The Beauty and Pleasure of Understanding: Engaging with Contemporary Challenges Through Science Education (Proceedings of ESERA 2019)

ISBN 978-88-945874-0-1

General Editors: **Olivia Levrini and Giulia Tasquier**

Co-editors:

Andrée Maria, Avraamidou Lucy, Bruun Jesper, Carvalho Graca, Corni Federico, De Ambrosis Anna, Dillon Justin, Evagorou Maria, Fazio Claudio, Fechner Sabine, Finlayson Odilla, Guisasola Jenaro, Haglund Jasper, Hernandez Marisa, Heron Paula, Iordanou Kalypso, Jimenez Liso María Ruth, Kapon Shulamit, Kaya Ebru, Kind Vanessa, Laherto Antti, Le Hebel Florence, Odegaard Marianne, Papadouris Nikos, Redfors Andreas, Rokos Lukas, Ropohl Mathias, Rybska Eliza, Ryder Jim, Siry Christina, Spyrtou Anna, Sundberg Bodil, Testa Italo, Verhoeff Roald, Vesterinen Veli-Matti, Welzel-Breuer, Manuela, Zeyer Albert.

The Proceedings of ESERA 2019 is an electronic publication for revised and extended papers presented at the ESERA 2019 conference in Bologna, Italy during the 26-30 August, 2019. All papers in the eProceedings correspond to communications submitted and accepted for the ESERA 2019 conference. All proposals to the conference went through a double-blind review process by two or three reviewers prior to being accepted to the conference. A total of 1314 proposals (out of which 65 were symposia) were presented at the conference and in total 238 papers are included in the eProceedings.

The authors were asked to produce updated versions of their papers and take into account the discussion that took place after the presentation and the suggestions received from other participants at the conference. On the whole, the eProceedings presents a comprehensive overview of ongoing studies in Science Education Research in Europe and beyond. This book represents the current interests and areas of emphasis in the ESERA community at the end of 2019.

The eProceedings book contains eighteen parts that represent papers presented across 18 strands at the ESERA 2019 conference. The strand chairs for ESERA 2019 co-edited the corresponding part for each strand 1 to 18. All formats of presentation (single oral, interactive poster, ICT demonstration/workshop and symposium) used during the conference were eligible to be submitted to the eProceedings.

The co-editors carried out a review of the updated versions of the papers that were submitted after the conference at the end of 2019. ESERA, the editors and co-editors do not necessarily endorse or share the ideas and views presented in or implied by the papers included in this book.

The appropriate APA style for referencing this eProceedings is as follows:

WITHIN THE PROCEEDINGS:

Part 1: Learning science: Conceptual understanding

Part 2: Learning science: Cognitive, affective, and social aspects

Part 3: Science teaching processes

Part 4: Digital resources for science teaching and learning

Part 5: Teaching-Learning Sequences as Innovations for Science Teaching and Learning

Part 6: Nature of science: history, philosophy and sociology of science

PART 1: STRAND 1

Learning Science: Conceptual Understanding

Co-editors: *Anna De Ambrosis & Odilla Finlayson*

CONTENTS

STRAND 1: INTRODUCTION

LEARNING SCIENCE – CONCEPTUAL UNDERSTANDING

Strand 1 focusses on the processes of learning science that develop understanding. The emphasis here is on the research that examines how students develop conceptual understanding and the processes and strategies used to determine and further this. This is a central focus of research in science education as it encompasses all disciplines and educational levels.

This strand is therefore wide and varied as it comprises of theories, models, and empirical results on conceptual understanding, conceptual change and development of competences; methodology for investigating students' processes of concept formation and concept use; and strategies to promote conceptual development. Seventeen papers are now included in the e-proceedings under this strand, highlighting many aspects of developing conceptual understanding.

Understanding of specific concepts and identification of underlying misconceptions are targeted by several authors e.g. in the area of hydrostatics (Kiss and Velmovska), cosmology (Colantonio et al.), temperature-thermal sensation (Ezquerra-Romano et al.), kinematics (Kekule), costal physics (Bliesmer and Komorek), genes (Tsopoglou-Gkina and Papadopoulou) and quantum physics (Giliberti et al.).

The impact of inquiry-based approaches on students' conceptual understanding and scientific knowledge at different ages and cultural levels is analysed from a vertical and interdisciplinary curriculum perspective in the paper by Fazio et al.

The use of visualisation techniques including modelling have been used by many authors to elicit students' understanding and to help to connect ideas e.g. drawings linking to formal reasoning as applied to understanding of atomic structure (Zarkadis et al.), and static electricity (Stefanidou et al.). Four archetypes for interpretation of mental models is proposed by Ubben and Heusler. Moutet discusses the use of the extended Mathematical Working Space (MWS) framework to analyze the tasks to be performed by students and carried out by them in a teaching sequence dealing with solution chemistry.

Use of concept maps to aid in multilevel thinking of representations in chemistry is discussed by Hamnell-Pamment and this includes discussion with peers – a theme that is also researched by Hundertmark et al. (analysing discursive processes in a collaborative learning situation) and Heeg et al., within a peer-interaction model. The educational value of communication within diverse cultures, peoples and contexts, also with the help of technology, is analysed by Chartofylaka, and Forissier, who investigate what type of elements of cultural understanding emerge after the completion of a collaborative experience between young learners from different contexts. Questioning strategies are highlighted by Trimble et al.

The research papers presented here in the e-proceedings for Strand 1 represent the varied and diverse range of papers in this strand. Many of the papers focus on specific disciplinary concepts, evaluating and addressing areas of difficulty. It is interesting to note the varied approaches taken and there is not a 'one pedagogy that fits all'. The varied aspects of the papers in this strand provide us with many ideas to address conceptual understanding within various context and hopefully will stimulate further research in these areas.

THE LEVEL OF UNDERSTANDING OF SELECTED CONCEPTS IN PHYSICS OF STUDENTS FROM DIFFERENT COUNTRIES

Tünde Kiss[1], Klára Velmovská[2]
[1,2]Department of Didactics in Mathematics, Physics and Informatics, Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava, Slovak Republic

Children start to perceive the world that surrounds them since the beginning of their lives. They start school with basic knowledge and there begins their education which includes classes of physics, too. During physics classes teachers encounter students' ideas about certain phenomenon every day. It would be ideal if teachers were aware of the students' ideas and should take their ideas to the account when introducing new physical knowledge. Based on this assumption we decided to focus on students' ideas in teaching physics in our study. Our main topic is the students' ideas connected with concepts and phenomena in Hydrostatics. Based on the analysis of movies sent by students to the Festival of Movies about Physics, and on the outcomes of another surveys and researches, we believe that students have incorrect ideas about certain concepts and phenomena in this thematic unit. To assess students' ideas, we have compiled a hydrostatics concepts and phenomena test. This test was filled in by students of primary schools from Slovakia and Hungary. The answers from students, who were part of our survey, were marked based on which country they come from and they were also compared with each other. We found out that involved students in both countries have incorrect ideas about different concepts and phenomena in Hydrostatics. One of these incorrect ideas relates to the behaviour of certain objects in liquids - involved students consider mass of the certain objects crucial when deciding how they act while submerged in liquids. According to the results of our survey we are able to conclude that involved primary school students from Hungary were less likely to have incorrect ideas about the topic than the involved Slovak students. As far as correct answers are concerned, we found no greater difference between the involved groups. In the following, we plan, based on the students' answers, the examination of students' quality of argumentation.

Keywords: Conceptual Understanding, Incorrect Ideas, Primary School

INTRODUCTION

The ideas which students have about the world around them when entering primary school can possibly match the theories already accepted in science, but they can also contradict them too. But how could we describe these ideas of the students?

How could we define the concept of preconception and misconception? Unfortunately, we cannot speak about unified terminology. According to Mandíková and Trna (2011), the reason for this is "the relative novelty of the concept and the relatively spontaneous research on this issue, without the existence of a generally accepted, basic theoretical research."

In the English literature (National Research Council, 1997), (Alwan, 2011) and (Read, 2014) we can find phrases as preconception, preconceived notion, alternative conception/framework, conceptual framework, intuitive theory, naive conception/theory, non-scientific belief, wrong physical concept, conceptual misunderstanding, misconception.

In the German literature (Weber, 2004), (Wilhelm, 2007) one can find the following phrases: Präkonzept, Alltagsvorstellung, Schülervorstellung, Schülervorverständnis, Fehlvorstellungen, Misskonzept.

In the Slovak and Czech literature (Haverlíková, 2013), (Mandíková and Trna, 2011), (Průcha, 2013) there are also different expressions and their different definitions and explanations.

The definition of preconception according to Mandíková and Trna (2011) is the following: "Preconceptions are the conception and interpretation of those objects and phenomena, which, from childhood onwards, are formed based on the direct observation of the surrounding world, that is, on the manipulation of the objects of the world and the instinctive generalization of one's own experience."

Haverlíková (2013) identifies preconceptions as primary ideas. She claims that "Preconceptions begin to evolve from the moment the individual interacts with the surrounding world. These are individual ideas, that emerge from a personal perspective based on experience from the past." Furthermore, she claims that the preconceptions are not always in line with the scientific views. However, we still cannot consider them incorrect. They are based on the individual's experience of everyday life, which means they are sufficient to solve everyday tasks. Therefore, they are resistant to changes and traditional teaching. Haverlíková (2013) defines the misconceptions as follows: "The misconceptions are deformed thinking structures, which lead to incorrect predictions, interpretations, explanations or problem solving in the field of science. Although the individual may use scientific concepts but argues with preconceptual mental structures."

Wijaya et al. (2016) states an easier definition to describe the concept of misconception. According to this misconceptions are the concepts created by the students that differ from explanations given by professionals.

As we can see, different authors define the concept of preconception and misconception in different ways. Under the phrase preconception we understand the ideas which students could acquire based on their own experiences in everyday life even before starting the primary school. These ideas might be correct or incorrect. Students' ideas after starting compulsory education are developing into an either correct or incorrect scientifically accepted idea. This incorrect idea is called misconception in our terminology. We use the terms correct and incorrect idea in our work, mainly because of their clarity.

SURVEY ABOUT STUDENTS' IDEAS IN HYDROSTATICS

As we mentioned before, physics teachers should be familiar with students' ideas about physical concepts or phenomena. Incorrect students' ideas may also affect their individual creative work, which for example includes shooting a short movie with physics theme at the Festival of Movies about Physics. We saw couple of these movies and found out that students' movies are dealing with a lot of various discrepancies. Based on these deficiencies connected with explanation and students' argumentation we have decided to closer examine students' ideas regarding concepts and phenomena from Hydrostatics.

The list of incorrect students' ideas in physics could be found in multiple other sources. At webpage *http://amasci.com/miscon/opphys.html* is shown the list below of incorrect ideas from category Forces and Fluids:

- Objects float in water because they are lighter than water.
- Objects sink in water because they are heavier than water.

- Mass/volume/weight/heaviness/size/density may be perceived as equivalent.
- Wood floats and metal sinks.
- All objects containing air float.
- Liquids of high viscosity are also liquids with high density.
- Adhesion is the same as cohesion.
- Heating air only makes it hotter.
- Pressure and force are synonymous.
- Pressure arises from moving fluids.
- Moving fluids contain higher pressure.
- Liquids rise in a straw because of "suction".
- Fluid pressure only acts downward.

Speaking of foreign literature, Wijaya et al. (2016) was focusing in their research on diagnosis of incorrect ideas regarding hydrostatic pressure in the group of high school students. The most common incorrect students' ideas, which are derived from the results of research, are as follows:

- Students believe that hydrostatic pressure is directly proportional to the distance of a point on the surface of the water.
- Students believe that hydrostatic pressure has a greater value in a narrow place.
- Students believe that hydrostatic pressure is directly proportional to the height.
- Students believe that the fluid is more concentrated when it is placed in a container, which is denser / narrower and the hydrostatic pressure becomes bigger.
- Students believe that the depth is measured from the bottom of the container.
- Students believe that hydrostatic pressure is bigger when a hole is wider.
- Students believe that hydrostatic pressure is bigger when it is near an open hole.
- Students believe that hydrostatic pressure is bigger when it is near a closed hole.
- Students believe that hydrostatic pressure is bigger in a narrower hole.
- Students believe that hydrostatic pressure is inversely proportional to the density of the fluid.
- Students believe that hydrostatic pressure is proportional to the mass of the object.
- Students believe that hydrostatic pressure is inversely proportional to the mass of the object.

The task of the survey

There are many different tools and options for diagnosing students' ideas. In our study in order to find out students' ideas in primary schools about phenomena in Hydrostatics or about the concept of density we chose a test using the concept of open-ended questions. When compiling the test, we used information which was found in the movies sent by students to the Festival of Movies about Physics. The sources of information were also from various cases found in the literature. Additionally, we used our own gained experience in physics teaching. The main goal of our survey was to identify how primary school students interpret selected expressions and phenomena in the thematic unit Hydrostatics (more precisely density, Pascal's law, Archimedes' law, buoyant force).

We assume that students have incorrect conceptions about certain concepts and phenomena in the thematic unit Hydrostatics. Based on other surveys and researches, and also the analysis of movies sent by students to the Festival of Movies about Physics, we are expecting the following statements:

- The students mostly consider the mass of the certain objects crucial when deciding how they behave in liquid.
- The students confuse the term of density with the term of viscosity.
- When solving a task on Archimedes' law, the students do not consider applying the law.
- The students believe that when the external force is applied on the liquid in a closed container, there will be the same pressure at each point of the liquid.
- The students believe that the magnitude of the buoyant force depends on the immersion depth even when the entire object is submerged in the water.

The methods of the survey

The survey was made in March and April 2017 and also in March 2018 in the form of a written test which contained open questions. There were 6 questions in the test. The tasks were focused on the understanding the concepts and phenomena in Hydrostatics. Three of the six questions (first, second and sixth) were related to the understanding of the concept of density and the behavior of objects in liquid. The remaining three questions (third, fourth and fifth) included questions regarding the Pascal's law, Archimedes' law and also the buoyant force. The students filled in the test during a 45-minute-long lesson. The analyzed and processed data were evaluated using the programme Excel.

In this report we are focusing mainly on the analysis of solutions to the one task based on students' ideas regarding the term of density. The assignment was as follows:

"Miško found an old aluminium spoon. He put it into a container filled with water. The spoon sank down to the bottom of the container. Then he put old aluminium coins, which he found, in the container in the same manner, as the spoon before. The coins sank down to the bottom of the container as well. Then he found an aluminium foil, which is actually a thin piece of aluminium. He tore off a piece of aluminium foil with size of 5 by 5 centimetres, submerged it under the surface of the water in the container and released it. How did this piece of aluminium foil act in the water? How would the smaller piece of aluminium foil act in the water? Please do explain your answers!"

Characterization of the group

Primary school students from Slovakia and Hungary joined the survey. From Slovakia 89 students from the Private Primary School Česká in Bratislava and Comenius Primary School in Tvrdošovce joined the survey. From the Private Primary School Česká 52 students answered the questions in the test: 7 students from the 7th grade and 45 students from the 8th grade. From Comenius Primary School 37 students filled in the test: 18 students from the 7th grade and 19 students from the 8th grade. 35 students from János Vaszary Primary School in Tata, Hungary, took part in the survey: 22 students from the 7th grade and 13 from the 8th grade. As we can see, 124 students participated in the survey from the three primary schools. Number of respondents involved in the survey could be seen in table 1.

Table 1. Number of respondents involved in research

Primary School Name	Grade	6.	7.	8.	Total
Private Primary School Česká in Bratislava	**Number of Students**	39	7	45	**91**

Comenius Primary School in Tvrdošovce		12	18	19	**49**
	Total	**51**	**25**	**64**	**140**

Processing and interpreting the results of the survey

The respondents were divided into two groups. The first group includes students attending primary schools in Slovakia, and in the second group are the primary school students from Hungary. The answers of the two groups were evaluated separately. We evaluated every task in every group separately. First, we categorized the answers to a given question based on the students' conclusion. After that we were looking for common signs in every category – what kind of assumption, thought led the students to the given answer. We divided the categories of the answers further into smaller groups. After that we created a table which contains the division of the answers with the relative frequency of each response by grade. In the table 2 provided below we highlighted the correct answers with orange colour. As a correct answer we accepted that one in which the student provided also an explanation. If the student answered correctly, but did not explain his statement, we did not consider it as a correct answer because we strictly requested an explanation. In the table the answers with the wrong ideas (which met our expectations) are marked in green.

Table 2. The relative frequency of each response by grade in Task 1 for both groups

Task 1		Relative frequency by grade / %		
		7^{th} grade Sk / Hu	8^{th} grade Sk / Hu	Both Sk / Hu
The larger and smaller pieces of aluminium foil also sink to the bottom of the container	correct explanation - the density of aluminium is bigger than the density of water	12 / 4,5	3,1 / 7,7	5,6 / 5,7
	without explanation	4 / 0	3,1 / 15,4	3,4 / 5,7
Neither the larger nor the smaller pieces of aluminium foil sink to the bottom of the container	incorrect assumption - flotation is only related to the mass	36 / 36,4	34,4 / 23,1	34,8 / 31,4
	incorrect assumption - the density of objects depends on their size even if they are made of the same substance	0 / 0	15,6 / 7,7	11,2 / 2,9
	without explanation	16 / 4,5	23,4 / 7,7	21,3 / 5,7
Bigger and smaller pieces of aluminium foil will not behave the same	incorrect assumption - the density of objects depends on their size even if they are made of the same substance	24 / 9,1	6,3 / 0	11,2 / 5,7
	using incorrect terminology	0 / 4,5	0 / 0	0 / 2,9
Other wrong answers		4 / 31,8	10,9 / 30,8	9 / 31,4
Unsolved		4 / 9,1	3,1 / 7,7	3,4 / 8,6
Both		100 / 100	100 / 100	100 / 100

According to the results of the survey 5.6% / 5.7% (Sk / Hu) of all respondents answered the first question correctly, which means 5 / 2 (Sk / Hu) students. The table shows that 34.8% / 31.4% (Sk / Hu) of the respondents incorrectly assumed that flotation of the object is only related to the mass of the object. Another rather numerous groups consist of students who think that the density of objects depends on their size even if they are made of the same substance. 22.4% / 8.6% of respondents (Sk / Hu) belong to this group.

DISCUSSION

The first task in the test was related to the behaviour of objects submerged in liquids. Flotation of objects is related to their density. But students have incorrect idea about whether the object floats, floats right under the surface of the liquid or sinks, because they think that it is related only to the mass of the object. The results of the survey show that even students, who were considering density in case of flotation of the object, have incorrect idea that it is related to their mass - a smaller piece of foil has smaller density. From this we have concluded that students would associate flotation of an object with the mass of the object. According to our survey, 57.2% of the respondents from Slovakia consider the mass of the object when deciding on its behaviour. 40% of respondents from Hungary are thinking the same way, too. As a typical incorrect answer, we could consider the following answer: “The aluminium foil will be on the surface of the water. The smaller piece too, because the aluminium foil is not so heavy at all.”

Therefore, the results of our survey in this task show that while there are no differences between the two involved groups in the number of correct answers, the involved primary school students in Slovakia were more likely to have a wrong idea.

In a similar way as the task mentioned above, we evaluated also the next task from our test. Here the students were supposed to think about the buoyant force. The magnitude of the buoyant force does not depend on the depth if the whole object is submerged in the water. Even so the students have wrong idea because they think that if we submerge the whole object in the water just below the water level and then deeper, higher buoyant force will apply on the object there. In the group of the involved Slovak students 10.1% of the respondents, and in the group of the involved Hungarian students 5.7% of the respondents claimed that the buoyant force depends on the depth even if the whole object is submerged in the water.

As we can see from the answers given to this task, the involved students from Hungary have incorrect ideas in a less extent about the topic in the task. Regarding correct answers, two respondents from Slovakia gave correct answers, while in the group of Hungarian respondents there was no correct answer.

Analysing the survey results led us to the confirmation that the primary school students taking part in the survey have the incorrect ideas of various concepts and phenomena in thematic unit Hydrostatics. One of the incorrect ideas is related to how the objects behave in liquids: the students consider mostly the mass of the object crucial when deciding about how the objects behave in liquid. It also turned out, that the students have incorrect ideas regarding the buoyant force: they think, that the magnitude of the buoyant force depends on the depth even if the whole object is submerged in the water.

There are several reasons for the differences between given two groups, which we would like to examine in more details later. We would like to focus on the basic curriculum, lesson distribution and teaching methods in both countries. Furthermore, we would also like to assess the level of their argumentation based on students' responses - to propose criteria how to evaluate students' argumentation and to evaluate their arguments on this basis.

ACKNOWLEDGEMENT

This paper was elaborated with the support of the projects VEGA no. 1/0396/18.

AN INVESTIGATION OF STUDENT'S CONCEPTUAL UNDERSTANDING ABOUT COSMOLOGY THROUGH CLUSTER ANALYSIS

Arturo Colantonio[1,3], Italo Testa[2], Irene Marzoli[1], Silvio Leccia[3]

[1]School of Science and Technology, Physics Division, University of Camerino, Italy
[2]Department of Physics "E. Pancini", University "Federico II", Naples, Italy
[3]INAF – Astronomical Observatory of Capodimonte, Naples, Italy

In this study, we analyse high school students' patterns of understanding about conceptual dimensions of Cosmology using cluster analysis of responses to an open-ended questionnaire. First, drawing from previous studies and accepted scientific models of the Universe, we identified seven different dimensions that we deemed as important for conceptual understanding of Cosmology. Then, we designed seventeen questions and categorized them according to the chosen dimensions. Content validity and categorization of the questions were checked with three professional astrophysicists. The questionnaire was administered to 432 high school students (17-19 years old) attending extra-curricular activities on modern physics. Students' responses to each question were first categorized using a grounded approach and then combined through cluster analysis to identify students' reasoning about the identified dimensions. Results confirm that students hold many misconceptions about Big Bang, as well as about the Universe expansion and its future evolution. Moreover, evidence suggests that a low level of knowledge of basic astrophysics definitions affects knowledge about fundamental concepts. Implications for designing teaching-learning sequences to address students' difficulties about the targeted concepts are briefly described.

Keywords: Conceptual understanding, Quantitative methods, Physics.

INTRODUCTION AND AIMS

Recent curriculum reforms in Italy have promoted the introduction at secondary school level of up-to-date physical topics, such as quantum mechanics, particles' standard model, and the origin of the Universe. However, the implementation of such reforms has proven to be difficult, since such advanced subjects require a deep understanding of the underlying physical mechanisms and theories. In this paper, we focus on Cosmology, which is a meaningful context not only to teach other contemporary physics topics, such as nuclear reactions, light spectra, redshift and dark matter, but also to explicitly address some aspects of the nature of science. Prior studies have addressed students' misconceptions about specific aspects related to the Universe, mainly at the undergraduate level (Prather, Slater & Offerdahl, 2002; Trouille et al., 2013; Wallace, Prather & Duncan, 2012). Their results suggest that students may begin university courses in astrophysics with pre-existing notions that may interfere with instructional efforts.

For instance, previous findings indicate that many students (about 70%) are unaware that the universe is expanding (Lightman et al., 1987; Lightman and Miller, 1989; Prather, Slater & Offerdahl, 2003) and think that matter, as we know it now, existed also before the Big Bang

(Lightman et al., 1987). The study by Trouille et al. (2013) also revealed some misconceptions such as the belief that the Big Bang theory, which describes the creation of planets and/or the solar system or the universe, always existed. Similarly, Prather et al. (2003) found that 42% of high school and 51% of college students regard the Big Bang theory as a theory describing the creation of the universe; 24% in both groups regard the Big Bang as a theory describing the creation of planetary systems and furthermore, 29% and 42%, respectively, believe that the Big Bang was an explosion of some kind. In some cases, students struggle to read and interpret the Hertzsprung-Russell and Hubble's plots or confuse the definitions of galaxy and solar system (Hayes et al., 2011; Wallace et al., 2012).

While providing valuable insights about students' difficulties when dealing with Cosmology, a more coherent picture of students' conceptual understanding in this content area is yet to be provided. By identifying common patterns amongst such beliefs and ideas, it would be possible to frame meaningful and more effective teaching activities to improve students' understanding of Cosmology. Therefore, the research question that guided the present study was: *to what extent can students' conceptions about relevant aspects of Cosmology be organized in coherent patterns of understanding?*

METHODS

Instrument

To answer our research question, we first identified, on the basis of previous studies and accepted scientific models of the Universe, seven conceptual dimensions that we deemed as important for a meaningful understanding of Cosmology (Prather et al., 2003; Bailey et al., 2012; Wallace, 2011; Trouille et al., 2013; Wallace, 2012). For the sake of clarity, these dimensions can be divided into two groups of concepts: "basic" and "advanced". Basic concepts concern fundamental astronomical entities as stars, galaxies, constellations, and nebulae and the physical relationships between them. For instance, in this group, we include the notion that stars are formed from a nebula due to gravitational collapse, while galaxies are approximately self-gravitating systems formed by stars and nebulae and so on. Moreover, drawing on results in astronomy education (Rajpaul et al., 2018, Cole et al., 2018) we also considered as basic concepts the time and distance scale of typical astronomical events and entities. For instance, we included in this group the notion that life appeared on Earth after the formation of solar systems and of our galaxy; similarly, we included the notion that the Sun is the closest star to Earth and that the centre of our galaxy is farther than the other galaxies. Advanced concepts include: the birth of the Universe; the universe age and how we can estimate it (expansion rate, background radiation, etc.); how temperature and chemical composition of the universe changed with time; the space-time expansion; hypothesis about the future evolution of the Universe. More advanced topics include also fundamental notions about black holes, dark matter and energy. For instance, we included in this group the notion that a black hole is an astronomical object characterized by its gravitational field.

Then, starting from previous work (Bailey et al., 2012; Coble et al. 2013a, b), we designed a written task with 17 open-ended questions that addressed two or more aspects of the identified dimensions, except for the first question that simply requested to define the term "Universe". In Table 1, we summarize the correspondence between the conceptual dimensions and the designed questions. The questions included three types of task (see Table 2): written, drawing, and ranking. The reason for including also a drawing task was to link students' representations with the reasoning emerging from the written answer (Tytler et al., 2020). Ranking tasks were designed only for the age and distance of astronomical objects. The content validity of the questions was checked with three professional astrophysicists. Examples of the three types of task are reported in Table 2.

Table 1. Question distribution across the conceptual dimensions of Cosmology.

	Conceptual dimensions related to Universe	Acronym	Questions [a]
Basic	Celestial objects and their relationships	CO	Q11, Q14a, Q14b, Q14c, Q14d
	Celestial objects age and distance	AD	Q12, Q13
Advanced	Universe age and its determination	AGE	Q2, Q3
	Birth of Universe	BB	Q5, Q6, Q7
	Universe temperature and composition	T&C	Q4, Q10
	Expansion and future evolution of Universe	EX	Q8, Q9
	More advanced topics (e.g., black holes, dark matter)	BHDM	Q16a, Q16b, Q17

[a.] Note that questions Q1 and Q15 were not analysed in this study.

Table 2. Type of questions.

