the training dataset to find the optimal threshold for each run of the third and fourth stage. The average threshold used for the second baseline was to classify the first 40% of the session as orientation and the remainder as discussion. The second baseline had an accuracy of 42.7%.

RESULTS

A comparison of the results of the manual and automatic content analyses is presented in the confusion matrix (Table 2). Each cell $C_{i,j}$ in the confusion matrix is the average number of utterances that were manually coded to IBL phase i and automatically coded to IBL phase j. Each cell $C_{i,j}$ represents an average across all the independent runs of the third and fourth stages of the automatic content analysis. The accuracy of the classifiers are the coincidences between the manual and automatic content analyses. As the resulting matrix in Table 2 is standardised to a total of 100, the accuracy is obtained by adding up the diagonal. The overall accuracy was 52.9% (SD = 4.8%). The precision of the classifier for each phase is the number of times that the automatically coded phase was the same as the manually coded phase. The precision of automatic coding of different IBL phases varied from 49% to 68% (orientation 50%, conceptualisation 49%, investigation 68%, conclusion 49%, and discussion 51%).

Table 2. Comparison of the results of the manual and automatic content analyses. The rows refer to the manual content analysis, and the columns refer to the automatic content analysis.

	Predicted Orientation	Predicted Conceptualisation	Predicted Investigation	Predicted Conclusion	Predicted Discussion
Orientation	16.3	0.4	1.1	0.0	6.8
Conceptualisation	2.8	2.2	0.8	0.0	5.7
Investigation	5.8	0.3	9.6	0.0	8.6
Conclusion	0.1	0.6	0.2	0.4	2.5
Discussion	7.6	0.9	2.5	0.4	24.4

In addition to the precision of the classifiers, there are other indexes that can be used to measure the reliability of the automatic coding. For example, the recall for each phase is the number of times that the automatic coding agreed with the manual coding, divided by the frequency of the phase. The recall of the automatic coding varied from 10% to 68% (orientation 66%, conceptualisation 19%, investigation 39%, conclusion 10%, and discussion 68%). These results show that the recall was rather low in the investigation phase compared to the orientation and discussion phases. This demonstrates that utterances manually coded to the investigation phase were automatically coded to the orientation and discussion phases many times, as shown in Table 2.

The results show that the precision of the automatic coding varied depending on the IBL phase. In particular, the precision of the investigation phase was higher than the precision of the other phases, i.e., when the utterance was automatically coded to the investigation phase, the utterance was also manually coded to the investigation phase with 68% probability (even though the recall was 39% for the investigation phase). The following is an utterance that was coded to the investigation phase both manually and automatically:

> Yes, it was something like 20, approximately [the number of collisions $N = 300$ in the Python programme]. Then it was a little bit more than 30. Let's now try when it [*N*] is 500. I'll try a couple of times: 11, 15, 25, 21, 15 … [manual coding: investigation; automatic coding: investigation]

In the investigation phase, the students had to, amongst other things, collect data to address the inquiry problem. The previous utterance shows an example of the data collection. During that collection, students collected the values of the displacement of an atom with different values of the number of collisions so they could infer the relationship between the displacement and time. Numbers were thus a characteristic of the investigation phase (cf. Topic 8 in Table 1). The following utterance demonstrates a challenge for the automatic coding: the utterance was manually coded to the discussion phase but automatically coded to the orientation phase.

> Would someone else like to tap [run the Python programme]? [manual coding: discussion; automatic coding: orientation]

Even though the classifier on which the automatic coding is based accounts for the previous and subsequent utterances as well as the relative position of the utterance in the whole discussion, the consideration of the overall context of the utterances is difficult to automatise. This specific utterance was manually coded to the discussion phase as it is about communicating and suggesting a new way to proceed with the inquiry problem (changing the student in charge of working with the Python programme). As can be seen from Table 2, the conceptualisation and conclusion phases were rare in the students' discussions compared to the other IBL phases, and there is thus not a representative example that illustrates inter-rater agreement between the manual and automatic coding in these phases.

DISCUSSION AND CONCLUSION

This study was a novel attempt to automate content analysis in authentic CIBL contexts in which students were working face-to-face in computer-supported settings. We compared the results of the manual and automatic content analyses, which were based on an SVM classifier.