Type	Questions [a]	Examples
Written text	Q2, Q3, Q4, Q5, Q6, Q7, Q8, Q9, Q10, Q11, Q14, Q16, Q17	(Q2) What is the age of the universe? (Trouille et al., 2013) (Q6) Describe what existed or occurred just before the Big Bang (Prather et al., 2003) (Q7) Describe what evidence you think supports the Big Bang theory (Q9) Explain, in as much detail as possible, what astronomers mean when they say ''the universe is expanding'' (Wallace, 2011)
Drawings	Q4, Q5, Q9, Q10, Q11, Q14	(Q4) Plot how the temperature of the Universe changes over time (Q5) How would you describe the Big Bang with a drawing? (Q9) Using a schema or drawing, explain what you mean when you say ''the universe is expanding" (Q10) Explain, using also a drawing, how the chemical composition of the Universe changes over time (Q11) Draw our galaxy and the sun's position
Ranking	Q12, Q13	(Q13) Rank the following celestial objects by their distance from the Earths surface: cluster of galaxies, galaxies, Jupiter, the international space station, nebulae, Proxima Centauri, Sun, the center of our galaxy, Moon.

[a.] Note that questions Q1 and Q15 were not analysed in this study.

To collect contextual information about student' self-efficacy in and attitudes towards science, we designed a six-item Likert scale (from 1 = not at all to 10 = completely), with three items for each variable.

Sample

We involved in this study a sample of 432 Italian secondary school students (43.8% female; average age 17.9±0.7 years old). Students attended three types of school: scientific (78.7%), humanities (14.4%), and vocational (6.9%). Scientific is a secondary school stream specially focused on science and mathematics. Humanities are more focused on literature and human sciences, while vocational schools are aimed at technical and job-oriented instruction. The involved students voluntarily attended extra-curricular activities about general physics topics at the authors' department from February to May 2019. Prior to these activities, they were taught about basic elements of Astronomy for a total of about 8 hours during their first year of secondary school as part of Earth Science curriculum. However, they were not involved in specific teaching-learning sequences or extra-curricular activities focused on Astrophysics. Students were on average self-confident (average score on the three items: 6.1±1.4) and motivated towards science and astronomy (average score: 7.6±1.5).

Data Analysis

First, we categorized the students' responses using a constant comparative method (Strauss & Corbin, 1998). Three researchers independently analysed the whole data set generating for each question a suitable number of categories to fit the students' responses. Then, we collapsed the initial categories into five hierarchical macro-categories, ranging from "not given or unclear response" to "scientifically correct or acceptable", depending on the content of the question. Two researchers reviewed again the students' responses to check the categorization. Inter-rater reliability was evaluated obtaining at the end of the process a satisfactory level of about 0.80. Categories for two questions concerning the AGE (Q3) and T&C (Q10) dimensions are reported in Table 3.

Table 3. Examples of categories regarding AGE and T&C dimensions.

Question	*Category*	*Description*
Q3.What is the age of the Universe and how do we know it?	1	No reference to how to estimate the age of Universe
	2	It is not possible to estimate the age of Universe or it has always been existing
	3	Student gives reference to archaeological, biological or geological evidences
	4	Some reference to astrophysical measurements but rather generic
	5	Correct reference to Hubble law or to recessional velocity of galaxies
Q10. Explain, using a also a drawing, how the chemical composition of Universe changes over time	1	No answer
	2	Generic or incorrect answer
	3	Basic elements with no evolution to more complex ones
	4	Basic elements gave rise to the more complex ones
	5	Basic elements gave rise to the more complex ones via nuclear fusion

Finally, we combined the students' responses to the questions related to the same dimension using cluster analysis (Fazio & Battaglia, 2018). In such a way, we could identify reasoning patterns corresponding to different levels of conceptual understanding about the targeted dimensions. We used cluster analysis: (i) because our sample was large and heterogeneous; (ii) in order to identify which dimension best distinguishes students' understanding (Aldenderfer and Blashfield, 1984; Ammon et al., 2008). We performed a separated clustering of each basic and fundamental conceptual dimension using the SPSS K-means routine. The choice of the number of clusters to be retained was iteratively carried out (using 2 to 10 clusters) double checking the variance of distance from the centres for each number of cluster, the iteration history of the K-means algorithm and the between-subjects ANOVA values for each of the questions related to the chosen dimension. The final interpretation of each cluster was validated by the same professional astrophysicists, who had already checked the question validity. For each dimension, we found five clusters, which reflect increasingly complex reasoning about the concepts related to that dimension. The clusters are schematically described in Tables 4 and 5. Finally, we investigated the correlation between the knowledge of basic and advanced concepts. To this aim, we recoded the clusters for all dimensions into two categories: clusters characterized by scarce or incorrect knowledge (Clusters 1 and 2) were coded with 0, whereas clusters characterized by a partial/correct knowledge with some inconsistencies (cluster 3 to 5) were coded with 1. Finally, using crosstabs, we performed a chi-square analysis to look whether the knowledge about basic concepts may affect the knowledge about more advanced concepts about the Universe.

Table 4. Clustering of students' answers related to basic conceptual dimensions.

Concepts	*Cluster*	*Description*	*%*
AD	1	Scarce or no knowledge about the topics	46.5
	2	Correct knowledge of recent and middle timeline, but they know only a near distance scale	16.0
	3	Correct knowledge only of recent timeline and of near and middle distance	15.7
	4	Correct knowledge only of recent timeline. Partially correct knowledge of celestial objects distances	12.1
	5	Correct knowledge of timeline and partially correct knowledge of celestial objects distances	9.7
CO	1	No knowledge about the topics	34.7
	2	No or incorrect definition of star and nebulae. They define the constellation generically as a group of stars, the nebulae as cluster of gas and the galaxies as set of celestial objects	27.1
	3	No or incorrect definition of constellation and nebulae. They define the star as an emitting light object and the galaxies as set of celestial objects	13.9
	4	No or incorrect definition of star. They define the constellation generically as a group of stars, the nebulae as cluster of gas and the galaxies as set of stars held together by gravitational force	10.2
	5	They define the constellation generically as a group of star near each other, the star as an emitting light object with a reference to chemical composition or chemical reaction, the galaxies as set of celestial objects and nebulae as cluster of gas and dust	14.1

Table 5. Clustering of students' answers related to advanced conceptual dimensions.

	Cluster	Description	%
AGE	1	Scarce or no knowledge about the topics and no reference to how to estimate it.	10.4
	2	Scarce or no knowledge about the topics, generic reference to how to estimate its age.	5.6
	3	Student knows the order of magnitude of the age of universe, but doesn't give any reference to how to estimate it.	34.3
	4	Student knows the order of magnitude of the age of universe and partial reference to how to estimate it.	31.2
	5	Correct estimate of age and partial reference to how to estimate it.	18.5
BB	1	Belief that the Big Bang is a terrestrial catastrophe and the Universe existed in some way before. Evidence cannot be obtained.	19.5
	2	Big Bang as an explosion of energy and matter, which existed in some way before. Some evidence is given but in an incorrect way.	20.8
	3	Big Bang as an explosion of energy and matter, there was nothing before. No reference to evidence.	27.3
	4	Big Bang as an explosion of energy and matter, there was nothing before. Incorrect or generic references to evidence are provided.	19.9
	5	Big Bang as an explosion generating the Universe, when before there was very dense matter and/or energy. Correct evidences are provided.	12.5
T&C	1	Scarce or no knowledge about the topics.	34.9
	2	Temperature increased, but no idea about composition.	42.6
	3	No idea about the temperature. Basic elements gave rise to the more complex ones.	3.5
	4	Changing temperature and basic elements with no evolution to more complex ones.	3.3
	5	Temperature decreases. Basic elements gave rise to the more complex ones.	15.7
EX	1	No idea about theories describing the future of the Universe and its expansion.	15.5
	2	Alternative/Non-scientific theories about the future of the Universe. No idea about expansion.	30.6
	3	No idea about theories describing the future of the Universe. Expansion as an increase of distance between celestial objects.	9.5
	4	There exists theories describing the future of the Universe with no details. Expansion as an increase of distance between celestial objects.	15.7
	5	Correct evidences about the future of the Universe are provided. Expansion as an increase of distance between celestial objects.	28.7
BHDME	1	No answer.	54.6
	2	No knowledge about dark matter and dark energy. Generic definition of black hole.	14.6
	3	No knowledge about dark matter and dark energy. The black hole is an object with a strong gravitational force.	15.7
	4	The student knows that dark matter and dark energy exist, but without any details. The black hole is an object with a strong gravitational force.	10.4
	5	Students give an correct definition of dark matter and dark energy. The black hole is an object with a strong gravitational force.	4.7

RESULTS

Figures 1 and 2 report the students' distribution in the emerging clusters for basic and advanced topics about the Universe.

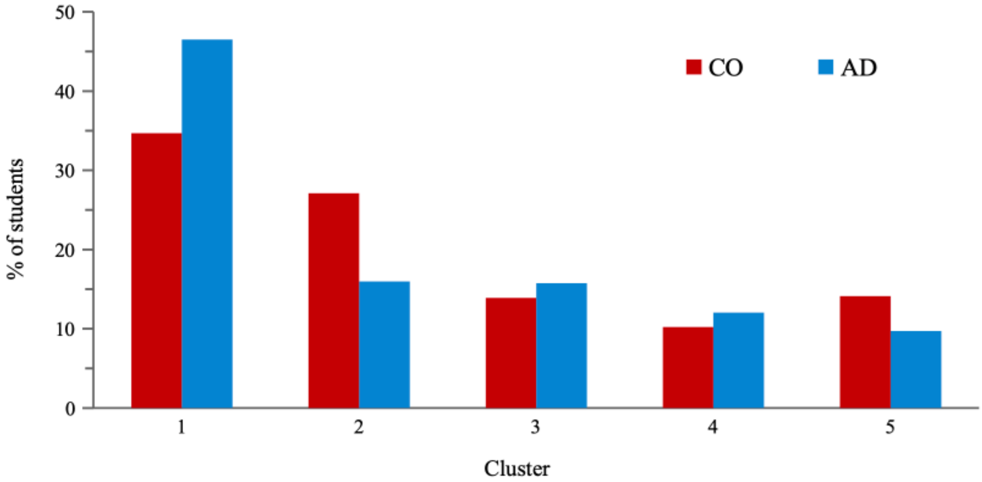

Figure 1. Students' distribution in the basics concepts clusters.

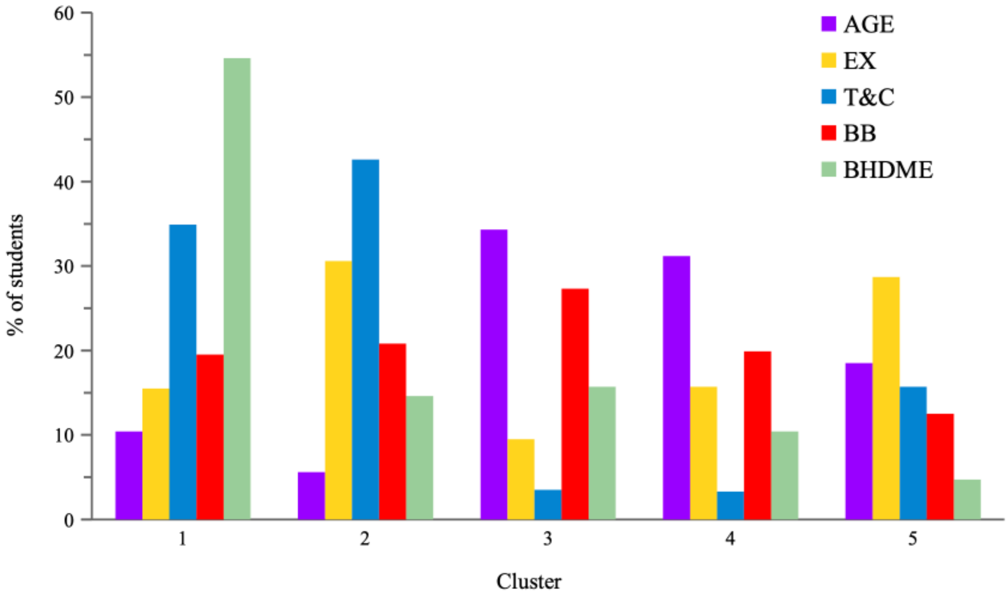

Figure 2. Students' distribution in the advanced concepts clusters.

Overall, students in our sample have a scarce knowledge of both basic and advanced concepts. Concerning basic concepts, on average 40% of the students belong to the scarce or no knowledge cluster, while only 10% show a more correct knowledge. Specific difficulties concern: the definition of star and the role of gravity; how to correctly estimate the relative distance between Earth, Sun, planets and the centre of the galaxy. Concerning advanced topics, data show a more complex pattern, according to the chosen dimensions. While expansion and age of the Universe seem slightly more understood by students (about 40% belong to clusters characterized by a partial or correct knowledge), on the other hand, for the T&C dimension, two-thirds students show a very scarce knowledge. In particular, they have no idea about the variations of temperature and of composition of the Universe. Also in the BB dimension, which is focused on topics that are taught since primary school, students show some difficulties. In particular, they consider the Big Bang as an explosion and are often unable to relate it with the birth of the Universe. Moreover, about half of the students think that the Universe has always existed, thus the Big Bang is viewed as a kind of catastrophe. This evidence also suggests a confusion between deep and geological time. To the same concern, the great majority of the students (about 90%) think that the Big Bang involved an explosion of energy and matter. Furthermore, few students were able to refer to experimental evidence to support the Big Bang or the estimate of Universe age.

In figure 3, we report the correlation between the knowledge of basic and advanced dimensions. Correlation is significant ($c^2 = 9.162$; df = 1; p = 0.002; Cramer' phi = 0.146), thus a scarce or generic (partial or correct) knowledge about basic concepts lead more likely to a scarce or generic (partial) knowledge about advanced concepts.

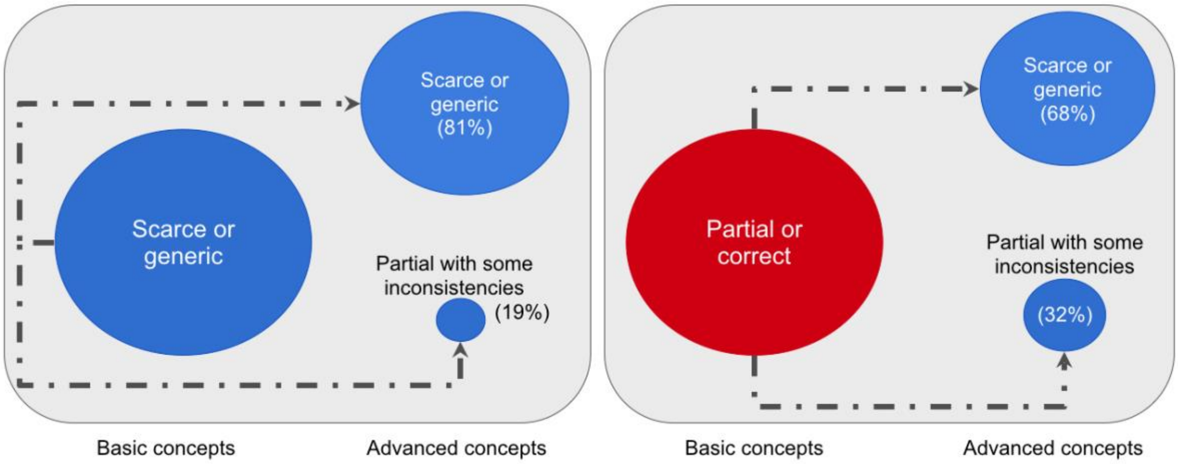

Figure 3. Correlation between basic and advanced topics knowledge.

DISCUSSION AND CONCLUSIONS

Our analysis reveals that the students' knowledge about the Universe is rather limited. While the collected students' responses suggest that Cosmology is addressed somehow during curricular teaching and dissemination activities in informal setting, results of the cluster analysis point out that some relevant aspects are neglected, for instance how scientists support claims about theories of the Universe.

Furthermore, curricular teaching seems to have a limited impact on students' ideas also about basic aspects such as: definition of stars, nebulae and galaxies, order of magnitude of distances between celestial objects, timeline of relevant events as the appearance of life on Earth and the formation of planets and stars, the role of gravity and other physical mechanisms (spectra, nuclear reactions).

Cluster analysis reveals also a fragmented knowledge about basic aspects in Cosmology. In particular, students found it difficult to relate the distance between celestial objects and timeline of events. Regarding advanced dimensions, as expected, knowledge is on average scarce (about 30% in clusters 1 and 2, on average). On the other hand, a better understanding of Universe birth, age, and expansion leads to a better understanding of concepts as a black hole.

As next step of our research, we are identifying transversal patterns of reasoning strategies about the targeted topics. In conclusion, our data suggest that typical high school teaching does not allow a deep conceptual understanding about Cosmology. To address this issue, we are also developing a teaching-learning sequence, which includes paper-and-pencil as well as laboratory activities.

DO MISLEADING THERMAL SENSATIONS UNDERLIE SOME HEAT AND COLD MISCONCEPTIONS?

Ivan Ezquerra-Romano[1], Federico Agen[2] and Angel Ezquerra[2]
[1]Institute of Cognitive Neuroscience, University College London (UCL), London, UK,
[2]Science, Social Science and Mathematics Education, Universidad Complutense de Madrid, Spain

Alternative conceptions are ideas found universally in people, regardless of their age, education, sex, race and religion. This suggests that there exists an underlying reason common to all human beings. Recently, it has been proposed that misconceptions might arise from the ambiguity in the perception of external stimuli (physical variables). The aim of this study was to explore whether misconceptions on heat and "cold" are based on thermal sensations. We prepared three objects with different thermal conductivity and we kept them at constant temperatures. Then, 160 students (12-15 years old) were presented with the objects along with a set of questions. Although the objects were at the same temperature, students reported different sensations and estimated temperatures. When students were asked to explain why they felt those sensations, we identified common misconceptions. The ambiguity of thermosensation and the identified common misconceptions suggest that misleading sensations contribute to the development of well-known misconceptions on heat and temperature. Finally, revealing the real temperature of the objects to students resulted in a tendency to reject their first explanation and to seek for an alternative one. Understanding how concepts are grounded on our perception will help developing teaching strategies that tackle these misconceptions.

Keywords: Misconceptions, Learning and Neuroscience, Conceptual Understanding

INTRODUCTION AND THEORETICAL FRAMEWORK

Feeling temperature is a matter of life or death. Humans show a broad range of highly elaborate responses to temperature changes such as wearing clothes, developing air conditioning systems or switching the heating on. These complex responses seem to be based on our mental representations –or concepts- of heat, "cold", temperature, etc.

It has been observed that concepts are developed in an ordered and universal sequence. This process was called conceptual trajectory by Driver (1989). The ideas found at each step of the conceptual trajectory are usually called alternative conceptions or misconceptions (Driver and Easley, 1978; Abimbola, 1988). These alternative conceptions are very common, and they transcend age, education, sex, and culture (Abrahams et al., 2015). They are also very persistent and resistant to change and to extinction (Chiappetta & Koballa, 2006). The universality and persistency of alternative conceptions suggest that there exists an underlying reason common to all human beings. Some researchers have suggested that the way our senses work influence the development of spontaneous ideas (Wenning, 2008). Recently, it has been proposed that misconceptions might arise from perceptual ambiguity in the perception of external stimuli (physical variables) (Ezquerra-Romano & Ezquerra, 2017; Kubricht, Holyoak & Lu, 2017; Ezquerra & Ezquerra-Romano, 2018).

The aims of this study were:

- To explore how we describe the thermal state of objects based on our thermal perception
- To analyse statements about the reasons for the given descriptions based on perceptual ambiguity
- To discuss the statements in the context of thermosensation

Firstly, we asked students to rate the sensations and the temperature of different objects. Then, students had to interpret their sensations. After this, we revealed the real temperature of the objects to students and asked students to interpret their sensations again.

RESEARCH METHOD AND DESIGN

We prepared three objects with different thermal conductivities (TC): polyethylene foam, K = 0.03-0.04 W/m·K (low TC); brick, K = 1.31 W/m·K (medium TC) and aluminium, K = 205 W/m·K (high TC). There were four conditions: 10.9 ºC, 23.0 ºC, 33.6 ºC, and 38.1 ºC. In each condition, all objects were kept at the same temperature. The experiment was conducted in 4 different high schools in Madrid (Spain). In total 160 students (12-15 years old) were presented with the objects alongside the following questions (36 students at 10.8 ºC; 39 students at 23.0 ºC, 42 students at 33.6 ºC, 43 students at 38.1 ºC):

- Question 1: What did you feel when you touched each object?
- Question 2: At what temperature do you think each object is?
- Question 3: Explain with your own words why you felt this sensation when you touched the object.
- Question 4: Once the temperature of the objects is known, explain why you think this is so.

Question 1 and 2 measured the perceptual quality and quantity of the thermal percepts. Question 3 aimed to trigger interpretation of the thermal sensations. After Question 3 was answered, students were asked to check the temperature of each object with an Infrared thermometer (model: Fisherbrand™ Traceable™ Infrared Dual Lasers Thermometer w/Type-K Probe). Then, the students replied Question 4, which goal was to again prompt interpretation of the sensations.

In our analysis, we did not control for group, age or school. We pooled all the values by conditions. We are interested in studying universal tendencies about how misleading sensations contribute to the development of well-known misconceptions on heat and temperature.

RESULTS

To analyse the answers to Question 1, we identified the units of information (words, expressions or sentences) used by students to describe what they felt. Based on Green, Roman, Schoen & Collins (2008), we grouped them in seven categories (icy, cold, cool, in-between, warm, hot, burning, and nothing). Table 1 shows students' responses when the objects were at 10.8 ºC and 38.1 ºC.

Table 1. Frequency and percentage of the units of information found in answers to question 1 to describe what students felt. The units of information were grouped in 7 categories (icy, cold, cool, in-between, warm, hot, burning, and nothing). Data is from conditions in which objects were at 10.8 ºC and 38.1 ºC.

	10.8 ºC						38.1 ºC					
	Foam Low TC		Brick Medium TC		Aluminium High TC		Foam Low TC		Brick Medium TC		Aluminium High TC	
Icy	0	0.0 %	6	16.7 %	27	75.0 %	0	0.0 %	0	0.0 %	0	0.0 %
Cold	2	5.6 %	13	36.1 %	7	19.4 %	2	4.7 %	5	11.6 %	0	0.0 %
Cool	4	11.1 %	12	33.3 %	2	5.6 %	2	4.7 %	2	4.7 %	0	0.0 %
In-between	11	30.6 %	3	8.3 %	0	0.0 %	9	20.9 %	8	18.6 %	1	2.3 %
Warm	17	47.2 %	2	5.6 %	0	0.0 %	20	46.5 %	14	32.6 %	0	0.0 %
Hot	2	5.6 %	0	0.0 %	0	0.0 %	10	23.3 %	12	27.9 %	15	34.9 %
Burning	0	0.0 %	0	0.0 %	0	0.0 %	0	0.0 %	1	2.3 %	27	62.8 %
NR	0	0.0 %	0	0.0 %	0	0.0 %	0	0.0 %	1	2.3 %	0	0.0 %
Total	36	100	36	100	36	100	43	100	43	100	43	100

We found that the distribution of responses was different for each object at all temperatures (Table 1). Specifically, most units of information found when describing the sensation elicited by touching foam fell in 'In-between' and 'Warm'. In the case of brick, the frequency of units of information varied across conditions. In the conditions at 10.8ºC and 23.0ºC, most units of information fell in the categories 'Cold' and 'Cool'. In the conditions at 33.6ºC and 38.1ºC, most units of information fell in the categories 'In-between', 'Warm' and 'Hot'. In the case of aluminum, we found a stronger deviation of the units of information from central categories. In the conditions at 10.8ºC and 23.0ºC, most units of information fell in the categories 'Icy' and 'Cold'. In the conditions at 33.6ºC and 38.1ºC, most units of information fell in the categories 'Hot' and 'Burning'.

Importantly, responses in all conditions (object and temperature) are distributed across categories (Table 1). Namely, sensations did not consistently fall within one category.

Overall, these results indicate that student's thermal perception depends on the temperature of the objects, and, given a constant temperature, perception depends on the TC of the materials. They also show a disagreement in the categorisation of sensations. Individuals categorise sensations elicited by objects differently. This could result in miscommunications, which could be problematic in educational settings.

Although objects were at the same temperature for each condition, the answers to Question 2 showed that students assigned different temperatures to each object. Figure 1 shows the distribution for the frequencies of temperatures reported by students when the objects were at 23.0 ºC. Table 2 shows the data for all temperatures.

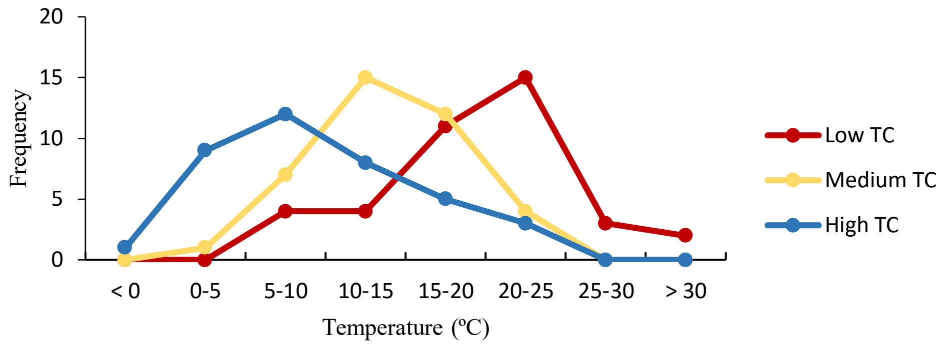

Figure 1. Frequency of temperatures reported by students when objects were at 23.0 ºC. Mean average: low TC, 18.3 ºC: medium TC, 12.4 ºC; high TC, 8.2 ºC.

As shown in Table 2, the means of the object temperature estimation within each condition differed. At each condition, pair-wise paired t-tests revealed significant differences ($p < 0.05$) within conditions except for foam vs brick at 33.6ºC and foam vs brick at 38.1ºC.

Table 2. Mean, standard deviation (S.D.) and kurtosis from temperature estimations in Question 2.

Condition	Statistical parameters	Foam Low TC	Brick Medium TC	Aluminium High TC
10.8 ºC	Mean	13.9	7.5	1.7
	S.D.	9.1707	10.3865	9.8556
	Kurtosis	0.2913	4.5644	1.3306
23.0 ºC	Mean	18.3	12.4	8.2
	S.D.	6.6598	4.9460	6.7310
	Kurtosis	-0.2529	-0.1279	-0.3125
33.6 ºC	Mean	19.9	22.8	41.6
	S.D.	11.1052	11.5876	18.3204
	Kurtosis	1.1404	-0.0617	0.7115
38.1 ºC	Mean	19.8	19.6	40.9
	S.D.	22.4555	17.0863	31.4946
	Kurtosis	28.7328	11.2502	16.2788

These results indicate that students were not able to make a correct estimate of the temperature of the objects with their thermal sensation. Consistent with the previous quesiton, these results suggest that object temperature estimation depends on the temperature of the object and its thermal conductivity. On the one hand, the estimated temperature is related to the temperature of the object. On the other hand, the estimated temperature varies as a function of the thermal conductivity for a constant temperature. The estimated temperature varies more when touching a material with high thermal conductivity as opposed to when a material with low thermal conductivity is touched. This suggests that the effect of thermal conductivity on the estimated temperature is lower for materials with low thermal conductivity.

Moreover, the standard deviation and kurtosis differs within and across conditions. At 38.1ºC, the kurtosis is positive and high, which indicates a sharp peak compared to a normal distribution. At this temperature, the responses gravitate closer to the mean (positive kurtosis). At 33.6ºC, the kurtosis was very close to cero with negative and positive values for different objects. At 23.0ºC, the responses were more spread (negative kurtosis and very close to cero). Therefore, at 33.6ºC and 23ºC, the responses are more spread than at 38.1ºC. At 10.8ºC, we observed positive values of the kurtosis, but not as high as those for 38.1ºC. Importantly, the mean temperature of the skin is 32-33ºC (Rajek et al., 2000). These results suggest that object temperature estimations are less spread at extreme temperatures than at less extreme temperatures.

To analyse the answers to Question 3 and 4, we identified, collated and classified the units of information (words, expressions or sentences) used by students to explain what and why they felt. Question 4 was formulated after students revealed the real temperature of the objects.

Consistent with the literature, students based their explanations on well-known alternative conceptions. Some examples were: “the heat (do not) travels to the fingers”, “Polyethylene is warmer because it keeps internal heat” or “metals are cold materials”. These statements reveal two kind of misconceptions. Firstly, these explanations assume that heat is a fluid that moves from object to object (caloric theory). Secondly, they also show the misconception that materials are naturally hot or cold (Brook et al., 1985), or attractors of hotness/coldness (Kesidou and Duit, 1993). Therefore, based on the literature, we grouped the units of information in 4 categories: material has heat/cold (mhhc); the materials are different (md); we perceive differently (pd); caloric theory (ct).

Figure 3 shows the frequency for each category. The analysis revealed that many students’ explanations contained units of information belonging to more than one category. We noticed that in many explanations the units of information identified were contradictory. Therefore, the total sum is greater than the number of students and it differs between Question 3 and 4. In our design, we did not expect this. Therefore, we could not conduct a properly designed statistical analysis.

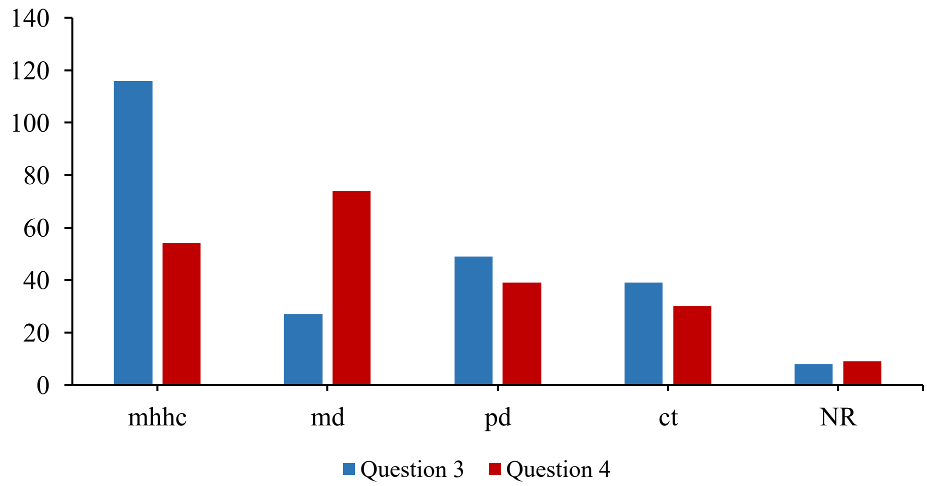

Figure 2. Frequency of the units of information found in the explanations given to Question 3 and 4.

However, we observed a trend in the frequency of units of information in Question 3 and 4 (Figure 2). It seems that knowing the real value of the temperature made students to change their explanations. In Question 3, most units of information fell in the category 'Material has heat/cold', whereas in Question 4 most units of information were classified in the group 'Materials are different'.

DISCUSSION AND CONCLUSIONS

In this study, we presented three objects with different thermal conductivity at constant temperatures to students in high school (12-15 years old). Although objects were at the same temperature in each condition (10.9 ºC, 23.0 ºC, 33.6 ºC, and 38.1 ºC), we found differences in the categorisation of sensations (Question 1; Table 1) as well as in the estimation of objects' temperatures (Question 2; Table 2 & Figure 1). Furthermore, we found common misconceptions when students were asked to explain the reasons why they perceived those sensations (Question 3; Figure 2). Finally, when the real temperature of the objects was revealed to students, we observed a tendency to reject their first explanation and to seek for an alternative one (Question 4).

The results obtained in Question 1 and 2 are coherent (Table 1 & 2 and Figure 1). They indicate that there is not common agreement when labelling the sensation. This is supported by the distribution of the frequencies in Table 1 and by the pattern of the responses in Table 2 and Figure 2. Additionally, these results also show that thermal perception depends on material's thermal conductivity and their temperature. This is consistent with previous literature that showed how subjects can discriminate between materials based on thermal cues (Ho & Jones, 2006). Our results show that thermal perception is ambiguous (Ezquerra-Romano & Ezquerra, 2017; Kubricht, Holyoak & Lu, 2017). They support the theory that perceptual ambiguity of physical variables influences the development of alternative conceptions (Wenning, 2008; Ezquerra & Ezquerra-Romano, 2018).

In the context of teaching, this observation has important consequences. It is challenging to find an agreement when labelling sensations, given that each individual will categorise the sensation differently. Consequently, miscommunications are likely to occur. When explaining concepts related to heat and temperature, pupils might get lost in the reasoning when, for instance, the teacher uses real-life examples. Each individual will picture a different sensation, which might lead to inaccurate understandings.

Furthermore, our results in Question 2 show that many students are very far from the real temperature of objects when they were asked to estimate their temperature. This observation reveals a problem in the context of education. Students find it difficult to estimate object's temperature, which seems to have an internal origin (perception). Moreover, their learning through daily-life experiences (external) has not provided them with the right tools to estimate objects' temperature. We suggest two solutions to tackle this problem. Firstly, students should be aware of the limitation of their thermosensation. To accomplish this, content about the workings of our thermosensory system should be included in lessons of thermodynamics (Ezquerra and Ezquerra-Romano, 2019). Secondly, students in early stages of the school curriculum should carry out activities in which they estimate and measure the temperature of objects in their familiar environments (e.g. At what temperature are the following items? Soup, shower, soft drink with ice).

Moreover, the explanations given in Question 3 and 4 were consistent with the sensations and temperatures reported in Question 1 and 2. Overall, analysis of the identified misconceptions showed that students based their explanations on their reported sensations. Interestingly, even when their perception was challenged with the real temperature (Question 4), their explanations kept relying on the perceived sensations. However, we found a trend to find alternative explanations after the real temperature of the object was revealed. This change does not result from a conceptual change. Nevertheless, this activity (to experience the thermal sensation of different objects and measure its temperature) triggered an immediate intention to change their explanation. There are two stages in this process. Firstly, they rejected their first explanation. Secondly, they sought for an alternative explanation. This activity catalysed a rupture of the cognitive equilibirum (Pritchard & Woollard, 2010).

Our results are coherent with the way that our thermosensory system works (Ezquerra-Romano & Ezquerra, 2017). We do not have a unique temperature detection mechanism (a thermometer), but a family of thermoTRPs that work at different ranges (Schepers & Ringkamp, 2010). Furthermore, thermal information is transmitted separately through two main channels in the nervous system, which contributes to the conceptual creation of two ranges: hot and “cold” (Craig, 2003; Ezquerra & Ezquerra-Romano, 2018).

It seems that the structure and arrangement of our thermosensory system shapes and constrains the creation of the concepts of heat and “cold”. Understanding how concepts are shaped by our perception will help developing teaching strategies that directly tackle ingrained misconceptions.

STUDENTS INTERPRETATION OF GRAPH SLOPE IN KINEMATICS INVESTIGATED BY THE EYE-TRACKING METHOD

Martina Kekule
Charles University, Prague, Czech Republic

We employed the eye-tracking method in order to observe students' strategies of choosing an option when they solved multiple-choice tasks focused on graph slope in kinematics. 32 high school students participated in the study. We provide comparison of attention allocation between two students group: those, who solved a test task correctly and those who did not. Correctly answering students paid more attention to all correct options than incorrectly answering students. And vice versa. Incorrectly answering students mostly paid the most attention to options which show typical identified misconceptions in graph (slope) interpretation.

Keywords: Physics, Graphical Representations, Eye-tracking

INTRODUCTION

Graph reading and interpretation is necessary skill for students focused not only on science in these days. Students' graph interpretation has been investigated in many studies not only in physics education field but in mathematics education and psychology field as well. See Susac et al. (2018) for the review. In physics field, we are mostly interested in scatterplots, which have several important features. In the research, we focused on the graph slope interpretation, which is intuitively not easily accessible concept for students. In several previous studies, typical students' misinterpretations of the concept have been identified. For example, *Slope/height confusion*, *Variable confusion* or *Nonorigin Slope Errors* (Beichner, 1994, McDermott et al., 1987). Moreover, typically students show misunderstanding where "graph is considered to be like a photograph of the real situation" as well.

Previous researches used interview or multiple-choice testing as a research method. Nowadays, we also employ the eye-tracking method, which allows us to get deeper insight into students' thinking processes (Susac et al., 2018, Klein et al., 2019). By the method, we can track students' eye-movements and so to follow their attention. A typical methodological approach is embedded in novice-expert paradigm, where we compare problem solving strategies of experts and novices, and experts' strategies are considered to be the better one. In the educational field, typically we compare students who solved a task correctly and those who did not.

Our research questions are as follows:

1. How does students' gaze allocation on options in a multiple-choice test differ according to correctly or incorrectly answering a test task?

2. And what students' (mis)interpretation of the graph slope concept can we conclude based on this eye-movements observation?

METHOD

Students were observed by the eye-tracking method, when they solved multiple-choice tasks focused on the graph slope in kinematics. Moreover, after the eye-tracking session, students fulfilled a questionnaire about their gender, age school, grades, and attitudes to science and “graph as a sketch of the real situation” typical students’ conception about graphs was examined by additional tasks.

Apparatus

Eye-tracker by Tobii was used, particularly TX300 with frequency 300 Hz, which has accuracy less than 0.5 °of visual angle. The infrared camera was placed under the 23-inch screen of the stimulus PC. The resolution of the screen was set to 1900 x 1280 pixels. A five point calibration and validation procedure was used before start of the experiment. Eye movements were recorded by Tobii Studio 3.2 and for identification of fixations inbuilt IVT filter was used. Eye movement was classified as a saccade when eye’s velocity exceeded 30°/s. Minimum fixation duration was set on 60 ms.

Test’s tasks

Each student solved 6 multiple-choice tasks (#3 upto #8) focused on graphs in kinematics. Five tasks were adopted from Beichner’s TUG-K test (Beichner, 1994) and one task was adopted from Czech research by Fenclova (1980). All tasks were focused on position-time graphs and determining velocity from the graphs as it is stated in the Objective 1 of the Beichner’s original test. Moreover, the first task (#1) was adopted from McDermott et al. research (McDermott, et al. 1987) and students should determine which object (A or B) was moving faster at the time = 2s. Position-time graph with two lines of different slopes was given. The task #2 was due to technical problems from further analysis omitted.

Sample of students

There were 32 participants in the study (53 % women, 47 % men) mostly focused on science, aged 18-20y.

Data analysis

In order to get answer on our research questions, we analyzed data obtained by the eye-tracker as it follows: For each task we created so called AOIs, Areas Of Interest, as it is shown in Figure 1. Because we always compared two groups we did not need to take into account areas size of these AOIs. Each stem-text, stem-graph and each option was marked as a separate AOI. Then we divided students into two groups whether they answered a task correctly or not, and compared the mean of total fixations duration which each student group spent on AOIs.

RESULTS AND DISCUSSION

Relative number of students (in %), who answered a task correctly, is shown in Table 1.

Table 1. Percentage of students, who answered particular task correctly.

Task no.	1	3	4	5	6	7	8
% of students	50.00 %	40.63%	22.58%	31.25%	25.81%	15.63%	65.63%

Almost 2/3 of students solved correctly task #8, whilst task #7 was the most difficult one. Students typically showed misunderstanding that *a graph is a sketch of a real situation*. Task #4 and #6 were focused on quantitative determination of slope at a particular time. In task #4 students worked with positive slope, in task #6 with the negative one. Surprisingly, slightly more students solved correctly task #6 than task #4.

Given position – time graph (right). Students should choose from five velocity – time graphs which describe the same motion.

(From Beichner 1994, task No. 11.)

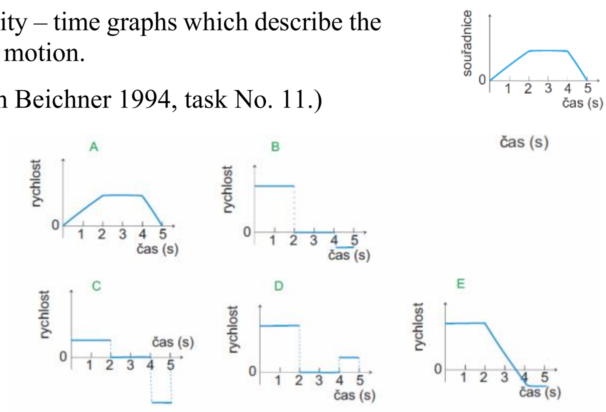

Figure 1. A task #3 and an example of created AOIs (right).

Total fixations duration of each participant related to their score is shown in Figure 2. Most participants solved the test in range 2 upto 7 minutes. Participants no. 20, 23 and 37 spent on tasks much more time than the others, particularly more than 9 min. We considered them as outliers and provided further analysis with and without them.

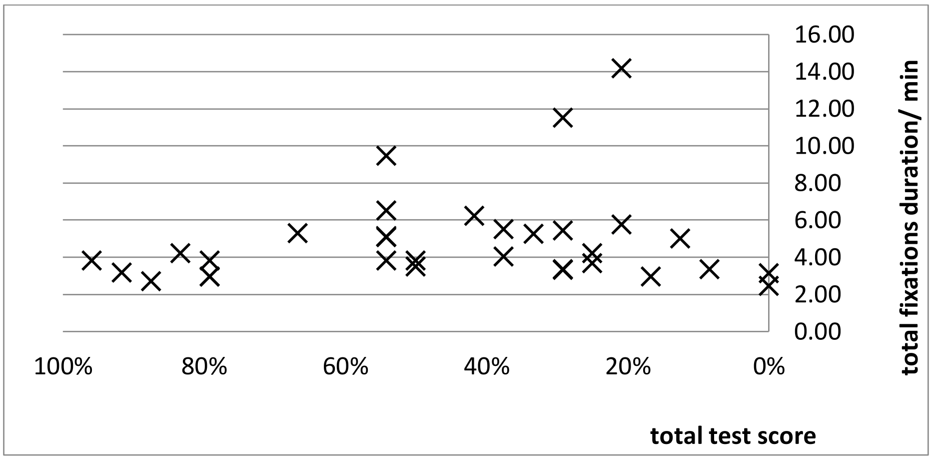

Figure 2. Total fixations duration of each participant related to their total test score.

Total fixations duration spent on each task by each participant is shown in Figure 3. Participants are ordered according to their total test score. Participant no. 11, left, gained the highest total test score (96%). In order to complete a task, roughly the best (left) and worst (right) performers needed shorter time than the other ones.

Most participants solved a task in less than 1 minute. Average total fixations durations of task #1, #3, #4, #5, #6, #7 and #8 are as follows: 24.5 s, 61.1 s, 46.9 s, 33.8 s, 43.4 s, 40.1 s and 42.1 s. (without “outliers” 23.8 s, 49.4 s, 43.2 s, 28.3 s, 37.3 s, 33.1 s and 34.4 s). The longest average total fixations duration was made on task #3, #4 and #6.

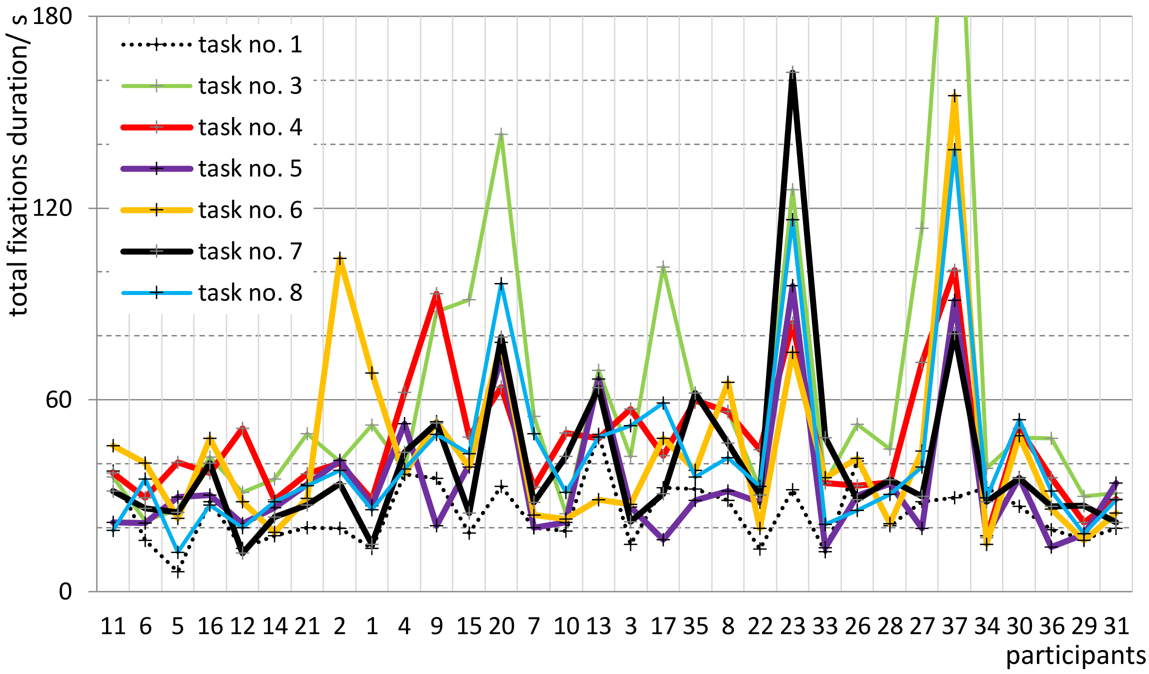

Figure 3. Total fixations duration of each participant for each task. Ordered according to the total test score (the best performer is in the left).

Correctly and incorrectly answering students showed different total fixations duration on options' AOIs. See Figure 4. In line with gaze bias hypothesis (Lindner et al., 2014), correctly answering students spent more time on correct options (3_c, 4_b, 5_e, 6_c, 7_b&c, 8_e), whilst incorrectly answering students were more focused on the other options. The correct options were the only options which correctly answering students spent more time on than incorrectly answering students. The finding suggests that total fixations duration mean could serve as good predictor between correctly and incorrectly answering students.

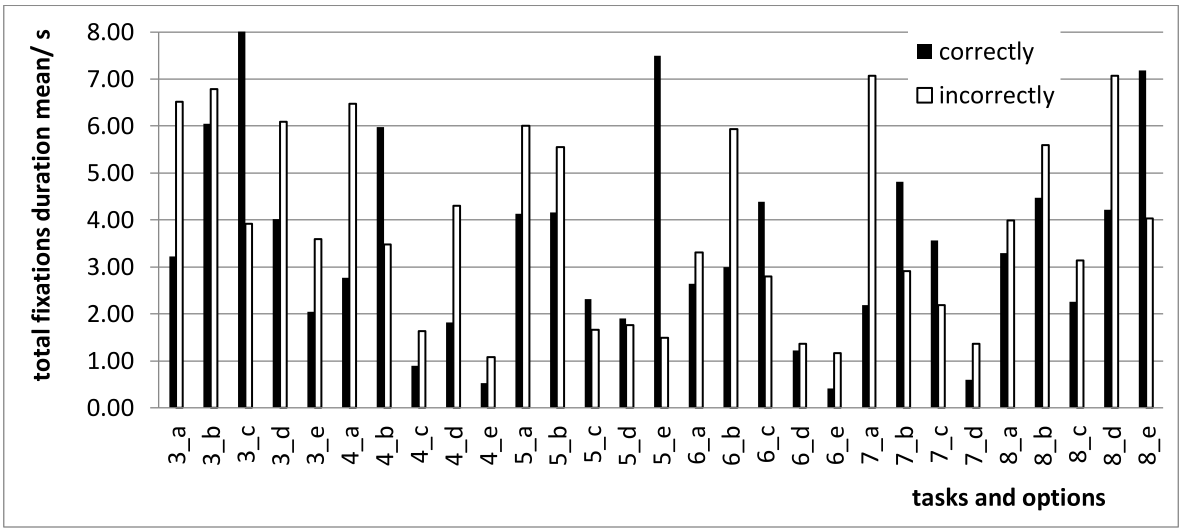

Figure 4. Total fixations duration mean on each task option. Group of students who answered correctly (black) and incorrectly (white).

Statistically significant differences are shown in Table 2. We used nonparametric Kolmogorov-Smirnov test by Statistica Software from Statsoft Inc. Company. We did not find any statistically significant differences in group means of task #8 options. However, the groups differ in their total fixations duration mean of options 8_d and 8_e the most. Option 8_e was much more fixated by the correctly answering students and option 8_d by the incorrectly answering students. The task was solved the most successfully. In contrast to the other options, option 8_e and _d offered graphs with very similar curves. In contrast, the groups statistically significantly differ in two options of task #7, which is shown in Figure 5. Incorrectly answering students who chose either option 7_a or 7_d showed typical “graph as a picture or sketch of a real situation” error.

Table 2. Statistical significant differences in total fixations duration mean of students who answered correctly (group 1) and incorrectly (group 2). Kolgomorov-Smirnov test by Statistica software. If we omitted “outliers” (see Figure 2), there is statistical significant difference in option 3_a as well.

Task	Option	Max Neg	Max Pos	**p-value**	Mean 1	Mean 2	Std.Dev. 1	Std.Dev. 2
5	e	0,000	0,955	**p < 0.001**	7,50	1,49	5,843	2,078
4	a	-0,690	0,042	**p < 0.025**	2,77	6,48	1,234	3,940
6	c	-0,043	0,715	**p < 0.005**	4,39	2,80	1,937	5,576
7	a	-1,000	0,000	**p < 0.01**	2,19	7,07	0,530	3,273
7	d	-0,857	0,000	**p < 0.05**	0,60	1,37	0,225	0,453

Task #4 and task #6 were focused on determining of slope (positive in task #4, negative in task #6) at a particular time. Students show typical *Nonorigin Slope Error* (Beichner, 1994), where they simply divide position (at the given time) by the given time. Even in the case, when slope does not intersect the origin. The incorrectly answering students chose such option as their answer and they also paid much more time to the option. The difference in total fixations duration mean for the two groups was statistically significant (see Table 2). Surprisingly, they were also interested a lot in option „time divided by position“ (see task #4, option 4_d). Both students’ groups showed the least total fixations duration mean on options which offered only *height of a graph*. So they do not show *Slope-height confusion error* (Beichner, 1994) when solving the type of a task.

In task #5 based on the given description of a motion (An object starts from rest and undergoes a positive, constant acceleration for ten seconds. It then continues on with constant velocity.), students should choose from five position – time graphs which describe the motion. (From Beichner 1994, task no. 9). Both correctly and incorrectly answering students paid the least attention to the two improbable options (5_c, 5_d). They differ (statistically significantly) in attention paid to the correct option 5_e. Incorrectly answering students paid similar amount attention to it like to the previously mentioned ones. They were interested much more in options, where the graph curve is at the end parallel with the time axis. Obviously, these students interpreted motion with constant velocity as horizontal line in the position-time graph. Task #3 is shown in Figure 1. The correctly answering students paid the most attention to option 3_b and to the correct one (3_c). Probably, in the given position-time graph they firstly identified positive and negative constant slope and they focused on their magnitudes later. Whilst incorrectly answering students spent the most time on options 3_a, 3_b and 3_d. Probably, in contrast to the correctly answering students, they (incorrectly) identified magnitudes of the slopes and then they focused on solving the problem whether they are negative or positive. This shows differently perceived importance of magnitude and negativity or positivity of a slope by the two groups. Focus on option 3_a is in line with typical error called *Variable confusion* (Beichner, 1994), where students tend to perceive graph curve describing the same motion event as the same or at least similar regardless graph variables.

Given position – time graph (see picture). Students should choose from five options which describe the motion.

a) A car is moving along inclined plane down.

b) A car is moving with a constant velocity.

c) A car is going back to the zero point.

d) A car is almost falling down.

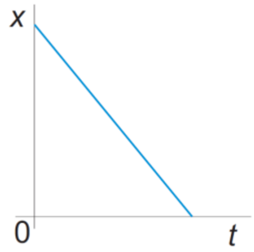

Figure 5. Task#7.

CONCLUSION

We showed differences in attention allocation (operationalized by total fixations duration) among correctly and incorrectly answering students which they paid to options in multiple-choice test focused on graph slope interpretation in kinematics. Correctly answering students paid more attention to all correct options than incorrectly answering students and vice versa. Incorrectly answering students mostly paid the most attention to options which show typical identified misconceptions in graph (slope) interpretation. They prefer interpretation which misleads abstract nature of a graph and sketch of a real situation. Obviously, correctly and incorrectly answering students differ in their perceived importance of magnitude and orientation of a graph slope. In the end, again we showed value of the eye-tracking method, which makes students' thinking and decision making processes visible.

EDUCATIONAL RECONSTRUCTION OF CURRENTS AND STRUCTURE FORMATIONS

Kai Bliesmer[1], Michael Komorek[1]
[1]Carl von Ossietzky University, Oldenburg, Germany

In a preliminary study, it is found that numerous out-of-school learning venues near the coast need help in addressing aspects of coastal physics in their educational offerings. Therefore, an Educational Reconstruction (Duit, Gropengießer, Kattmann, Komorek & Parchmann, 2012) of coastal physics is carried out in the present research and development project. The aim is to outline principles and formulate educational guidelines for the operators of out-of-school learning venues to support them in their effort to integrate aspects of coastal physics into their existing educational offerings. As part of the Educational Reconstruction, a document analysis of scientific literature is undertaken to clarify the subject matter structure. This is followed by an empirical study in which the learners' conceptions of coastal phenomena (currents and structure formations) are investigated. The creation of educational guidelines is ultimately based on both the learners' conceptions and the results of the subject matter clarification.

Keywords: Coastal Physics, Model of Educational Reconstruction, Out-of-school learning

INTRODUCTION AND PRELIMINARY STUDY

As the effects of climate change on the Trilateral World Heritage Wadden Sea are particularly severe, more than 30 out-of-school learning venues have been founded in Germany alone to emphasise the dynamics and sensitivity of the Wadden Sea attracting millions of visitors each year. To learn more about the educational offerings, expert interviews (Bogner, Littich & Menz, 2009) are conducted with the operators of the out-of-school learning venues. These expert interviews serve as a preliminary study because the interviews helped to concretise the research and development tasks in the present project. It is investigated to what extent coastal physics already appears in educational offerings of out-of-school learning venues and whether the operators want more coastal physics in their offerings. It is found that almost no physics is addressed yet: ocean currents, structure formations in the sand, and the formation of islands are missing along with physical explanations and models. Most of the educational offerings are firmly focussed on biological content. The operators of the out-of-school learning venues are aware of that imbalance. Still, they are not able to fix it on their own, as the operators typically come from the fields of biology or environmental science and do not have much experience with coastal physics. Therefore, they need help integrating coastal physics into their offerings. This help is provided in the present research and development project.