The average accuracy of the SVM classifier (52.9%, SD = 4.8%) was 15% lower than the agreement between human coders (67.7%). Regarding the baselines, the first classified all the utterances as discussion and had an accuracy of 36.1% (SD = 5.8%). The second baseline classified the first part of the IBL sessions as orientation and the rest as discussion and had an accuracy of 42.7% (SD = 5.3%). The SVM classifier performed significantly better than the baselines; therefore, the topic description of the sentences provided information that enabled the SVM classifier to distinguish the IBL phases. Overall, these results highlight the potential for using automatic content analysis both in CIBL contexts and in face-to-face interaction in general.

There are still issues that future research should consider. First, the results for the recall and precision per phase indicate that the SVM classifier was biased against the most frequent phases. This is known as an unbalanced dataset problem. In our study, the precision was notably higher in the investigation phase than in the other phases. The recall of investigation was 39%, and the classifier frequently confused the investigation phase with orientation or discussion. When the classifier correctly coded investigation, topics 8 (numbers and units), 19 (so, for example, same, or, …) and 33 (question mark, units, how, large, calculate, ...) were present. In the future, this bias could be addressed by gathering more examples of the less-frequent phases (conceptualisation and conclusion).

Second, we treated the results of the manual content analysis as reliable so they could be compared with the results of the automatic content analysis. However, inter-rater agreement in the manual content analysis indicated that the codes for many utterances were not unambiguous, but were decided after careful joint consideration. In future, research could check whether disagreement between computer coding and human coding appears more frequently in utterances in which there is disagreement between the human coders. Third, to build the numerical representation of the utterances, we used an LDA model. As our dataset was small (11 group discussions), we trained the LDA model with physics textbooks, which contained only some of the language that appears in authentic face-to-face discussions. In the future, we will integrate transcriptions from student discussions into the LDA training.

Combining emerging automatic content analysis methods with ASR applications could be beneficial for both researchers and teachers. Automatic content analysis could support researchers with preliminary coding so they can focus more on tasks that cannot be automated, such as designing experiments and the interpretation of results, instead of time-consuming data transcription and coding. As productive CIBL activities do not necessarily emerge without assistance (Alfieri et al., 2010; Kobbe et al., 2007), a tool that can detect the stage of group discussions in real time could help in adapting support to the needs of different groups. An advantage of building the feature vectors based on LDA and using the SVM classifier is that the analysis is not necessarily language-specific. Even though we trained the LDA model using Finnish textbooks, our novel methodological approach is applicable to automatising content analysis in any language in which there are available textbooks (or other similar materials to train the LDA model) matching the language and subject of the CIBL activities.

ACKNOWLEDGEMENTS

We would like to express our gratitude for the financial aid provided by Basal Funds for Centers of Excellence Project BF 0003 from CONICYT in Chile and the Academy of Finland [grant numbers 292466 and 318095, the Multidisciplinary Research on Learning and Teaching profiles I and II of JYU].

DESIGN BASED RESEARCH AND THE MODEL OF EDUCATIONAL RECONSTRUCTION – A COMBINED APPROACH TO DESIGN SUCCESSFUL SCIENCE INSTRUCTION

Floor Kamphorst [1], Magdalena Kersting[2,3]
[1] Freudenthal Institute, Utrecht University, the Netherlands
[2] Department of Physics, University of Oslo, Oslo, Norway
[3] OzGrav-UWA, Department of Physics, The University of Western Australia, Australia

One of the main challenges that science educators face is to develop teaching-learning sequences that both engage students and convey the science content successfully. In particular, new curriculum topics such as topics of modern physics pose challenges for teachers and educators because of a scarcity of teaching experience and learning resources. What is needed is a powerful and flexible methodological framework that can guide the design of new instructional material. We argue that a combination of Design Based Research and the Model of Educational Reconstruction provides such a framework. To exemplify the efficacy of such a combined approach, we present two educational projects that have leveraged the Model of Educational Reconstruction and Design Based Research successfully to bring topics of modern physics to science classrooms.

Keywords: Design Based Research, Instructional Design, Secondary Education

INTRODUCTION

Developing teaching-learning sequences that engage students and that convey science content successfully is one of the main challenges that science educators face in their research and practice. This challenge has become more urgent as new learning domains such as modern physics, nano-science, or climate change have started to enter science curricula (Henriksen et al., 2014; Laherto, 2012; Niebert & Gropengießer, 2013). To guide educational design processes, researchers routinely draw on frameworks and methodological support structures. Often, these frameworks integrate perspectives of scientists, practitioners, and students to develop research-based instructional activities (Méheut & Psillos, 2004).