MODEL OF EDUCATIONAL RECONSTRUCTION

The Model of Educational Reconstruction (Duit et al., 2012) serves as a theoretical framework for all research and development tasks carried out in the present project. The model was created by science education researchers and calls for the same attention to be paid to the clarification and analysis of science content and the examination of relevant learners' conceptions. The outline of principles and the formulation of educational guidelines that help the operators to design new teaching and learning environments is therefore based equally on both the clarification and analysis of science content and the research on teaching and learning. The following figure shows the three components of the model. Each element represents a task that must be accomplished for an educational reconstruction of the topic of interest.

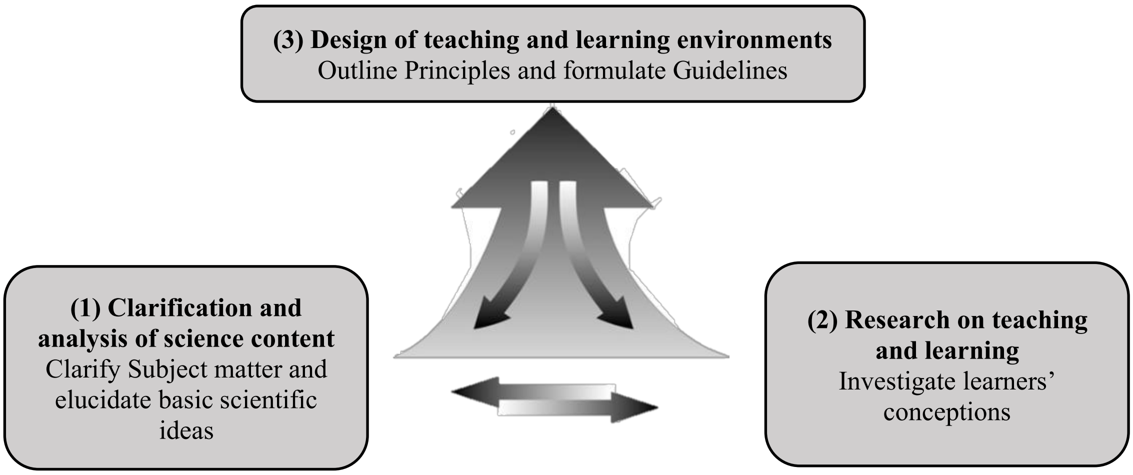

Figure 1. The three elements of the Model of Educational Reconstruction (based on Duit et al., 2012)

Since the Model of Educational Reconstruction is a theoretical framework, in each of the three elements, it must be determined how the respective task should be mastered based on further science education research concepts. Therefore, the elements of the model represent the following three chapters, in which it is specifically shown with which concepts the respective task is processed.

(1) CLARIFICATION AND ANALYSIS OF SCIENCE CONTENT

In coastal regions, learners are mainly confronted with phenomena that can be assigned to (a) currents and (b) structure formations of granular matter (sand). For this reason, these two areas of phenomena will play a significant role in future educational offerings and are therefore subject to clarification. The concept of Elementarisation (Duit, Schecker, Höttecke & Niedderer, 2014) is used in this project to provide the necessary clarification of the subject matter structure. The concept of Elementarisation aims to elucidate the basic scientific ideas, principles, and general laws of the topic to be educationally reconstructed. Hence, a document analysis of scientific literature is carried out that is dedicated to the subject of interest. Because of the focus on currents and structure formations, scientific literature from the fields of continuum mechanics (Haupt, 2002), thermodynamics (Blundell & Blundell, 2010), non-equilibrium thermodynamics (Demirel, 2014) and the theory of complex systems (Bar-Yam, 2003; Nicolis & Prigogine, 1977) is analysed to elucidate basic scientific ideas, principles and general laws used to explain currents and structure formations in the context of coastal regions.

a) Currents: Basic Idea of Equalisation

There are two types of currents described in the scientific literature, each triggered by different causes. On the one hand, there is natural convection and, on the other hand, forced convection. Natural convection occurs as a result of temperature or concentration gradients in a fluid. When sufficient temperature or concentration gradients occur, density differences result, causing the fluid to begin to flow. Molecular transport processes of heat and mass, which are associated with conduction and diffusion, are then superimposed by convective transport processes. Forced convection is driven by external forces on a fluid. Related to a surface area, the external force can be described as a pressure that acts on the fluids' surface. If there is a pressure gradient in the fluid, it changes its shape and starts to flow. The shear stresses that the fluid experiences depend on its viscosity. That emerging gradients are associated with transport processes can be seen particularly well in the equations for each molecular transport process. They always have the same shape: Gradients are proportional to molecular transport processes via a proportionality factor, which is either the thermal conductivity coefficient, the diffusion coefficient, or the viscosity. But it is remarkable that in all cases, the emerging currents reduce the causative gradients: Due to natural convection, conduction, and diffusion temperature gradients and concentration gradients decrease. Due to forced convection and the associated change in the shape of the fluid, the pressure gradients are also reduced. Occurring gradients cause processes (called natural convection, forced convection, conduction, or diffusion) that lessen the gradients again. So, all molecular and convective transport processes have a particular direction. They always lead to an equalisation of prevailing gradients. Gradients decrease over time because the equalised state has higher entropy than an unequalised state (Demirel, 2014). Therefore, the equalised state is the most likely to occur in the long term and becomes a stable attractor. For this reason, currents are interpreted as a phenomenological expression of an equalisation principle.

b) Structure formations: Basic Idea of self-organisation due to positive and negative feedback

On the coast, currents and granular matter interact far from the thermodynamic equilibrium. Thus, there are no stable attractors so that random fluctuations can initially increase undamped. The excess entropy (Nicolis & Prigogine, 1977; Demirel, 2014) acts as a stability criterion for systems outside the thermodynamic equilibrium and describes whether random fluctuations lead to positive or negative feedback. If positive feedback occurs, influences are not damped, the system is unstable, and it may change into a new state. In the case of negative feedback, influences are damped so that the system always falls back into its original state. Structure formation through self-organisation is based on an interplay of positive and negative feedback: A system leaves its original state through positive feedback. At some point, it will be finally stabilised into a new state by negative feedback occurring. Structures in the sand, for example, depending on the initial distribution of sand grains and obstacles (Anderson, 1990). In places where there is more sand, there are more impacts between the grains and, thus, a higher dissipation rate. Accumulations arise. The emerging gatherings lead to even more impacts between the grains and thus to an even higher dissipation rate so that the accumulations are self-amplifying. This is a positive feedback mechanism. However, the accumulation eventually reaches a critical slope and cannot continue to grow due to any more grains of sand roll off the pile, which is a negative feedback mechanism. The interplay between positive and negative feedback leads to a new dissipative structure formation through self-organisation: metastable states are reached. In the course of the document analysis, many other phenomena are identified, which are also described based on an interplay between positive and negative feedback mechanisms. These include cyclones (Ooyama, 1982), tidal deltas (Fagherazzi, 2008), ripple marks (Anderson, 1990), meandering rivers (Stølum, 1996), ocean waves (Smyth und Moum, 2012), and vortex streets (Ikeda & Apel, 1981; Banerjee, 2005). In the present project, structure formations are interpreted as a phenomenological expression of the interplay between self-amplification (positive feedback) and self-inhibition (negative feedback).

(2) RESEARCH ON TEACHING AND LEARNING

In the course of the second component of the Model of Educational Reconstruction, the learners' perspectives and conceptions in the relevant subject area are empirically investigated. The investigation is divided into two phases: first of all, the focus is only on the notions (the terms) "current" and "structure formation". The aim is to find out what the learners associate with both notions and what properties must be fulfilled from their perspective in order to call something "current" or "structure formation". This is of interest because both notions are used in many everyday life contexts and have a different meaning there than in science. In the second phase, it is probed how learners explain currents and structural formation phenomena. These two investigation phases lead to the following research questions:

(i) What characteristics do the notions "current" and "structure formation" have from the learners' perspective?
(ii) Which scientific ideas, laws, and principles do learners use to explain currents and structure formations?

Methods

In total, 22 structured guideline interviews are conducted with visitors to out-of-school learning venues. Since the learning venues are open not only to schoolchildren but to anyone interested, people between the ages of 15 and 70 are interviewed. People under the age of 18 are interviewed in pairs, as experience has shown that couple interviews lead to an increased willingness to talk and discuss, which is vital since younger subjects often do not dare to give detailed answers in a one-on-one interview. Interviews are divided into two series, each dedicated to answering one research question. The same people take part in both interviews of the series, which are conducted approximately one week apart.

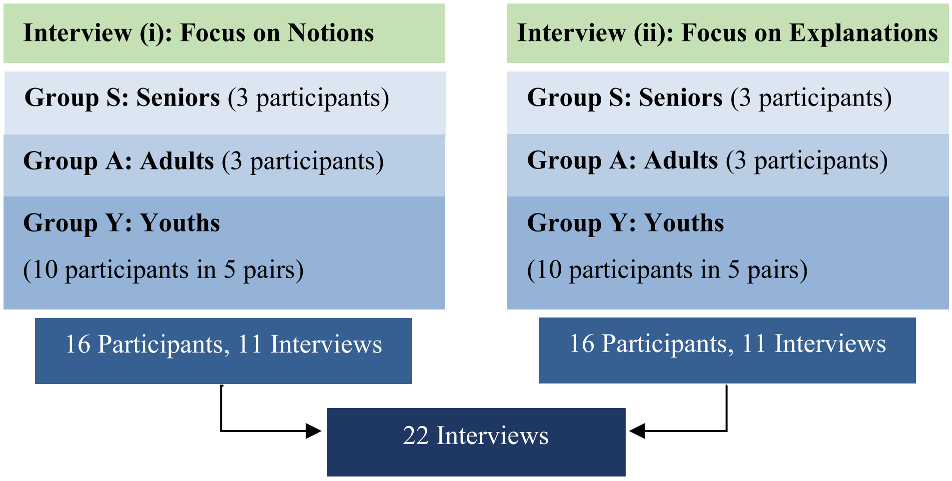

Figure 2. Distribution of test subjects across the various interviews conducted.

(i) In the first series of interviews, pictures, and videos are used to determine the characteristics of currents and structure formations from the learners' perspective. They are given 30 images showing many different everyday phenomena, including currents and structure formations. The interviewees are then asked to select the images that they viewed as currents. After the pictures are chosen and a stack is formed, there is an intense discussion about what must be fulfilled from the learners' point of view to include a picture in the group of currents. Besides, they are asked to name counterparts, synonyms, and definitions of currents and had to justify them. Subsequently, the same procedure is repeated for structure formations.

(ii) In the second series of interviews, two experiments are used: in one, learners observed a convection cell, and in the other, a structure formation in the sand is created.

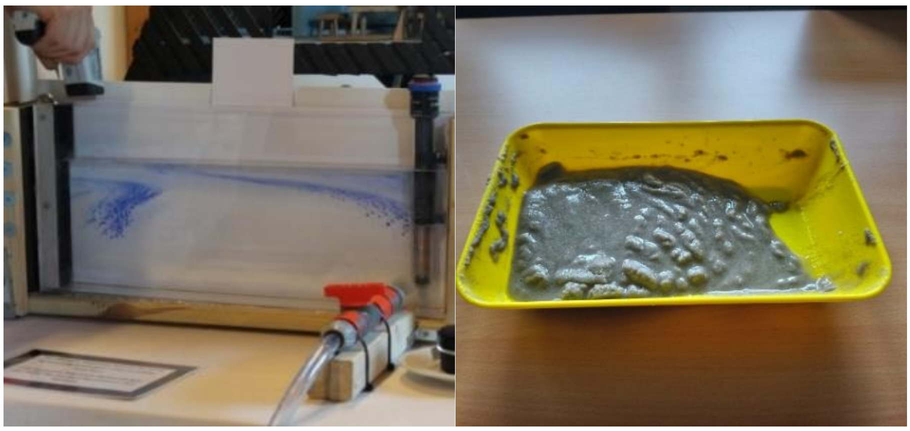

Figure 3. Experiments are carried out to create a convection cell (left) and a structure formation (right)

To create a convection cell, a water basin is used, which is heated by an aquarium heater on one side and cooled by Peltier elements on the other side. The current can be observed after the addition of ink. To form a structure in the sand, a tray is filled with sand and a little water. If the tray is moved back and forth, a pattern is formed in the sand. To investigate the concepts used to explain the phenomena, the interview is structured according to the POE method (White & Gunstone, 1992). The letters stand for **p**redicting, **o**bserving, and **e**xplaining. Therefore, the second interview is divided into these three sections, each for currents and structure formations.

Both interviews are evaluated using qualitative content analysis (Mayring, 2014): Categories are formed which are statements about the characteristics of the notions "current" and "structure formation" (interview (i)) and statements about explanatory concepts on the emergence of currents and structure formations (interview (ii)).

Results

(i) Currents are considered to be a particular form of movement characterised by three features: currents are joint movements (collectivity) of a large number of individual objects that are distributed quasi-continuously (continuity) and move with a minimum of speed and extension (intensity). For this reason, the interviewees consider not only the directional movement of water and air as currents but also the collective motion of a large number of animals, people or cars. However, the interviewees decide subjectively whether a phenomenon seen in the picture has the three characteristics mentioned or not. That is why the learners come to a different grouping of the images despite arguing with the same characteristics since some already see an almost collective movement as a current. In contrast, others insist on an utterly joint movement. When confronted with structure formations, the learners distinguish between two types of structures: temporal sequences of events (e.g., a daily routine) and spatial arrangements (e.g., a dune). The characterisation of these two types of structures causes them significant problems. Many learners use the term "regularity" to describe structures in the context of the coastal regions. Others, on the other hand, use the exact opposite and explain that structures are characterised by "irregularity". Still, others see a mixture of both characteristics, which is particularly clear from the statement of a learner who says that structure formations are characterised by an "irregular regularity". The difficulty in assigning a consistent feature to structure formation is because it depends on what the respective structure is mentally compared with: Structures in nature are never entirely regular. If compared with a structure created by humans (e.g., a very regular tile pattern), it is concluded that natural structures are somewhat irregular. However, if natural structures are compared with an extremely unstructured state (e.g., a very smooth, uniform surface), it is concluded that structures are characterised by regularity.

(ii) To explain the convection cell in the experiment, learners refer to the density of the water. They state that the density of the water depends on its' temperature. Since they know that ice floats on water, they falsely conclude that the density of cold water is lower than the density of heated water. However, this contradicts their observations in the experiment and leads to cognitive conflict. Hence, they fail to explain the convection cell consistently. In general, it is found that learners prefer forced convection over natural convection. Although the interview focusses on natural convection, they keep talking about forced convection and offer explanations in this regard. As an explanatory strategy, they use the principle that other already existing movements are transferred to still water or still air (e.g., with a fan or a pump). As a result, the still water or the still air begins to flow. To explain structure formations, learners mostly use two explanation strategies. In the first explanation strategy, they interpret structure formations as an imprint. To illustrate this, they speak of a shoe print that is created because the structure of the sole is transferred to the sand. Analogously, the interviewees falsely explain that the ripple marks are an imprint of the water waves. And in their opinion water waves get their structure from the fact that the structure of the wind is transferred to the water. Accordingly, the learners are only able to explain structures if structures already exist. The learners thereby create a *chicken and egg problem* and are unable to explain structures from a state of total unstructuredness. In the second explanation strategy, the learners try to explain occurring structure formations with the help of irregularities. They describe that the grains of sand are of different sizes, or the tray in which the sand is located cannot be moved back and forth perfectly regular. These are irregularities that ultimately result in irregularities in the sand, which are recognised as structure formations. This frequently happens in the interview: the learners mention irregularities in the environmental conditions and thus see the structure formation as clarified. However, the learners cannot explain which exact mechanisms work so that initial irregularities ultimately lead to the formation of structures.

(3) DESIGN OF TEACHING AND LEARNING ENVIRONMENTS

In the final step of the Model of Educational Reconstruction, educational guidelines are formulated to help design teaching and learning environments. For this purpose, the analysed scientific content and the empirically examined learners' perspective on currents and structure formations are being compared with each other (Duit et al., 2012). It is ascertained to what extent the learner's perspective differs from the scientific view on currents and structure formations. Based on the results, suggestions are made for the teaching-learning environment on how to make a connection between the learner's perspective and the scientific perspective if the two are close to each other (continuous teaching-learning pathways). If the two perspectives differ greatly, a discontinuous teaching-learning pathway is indicated so that it is shown how the learners' conceptions can be confronted (Scott, Asoko & Driver, 1992; Amin, Smith & Wiser, 2014). The formulated educational guidelines are presented in the following subsections. They are intended to help the operators of the out-of-school learning venues to integrate coastal physics into their educational programs.

I) The teaching-learning environment is phenomenon-based

The out-of-school learning venues are visited by many different people who vary in their abilities. For this reason, the educational offerings should start with an observation of phenomena (here: currents and structure formations phenomena) to ensure everyone being able to take part in the educational offerings (differentiated learning).

In the interviews, learners prefer forced convection to discuss the characteristics of currents. For this reason, the phenomenon of forced convection will be thematised first before addressing natural convection. Since the learners see water as a prototypical medium for currents, phenomena such as the tides, rip currents, or flowing rivers must be addressed. Finally, structure formations are introduced. Here the learners often refer to structures in the sand and the clouds. For this reason, ripples, dunes, and cloud streets must be discussed in a teaching-learning environment.

II) The characteristics of currents and structure formations are being addressed.

The discussion about the characteristics of currents and structure formations proved to be very fruitful in the interview because this way, the learners are intensively occupied with both phenomena. This potential should also be exploited at out-of-school-learning venues. Hence, after observing currents and structure formations phenomena, their characteristics are discussed.

In the case of currents, a connection can be made between the scientific perspective and the learners' conceptions: the named characteristics "collectivity" and "continuity" can be clearly illustrated using the example of water currents. In the interview, the learners also mention the characteristic "intensity". This differs from the scientific view because it does not require a certain intensity to classify movements as currents. Here their ideas must be confronted. Since the interviewees describe currents as dangerous in the interview, they presumably name the characteristic "intensity" to underline that currents can be life-threatening. A connection to this can be made in a teaching-learning situation by also dealing with the possible dangers that arise from currents.

Regarding structure formations, the learners fluctuate between the two characteristics "regularity" and "irregularity", so that they fail in characterizing structure formations consistently. The problem with the two characteristics is that they represent two extremes on a mental scale. Therefore, the characteristic of similarity is offered. On the mental scale mentioned, the term similarity is located between regularity and irregularity. Maximum similarity (e.g. a tile pattern) would mean an absolute regularity, while minimal (e.g. a chaotic state) similarity could be described as a total irregularity. In a teaching-learning environment, structures are defined by the characteristic of similarity, and it will be made clear that specific spatial arrangements or temporal sequences are repeated with a certain similarity.

III) For an explanation, the principles of equalisation and feedback are introduced.

Explaining the emergence of currents and structure formations means the highest cognitive demands for the learners. Thus, the explanations are given only after observing the phenomena and after discussing their characteristics. In this way, all visitors can take part in the educational offerings and decide for themselves whether they only want to observe the phenomena or whether they also require explanations.

Since, as described in the first guideline (I), the teaching-learning environment starts with forced convection, pressure differences are used for an explanation. A fan or a pump can be discussed as an example from everyday life to create forced convection. The currents resulting there are interpreted as equalization processes: the pressure differences are reduced by the emerging currents. Thinking about equalisation serves as an excellent transition to finally discuss free convection too. Temperature differences and concentration differences are introduced as causes of free convection. To establish a connection to the learners' conceptions, both temperature differences and concentration differences are related to differences in density. As indicated in the interview, the density anomaly of the water must be pointed out in this regard to prevent cognitive conflicts that have arisen in the interview. Explanations in the teaching-learning environment go beyond the statements of the learners in the interview since free convection is also described via equalisation: The emergence of currents reduces differences in temperature and concentration so that differences in density also decrease. Free convection can, therefore, also be interpreted as an equalisation process.

Because the interviewees often explain structure formation based on existing structures, which transfer their structure like an imprint, they must be confronted with the resulting *chicken and egg problem*. It must be made clear that structures in the sand or the clouds form differently than structures that are created by a shoe print. The term self-organization can be applied very well here. Because the term makes it clear that the structures are not imprinted from the outside but that they are self-organized without external control. This way, a connection can be made to the perspective of the learners because, in the interview, they also underline that structures arise from irregularities in the initial conditions (e.g., different grain sizes of the sand). The connection is made by explaining that initial irregularities can self-amplify. If there is an irregularity (e.g., a little more sand in a certain place in the beginning), more and more moving sand gets stuck there, and the accumulation of sand continues to grow, which is positive feedback. However, the gathering does not grow forever because the accumulation becomes steeper and steeper, and the currents (wind or water currents) that move the sand eventually become turbulent. At some point, the maximum size is reached, and more sand that hits the accumulation rolls down again, which is negative feedback. Overall, the interplay of positive and negative feedback explains the structure formation in the sand. Positive and negative feedback are then also used to describe other structure formation phenomena, which are named in the analysis and clarification of science content (e.g., cyclones, tidal deltas, etc.)

OUTLOOK

The research and development work carried out so far leads to two new tasks that need to be mastered in the present project as well.

1) Interviews with the operators of the out-of-school learning venues must be conducted. The interview aims to discuss the developed educational guidelines. This is necessary because the operators have to accept the educational guidelines and support their usage. The results of the interviews are used to revise the guidelines and adjust them to the needs of the operators.

2) Based on the educational guidelines, specific educational offerings (e.g., learning stations, exhibits, etc.) must be developed, which are then empirically examined in the field of the out-of-school-learning venues. With the results of the empirical study, the specific educational offerings are adapted, and the guidelines are further developed.

ACKNOWLEDGEMENT

The present project is funded by the German Environmental Foundation (DBU) and is part of a graduation program of the Ministry for Science and Culture of Lower Saxony. We thank both for their support.

GENETIC CONCEPTS, REPRESENTATIONS AND MODELS IN STUDENTS' AND EDUCATORS' CONCEPTIONS

Despina Tsopoglou-Gkina[1], Penelope Papadopoulou[1]
1School of Social Sciences & Humanities - University of Western Macedonia, Florina, Greece

Scientific literacy is considered, internationally, one of the fundamental goals of education, with genetic literacy being a crucial part of it. In this framework, an extensive literature review of students' and teachers' conceptions on the gene was conducted, followed by a meta-analysis of 45 papers in order to trace in these conceptions the five historical models for the gene and its function; Mendelian, classical, biochemical-classical, neoclassical and modern model. The findings of the meta-analysis outline systematic difficulties and misconceptions in students' and educators' conceptions in genetics, as well as outdated perceptions of the gene model that lacks modern aspects.

Keywords: Educators, Students, Gene historical models

INTRODUCTION

In a society infused with scientific and technological achievements, which are a great part of modern everyday life, citizens are involved in democratic procedures that require a deep understanding of science. Therefore, the inclusion of basic concepts and possibilities of those scientific accomplishments in the education of students is deemed crucial for their future in society (Gericke & Hagberg, 2010a). More specifically, citizens are increasingly facing matters that require critical thinking and understanding of genetic concepts, methods and processes namely gene therapy, genetic testing, reproduction, hereditary and behavioural issues, as well as social controversies concerning origins and race (Ahmed et al., 2018; Aldahmash et al., 2012; Stern & Kampourakis, 2017). Such extended range of genetics applications renders genetics literacy, an important pillar of scientific literacy, a pivotal aspect of the modern citizen. Genetics, apart from an integral part of modern biology, constitutes a solid branch of secondary and upper education biology curricula (Agorram et al., 2010; Dorji, Tshering, & Dorji, 2017; Gericke & Hagberg, 2007). Despite its central role in science education, it is one of the most problematic areas of the curriculum of biology, mostly due to the conceptual, linguistic difficulties students face; these difficulties may emerge either from students' inability to connect the different organizational levels of genetic phenomena and processes (Duncan & Reiser, 2007; Marbach-Ad & Stavy, 2000), or the incongruency between the level of conceptual difficulty and students' cognitive level (Lewis & Kattmann, 2004; Lewis & Wood-Robinson, 2000), or inaccurate or even lack of previous knowledge (Donovan & Venville, 2014; Venville et al., 2005). Students' difficulties are subsequently reinforced by low-quality textbooks lacking cohesion, poor didactic transformation of scientific to scholar knowledge from the educators, and lastly, by the preconceptions both parts hold before instruction which are also formed by the mass media (Stern & Kampourakis, 2017).

In addition to the afore-mentioned issues, the intrinsic complexity of genetics resulting from the conceptual variation of core terms, such as that of the "gene" is aggravating the perplexity of genetics instruction and understanding. As the "gene" term and its function has undergone a conceptual change since its first appearance in the beginning of the twentieth century, there have been multiple scientific gene models describing its structure and function in different historical contexts (Gericke & Hagberg, 2010b). It has been proven (Blonder & Mamlok-Naaman, 2019) that didactic approaches integrating historical aspects into the science curricula enhance the understanding of the nature of science (NOS) and, therefore, aide in coping with alternative conceptions both educators and students may hold, causing implications in instruction.

The gene concept and function has undergone a lot of discussion and analysis in the scientific world (El-Hani et al., 2014; Kampourakis, 2017) and of course at the implications it conceptual change in education and the learning process. Multiple studies have focused on how the gene concept is portrayed in biology textbooks (Aivelo & Uitto, 2015; Christidou & Papadopoulou, 2018; Gericke et al., 2014; Gericke & Hagberg, 2010a, 2010b; Santos et al., 2012), but also researched students' and educators' conceptions in genetics (Table 3). The need for a review of the curricula worldwide is prominent (Aivelo & Uitto, 2015), and it is suggested that it should be based on systematic research conducted on the conceptions of both students and educators (Osman et al., 2017).

The latter has been the scope of our literature review where we researched the international literature for the conceptions of students and educators about the gene and its function. Moreover, we conducted a meta-analysis of the results in order to trace in those conceptions the epistemological features from the five historical models of the gene and its function (Mendelian, classical, biochemical-classical, neoclassical, modern) as described by Gericke and Hagberg (2007). The models share the idea of a hidden hereditary factor (gene) influencing a characteristic or function of an organism, while each of them represents a significant change in the way the function of the gene has been perceived through history (Gericke & Hagberg, 2010b).

METHOD

We conducted a literature review on students' and educators' conceptions, focusing on secondary education, in regards to genetics, and more specifically, to the concept of gene and its function. Our research extended in 105 scientific journals on education with the following keywords: students'/ teachers' conceptions, genetics, alternative ideas, gene concept.

The meta-analysis was based on the five historical models of the gene and its function as described by Gericke και Hagberg (2007). Using the secondary attributes of the historical models which are described by the epistemological features-variants as presented in Table 1, students' and teachers conceptions were analysed and classified under the respective models (

For instance, middle school students' conceptions researched by Donovan and Venville (2012) were driven by the deterministic belief that genes are determined by the corresponding traits they code for, or that there is no separation between the gene and the trait as concepts. This type of gene view is matched with the epistemological feature which explains the relationship of genotype with phenotype (symbolized as 4a, Table 1) as described in the Mendelian model (**Error! Not a valid bookmark self-reference.**). Furthermore, the two researchers found that students' perception for genes' structure was mainly references to heritable particles of abstract material structure (1a – Mendelian model) or of DNA segments (1c – neoclassical model). Therefore, this study's students' conceptions were categorized as hybrid, as there was prominent coexistence of epistemological features of different historical models.

Table 2). From the papers studied, a total of 45 were included in the meta-analysis (Table 3); the majority of research studies analysed used written questionnaires and/or interviews for the extraction of conceptions; their results' section was analysed in order to find words or phrases correlated with the models. The main epistemological features' categories discovered concerned the materialistic (or not) view of the gene, its definition from a (phenotypical) characteristic, the description of the relationships among the entities in the model, and the gene's function.

Table 1. Description of the epistemological feature-variants used in the classification of the textbook models (Gericke & Hagberg, 2010a).

Epistemological features	Legend for feature-variant
1	**The relationship between the structure and function of the gene**
1a	The gene is an abstract entity and has no structure.
1b	The gene is a particle on the chromosome.
1c	The gene is a DNA segment.
1d	The gene consists of one or several DNA segments with various purposes.
2I	**The relationship between organizational level and definition of gene function**
2Ia	The model has entities at the macro- and symbolic levels.
2Ib	The model has entities at the macro- and cell levels.
2Ibx*	The model has entities at the macro-, cell- and molecular levels.
2Ic	The model has entities at the molecular level.
2Icx*	The model has entities at the cell- and molecular levels.
2II	**The relationship between organizational level and definition of gene function**
2IIa	The correspondence between the gene and its function is one-to-one.
2IIb	The correspondence between the gene and its function is many-to-many.
3	**The "real" approach to defining the function of the gene**
3a	The function of the gene is defined top–down.
3b	The function of the gene is defined bottom–up.
3c	The function of the gene is defined by a process.
4	**The relationship between genotype and phenotype**
4a	There is no separation between genotype and phenotype.
4b	There is a separation, without explanation, between genotype and phenotype.
4c	There is a separation between genotype and phenotype, with an enzyme as the intermediary.

4d	There is a separation between genotype and phenotype with a biochemical process explanation.
5I	**The idealistic versus naturalistic relationships in the models**
5Ia	The relationships in the model are idealistic.
5Ib	The relationships in the model are naturalistic.
5II	**The idealistic versus naturalistic relationships in the models**
5IIa	The relationships in the model are causal and mechanistic.
5IIb	The relationships in the model are process oriented and holistic.
6	**The explanatory reduction problem**
6a	There is explanatory reduction from the macro level to the symbolic level.
6b	There is explanatory reduction from the macro level to the cell level.
6bx*	There is explanatory reduction from the macro to the molecular level.
6c	There is no explanatory reduction.
7	**The relationship between genetic and environmental factors**
7a	Environmental entities are not considered.
7ax*	Environmental- and genetic entities result in a trait/product/function.
7b	Environmental entities are implied by the developmental system.
7c	Environmental entities are shown as part of a process.

**The non-historical features were found in the textbooks by Gericke & Hagberg (2010a), but are not present in any of the historical models*

For instance, middle school students' conceptions researched by Donovan and Venville (2012) were driven by the deterministic belief that genes are determined by the corresponding traits they code for, or that there is no separation between the gene and the trait as concepts. This type of gene view is matched with the epistemological feature which explains the relationship of genotype with phenotype (symbolized as 4a, Table 1) as described in the Mendelian model (**Error! Not a valid bookmark self-reference.**). Furthermore, the two researchers found that students' perception for genes' structure was mainly references to heritable particles of abstract material structure (1a – Mendelian model) or of DNA segments (1c – neoclassical model). Therefore, this study's students' conceptions were categorized as hybrid, as there was prominent coexistence of epistemological features of different historical models.

Table 2. The historical model-categories of gene function as defined by the different epistemological feature-variants (Gericke & Hagberg, 2010a).

Historical model-category	Epistemological feature-variants								
	1	2I	2II	3	4	5I	5II	6	7
Mendelian model	1a	2Ia	2IIa	3a	4a	5Ia	5IIa	6a	7a
Classical model	1b	2Ib	2IIb	3a	4b	5Ia	5IIa	6b	7a
Biochemical-classical model	1b	2Ib	2IIa & 2IIb	3a &3b	4c	5Ia	5IIa	6b	7a
Neoclassical model	1c	2Ic	2IIa	3b	4d	5Ib	5IIa	6c	7b
Modern model	1d	2Ic	2IIb	3c	4d	5Ib	5IIb	6c	7c
Non-historical		2Ibx, 2Icx						6bx	7ax

The main categories of epistemological features identified in the studies analysed referred to, the relationship between the structure and function of the gene (1a, 1b, 1c), the relationship between organizational level and definition of gene (2Ia-2Ic & 2IIa), the "real" approach to defining the function of the gene (3a, 3b), the relationship between genotype and phenotype (4a, 4b, 4c) and a few references to the idealistic versus naturalistic relationships in the models (5IIa) and the relationship between genetic and environmental factors (7ax). Lastly, all conceptions were categorised based on the epistemological features found in the papers studied.

Table 3. Total scientific papers analysed in meta-analysis on students' and educators' conceptions.

RESULTS

Students' conceptions

From the totality of research papers reviewed, we found 36 studies in 17 countries (Figure 1), where it was feasible to categorise students' conceptions according to the five historical models of the gene and its function (Gericke & Hagberg, 2007). The most prevalent models were found to be the Mendelian and the classical, individually or in combination (hybrid), while elements from the biochemical-classical and the neoclassical emerged in a few results, but for the most part in hybridisation with other models, as shown in Figure 2. Furthermore, genetic determinism appeared in students' conceptions on genetics, reflecting predominantly the causal relationship of gene-trait, which constitutes a difficult core concept in teaching genetics (Wahlberg et al., 2018), leading to alternative conceptions/ misconceptions. The modern model was hardly detected in any study, as no epistemological feature-variant belonging to solely this model was found in the papers reviewed.

Educators' conceptions

In relation to the literature on students' conceptions on genetics, the research studies on educators' or pre-service teachers' conceptions were almost half (9 studies in 10 countries). The trend, however, is similar to that of the students' conceptions (Figure 2), as the predominant models were the Mendelian, the classical and the biochemical-classical, while there was a complete lack of the modern model. Hybridization of different models through instruction is a common finding, as educators rarely shifts from one view of a gene (abstract entity) to another (physical entity) without former explanation, therefore implicating students' understanding or conceptions (Thörne et al., 2013).

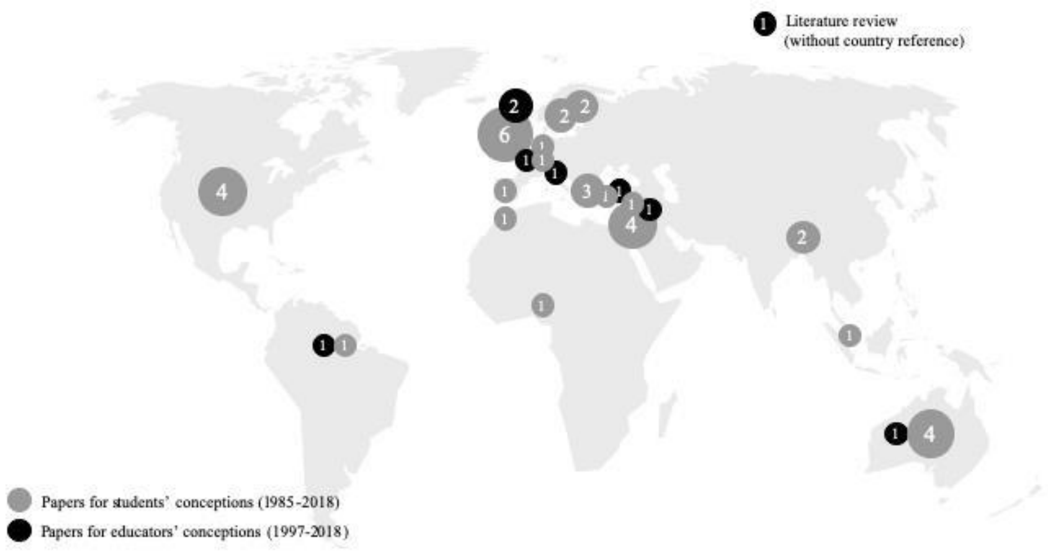

Figure 1. Map of literature results analysed in the meta-analysis. All studies for students' (with grey colour) as well as educators' (with black colour) conceptions are depicted according to the country they took place.

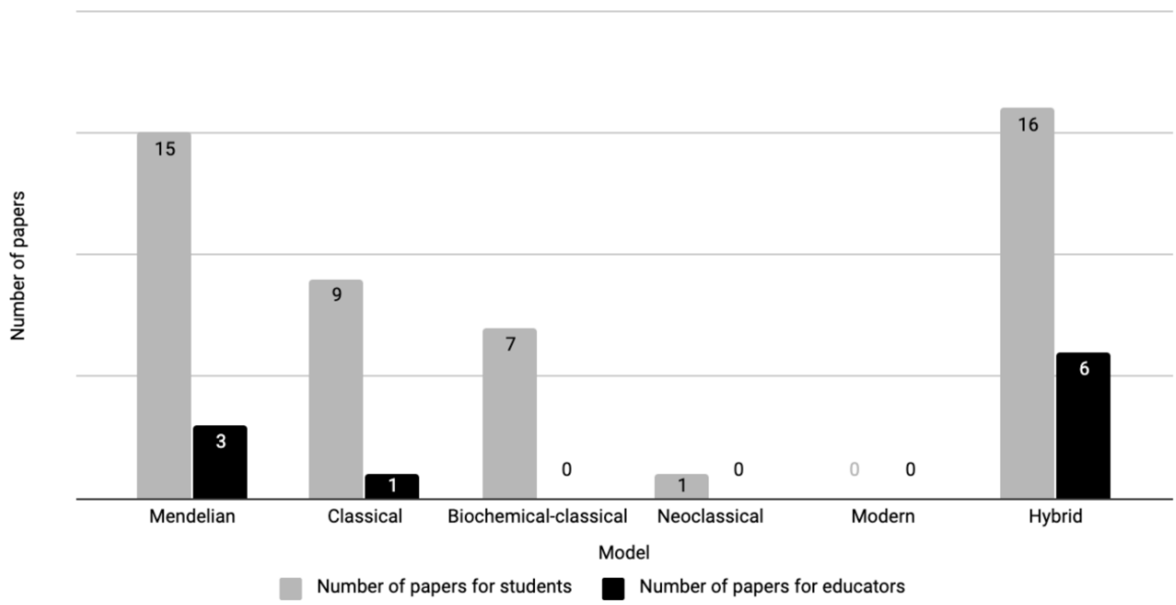

Figure 2. Models of gene function as identified in the papers for students' and educators' conceptions, in regards to the epistemological features-variants as described by Gericke and Hagberg (2007). (The identification of multiple models in one study is shown by the increased number of models in the Figure 2 (48) in contrast to the total number of papers analysed (36)).

DISCUSSION AND CONCLUSIONS

In conclusion, it is evident from our literature review that from the total of research papers studied and from the 45 which were analysed, 36 referred to studies investigating secondary school students' conceptions on genetics, whereas only 9 detected conceptions of educators, both pre-service teachers, as well as primary school teachers. All studies pinpoint misconceptions that students hold and are of importance in the planning of instruction by the educators. Additionally, the prevalence of confusion about the various models for the concept and function of gene, indicates the difficulties in conceptual understanding and consequently in their use by both students and educators. The conceptual variation, which is a consequence of the use of multiple historical models, is not intrinsically problematic, as it is highly useful to scientists (Aivelo & Uitto, 2015); however, in the school environment, it appears that the plurality in the depiction of gene function impedes its deeper understanding, resulting in hybridisation of the models used (El-Hani et al., 2014).

To sum up, literature worldwide presents systematic difficulties students and educators face in regards to genetics, as well as misconceptions formed when the former are not tackled. Hence, there is a need for further research so as to update the curricula and the outdated teaching methods which lack modern concepts in genetics.

ACKNOWLEDGEMENT

This research is co-financed by Greece and the European Union (European Social Fund- ESF) through the Operational Programme "Human Resources Development, Education and Lifelong Learning" in the context of the project "Strengthening Human Resources Research Potential via Doctorate Research" (MIS-5000432), implemented by the State Scholarships Foundation (IKY).

THOUGHTS ABOUT QUANTUM PHYSICS EDUCATION – QFT FOR SECONDARY SCHOOL: THE MILAN-ROME APPROACH

Marco Giliberti[1], Michela Cavinato[1], Giovanni Organtini[2]
[1] Università degli Studi di Milano, Milano, Italy
[2] Sapienza Università di Roma, Roma, Italy

We describe the conceptual frame and the general guidelines of the Milan-Rome approach to develop a consistent learning path about quantum physics involving Quantum Field Theory. Most current educational presentations of quantum physics still propose most of the same difficulties emerged during the early '900 years and construct Quantum Physics "against" classical physics. The latter is often compared to modern physics as a radically different theory (or, maybe, set of theories) and quantum physics is introduced as a "revolution", insisting on its apparently paradoxical aspects. We will discuss this problem, both from the epistemological and the educational point of view and give indications to provide an increasingly solid foundation for the educational reconstructions of quantum physics starting from classical physics, which must be reconsidered in view of the final objective, rather than opposing it to modern physics.

Keywords: Quantum Physics Education, Classical Physics Education, Quantum Field Theory

INTRODUCTION

The importance of quantum physics for the education of the future citizens has been – and still is being - put forward by several educators and associations (Mishina, 2019 and references therein; Am. J. Phys., 2002, March). On the other side, despite the large presence in textbooks of modern physics topics, the didactical quality of most presentations is clearly unsatisfactory (Cavallini & Giliberti, 2008). The results coming from Physics Education Research are sufficiently unambiguous and known for at least twenty years: many students (even graduate and master degree students in physics) show great difficulty in understanding the relevant aspects of quantum physics (Michelini, Santi, Ragazzon & Stefanel, 2008; Giliberti, 2007, Tarsitani, 2008). In fact, often, even secondary school teachers do not have a coherent picture of quantum physics.

The traditional approach to quantum physics is probable responsible of profound misunderstandings and, therefore, it is not sufficient a careful and somewhat coherent teaching to solve the problem, if one remains within the "standard" approach. Many educational difficulties emerge from the lack of awareness of the nature of the theories, which, we propose, are to be identified with their mathematical formalism together with a coherent physical interpretation that sets the rules of correspondence with possible experiments and their interpretation (Cavallini & Giliberti, 2008; Ludwig & Thurler, 2007).

On the contrary, physical concepts are often proposed making reference to a mixture of ideas that are uncritically taken from other areas and from other theories, with the addition of pre-scientific or common sense schemes.

To avoid misleading interpretations, we propose, instead, to conceptually start from the mathematical formalism of the theory and develop the educational path within this disciplinary framework (Giliberti, 2014).

This assumption, does in no way mean that the proposed secondary school path should be axiomatic and top-down; on the contrary, starting from some crucial experimental results, one have to induce the basic principle of the theory, that are to be understood in their mathematical and physical meaning and used to describe important real-world properties.

THE CHOICE OF QUANTUM FIELD THEORY

The expression "quantum physics" hides very different ideas and comprises various theories and visions. The old Quantum Mechanics (QM), developed between 1900 and 1925, has to do with experimental facts and their interpretation like the black body radiation, photoelectric effect and atomic spectra. It can be regarded as a set of phenomenological models sharing the same idea of the existence of quanta.

One can start talking of real quantum theories with the advent of the formalism by Heisenberg, Jordan, Bohr, Schrodinger and Dirac. The resulting theory is non relativistic and describes the behavior of a finite (usually small) number of interacting particles. Most of its results have no direct physical meaning, in the sense that the physical systems for which one can find a solution are often very crude approximations of real ones.

Quantum Field Theory (QFT), instead, is a relativistic theory that works sufficiently well at both low and high energy and, in fact, is able to derive exact predictions for the observable in real systems. As a matter of fact, QFT is the most precise and validated theory in physics, being tested over many orders of magnitude in energy regimes and to precision degrees that are indeed unconceivable for classical physics. The idea that classical physics is more "understandable" might then be contradicted by the facts (Organtini, 2017).

The most successful theories nowadays are QFT. Quantum Electrodynamics is a QFT in which matter and fields are very well defined. The Standard model of electroweak interactions and Quantum Chromodynamics are QFT, as well.

Most of the physics around us is governed by the interaction between charged particles. Quantum electrodynamics thus becomes the reference theory, indispensable for treating the electromagnetic field; furthermore it is even the conceptual basis of the Standard Model.

Its "ontology" is indeed simpler than that of the old QM, hence it is the best candidate for an introduction to QM.

THE MILAN-ROME APPROACH

The Milan-Rome approach is then twofold: it consists of a research to introduce, in a consistent and rigorous, though simplified, way a theory of quantum fields, as well as a review of the classical physics concepts needed to allows the introduction of quantum physics as a "natural" evolution of classical physics.

It is worth noting that this is not the first occasion in which an apparently more complex theory replaces an apparently more intuitive one. It happened with Newtonian physics, for example. The current way of teaching it has nothing to do with its original formulation. The latter was mostly based on geometrical entities, while the current approach adopts the vision of Euler who was the first to introduce the concept of vectors to describe motion as well as in introducing the physics laws in terms of equations.

Also, the current way of introducing electromagnetism has almost nothing to do with what was this theory in the Maxwell's Treatise. The current formulation must be ascribed to Heaviside that made electromagnetism much simpler to learn, even if nowadays we are looking for a revival of the physical aspects of the potentials, somewhat hidden in Heaviside formulation.

There is no reason, then, to continue to insist in introducing a vision of QM that has been surpassed. Using old concepts like the wave function, as a matter of fact, is just a way to simplify certain calculations in selected systems, for which a QFT approach would be harder. We propose not to start from those old concepts to develop a theory whose objects are the fields, the states and the operators that must be consistently introduced. We believe that QM have to be seen, described and used as the limit of QFT when the number of particles is fixed and relativity can be neglected.

Of course that does not mean to completely forget the historical aspects of the development of the theory that, however, must be treated as such (as it often happens in classical physics).

Using those concepts we can talk of scattering processes, evolution of a state and probability of obtaining a result in a measurement. Most importantly, we can introduce Feynman Diagrams as a well known and effective way of understating the interactions between particles and fields. In many textbooks Feynman diagrams are already introduced, but just as a pictorial description of a process that does not imply any physical interpretation. In our approach, Feynman diagrams can be introduced as what they really are: a computational tool. In fact, though we cannot pretend to teach how to calculate the amplitude of a process using this technique, it is very possible to compute ratios of probability of processes illustrating just few very basic properties of the diagrams (Organtini, 2011).

The choice of QFT helps in avoiding misunderstandings and words that are used by the theories, but come from preceding conceptions (pre-theories, or even common sense) rooted in the biased idea that, as we have already noticed, physics reality can be identified even out of a formal theory (Giliberti, 2014). In QFT locality is easier, particles are seen as excitations and superposition of states is very natural.

As said, in order to successfully introduce QFT we have to rethink key concepts of Classical Physics. To that purpose, we need to start and redesign some paths in order to explicitly include some fundamental concepts.

We have to clearly introduce the concept of state (for a point like particle, a gas, a thermodynamic system, a circuit, etc.). Interference must be anticipated and the idea of evolution from an initial state to a final state must be stressed. Physics laws must be seen as something that allows to predict the final state of a system given the external conditions, represented by the action of operators. In classical physics evolution operators are often represented as algebraic equations, however one can have alternative representations (e.g., the state of a gas can be represented as a point in the Clapeyron plane, and transformations can be represented as a curve). The concept of force must be reviewed and rapidly turned into the general concept of interaction. Just as the interaction of a heat source with a gas can change the state of the gas (and of the source), similarly the interaction of a mass with a gravitational field can vary the state of the mass (and of the field). It is useful to stress the importance of the concept of measurement and the relational status of properties attributed to objects to define their state. Of course the concept of field is of capital importance (starting form mechanics: pressure fields, potential fields, temperature fields, velocity fields…).

Particular attention should be given also to oscillations, harmonic motions and normal modes (that are at the basis of the quantization process in QFT) already in classical physics.

Some "ancillary" physics must be promoted to fundamental: in particular, we must review optics as a process in which the scattering is the fundamental process occurring. Last, but not least, probability and statistical physics are be introduced (even by including some numerical computations). Moreover, some important classical concepts, like those of the magnetic vector potential (Barbieri & Giliberti, 2015; Barbieri, Giliberti & Cavinato, 2014; Barbieri, Giliberti & Fazio, 2014; Barbieri, Cavinato & Giliberti, 2013), often neglected as "non physical", have to be discussed and introduced in order to better understand electromagnetism (especially the phenomenon of induction) (M. Giliberti, E. Giliberti & Cavinato, 2019), to allow a clear introduction of the electromagnetic quanta and to be able to explain some important "applications" of the quantum theory, such as superconductivity (Barbieri & Giliberti, 2012; Giliberti, Perotti & Rossi, 2018; Barbieri, Giliberti & Fazio, 2012).

CONCLUSIONS

In order to avoid misleading interpretations of quantum concepts coming when they are mixed to classical concepts in common sense patterns, in quantum physics teaching, we propose to strictly adhere to its mathematical formalism and develop the educational path within this disciplinary framework.

To that purpose, the didactic reconstruction of the contents has to make precise references to the theory and has to be able to address the most common, already known concepts of Newtonian Mechanics such that it can be recovered ad a limit case of the new theory. We believe that a rethinking of this kind is particularly useful for the teaching of quantum physics, both for its intrinsic potentiality, and because it can help also clarify many aspects related to key concepts of classical physics, highlighting non trivial connections and interpretations.

Our current comprehension of the physical world is given though QFT; in fact, QFT makes it relatively easy to introduce fundamental interactions, in a way that is by far much more quantitative and rich than is typically done (e.g. Feynman diagrams are often presented as a picture of what really happens at microscopic level, though in a completely qualitative form) (Organtini, 2011). QFT can also shed new light on concepts, like the concept of energy that, as we all know, are very difficult to understand. One of us, in fact, exploited this feature in providing a non metaphoric explanation of the Higgs mechanism that is suitable to be presented to high school students (Organtini, 2016).

In summary, we propose to face the difficult task of teaching quantum physics starting from the ideas and concepts rooted in QFT and to construct an educational reconstruction of some key aspects of classical physics precisely starting from them. A first basic list of concepts involved in QFT teaching are: field, state, creation and destruction operators, waves, scattering, evolution and probability. These are, therefore, in the proposed Milan-Rome approach, the concepts that should give us the guide-lines to lead to a simultaneous reconstruction of classical and quantum physics for educational purposes.

It is widely acknowledged today that an Inquiry-Based approach to Research and Innovation processes can improve the interest of students in studying scientific topics. Such approaches can enable students to have the opportunity to interact with cutting edge topics, research results and work with researchers and other societal actors to better align research processes and their outcomes with the values, needs and expectations of today's society. However, there is still no clear consensus between researchers about the impact that inquiry-based approaches have on the student scientific knowledge and conceptual understanding at different ages and cultural levels. This paper discusses these aspects from a vertical and interdisciplinary curriculum perspective. Firstly, the impact of a series of inquiry-based learning activities on the acquisition of scientific knowledge and in the development of pupils' positive attitudes toward science in pupils aged 10–13 is discussed. Secondly, a discussion on important pre-conditions needed for an introduction of cutting-edge topics to the classroom, and the role of the inquiry that has to be offered to students to effectively construct knowledge is considered at the pre-university level. Following this, an approach adopted by three large scale European projects (ESTABLISH, SAILS and OSOS) that focus on enhancing science education curricula, pedagogy and assessment practices and supporting science educators in embedding Inquiry-Based Education or Responsible Research and Innovation principles in science education is presented. Finally, an innovative Doctoral Degree in Sustainability Science, which seeks transformative education that challenges the attitudes of both professors and students is presented and some of its most relevant aspects are discussed.

Keywords: inquiry-based learning; responsible research and innovation; responsible citizenship.

INTRODUCTION

Inquiry-Based Science Education (IBSE) strategies have received considerable attention over the last several years and are often presented in the scientific literature (Hake, 1998; Sharma et al., 2010) as a credible solution to the reported lack of efficacy of more 'traditional' educative approaches. Inquiry-based learning strategies are credited to improve student understanding in many conceptual fields, due to their strongly contextualized nature, that focuses on the interdependence of situation and cognition. Many research project reports (e.g. IRRESISTIBLE, 2013; Ark of Inquiry, 2013) have also shown that an Inquiry-Based approach to Research and Innovation (RRI) processes (Sutcliffe, 2006) can improve the quality of student interest in scientific subjects, as students can be actively involved in studying cutting edge topics and research results and possibly in working together with researchers and other societal actors to better align both the research processes and their outcomes with the values, needs and expectations of today's society. Moreover, the EU Framework for Science Education for Responsible Citizenship calls on science educators to embed social, economic and ethical principles along with inquiry approaches into their science teaching and learning, at all levels, in order to prepare students for active citizenship.

However, some still remain skeptical about IBSE and RRI real efficacy. Although intensive research on effectiveness of inquiry-based teaching and learning has been carried out since 1980, there is still no wide consensus between researchers about the specific impact that using inquiry approaches on the increase of scientific knowledge and conceptual understanding. Also, more evidence is needed about how best to support in-service and pre-service teachers in embedding IBSE or RRI principles in science classroom, and to enhance science education curricula, pedagogy and assessment practices.

In this paper, we discuss these aspects from a vertical and interdisciplinary perspective in science education, discussing four different research studies. First, the impact of a series of inquiry-based learning activities on the acquisition of scientific knowledge and in the development of pupils' positive attitudes toward science in pupils aged 10–13 is discussed. Special attention is paid in this first study to medium-term retention of learning outcomes through inquiry. Three basic skills typical of IBSE are specifically targeted in this study: putting forward hypothesis, planning investigation and drawing conclusions. Then, a discussion on important pre-conditions and necessary steps needed for an introduction of cutting edge topics and new research findings to the classroom, and the role of the inquiry that has to be offered to students to effectively construct knowledge is done, together with some considerations on opportunities and challenges new findings in science bring to the science education at the pre-university level. Following this, an approach adopted by three large scale European projects (ESTABLISH, SAILS and OSOS) that focus on enhancing science education curricula, pedagogy and assessment practices and supporting science educators in embedding IBSE or Responsible Research and Innovation (RRI) principles in science education is presented. Particularly, the opportunities and challenges for integrating IBSE and RRI principles in science education are discussed using examples of classroom practices designed and implemented in these three projects. Finally, an innovative Doctoral Degree in Sustainability Science, which seeks transformative education that challenges the attitudes of both professors and students is presented. Main drivers include building a new body of interdisciplinary knowledge leading to the application of science to address real problems, and the integration of knowledge and innovation with the participation of society and citizens. Issues related to the involvement of students in a project work based on an inquiry perspective, and dealing with different dimensions are discussed, also in the aim to understand if this methodological approach is perceived by students as important to their learning as professionals and citizens.

RETENTION OF LEARNING THROUGH INQUIRY IN PUPILS AGED 10–13

Inquiry-based learning (IBL) occurs in repeated cycles of scientific investigation, and may be developed at different levels, related to different degrees of learner's dependence on teacher instruction, (e.g. Colburn 2000).Teaching through inquiry has been disseminated in science education for decades, yet the implementation of the method is not common in schools. Among many obstacles, teachers point out their concern about students' learning outcomes as measured by standard tests (Tan and Caleon 2016). Thus, ensuring the acquirement of basic knowledge through IBL seems to be one of the most important aspects determining the success of IBL implementation in a schooling system (Miner et al. 2009).
Although intensive research on effectiveness of teaching and learning through inquiry has been carried out since 1980s, there is still no consensus between researchers about the impact of teaching through inquiry on the increase of scientific knowledge, i.e. scientific investigation skills and content knowledge. Nevertheless, studies seem to confirm repeatedly that the effectiveness of learning through inquiry decreases with age (Hattie 2008). Also, quite common across different studies is the inference that IBL can be more effective than other instructional approaches provided that learners are supported and guided adequately (Lazonder and Harmsen 2016).
It is quite astonishing that rich spectrum of papers about research on impact of the inquiry-based approach on learning outcomes encompasses only a few studies in a medium and long term (e.g. Metz 2008), interesting and significant to teachers considering inclusion of IBL method in their teaching practice. Thus, to address this issue we proposed a 10-hour IBL implementation in ten classes of learners aged 10-13 during their science lessons and designed a research on retention of learning outcomes in a medium term (Sokolowska 2018).