This work seeks to support educators in the gradual process of synthesising perspectives and designing successful science instruction by showing how two well-established methodological frameworks, the Model of Educational Reconstruction (MER) and Design-Based Research (DBR), can be fruitfully combined. While MER serves as an overarching framework to reconstruct novel scientific topics from an educational perspective (Duit, Gropengießer, Kattmann, Komorek, & Parchmann, 2012), it does not explicitly specify the research methods to do so. However, the framework offers a design-oriented research approach. Thus, we argue that it is natural to complement a research design based on MER with methods of DBR (Anderson & Shattuck, 2012). To guide our explorations, we ask: **How does a combination of DBR and MER offer new opportunities to design teaching and learning sequences?**

In the following, we present MER and DBR in more detail before turning to two case studies that illustrate the merits of combining both frameworks in the learning domain of modern physics. We use these two cases to show how a combined approach MER-DBR allows bridging the gap between theoretical perspectives on teaching and learning and the actual science classroom practices.

METHODOLOGICAL FRAMEWORK

In this section, we briefly outline Design Based Research and the Model of Educational Reconstruction as two methodological approaches to develop solutions to educational problems. In the next section, we present two cases that exemplify how both approaches can fruitfully be combined to design successful science instruction.

Design Based Research

Design Based Research (DBR) aims to solve educational problems by designing new educational solutions that work in the "messy" setting in which day to day education takes place. To this end, educators who use this framework not only want to know if an educational solution works, but also why it works (Bakker, 2018, pp. 3-18). In DBR, the design is guided by certain design principles or design hypotheses (provided by a learning or design theory) to generate certain learning outcomes in a certain context. The design is then tested in real educational settings and practitioners contribute to the design over multiple design cycles (Plomp, 2013, pp. 20-25). Eventually, methods of DBR result in new learning resources (the design) and a local theory that describes if and how the design works. These local theories are humble in the sense that they cannot be generalized over populations per se, but usually they are general enough to be also applicable in other classrooms settings.

Redraw picture of DBR and insert it here.

Model of Educational Reconstruction

The Model of Educational Reconstruction (MER) aims to make novel learning domains accessible to students by offering a methodological framework that integrates three strands of educational research: curriculum development, design of learning environments, and assessment of learning processes. To this end, MER provides guidance for science educators on how to integrate empirical research on teaching and learning in the development of learning resources. MER comprises the basic idea that "science subject matter issues as well as student learning needs and capabilities have to be given equal attention in attempts to improve the quality of teaching and learning" (Duit et al., 2012, p. 13). The holistic approach of MER serves as a useful and flexible tool to scrutinize the educational relevance of learning domains that have not entered mainstream science education yet. Eventually, methods of MER result in an educational reconstruction of a learning domain that contains a content structure for instruction, learning resources, based on that content structure and findings on student perspectives.

Insert picture of Magdalena's article of MER.

CASE STUDIES

In the previous section, we introduced DBR and MER as two frameworks to develop design solutions in educational settings. Both Special Relativity (SR) and General Relativity (GR) are new physics topics that have found their way to secondary school curricula in many countries (Kamphorst, Vollebregt, Savelsbergh, & van Joolingen, 2019; Kersting, Henriksen, Bøe, & Angell, 2018; Kim & Lee, 2018) . Yet, field-tested and research-based educational material is rare in this emerging learning domain of relativity education. In this section, we present two specific cases from the Netherlands and Norway in which we have combined the frameworks of MER and DBR to design teaching-learning sequences for secondary school students.

Relativity Education

Our modern scientific understanding of the universe rests on the special and the general theory of relativity. These theories present Albert Einstein's revolutionary description of space, time, light, and gravity. According to Einstein, space and time are dynamic entities that dynamically interact with matter and light. In contrast to classical physics where space and time are absolute and separate from the laws of physics, SR and GR thus ask us to let go of absolute space and universal time, concepts that seem integral to our experiential understanding of the world (Woodhouse, 2014). The abstract character of these physical insights seem counter-intuitive or even contradictory to the common-sense understanding of students (Kamphorst et al., 2019; Kersting et al., 2018). Moreover, the formulation of SR and GR necessitated philosophical changes in the world view of many scientists (Kersting & Steier, 2018). Consequently, there is potential to design learning resources that have a specific emphasis on the history and philosophy of science (Levrini, 2014).

In response to the conceptual challenges of SR and GR and acknowledging the need to convey historical and philosophical perspectives as well as content knowledge, the following two case-studies combined methods of MER and DBR to develop research-based learning resources.