Research method

The aim of the intervention was to implement a series of guided-inquiry activities and to investigate the effects of implementation on students' learning outcomes. Two rural and two urban schools were selected in a convenient neighborhood on the basis of they rank in official school ranking. Implementation of inquiry took place in all classes at the same time over 5-7 weeks. The IBL intervention involved altogether 170 students from ten classes. It was the first contact of learners with the method of teaching through inquiry. Each class was provided with ten lessons of guided inquiry, in which the teacher posed a problem to investigate and provided resources, and students planned investigation, conducted experiments, collected the data and drew research-based conclusions at the end.

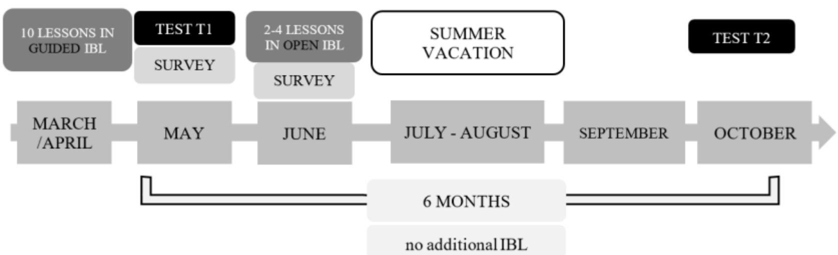

Figure 1. Research design schema for an investigation of the medium-term retention of learning outcomes acquired through guided IBL

The core instrument implemented in order to enable the measurement of learners' acquisition and retention of knowledge through guided-inquiry was the test T1 administered in April 2015, just after completing the series of the guided-inquiry lessons, and repeated as test T2 six months later (for research design schema, see Fig. 1). Three different tests were designed with respect to students' grade, all of them encompassed: multiple choice and open-ended questions, tasks involving reasoning and scientific inference, tasks requiring explanation of phenomena or observation, as well as one task of designing the experiment (consisting of putting forward the hypothesis, choosing adequate materials and tools, planning the investigation and drawing conclusions).

Results

In order to describe the change of an individual's learning gain in a medium term (6 months) we calculated the normalized change factor, c (Marx and Cummings, 2007). Mann-Whitney test (double-tailed) indicated no statistical significant difference in normalized change between boys ($c_{Mdn} = -0.079$) and girls ($c_{Mdn} = -0.086$) at the level of $p < 0.05$ (Sokolowska 2018). ANNOVA Kruskal-Wallis one-way analysis of variance by ranks, revealed no statistically significant difference of a normalized change across three ability groups, defined as: Level 1 (L1) – students with average scores below 70%, Level 2 (L2) – students with average scores of 70–80% and Level 3 (L3) – students achieving average scores above 80% in their regular science classes (Sokolowska 2018).
While studying solely the retention of three basic research skills: putting forward hypothesis, planning investigation and drawing conclusions, we found the two latter similarly difficult for learners, and the drop of planning skills as the only statistically significant change among these three research skills over the period of 6 months. Poor development of planning skills was confirmed by class observations and examination of students' worksheets, as well as answers given by students in Survey 1 and Survey 2.

INTRODUCTION OF NEW FINDINGS IN SCIENCE TO PRE-UNIVERSITY EDUCATION USING INQUIRY BASED LEARNING

Pre-university science is often considered as old and boring (Osborne, 2003), however scientists, pursuing new findings in laboratories and behind computers, have a diametrically opposite opinion. Physics, for example, is a vivid science with interesting challenges, full of surprises and beauty. Why such a difference in opinion? Several reasons were discussed, from a general public opinion that physics is very difficult and only very smart, but usually strange people, can understand it, to the modes of teaching focused on abstract calculations irrelevant for everyday life, and the rigid curricula that consider only topics more than hundred years old, an eternity from the standpoint of students.
Introduction of contemporary science to the pre-university classroom is very rare as we only found two examples beside ours (Garcia-Carmona, 2009; Pavlin 2013; Mandrikas, 2019). Nevertheless, we believe that front-end science can be, and has to be, introduced to students at the pre-university level, and its relevance for technology we meet every day has to be demonstrated. As new findings in science often consider phenomena not included to regular curriculum, the experimental inquiry type support providing preliminary experience through inquiry-based learning, is crucial.

New scientific Findings in pre-university education

Students nevertheless acquire some information on new findings through informal channels. But how extensive is this information? Around 400 students enroll to pre-service teacher studies at the Faculty of Education, University of Ljubljana, which include the pre- and primary school teachers' programs, art and STEM subjects trainings, and social and special education programs. Students come from groups with very different social status, abilities, personal motivations and interests and form a good representative sample for the population of students absolved the high school in general. To investigate the existing information on new findings, we chose five science topics: liquid crystals, hydrogels, biodiesel, gels and osmosis, and microwaves in anisotropic materials. The first-year students filled-in questionnaires which included a set of short questions on those topics allowing identification of the level of familiarity and knowledge related to them. Here we present more detailed analysis on two issues: familiarity with the name of the topic, and a self-assessed level of knowledge about it. The familiarity with the name was investigated by the yes/no question: Have you already heard about liquid crystals/hydrogels/...? Self-assessed knowledge offered more options for answering the question: How much do you know about liquid crystals/hydrogels/...? nothing/ very little/little/some. Results are given in Table 1 where we collected answers little and some to one category. Not surprising, the results evidently show that familiarity with the topics ends with the recognition of names, however the familiarity with the name provides the context.

Table 1. Self-assessed knowledge about contemporary topics. The questionnaire was filled in by N=257 first year students, age between 19 and 20. *The data for liquid crystals comes from a preliminary study with different participants (Pavlin, 2010).

Topic	I am familiar with the name [%]	I know little/some about the topic [%]
Liquid crystals*	33.0	5.2
Hydrogels	18.7	2.3
Microwaves	75.1	6.6
Polarization of light	55.6	6.6
Biofuels	88.4	11.6
Osmosis	90.9	24.9
Diffusion	90.9	23.2

Experiments in teaching units

To effectively introduce new findings in science to the pre-university education, a strong collaboration of active researchers, educators and teachers is needed. The researcher is the source of knowledge about a new topic, the educator finds appropriate places in the curriculum, analyses the role of the topic, together with the researcher adapts the topic to the cognitive level of students. Both also develop experiments to provide experience to students. The in-service teacher acts as a critical friend, who introduces the reality of the classroom to the team, and provides the "in-vivo" testing of newly developed units.

The experimental support for introduction of new findings is crucial. Very often, scientists that are invited to events aiming to popularization of science, prepare lectures, with a lot of nice photos and stories about discoveries, but the load of new information and the pace of the lecture does not allow a non-expert to develop an understanding. To avoid this, students have to experiment in person, in an inquiry way, which allows them to construct the new knowledge during the process. As an introduction of a new phenomenon usually meets an absence of preliminary knowledge, the inquiry provides the experience related to the unfamiliar topic. Although it is widely believed that laboratory equipment to teach new findings is not accessible to school, simplified qualitative experiments can be developed. Fig. 2 presents a few such experiments students meet during introduction of two topics: hydrogels and liquid crystals.

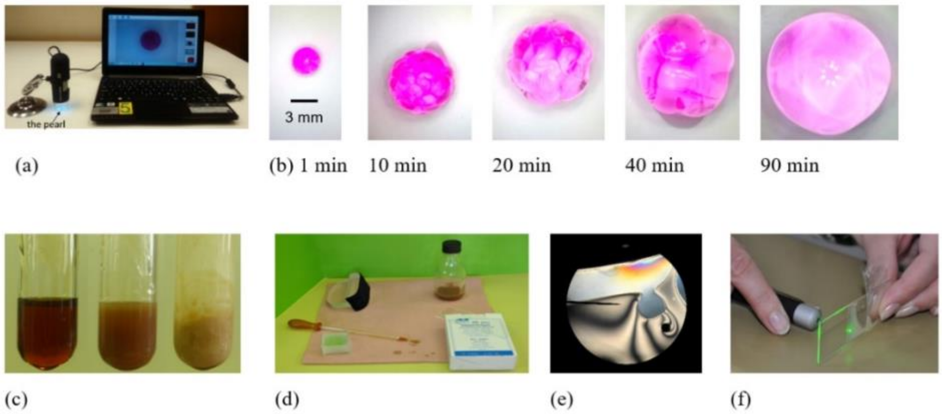

Figure 2. The growth of a hydrogel pearl observed under USB microscope. (a) The simple setup which allows for observation of hydrogel growth. (b) The shape of the surface changes drastically in time stimulating discussion and testing on possible reasons for the behaviour. (c) Three phases of a liquid crystal. (d) Equipment for making a cell for observation of liquid crystals (e) and propagation of light through them (f).

CHALLENGES AND OPPORTUNITIES FOR RETHINKING INQUIRY BASED SCIENCE EDUCATION

UNESCO's recent report "Rethinking Education: Towards a common global goal?" (UNESCO, 2018) reminds us that the changes that we face in the world today are characterized by new levels of complexity and contradiction. Today's citizens need a deeper understanding of global societal challenges and their implications for themselves, their families and their communities. This requires a broader vision of an active, engaged and responsible citizenship for the 21st century (Hazelkorn et al., 2015) and recommends that *"Science educators, at all levels, have a responsibility to embed social, economic and ethical principles into their teaching and learning in order to prepare students for active citizenship"* (Hazelkorn et al., 2015 p.35). In particular, this report advocates that "*education policies and systems should support schools, teachers, teacher educators and students of all ages to adopt an inquiry approach to science education as part of the core framework of science education for all*" (Hazelkorn et al., 2015 p.29). These objectives are further highlighted in the OECD Education 2030 framework which aims to build a common understanding of the knowledge, skills, attitudes and values necessary to shape the future towards 2030 (OECD, 2018). These reports highlight that in order to equip today's learners with agency and a sense of purpose, and the competencies they need, to shape their own lives and contribute to the lives of others requires changes to be made in science education curricula, pedagogy and assessment practices in the classroom. Over the past decade, several large-scale projects have focused on addressing these challenges and have supported teachers in adopting the principles of Inquiry-Based Science Education (IBSE) (Bevins and Price, 2016) and Responsible Research and Innovation (RRI) (Sutcliffe, 2006) in their classroom practices.

Methods

This research examines how IBSE and RRI are conceptualized and implemented across a diverse range of educational and cultural contexts under three large-scale European projects namely, ESTABLISH (2010), SAILS (2014) and OSOS (2017). The ESTABLISH (2010) and SAILS (2014) projects adopted an understanding of inquiry as the intentional process of

"diagnosing problems, critiquing experiments, and distinguishing alternatives, planning investigations, researching conjectures, searching for information, constructing models, debating with peers, and forming coherent arguments" (Linn, Davis & Bell, 2004). ESTABLISH (2010) designed a pedagogical framework for the development of IBSE units that were used to support teacher's use of inquiry based approaches in the second level science classroom. Each IBSE unit was presented over six parts: (1) Science topic; (2) IBSE character; (3) Pedagogical Content Knowledge; (4) Industrial Content Knowledge; (5) Learning Path(s) and (6) Student Learning Activities. A total of 18 IBSE units (with 281 learning activities) were developed across Physics, Chemistry, Biology and Integrated Science topics. SAILS (2014) presented a Framework for Inquiry and Assessment that addressed two key questions in science education: what to assess and how to assess? SAILS (2014) developed 19 Inquiry and Assessment Units that exemplified a range of strategies and tools to assess science inquiry skills. The SAILS units also included 93 case studies of service science teacher experiences of assessing inquiry learning in the science classroom. OSOS (2017) designed a framework that supported schools in embedding RRI principles and adopting an Open School Model to embed strategies that link education content to wider societal goals and engage learners to become responsible citizens. The Open School model supported student development of innovative and creative projects through a Feel, Imagine, Create and Share methodology (OSOS, 2017).
The research questions were: (1) How are IBSE and RRI (social, economic and ethical) principles conceptualized in science education and (2) What is the impact on teachers of using IBSE and RRI principles in the classroom? Data was collected from participating teachers in all three projects using questionnaires that had a combination of Likert scale and open response questions that were using at the start and end of the professional development programmes for science teachers.

Results

Analysis of science teacher's responses to questionnaires prior to participation in professional development programmes, revealed that teachers use of inquiry practices was low and some of the obstacles to their use of inquiry was "uncertainty of how to ask higher order questions that promotes thinking", "managing a classroom where each student group is doing different activities is difficult" and "feeling uncomfortable with teaching areas of science that I have limited knowledge of and of asking questions that I do not know the answer to" (N=458) (ESTABLISH, 2010). In general, the teachers that participated in the teacher education programmes of the ESTABLISH (N=2090) and SAILS (N=2500) projects, indicated increased understanding, attitudes and confidence of utilizing inquiry approaches. In addition, the SAILS approach strengthened teacher's assessment practices through developing their understanding of the role of assessment (SAILS, 2014). The SAILS approach exemplified how assessment practices can be embedded into inquiry lessons and illustrated a wide variety of assessment opportunities and /or assessment processes that are available to science teachers. Data from teachers that participated in OSOS project demonstrated how adopting RRI principles in science education promoted the development of strategies that link student learning (including knowledge, skills, attitudes and values) to wider societal goals and engaged learners in becoming responsible citizens (OSOS, 2017).

INQUIRY IN HIGHER EDUCATION: AN EXAMPLE OF CROSSING DISCIPLINARY KNOWLEDGE BOUNDARIES

The challenges which society faces are complex and multidimensional, leading to new paradigms associated with sustainability. To be promoters of change, the 21st century professionals must be endowed with solid scientific knowledge and, most importantly, must

hold the capacity to incorporate it in order to understand the interactions between global, natural, social and human systems, and how such interactions affect the sustainability contexts (UNESCO, 2015).
Societal challenges are complex and usually correspond to open questions that do not have neither a single answer nor unique explanations. In the search for a solution to socio-scientific problems, individuals are led to mobilize dialogical discourses, of a deliberative nature, in which they have to reason, criticize and justify, that is, they have to argue with the use of evidence. Hence, addressing sustainability clearly demands scientific literacy (understood in a comprehensive view of culture) to enable citizens to take and act in the defense of certain positions, in an informed and well-founded way (Bencze & Alsop, 2014; European Commission, 2015).
Building a new scientific area of Sustainability Science requires assimilation of knowledge and mastery of tools that are seldom addressed by individual disciplines and scientific areas with an integrated approach. Today, disciplinary science deeply contributes to understand the function of the various pieces that make up our world but has gaps in understanding how these parts relate to each other (Pellegrino & Hilton, 2012).
The required change to reach sustainability needs a responsive pedagogical model that is also attentive to the transition to new forms of skill acquisition and knowledge-building. The Doctoral Degree in Sustainability Science addresses this challenge by offering an innovative program which seeks transformative education that challenges the attitudes of both professors and students, combining a multidisciplinary composition of its Faculty members, gathering a wide range of disciplinary knowledge committed with a shared responsibility between natural sciences and social sciences in the coordination, organization and teaching of each curricular unit and in thesis supervision. This is a collaborative experience that relies on sharing all the class materials and establishing a bidirectional permanent work channel between students and professors through an ITC e-learning platform. Taking as an example the organization of four multidisciplinary thematic curricular units, we created an inquiry scenario, using a local multidimensional context, and the students, working in groups, should contribute to solve real and contemporary problems. Curricular units were paired according to common underlying themes to cope with a same starting point, so the results here presented relate to two project work problems. Contributing to take urgent action to mitigate climate change and its impacts framed the question addressed under the scope of the first pair of curricular units. Organizations should be aware of the implications of reducing their greenhouse gas emissions and in a scenario of need to reduce emissions by 2/3 of today's levels, students were challenged to work on a multilevel explanation model for the problem and to present a critical proposal for an adaptation program for the primary sector in the specific ecosystem of the Tagus "Lezírias". The problem addressed collectively while working the second pair of curricular units was to devise a city-wide planning model for the scenario of an inter-municipality agreement in the Lisbon metropolitan region that determines supplying public organism cafeterias with at least 60% of products with proximity origin.

Methods

This research intends to understand if the PhD students involved in a project work, based on an inquiry perspective, dealing with different dimensions, offers contribution to solve a problem on sustainability; and also to understand if this methodological approach is perceived as important to their learning as professionals and citizens. We worked with 14 doctoral students with different academic backgrounds that are simultaneously working as consultants, experts in environmental institutions, or on their own businesses. These students were organized in five groups, each one responsible for researching two specific dimensions per work, which are part of the real problem to be solved. The dimensions involved were: a) Technologies and innovation; b) Economics, management and marketing; c) Social practices; d) Policies, institutions and governance; e) Human and environmental health. Ethics and values dimension was transversally addressed.

The research questions were: 1) To understand the potentialities and advantages of following project work, based on an inquiry perspective, in trying to solve a real and multidisciplinary problem; 2) To understand the difficulties experienced by students with this type of methodology; 3) To understand the students' opinion concerning the potentialities and advantages or the drawbacks of project work methodology to their professional and personal development; and 4) To understand the perceived trade-offs of working a limited number of dimensions and therefore relying on the colleagues' complementary work to reach the wider perspective that contributes to a result.

Data were collected by direct observation of the working sessions, a questionnaire applied to the students at the end of the units, and individual reflections. Additionally, the evaluation of the final work of the groups was based on several rubrics created for the assessment of the oral presentation and written work. These rubrics were discussed with students and teachers from the beginning of the course.

Results

The Sustainability Science Doctoral Course was designed to progress stepwise in two main phases. In the first phase, curricular unit syllabus and teaching are multidisciplinary although an environment that prompts interdisciplinary thinking among students is promoted. During the course preparation, all professors were very enthusiastic in developing the curricular units using collective and participatory rounds of debate with colleagues with distinct academic backgrounds, ranging from natural/exact sciences to humanities/social sciences, which resulted in final syllabus that can hardly be connected with a specific disciplinary knowledge domain. Equally, during the first edition, all professors were fully engaged with the pedagogical model assumed and were active on preparing extended summaries and selected core materials to frame their topics, and producing dedicated e-learning materials, including professional video recording of short lessons. All materials were made available in the ICT e-learning platform to which students were granted access one week before the corresponding session. Field visits related to project work problems were organized and were successful in joining a multidisciplinary group of professors. Most importantly, "in class" sessions took always place with the simultaneous participation of, at least, three professors with distinct knowledge backgrounds and academic competencies, resulting in debates that successfully challenged concept and methodological confrontations. Evaluation of project works through a methodology rooted in individual evaluation by professors from distinct disciplinary areas followed by discussions to reach consensus grades showed great potential to pave the way for their interdisciplinary thinking.

DISCUSSION

The implementation of IBL method in science classes of 10-13 year old learners discussed in the first research we present here resulted in achievement of learning outcomes similar to the learners' prior accomplishments with use of standard teaching approaches. Examination of scores achieved in test T1 revealed that guided IBL approach did not favor any gender. The method also retained the students' belonging to the ability groups: L1, L2, L3. At the same time medium-term retention of learning achievement, studied as comparison of scores in test T1 and T2, with use of a normalized change revealed high retention of learning over the span

of six months after the guided-inquiry intervention and showed no statistically significant difference between genders and between different ability groups thus confirming effectiveness of IBL approach and its sustainability for learning outcomes. Observation of students during IBL implementation and examination of their worksheets revealed their extreme difficulties in designing a plan of investigation, subsequently confirmed also by the results in T1 and T2. Instead of writing a strict plan, students rather applied a trial-and-error approach when conducting the experiments. Thus, we conclude that at age 10-13 it is unnatural to learners to stop in the middle of inquiry process and write a rigorous plan before conducting an experiment. In order to secure development of planning skills and at the same time – to preserve learners' active involvement in inquiry approach, it would be more adequate and efficient to let them do investigation first and ask them to design a coherent investigation plan afterwards.
In the second research here described, we showed how a coherent investigation plan on innovative topics, including also "Modern Physics", at pre-university level can be fostered by Inquiry-Based Learning approaches, discussing the role of hands-on and minds-on experiments supporting learning. Introduction of such topics faces several challenges from absence of teachers' knowledge to the lack of materials adapted to the proper cognitive level. Here we discussed the test of units on liquid crystals and hydrogels. Students learned the basics (Pavlin, 2013), and were enthusiastic about meeting a new contemporary topic. However, to study the role and effect of inclusion of contemporary science to the pre-university level, more tested units are needed. Nevertheless, we demonstrate that such introduction is possible. As students' knowledge about new findings in science opens a new perspective to science as a relevant subject with a vivid research, the new knowledge may stimulate the awareness of the impact science might have on the society as whole.
Bevins and Price (2016) argue that many models of inquiry are limited and that a more integrated three-dimensional approach that depends on conceptual, procedural and personal learning is required, that is more likely to promote effective learning and a willingness to engage in science. The third research described here helps us to conceptualize IBSE and RRI in diverse science education contexts, under three large-scale EU projects, ESTABLISH (2010), SAILS (2014) and OSOS (2017). The combined learning arising from these three projects are:

(1) Learning science through inquiry can result in better understanding and more broadly applicable scientific knowledge along with the development of transferable skills and competencies.
(2) Many models of IBSE exist, so it is important to adopt an approach that achieves learning outcomes in terms of knowledge, skills, attitudes & values.
(3) Teaching and assessment need to be considered as a dynamic and iterative process so as effectively support IBSE.
(4) Sustained collaboration is crucial in science education – between teachers and educators and across borders, both classrooms and countries.
(5) Schools need to be facilitated to act as shared sites of science learning for which leaders, teachers and the local community share responsibility for embedding social, economic and ethical principles into science education in order to prepare students for active citizenship.

This study highlights the importance of examining how IBSE and RRI are conceptualized and implemented in science education in order to bridge the gap between science education research, educational practices and the varied perceptions of teachers, students, parents and other stakeholders in science education.
The results of the last research here presented clearly show how an Inquiry-Based approach can foster an unifying view of science, at doctoral level. The dynamic and fruitful collaboration that can be achieved when common objectives are planned and pursued in a Sustainability

Science Doctoral Course, and the great potentialities of inquiry perspective in trying to solve a real problem are discussed. Students ' proposals were realistic and viable and were complementary enough to contribute to collectively respond to the global problem. The use of approaches from different areas of knowledge was clear and the project methodology was well understood by the students. Some difficulties concerning team work and information management were observed, particularly during the first work, but significant improvements were attained when the groups addressed the second problem. Students considered the experience to be very rewarding in terms of learning, concerning both the thematic areas and the methodological process, contributing very positively to their personal and professional valorization.

ATOMIC STRUCTURE - THE EFFECTS OF TWO COGNITIVE FACTORS ON SECONDARY STUDENTS' UNDERSTANDING OF THE 'ORBITAL' AND 'ELECTRON CLOUD' CONCEPTS

Nikolaos Zarkadis, George Papageorgiou and Angelos Markos
Democritus University of Thrace, Alexandroupolis, Greece,

The study investigates the role of students' understanding of 'orbital' and 'electron cloud' concepts in the representation of the atomic structure, as well as the effects of the curriculum and the cognitive factors of formal reasoning and filed dependence/independence on such an understanding. Participants were 127 secondary students (grade 12, age 17-18) from Northern Greece. Results show that the quantum approach of the atomic structure prerequisites the conceptualization of the 'electron cloud' and 'orbital' concepts through an appropriate curriculum when students have developed high levels of formal reasoning.

Keywords: Cognitive skills, Mental Models, Conceptual Understanding

INTRODUCTION

Understanding atomic structure through the quantum approach is one of the ultimate targets for science teachers of secondary or even tertiary education. However, such an approach is characterized by a number of difficulties referring to several quantum concepts (e.g. Nakiboglou, 2003; Park & Light, 2009; Emigh et al., 2015). The concepts of 'orbital' and 'electron cloud' are included in such a quantum approach, having as prerequisites the understanding of concepts like 'wave function' and 'probability density' (Emigh et al., 2015) and 'probability' and 'energy quantization' (Park & Light, 2009). However, students have difficulties in understanding such concepts and often conflate characteristics of different models (e.g. Papaphotis & Tsaparlis, 2008; Park & Light, 2009; Tsaparlis & Papaphotis, 2009; Kiray, 2016; Zarkadis et al., 2017; Allred & Bretz, 2019). Since students quantum model ideas are often influenced by the Bohr model ideas, different shapes of orbitals are represented as orbits of different shapes in the Bohr model context (e.g. Park & Light, 2009; Kiray, 2016) or orbitals are represented as a set path of electrons (Park & Light, 2009; Muniz et al., 2018) without understanding energy quantization. On the other hand, some students adopt quantum terms such as the 'orbital' concept to describe the orbit around nucleus in a Bohr model representation (Allred & Bretz, 2019), whereas they have difficulties in distinguishing concepts such as 'orbital', 'shell', 'sub-shell' and 'energy level' (e.g. Taber, 2002). Also, they often identify orbitals as a region (of/in space) where there is a (high) probability for an electron to be found or, where the electrons can move (e.g. Cervellati & Perugini, 1981; Taber, 2002; Nakiboglu, 2003; Stefani & Tsaparlis, 2009; Allred & Bretz, 2019; di Uccio et al., 2019).

In addition, the 'orbital' concept is often confused with the 'probability' concept, since an atomic orbital is defined as the probability of finding an electron (Stefani & Tsaparlis, 2009). Also, orbitals are confused with visual representations of probability envelopes (Taber, 2002) or they are seen as clouds of specific shape (Stefani & Tsaparlis, 2009).

Students often have difficulties in understanding the 'electron cloud' concept, which for some, it seems to be synonymous with the 'orbital' or the 'energy level' concepts (e.g. Allred & Bretz, 2019). The influence of Bohr model is also evident, since students confuse the 'electron cloud' with the concept of a 'shell' (Harrison & Treagust, 2000) and represent electron clouds moving on specific orbits (Tsaparlis & Papaphotis, 2009). Some students represent an orbiting electron cloud (Papahotis & Tsaparlis, 2008), while others represent an *Electronium orbit model,* where certain orbits are depicted around nucleus as nebula due to electrons' very fast rotational movement (Kiray, 2016).

For some students dots of the *electron probability representation* are interpreted either as places where the electron could be or the location of electrons over time, or even as multiple particles (Allred & Bretz, 2019), whereas for some others the electrons are considered as particles represented as dots moving in a circular orbit or a nebulous around the nucleus (Kiray, 2016) indicating a *probability model*. The 'electron cloud' is also considered as concrete concept, since students confuse it with the cloud in the sky (e.g. Harrison & Treagust, 1996; Kiray 2016) or they believe that electron clouds contain electrons (e.g. Harrison & Treagust, 1996; Zarkadis et al., 2017).

However, the understanding of concepts such 'electron cloud' and 'orbital' and the abolishment of the deterministic/mechanistic approach prerequisite the understanding of the 'quantum level' and the development of the visualization/representational abilities (Dangur et al., 2014) and abilities reported as 'high level of abstract thinking' (Cokelez, 2012), high-order cognitive skills (HOCS) (e.g. Zoller & Tsaparlis, 1997) or 'post-formal operations' (e.g. Castro & Fernández, 1987). Since students' mental models' complexity concerning the atomic structure range from the most concrete to the most abstract, it could be considered that students could be also affected by a number of cognitive factors. Individual differences such as *Formal Reasoning (FR)* and *Field Dependence/Independence (FDI)* have been found to be significant predictors of student performance in understanding the particulate nature of matter (Stamovlasis & Papageorgiou, 2012; Tsitsipis et al., 2012), the concept of chemical change (Kypraios et al., 2014) and the atom and its structure (Papageorgiou et al., 2016a, 2016b). However, to our knowledge, no study has investigated the effect of these cognitive factors on students' understanding of specific quantum concepts, such as the 'orbital' and 'electron cloud'. Therefore, it seems quite interesting to investigate the effects of FR on students' understanding of the 'orbital' and 'electron cloud' concepts.

Taken also into account that students' representations of the atomic structure are affected by students cohort characteristics and cognitive factors such as formal reasoning and filed dependence/independence (Papageorgiou et al., 2016a), it was considered as important to investigate the role of students' understanding of 'orbital' and 'electron cloud' in the representation of the atomic structure, as well as the effect of cognitive factors and student cohort characteristics on such an understanding.

RESEARCH QUESTIONS

The present study took place in the context of a wider piece of research targeting students' ideas on the atom and its structure, parts of it have been already published (Papageorgiou et al., 2016a, 2016b). Research questions were:

1. What are the effects of formal reasoning and field dependence-independence on students' understanding of 'orbital' and 'electron cloud', considering their cohort characteristics?

2. To what extent students' understanding of the 'orbital' and 'electron cloud' concepts and possible relevant misconceptions affect students' representations of the atomic structure?

METHODOLOGY

Subjects and Procedure

The present study involves two student cohorts of 127 (in total) voluntary secondary students (grade 12, age 17-18) from Northern Greece. The first cohort comprised of 82 students of the 'technological direction' (TD) and the second, 45 students of the 'science and math direction' (SMD). SMD students were taught more in-depth the quantum mechanical model and related concepts, whereas TD students were taught more in-depth the Bohr model and related concepts. Data were collected during the last semester of the school year through anonymous paper-and-pencil tests for the two cognitive variables and the atomic structure.

Instruments

Students' ability of *Formal Reasoning (FR)* was measured on the basis of the Lawson paper-and-pencil test (Lawson, 1978) lasted 45 min. The test consisted of 15 items dealing with conservation of mass, displaced volume, control of variable), proportional reasoning, combinational reasoning and probabilistic reasoning. A satisfactory internal consistency was found with a Cronbach's alpha of 0.77.

The ability of *Field Dependence/Independence (FDI)* was measured on the basis of the Group Embedded Figures Test (Witkin et al., 1971) lasted 20 min, where students had to dissembled simple figures incorporated in twenty complex ones. Cronbach's alpha reliability coefficient was found to be 0.84.

Students' understanding of the 'orbital' and 'electron cloud' was measured along with their representations of the atomic structure through a paper-and-pencil test especially designed for the piece of research targeting students' ideas on the atom and its structure (45 min duration). Tasks concerning the present study are presented in Table 1. Internal consistency reliability was found acceptable, with a Cronbach's alpha of 0.62.

Table 1. Description of the tasks.

Tasks	Description of the tasks

1	Students were asked to draw and describe the 'atom', if they could observe it through a 'powerful microscope'
2	Students were asked to describe the concept of 'electron cloud' on the basis of what they know or imagine
3	Students were asked to describe the concept of 'orbital' and its relation τo the 'electron cloud'

RESULTS

Students' representations of task 1 were categorized in five general categories of students' mental models as reported in Papageorgiou et al. (2016a): Category A: the *'atom-cell model'*, Category B: the *'particle model'*, Category C: *'nuclear model'*, Category D: the *'Bohr's model'*, Category E: *'quantum model'*.

Table 2. Distribution of students' representations of the atomic structure in tasks1

Cohort	Categories of students' representations											
	«A»		«B»		«C»		«D»		«E»		Missing	
	N	%	N	%	N	%	N	%	N	%	N	%
«TD»	1	1,2	16	19,5	19	23,2	45	54,9	1	1,2	0	0,0
«SMD»	0	0,0	1	2,2	11	24,4	27	60,0	6	13,3	0	0,0

Students (TD and SMD) represented the atomic structure according to *Bohr's* model, reaching high percentages in task 1 (54,9%, 45 students and 60,0%, 27 students, respectively), as shown in Table 2. In task 1, quantum model reached a percentage of 13,3% for the SMD students when only 1,2% for the TD students.

Students' responses to tasks 2 and 3 were categorized in four levels of understanding (LU), taking into account similar categorization schemes (e.g. Nakiboglu, 2003) and is presented below as Table 2.

Table 2. Levels of understanding with the corresponding criteria

LU	Criteria
SA	Responses containing ideas which are all scientifically accepted.
PA	Responses containing incomplete reference to scientific view or coexistence of alternative ideas and scientific view
M	Responses containing alternative ideas/ significant misconceptions
NU	Unclear or wrong responses - No responses

Note. SA = Scientifically Accepted, PA = Partially Accepted, M = Misconception, NU = No Understanding

Only few SMD students provided scientifically accepted responses in task 3 (Table 3), where the electron cloud concept is presented in terms of electron probability density (11.1%, 5 students). The results also show a coexistence of alternative ideas and scientific view in SMD responses, since 'electron cloud' is defined as a region where the electron can move or be found, or as a result of electron's high speed, including however the concept of probability in a hybrid model (17.8%, 8 SMD students). According to Table 3, 53.5% of SMD and 40.3% of TD students, respectively, showed misconceptions, where 40.2% of the SMD and 25.6% of the TD students described the electron cloud as a region of space in an atom, where the electron can move or can be found. In addition approximately 11% (both SMD and TD students) affected by the Bohr's model showing a group of electrons (as a cloud) moving in orbits around the nucleus.

Table 3. Distribution of students into the levels of understanding concerning the 'Electron Cloud' concept

Students levels of understanding and corresponding categories of responses	(SMD) N(%)	(TD) N(%)
A. Sound Understanding	5 (11.1)	-
The density of the 'Electron Cloud' defines the probability of finding an electron in a (certain) position	5(11.1)	-
B. Partial Understanding	8(17.8)	-
1. 'Electron Cloud' is something created (probabilistically) by the electron high speed motion, reflecting possible positions	4(8.9)	1(1.2)
2.'Electron Cloud' is the region where the electron has a high probability to be found.	4(8.9)	1(1.2)
C. Misconceptions	24(53.5)	33(40.3)
1. The space/region/points where the electron can move or be found/accumulated, having the shape of a cloud	18(40.2)	21(25.6)
2. A group of electrons / a cloud moving in orbits around the nucleus	5(11.1)	9(11.0)
3. The orbit/ shell where the electron moves	1(2.2)	3(3.7)
D. No Understanding	8(17.8)	47(57.3)
Total	45(100.0)	82(100.0)

Similarly to the findings concerning the electron cloud concept, only few SMD students provided scientifically accepted responses in task 3 (Table 4), where the orbital concept is presented in terms of probability and wave function concepts (11.1%, 5 students). In agreement with the results for the 'electron cloud' concept it is identified the co-existence of alternative ideas and scientific view in SMD responses, since the 'orbital' is defined as a region where the electron can be found, including however the probability and wave function concepts in a hybrid model (46.6%, 21 students). According to Table 4, 24.3% of SMD and 34.1% of TD students, respectively, showed misconceptions, where orbitals were confused either with other concepts such as 'subshell', 'probability' and 'electron cloud' or they considered as fixed positions or regions of space in an atom where the electron can be found. Students were also affected by the Bohr's model showing an 'orbital' as 'orbit' or 'shell' (8.9%, 4 SMD students and 28.1%, 23 TD students).

Table 4. Distribution of students into the levels of understanding concerning the 'orbital' concept

Students levels of understanding and corresponding categories of responses	(SMD) N(%)	(TD) N(%)
A. Sound Understanding	5 (11.1)	-
Orbitals are solutions of the Schrödinger equation/wave functions, defining the probability of finding an electron in a position – No physical meaning	5(11.1)	-
B. Partial Understanding	21(46.8)	2(2.4)
Orbitals, as solutions of the Schrödinger equation/wave functions, determine the regions where the electron can be found	21(46.8)	2(2.4)
C. Misconceptions: alternative ideas - significant misconceptions	11(24.3)	28(34.1)
1. The orbitals are the subshells s, p, d, f	2(4.4)	-
2. An orbital is the probability of finding an electron in a certain position	2(4.4)	-

3. The orbitals are fixed positions/coordinates/regions, where the electron can be found	2(4.4)	3(3.6)
4. An orbital is similar to an electron cloud concept	1(2.2)	2(2.4)
5. The orbitals are imaginary 2D circles/orbits/shells	4(8.9)	23(28.1)
D. No Understanding	8(17.8)	52(63.5)
Total	45(100.0)	82(100.0)

In response to the first research question, a Categorical Regression Analysis took place with the three tasks as dependent variables and the two cognitive factors and student cohort as independent (Table 5). FR was found to have a statistically significant effect on student performance in tasks 1, 2 and 3, over and above the effect of curriculum. The effect of the cohort (which is related to the corresponding curriculum) was also found significant, especially in task 3. The effects of FDI were not significant.

As for the second research question, Chi-square tests showed significant relationship between student performance in tasks 1 and 2 ($\chi^2(12) = 41.369$, $p < 0.001$, Cramer's $V = 0.33$) and a weaker but also significant relationship between student performance in tasks 1 and 3 ($\chi^2(12) = 21.858$, $p = 0.039$, Cramer's $V = 0.24$). Crosstabulation also showed that, the more complex the representation, moving from model A to E in task 1, the more likely it is to have a higher level of understanding in tasks 2 and 3 (and vice versa).

Table 5. Results of Categorical Regression Analysis

Task	Factor	*Beta*	*df*	*F*	*p*	*Adj. R^2*
1	FR	.308	2	8.029	.001	23.2%
	FDI	.099	3	.456	.714	
	Cohort	-.244	1	9.043	.003	
2	FR	.236	4	5.876	<.001	28.9%
	FDI	-.199	3	1.498	.219	
	Cohort	-.442	1	19.293	<.001	
3	FR	.269	2	9.523	<.001	49.2%
	FDI	.060	2	.181	.835	
	Cohort	-.629	1	75.452	<.001	

Note. FR = Formal Reasoning, FDI = Field Dependence-Independence, *Beta* = Standardized beta coefficient

DISCUSSION AND CONCLUSIONS

Taking into account the effect of curriculum (cohort), as well as the significant relationship between student performance in task 1 and those in tasks 2 and 3 respectively, it seems that quantum approach of the atomic structure prerequisites the conceptualization of the 'electron cloud' and 'orbital' concepts through an appropriate curriculum that is designed for students' ages/grades having possibly acquired abstract thinking and high-order cognitive skills.

As for the individual differences, although visualization abilities are reported to be important for their understanding (Dangur et al., 2014), the effects of FDI were not found significant. However, the effect of FR was found to be significant and since the understanding of such abstract concepts requires a high level of visual-spatial thinking (Wang & Barrow, 2013), it may be interesting to investigate possible effects of other main components of spatial ability, such as spatial visualization and spatial orientation on the understanding of both atom representations and orbital and electron cloud concepts. Since spatial orientation of orbitals requires visualization and mental manipulation in 2D or 3D (Coleman & Gotch, 1998), it is essential to integrate them by multiple visual representations within appropriate teaching contexts. Integration of visual representations (visual-conceptual approach) could possibly promote students' learning of quantum concepts (e.g. Kalkanis et al., 2003; Dangur et al., 2014) by facilitating them in order to make connections among multiple graphical representations acquiring critical representational competences (Rau, 2015).

Although developmental factors, like formal reasoning, seem to play always an important role in the learning process, having a significant effect on students' representations of the atom and also on the electron cloud and orbital concepts, the success of the learning process is actually defined by the role of the teacher and the curricula designers. A science curriculum that takes into account student cohort characteristics and individual differences can provide opportunities for appropriate teaching methodologies in order to have a more effective teaching of these concepts.

DRAWING MENTAL MODELS OF STATIC ELECTRICITY: WHAT WE CAN GAIN

Constantina Stefanidou[1], Anastasia Ferentinou[2] and Konstantina Tsalapati[1]
[1]National and Kapodistrian University of Athens, Athens, Greece
[2]University of Thessaly, Volos, Greece

The interpretations of static electricity phenomena are not obvious, even in higher education. This study was conducted to investigate to what extent could model-based structured inquiries develop prospective teachers' conceptual understanding of static electricity phenomena; friction and contact electricity as well as conductors' and insulators' properties. Learners' drawings of mental models were progressively developed towards more accurate teaching models of the corresponding microscopic procedures. Sixty-eight prospective primary teachers conducted electrostatic experiments focused on different types of electricity, in the context of an Introductory Physics Laboratory Course. The data collected through their worksheets. Qualitative content analysis method and descriptive statistics were used. The analysis showed that learners can surpass their conceptual difficulties regarding static electricity and incorporate complete explanations in their written answers. The proposed teaching models allowed learners to develop adequate explanations including microscopic procedures, such as the electrons' transfer during friction electricity and the different role of electrons in conductors and insulators. The findings implied emphasis on microscopic models during the macroscopic experimental processes.

Keywords: model-based learning, inquiry-based teaching

INTRODUCTION

It is argued that a central role for models and modelling would greatly increase the authenticity of the science curriculum. Models are essential to the production, dissemination and acceptance of scientific knowledge (Gilbert, 2004). Linus Pauling, a two Nobel prizes recipient, once remarked: "The greatest value of models is their contribution to the process of originated new ideas". Scientific models evolve through the processes of scientific inquiry and discourse and can be sophisticated and highly abstract. School science as a curriculum subject represents science to learners and in this process of representation, the models of science become transformed (Justi & Gilbert, 2000). Curriculum models are simplified versions of scientific knowledge which are prescribed as target knowledge for learners at an education level. Teachers use teaching models that may be further simplifications such as standard diagrams, simple physical models, teaching analogies and so forth (Gilbert, Jong, Justi, Treagust, & Driel, 2003) and range from those representing phenomena in the observable macroscopic world to those representing the theoretical entities conjectured to exist at submicroscopic levels and from very simple to intellectually highly challenging ones (Abdo & Taber, 2009).

The study of mental representations constructed by students in their interactions with the world, its phenomena and artefacts, constitutes an important line of research in science education. The main role of a mental model is to allow its builder to explain and make predictions about the physical system represented by it. It must be functional to the person who constructs it, internal, personal, and idiosyncratic (Greca & Moreira, 2000). Teachers try to have their students construct mental models that are coherent with the teaching models and the shared theories presented in the class. In many schools, students draw molecules, cells, waves, planets and other science concepts as part of a dynamic instructional method called drawing mental models (Duit & Glynn, 1996). This method opens windows into students' minds allowing teachers to examine students' mental models of science concepts. Students' initial mental models are simple representations of a concept, but as students learn more, their mental models evolve and become more sophisticated. One advantage of this method is that students' development of understanding can be traced by having them create a series of mental models over a period. Drawing mental models can benefit students in all science disciplines because the process helps students consolidate information about a concept and identify any misconceptions. Considerable research has revealed how individuals update their mental models as they encounter new information (Rapp, 2005). Students' engagement with scientific inquiry and model construction and revision seem to be promising toward achieving progress in science classrooms (Khan, 2007). Therefore, the study aims to investigate to what extent could model-based structured inquiries that focus on microscopic procedures, develop prospective teachers' conceptual understanding of static electricity phenomena; friction and contact electricity as well as conductors' and insulators' properties. This study was conducted in the context of broader research in progress.

METHODOLOGY

This study follows a qualitative descriptive cross-sectional research approach. Qualitative content analysis method (Mayring, 2000) and descriptive statistics were used (e.g. frequencies) to quantify the findings and present a clearer picture of students' conceptual understanding (Gay, Mills, & Airasian, 2012). Fieldwork was carried out at the Department of Primary Education, of the National and Kapodistrian University of Athens, during the winter semester of 2018-19. The sample consisted of 68 second-year university prospective primary teachers (learners) who undertook the Introductory Physics Laboratory Course (IPLC) and were selected due to convenient access. All learners completed individual worksheets as part of their final assessment (response rate 100%). As a result, for this study 68 worksheets were collected and analyzed.

Learners were divided into three classes of 16 persons and one class of 20 persons whose members worked in pairs. The IPLC comprised of five rotation independent two-hour laboratory exercises once a week: 1) taking measurements, 2) mechanics, 3) optics, 4) static electricity, and 5) heat.

In static electricity, the teaching-learning sequence included three experiments. The first experiment was about friction electricity and particularly the phenomenon of rubbing a glass rod with a piece of wool. The second experiment was about contact electricity and particularly the phenomenon of touching the metal disc of the electroscope with the charged rod. The third experiment had to do with differences between inductors and insulators focusing on the different phenomena of touching the metal disc of an electroscope with either the rubbed end of a glass rod (insulator) or the other end and either the rubbed side of the metal cylinder or the other side.

All phenomena were approached in an inquiry-based teaching context (Pedaste et al, 2015). At first, prospective teachers were asked to propose a hypothesis about a phenomenon and its explanation, then they conducted the experiment and drew their *mental* models to explain the phenomenon observed. Subsequently, learners were provided with the corresponding *teaching* models which represented the microscopic procedures under consideration (e.g. PhET Colorado). At this point, they had to compare their drawings to the *teaching* models and discussed their findings with the tutors. Finally, they were asked to write in detail their improved explanation. The tutors highlighted the limits of the *teaching* models, to prevent learners' from developing new misconceptions.

Regarding contact electricity, prospective teachers had to make a hypothesis about what would happen if an electrified glass rod touched the metal disc of the electroscope. Experimentation followed (Fig.1). Prospective teachers were asked to draw their mental models explaining the phenomenon (Fig.2). Just after that, prospective teachers were asked to compare the *mental* models with the *teaching* models, provided by the tutor (Fig.3).

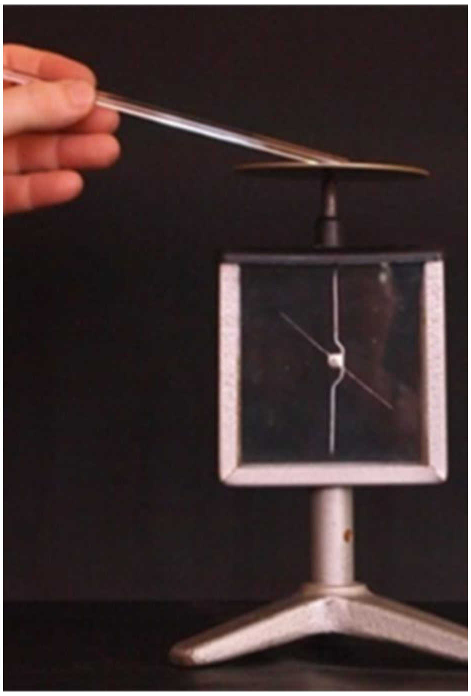

Figure 1. Contact electricity experiment

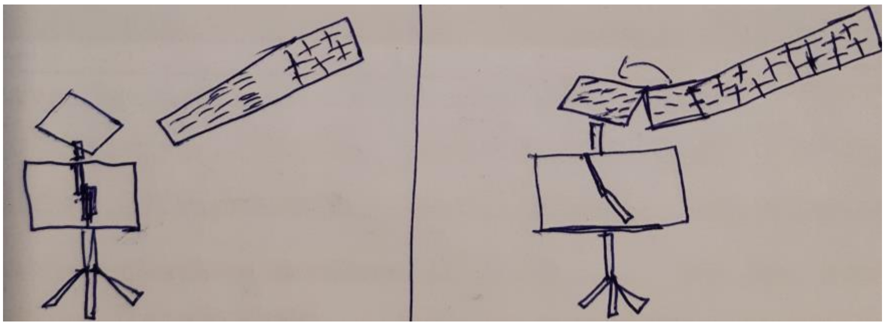

Figure 2. Contact electricity *mental* models

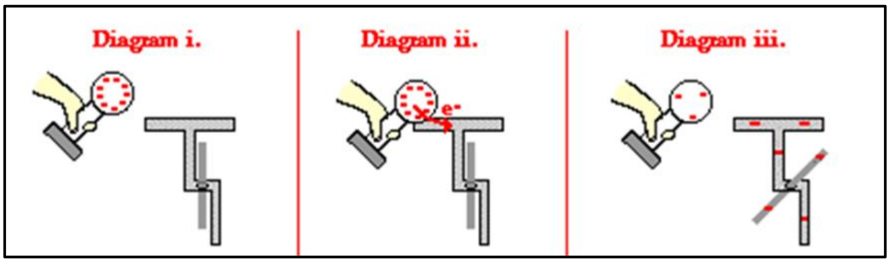

Figure 3. Contact *electricity* teaching models (Physics Tutorial:Charging by Conduction, n.d)

RESULTS

The analysis of the data indicated that the combination of learners' drawings and corresponding *teaching* models of microscopic procedures contributed to the construction and development of a meaningful conceptual understanding of static electricity phenomena. More specifically, regarding friction electricity, during the hypothesis phase 57% of learners attributed friction electricity to electrons transfer, whereas at the end of the teaching-learning sequence, the corresponding percentage increased to 95% (Fig.4). In contact electricity, learners were asked to express their opinion on what could happen if an electrified plastic ruler was in contact with the metal disc of an electroscope. Most learners (59%) stated that the electroscope's plates would open but they could not either write or draw the explanation of why this would happen. After the integration of the teaching models, 87% of learners explained completely the phenomenon referring to electrons transfer from one object to another. In the case of a positively charged object which got in touch with a neutral object, 56% provided a complete answer using the law of conservation of charge while 31% described the mechanism of electron transfer with no reference to the law (Fig. 5).

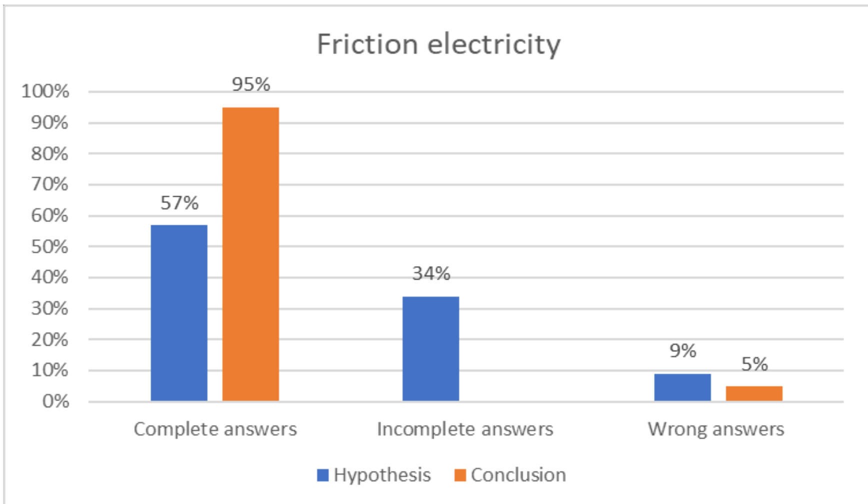

Figure 4. Learners' explanations of friction electricity

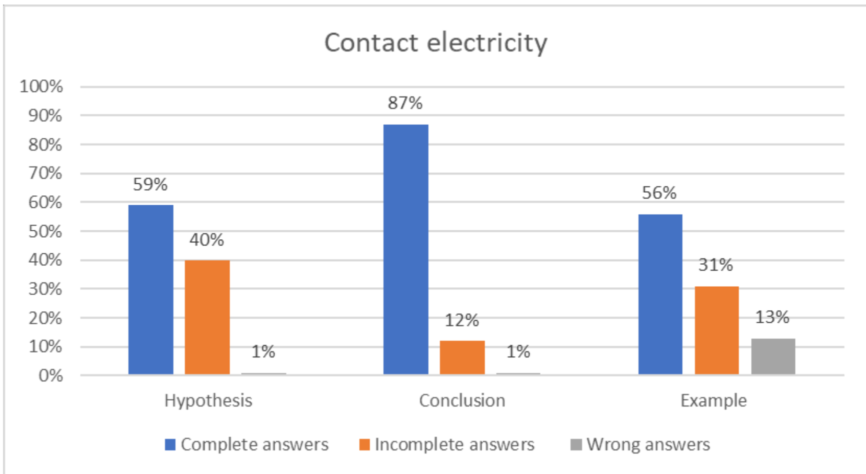

Figure 5. Learners' explanations of contact electricity

Regarding conductors' and insulators' properties, 74% predicted conductors' behavior and 62% insulators' behavior but they could not provide explanations in microscopic level. When learners draw their models and compared them to the corresponding *teaching* models, they gave appropriate answers based on the different role of electrons in conductors and insulators (Fig. 6).

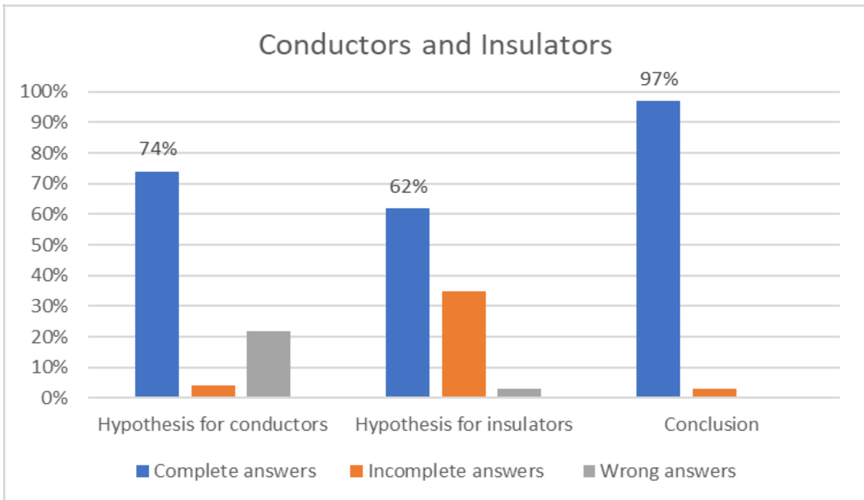

Figure 6. Learners' explanations of conductors' and insulators' properties

CONCLUSION

This study attempted to investigate if model-based structured inquiry teaching of static electricity could help prospective primary teachers surpass their conceptual difficulties related to friction and contact electricity and the properties of conductors and insulators. Following the statistical analysis, it can be suggested that the combination of *mental* models and *teaching* models helped learners construct conceptual understanding, especially in a microscopic level. Also, the findings revealed that learners' initial conceptual difficulties were related to their inefficient knowledge of microscopic procedures. Therefore, when these procedures, such as the role of electrons in conductors and insulators, the role of protons in the shaping of the atomic nucleus etc. became clear, learners incorporated enough scientific explanations in their answers. Further research in the field could shed light on the development of teaching-learning sequences that consider the microscopic procedures, in the area of electricity and beyond, e.g. thermodynamics.