Example 1 – Special Relativity

Special relativity was introduced in the Dutch upper level secondary physics curriculum in 2013. This curriculum reform placed a bigger emphasis on scientific literacy and the process of knowledge formation in physics as well. The curriculum goal of SR reflects this change: 'The candidate can explain the phenomena of time dilation and length contraction in thought experiments and applications, using the concepts of lightspeed, simultaneity and reference frame.' (ref to curriculum document) Although the big ideas in this goal are clear, it is not known how they can be achieved.

Drawing on the model of educational reconstruction we were able to design a teaching and learning sequence in which students can experience the prototypical thinking and reasoning that introduces the concepts of SR for themselves. The teaching and learning sequences takes students' spontaneous reasoning with light propagation (ref. Kamphorst) as a starting point. Through subsequent reasoning activities students introduce and explain new relativistic concepts and phenomena. A first experimental exploration in small groups with multiple versions of the design offered a proof of principle and insights to improve the task design (ref GIREP&derde artikel). However, the design was not yet suitable to use directly in the classroom. To that end we involved teachers as co-designers, informed by the DBR framework. The teachers offered a deeper understanding of students' difficulties with some aspects of the initial designs and adapted the task design so the proposed learning could be fostered in the classroom context. Furthermore, this close collaboration with teachers ensured the intended performance of the educational design.

Combining the frameworks of MER and DBR stimulated us to create a detailed view on student learning processes and the content structure of SR on the one hand and look for design guidelines that can inform future educational design on the other hand. The result is an educational design that takes both students' conceptual difficulties and the classroom reality into account.

Example 2 – General Relativity

As part of the school reform introduced in 2006, GR became part of the Norwegian curriculum for upper secondary physics. However, the specific curriculum goal for GR remained vague: "The aims of the studies are to enable pupils to give an account of the postulates that form the basis for the special theory of relativity, discuss qualitatively some of the consequences of this theory for time, momentum and energy, and give a qualitative description of the general theory of relativity" (The Norwegian Directorate for Education and Training, 2006). This broad curriculum goal left scope for different interpretations of what a qualitative description of GR might look like.

Using MER as overarching framework, the Norwegian project ReleQuant unpacked the curriculum goal by attempting an educational reconstruction of GR (Kersting et al., 2018). This reconstruction entailed the development of a content structure for instruction, the development of a digital learning environment that is freely available in English and Norwegian (www.viten.no/relativity), and in-depths studies of students' conceptual understanding of key ideas in GR (Kersting, 2019; Kersting & Steier, 2018). A key feature of the design process related to the methodological issue of combining MER and DBR. To develop the content structure of instruction, which characterises MER, we drew on DBR methods to supplement this content structure with design hypotheses. We tested these hypotheses in iterative rounds and eventually formulated design principles that encapsulate successful ways of teaching relativistic concepts based on the empirical evidence from the classrooms (Figure ?). The design principles encompass overarching themes that characterise appropriately designed learning resources and specific recommendations that promote successful instruction in GR (Kersting et al., 2018).

CONCLUSION - DBR & MER COMBINED

We live in a changing world where science educators are continuously invited to integrate new domains to the curriculum. The difficulty for this particular challenge is that for these kinds of topics, little is known on student learning and teachers lack practical experience teaching these topics. This faces the science educator not only with the question what to teach, but also how to teach. The combined framework of MER&DBR offers a guide to answer to these types of challenges science educators face.

DBR and MER are two complementary methodological frameworks. MER provides a framework that includes a broad perspective on theory, teaching and learning perspectives. DBR provides a structure to include practitioners and design hypotheses. The common denominator in both frameworks is the iterative approach in which field testing informs the improvement of the design. We have added features of both frameworks to this the common iterative approach. Of the MER framework we incorporated the analysis of the theory and student perspective to create a content structure for instruction. DBR added design hypotheses and involve practitioners as co-designers to the framework. The combination of these two frameworks has shown its benefits for the subjects of SR and GR.

Although this framework offers guidance in the design process, it is still an open process. First of all on what aspects of MER and DBR one wants to integrate into the design process. But second of all, in the process itself. The design process brings forward a lot of choices that may be taken one way or the other, based on the views on teaching and learning the designer holds. However, we expect that structuring the design with the combined framework of DBR and MER, will result in common features in the eventual design. It are these features, design hypotheses or design principles, in addition to the content structure that are the scientific outcome of design research.