GESTALT AND FUNCTIONALITY AS INDEPENDENT DIMENSIONS OF MENTAL MODELS

Malte S. Ubben[1], Stefan Heusler[1]
[1]Institut für Didaktik der Physik, Münster, Germany

In teaching science, models are often used to introduce, elaborate or simplify concepts or real-world phenomena. It is, however, often the case that misconceptions arise from or are facilitated by these teaching models during their transition to mental models of the individual learners. Models are often seen as direct replicas of something real – scaled versions of reality. Even though for structural models, this approach is mostly sufficient, in science, other model types must also be taken into account. For example, in quantum physics, the ability for abstract model building is essential. In an exploratory study with 3108 participants, dispositions towards models in physics in general and mental models of the atomic hull in particular were analyzed. Based on these quantitative data, two independent dimensions of participants' dispositions on mental models were extracted: (i) Functional Fidelity and (ii) Fidelity of Gestalt. Based on these empirical findings, four archetypes for interpreting mental models are proposed.

Keywords: mental models, concepts

INTRODUCTION

The formation of mental models is essential for learning and therefore understanding situations or phenomena more deeply. There are, however, many problems associated with the usage of models in science education, one of which is an overly literal interpretation of the models given to students (e.g. Grosslight, Unger, Jay & Smith, 1991; Treagust, Chittleborough & Mamiala, 2002; Tsaparlis & Papaphotis, 2009). But not only models explicitly given by instructors can be a problem for learners – their own mental models can be a hindrance in learning processes as they often are not easily given up in favor of completely new ideas (e.g. Petri & Niedderer, 1998). By considering these two common findings in science education, one has to ask whether these two are in some way linked: Is there a correlation between learners' problems with letting go of older mental models in favor of new ones and the overly literal interpretation of models as given by instructors? For trying to answer this question, two steps in preparation are needed: Firstly, a definition of the term 'mental model' in the context of this research has to be given. Secondly, a topic has to be chosen where it is the case that learners show a resilience to let go of their mental models. These two aspects will be addressed before a further analysis of the link between mental models and models as given by instructors is carried out.

Mental models

The first step necessary for further delving into the subject of mental model interpretations is to clearly define what the term 'mental model' means in this context. The term 'mental model' has been previously used on many occasions, both in psychology (e.g. Johnson-Laird, 1983; Horst, 2016) and educational research (e.g. Nersessian, 1992; Greca & Freire, 2000). Here, we will use the following definition: *A mental model is the individual coding of a functionality via* *a gestalt*. This definition was chosen as it entails the common ideas associated with mental models or similar concepts in the corresponding literature: A mental model is in most cases characterized by a certain structural component and another abstract, functional one. These have been dubbed as 'gestalt' and 'functionality' respectively. The idea that mental models use some sort of 'gestalt' dates back to Piaget (1951), who proposed that symbolic 'signifiers' codify behavior and information. In most cases, the 'gestalt' part is seen as a visual characteristic (Levy & Trevarthen, 1976; Nersessian, 2002), in some cases it is linked to other modal characteristics such as sensori-motor patterns (Ke, Monk & Duschl, 2005) or auditory patterns (Mayer, 2001). 'Functionality' is an aspect that seems mostly associated with a relational, abstract, functional idea, that is encoded via certain 'gestalts'. As Aebli (1968) interpreted it, the 'signified' is an internalized operation. This core idea – a gestalt or a sensory pattern encoding some function, some operation – can be found in many instances in the corresponding literature. An overview of the other often used phrases for the terms 'gestalt' and 'functionality' in different areas of research is given in table 1. Models given by instructors are often seen as having the same two properties except that they are not individual to the learner.

Table 1. Uses of ideas similar to 'gestalt' and 'functionality' in the context of mental models in different disciplines.

Author	Area of research	Term comparable to 'Gestalt'	Term comparable to 'Functionality'
Piaget (1951, p. 273)	Psychology	signifier	signified
Aebli (1968, p. 56)	Educational Psychology	image/ symbolic representation	operation
Horst (2016, p. 84)	Philosophy/ Psychology	representation	systematic relational information of domain
Levy & Trevarthen (1976)	Neurology	appearance	function
Nersessian (2002, p. 141)	Educational Science/ Physics Education	representation/symbol	behaviour/operation

Selected exemplary subject of research

The planetary atomic model was used as an instance of a mental model that has been found to be resistant to being discarded in favour of a more functional mental model. This case is an example for a conceptual barrier addressed in several studies in the context of quantum physics (e.g. Petri & Niederrer, 1998; Müller, 2003; Krijtenburg-Lewerissa, Pol, Brinkman & Joolingen, 2017): A more advanced model that learners develop is a mental model of circular electron trajectories. It has been given several names, ranging from 'solar system model' to 'Bohr's model' (Fischler & Lichtfeldt, 1992; Harrison & Treagust, 1996; Nicoll, 2001;

Nakiboglu, 2003; Park & Light, 2009; Stevens, Delgato & Krajcik, 2010), although the trajectory concept at its core still remains the same. This model seems to be the most dominant mental model of the atomic hull's structure that is held by students, even by the time they leave school (Müller, 2003).

During quantum physics courses, another radically different mental model emerges and competes with the previous knowledge: Students often develop a 'quantum mechanical model' (Papageorgiou, Markos & Nikolaos, 2016), which has more abstract characteristics such as 'orbitals' (Taber, 2002a; Taber, 2002b; Nakiboglu, 2003) or 'electron clouds' (Harrison & Treagust, 1996; Müller & Wiesner, 2002), representing the stochastic nature the wave-function, which contradicts the deterministic nature of well-defined trajectories. In most cases, this new model is not favoured, and the previous mental model remains the prevailing one. Therefore, we chose this common case as an instance for a mental model that is often not discarded in face of a more sophisticated one.

METHODOLOGY

To examine a possible link between reluctance to discard mental models and understanding of physical models, we decided to use modified questions of the 'models as exact replicas' (ER) dimension from the 'Students' Understanding of Models in Science' (SUMS) instrument by Treagust et al. (2002) and questions from the evaluation of the Munich Concept (Müller, 2003) on mental models of the atomic hull. The test instrument consisted of 15 questions with a four-point Likert-esque scale with the options being: strongly disagree (1), disagree (2), agree (3), strongly agree (4). An additional option of 'don't know' was given to not force participants to answer in a case of uncertainty or no prior knowledge. For analysis of the collected data, the Statistical Package for Social Scientists 25 (SPSS 25, 2017) was used.

The study was conducted via an online platform. The participants had to answer the items of the study before access to an online course on visualizations of quantum mechanics was provided (see for an English version quantumreflections.com). In total, 3108 people in Germany participated in the study (27 July 2017 to 30 March 2018) and also completed it (in addition, 924 persons started the questionnaire, but did not finalize it). Their professions ranged from pupils to university professors.

The analysed dataset was appropriate for evaluation via factor analysis, as shown elsewhere (Ubben & Heusler, 2019). Therefore, we used a multivariate analysis with several different rotations, though the results were so similar that we used the results from a varimax rotation in exemplary function. A more thorough description of the studies' methodology is given by Ubben and Heusler (2019).

RESULTS

Our analysis shows that strong correlations between a reluctance to discard mental models and understanding of physical models exist, as they both load on the same factors about equally. However, the key result is more general: by using factor analysis, two independent factors characterizing participants' views on mental models have been extracted. The two factors are best described as 'Fidelity of Gestalt' and 'Functional Fidelity'. All strong correlations with the two factors can be read from figure 2.

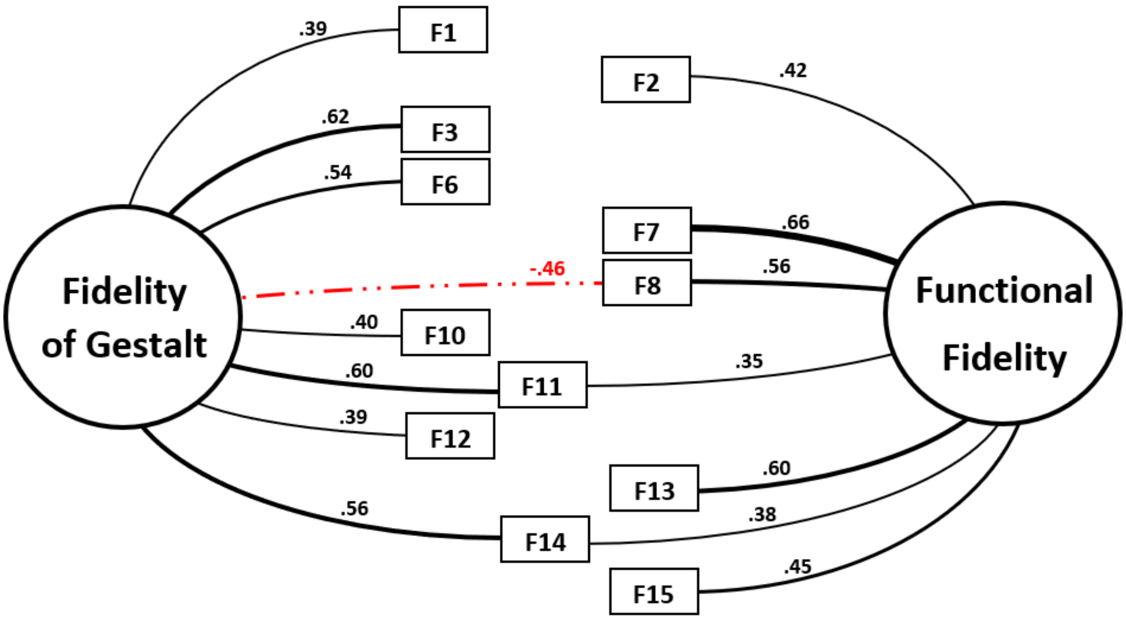

Figure 2. All strong item correlations ($r_s > 0.35$) of the test items with the two factors *Fidelity of Gestalt* (FG) and *Functional Fidelity* (FF). Even though F1 and F12 were excluded during the extraction of the factors, they still correlate highly with FG. The strong negative correlation of F8 with FG was highlighted in red. For a more thorough description of the analysis, see Ubben & Heusler (2019).

Fidelity of Gestalt

The 'Fidelity of Gestalt' trait (FG) describes how far the mental models in physics of the participants were thought of as exact visual representations of phenomena - of exact depictions of how things look. Examples for items of this trait are: 'Electrons within the atomic hull move along set trajectories with high velocities around the core.' (F3) and 'Models in physics show something real in manageable size.' (F11). If someone, for example, were to have an image of the 'planetary model' and thought of it as picturing reality, they would have a high expression of this trait in the given context. If someone, however, were to have an image of the 'planetary model' but would not take it literal, but more metaphorical, they would have a low expression of this trait in the given context.

Functional Fidelity

The ‘Functional Fidelity’ trait (FF) describes how far the mental models in physics of the participants were thought of as appropriate descriptions of how phenomena work — what abstract concepts underly the corresponding models. Examples for items of this trait are: ‘Possible locations of an electron within the atomic hull are described by its orbital.’ (F7) and ‘Every part of a model in physics should be able to tell what it represents.’ (F13). If someone, for example, were to have an image of the ‘planetary model’ and thought of it as describing the behaviour of electrons, they would have a high expression of this trait in the given context. If someone, were to have an image of the ‘planetary model’ but would not think of it as describing how electrons behave in the atomic shell, they would have a low expression of this trait in the given context.

Because the two factors ‘Fidelity of Gestalt’ and ‘Functional Fidelity’ are not correlated to each other (see Ubben & Heusler, 2019), four types of relating one’s mental models to reality are theoretically possible (see also figure 3):

- The *non-developed type* does not understand the model as either depicting or describing external reality. This might show as one not having a meaningful concept of something and only being able to recite or reproduce e.g. meaningless facts or automatisms without meaning. One could for example repeat the word ‘atomic shell’ but not relate it to ‘external reality’ in gestalt and functionality (see e.g. Griffiths & Preston, 1992).
- The *architectural model type* mainly understands a mental model as depicting ‘external reality’ but does not ascribe value for the processes the mental model codifies. One could for example imagine the atom as looking like a static electron cloud (e.g. Harrison & Treagust, 1996)
- The *dual type* sees a mental model as both depicting and describing things in ‘external reality’. This is consistent with the finding of learners often seeing models as replicas of reality. One might for example imagine the atom as a tiny planetary system and think that it describes and depicts ‘external reality’ aptly (see e.g. Ke et al., 2005)
- The *functional type* sees mental models only as describing something in ‘external reality’ more or less *aptly* (see for a similar idea Horst, 2016, p. 86). This means that the appearance is not seen as relevant, but how the mental model works and behaves. For example, a mental model of the atom might be only seen as behaving like the ‘external reality’ to a certain extent (e.g. comments on ‘most sophisticated models’ by Zarkadis, Papageorgiou & Stamovlasis, 2017, p. 894)

DISCUSSION

There are two aspects to be further addressed in the context of our findings:

(i) The relation between mental models and reality as described by the two factors.
(ii) The four archetypes of mental model interpretations.

Though the results have been gained from questions on model understanding in physics as well as mental models of the atomic shell only, there are many similar cases in the literature on science education in general, as will be shown elsewhere.

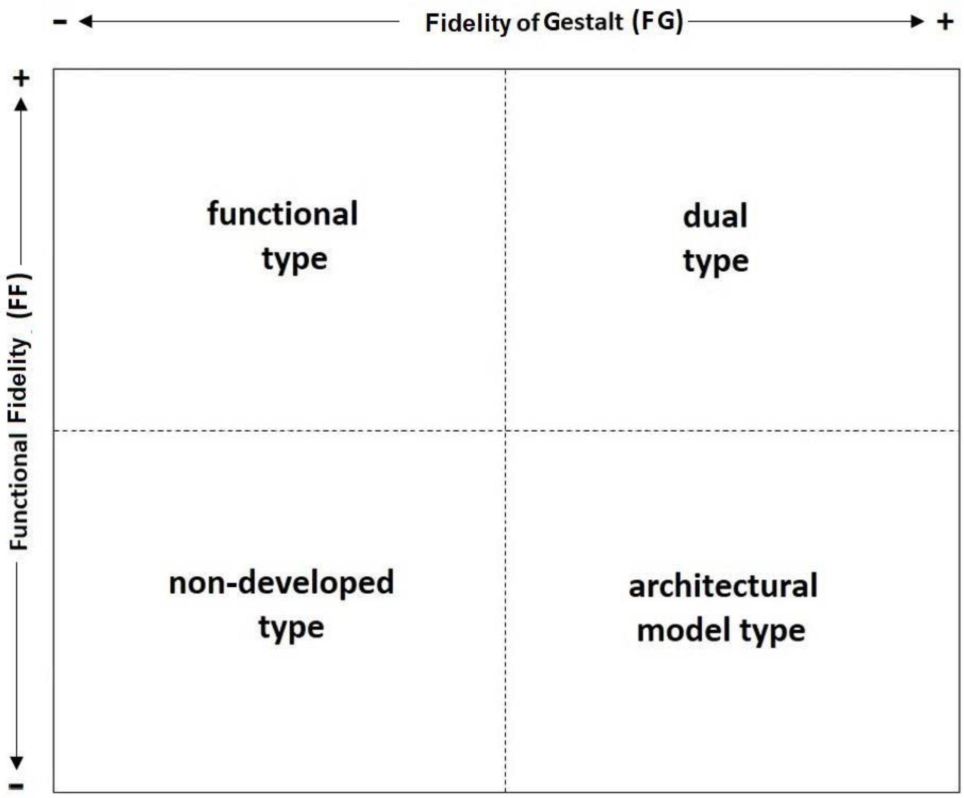

Figure 3. The main types of mental models as described by the FF and FG scales. From high trait expression (+) to low trait expression (−), the four archetypes of relating mental models' properties to 'eternal reality' arise.

Mental models and 'external reality'

As previously presented, mental models in the sense of our research can be characterized as being individual mental constructs that have the properties 'gestalt' and 'functionality'. Our study implies that these to aspects can be interpreted as addressing two different relations to 'external reality' (see e.g. Craik, 1943). A mental model can be seen as being the same as or different from the appearance of something in 'external reality', given by the trait expression of *Fidelity of Gestalt*. Accordingly, a mental model can be seen as functioning the same as or different from something in 'external reality', given by the trait expression of *Functional Fidelity*. Modelling the relation between mental model and 'external reality' with two independent relations is also consistent with findings from neurology: It was shown that the brain has certain parts specialized for 'appearance mapping' and certain parts for 'functional mapping' (Levy & Trevarthen, 1976; for a more recent overview see Gazzaniga, 2005).

At first glance, mental models one holds are different from the models given e.g. by physics teachers. Both – mental models and models in physics – however did not cluster into two distinct categories during the factor analysis of our data. On the contrary: In both in the 'Fidelity of Gestalt' and the 'Functional Fidelity' case, the two highest correlating items are from the SUMS (Treagust et al., 2002) and Müller (2003) respectively. This means, that the two extracted factors can characterize dispositions towards both mental models and models in physics. If one considers that models given by the teacher or a researcher have once been mental models themselves but were externalized for communicative and educational purposes, the similarities of those two is not surprising but, in a way, expected.

The four types of relating mental models to 'external reality'

A progression from the non-developed type to the functional type via firstly the architectural model type and secondly the dual type seems likely. In fact, these steps can be found in several theories on understanding (e.g. Aebli, 1968; Greca & Freire, 2000). The reason for many people having problems with letting go of mental models in favour of ones that give better explanations can be understood by these steps: A high perception of the model *depicting* reality, could make it harder to accept a radically different depiction of reality. It might therefore help to first try to reduce the 'Fidelity of Gestalt' before trying to teach via another gestalt. After that, showing that the new model is more apt at describing how the thing from 'external reality' behaves (conceptual change) might become easier. Support for this hypothesis will be laid out elsewhere in detail.

Whilst many mental models relating to everyday perception can probably be seen as being perceived high in regards to 'Fidelity of Gestalt' and 'Functional Fidelity', mental models used for thinking about problems and processes in science do not have to be seen as being high in 'Fidelity of Gestalt': In fact, many mental models of scientific processes are described by mathematics and their gestalts are thus not like the external reality – however, their functionality is more or less apt.

Conclusion

To summarize, the relations between mental models and 'external reality' can be characterized by two independent traits: 'Fidelity of Gestalt' and 'Functional Fidelity'. Both are criteria by which a mental model is judged in relation to 'external reality'. These two traits are not only able to describe characteristics of mental model understanding, but also for understanding physical models in general.

THE EXTENDED THEORETICAL FRAMEWORK OF MATHEMATICAL WORKING SPACE: TASK ANALYSIS ON A CHEMISTRY PROBLEM

Laurent Moutet[1]
[1] LDAR, Département de mathématiques, Université Paris Diderot, bâtiment Sophie Germain, case courrier 7018, 75205 Paris cedex 13, Paris, France

The theoretical framework of the Extended Mathematical Working Space (Extended MWS) allows to analyse the tasks implemented during a few steps modelling cycle of a physics or chemistry problem. The analysis of the work will be also carried out with the anthropological theory of the didactic (ATD) to compare the two theoretical frameworks in the a priori analysis of the tasks to be performed by the students. Then, only the extended MWS model will be used for post-analysis. We will analyse a teaching sequence with an experimental part dealing with solution chemistry in secondary education. The construction of graphs makes it possible to work on the notion of stoichiometry with a dynamic geometry software, GeoGebra, and to deduce the mass titter of a pharmaceutical product. The methodological framework used is didactic engineering. We will see that it is possible to propose a new register of semiotic representation with graphics to help solve problems using GeoGebra.

Keywords: Interdisciplinarity, Learning Theory, Chemistry

INTRODUCTION

We are interested in a pedagogical sequence including a practical session work carried out in a class of 21 students in Terminale S (Grade 12) in a high school of Picardie Maritime in the north of France (Gauchon, 2008). The notion of stoichiometric relationship corresponds to the disciplinary work targeted here. It concerns the dosage of diiodine by a sodium thiosulphate solution in the presence of a coloured indicator. Equivalence corresponds to the situation when all the two species have reacted. It is shown experimentally by the change in colour of the dosed solution when equivalence is reached. Knowing the quantity of sodium thiosulphate added at equivalence, it is possible to deduce from this, using an algebraic relationship, the concentration of diiodine initially present. Based only on a semiotic genesis, a novice observer sees a change in colour. He is conscious that something is happening, but he can' t explain it. The instrumental genesis is associated with the manipulation of the material. The experimenter follows a protocol leading to the colour change. The only activation of this genesis does not allow the understanding of the actions that he is led to carry out. The notion of equivalence is difficult to make the students understand (the two chemical species have reacted completely to equivalence; it is not necessarily a simple equality between the quantities of each chemical species). Several semiotic registers can be used to facilitate the understanding of this notion: tables, graphs, algebraic relations, natural language, or in this case a much more "visual" experience for the students. The work of Duval (1993) has shown from both a cognitive and a semiotic point of view that the understanding of a concept is improved when at least two registers of representation are mobilized and when translations between registers are favoured. Thus, a semiotic register based on graphs seemed to us to be mobilizable for our teaching sequence. We also take inspiration from the work of Cazes and Vandebrouck (2014). They have studied the use of GeoGebra, on the progress of a sequence designed to teach functions in a context of classical kinematics. We make the hypothesis that an expert visualizes the equivalence of a chemical dosage by associating it intimately with the notion of stoichiometry. It could thus be relevant to use the advancement and stoichiometric numbers during a reasoning process using graphs representing the advancement *x* as a function of time *t* with GeoGebra. Our study will thus use this software to represent and use *x*(*t*) graphs. We hypothesize that the task to be performed by the students to find an unknown concentration could be facilitated at the beginning of the learning process by using an instrumental genesis of a different nature than the experimental device using GeoGebra. The teaching sequence with an experimental part dealing with solution chemistry in secondary education will be thus analysed using two theoretical frameworks (Extended MWS and ATD) in order to specifically analyse interactions between the cognitive plane and the epistemological planes of chemistry or mathematics. An a priori analysis based on the study of the tasks to be performed by the students was then carried out. The post-analysis of a student's work will be presented. The methodological framework used in this study will be didactic engineering.

METHOD

The Mathematical Working space (MWS) was developed to better understand the didactic issues around mathematical work in a school environment by Kuzniak, Tanguay & Elia (2016).

The epistemological plan contains a set of representations (signs used), a set of artefacts (drawing instruments or software) and a theoretical reference set (definitions and properties). The cognitive plane contains a visualization process (representation of space in the case of geometry), a construction process (function of the tools used) and a discursive process (arguments and evidence). Mathematical work results from an articulation between the cognitive and epistemological planes through instrumental genesis (operationalization of artefacts), semiotic genesis (based on the register of semiotic representations), and discursive genesis (presentation of mathematical reasoning). The different phases of mathematical work associated with a task can be highlighted by representing three vertical planes on the MWS diagram. Semiotic-instrumental interactions lead to a process of discovery and exploration of a given academic problem. Those of an instrumental-discursive type favour mathematical reasoning in relation to experimental evidence. Finally, those of the semiotic-discursive type are characteristics of the communication of mathematical results as well as more elaborate reasoning. The MWS diagram was transformed by Moutet (2018, 2019a, 2019b) by adding an epistemological plane corresponding to the rationality framework of physics (figure 1) or of chemistry (Moutet, 2019a, 2019c). It was chosen to keep only one cognitive plane because we assume that it is independent of the epistemological plane associated with it. We also hypothesized that students' conceptions of mathematics and physics can be described using a personal extended MWS. This framework makes it possible to specifically analyse the interactions between the cognitive plane and the epistemological planes of chemistry or mathematics.

We also used another theoretical framework. The anthropological theory of didactics (ATD) was developed by Chevallard (1999). Any human activity can be described by a praxeology. A type of task, noted T, requires a technique τ in order to be carried out successfully. The block $[T/\tau]$ of praxeology is called the practical-technical block and is associated with what is generally referred to as know-how. The technology, noted θ, makes it possible to describe "rationally" the technique used by ensuring that the task T is well processed. Finally, the theory, noted Θ, makes it possible to theoretically justify the discourse of the technology. The $[\theta/\Theta]$ block is identified with a knowledge. Praxeology associated with a task type T can therefore be described by a task T, a technique τ, a technology θ and theory Θ, all noted $[T/\tau/\theta/\Theta]$. Some praxeologies age, some theoretical and technological components are less used as new technologies emerge, leading to abandon techniques and/or develop new ones in order to accomplish certain types of tasks. The ATD studies questions associated with the performance of specific tasks. This leads to the development of new praxeologies whose efficacity can be evaluated.

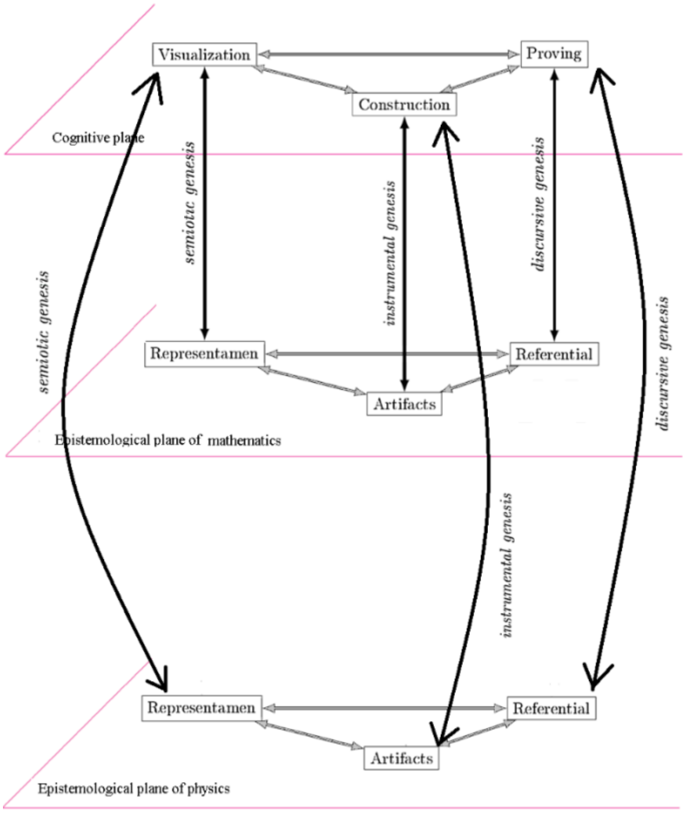

Figure 1. Extended MWS Model.

The methodological framework used is didactic engineering (Artigue, 1988). It is structured in four stages:

1. The preliminary analyses consist in performing an epistemological study of the different concepts that will be addressed in the teaching sequence and to review the difficulties of students that may be listed in the literature.
2. A priori analysis and conception consist in developing a teaching sequence (with one or more pilot sessions) and analysing the different tasks that students will have to perform using an appropriate theoretical framework.
3. The experimentation phase makes it possible to describe the conditions for data collection (audio recording, videos, interviews or analysis of paper and pencil activities, etc.) as well as the context of the study (number of students, grade level, type of school, etc.). Here the teacher is also the researcher involved in the study. Generally, the sample of students involved remains relatively small. It is not possible to carry out a statistical study of the responses obtained.
4. Post-analysis and validation allow the analysis of the tasks carried out by the students to solve the problem they have been assigned. Comparison with the a priori analysis allows us to validate or not the hypotheses that were formulated when the research questions were established.

A first teaching sequence developed by Moutet (2018, 2019a, 2019b) was destined for students in the final year of secondary school (grade 12) in France, on the topic of special relativity following the work of de Hosson, Kermen & Parizot (2010). Another problem in chemistry, is also studied here (Moutet, 2019a, 2019c). Data collections can be videos, audio recordings or GeoGebra files. We used the modelling cycle proposed by Blum & Leiss (2005, figure 2) to position our teaching sequences. We have already realized a sequence in physics studying the passage from the "real model" to the "real results" and here we want to develop a sequence in chemistry allowing a description with a more complete modelling cycle from the "real situation" to the "real results".

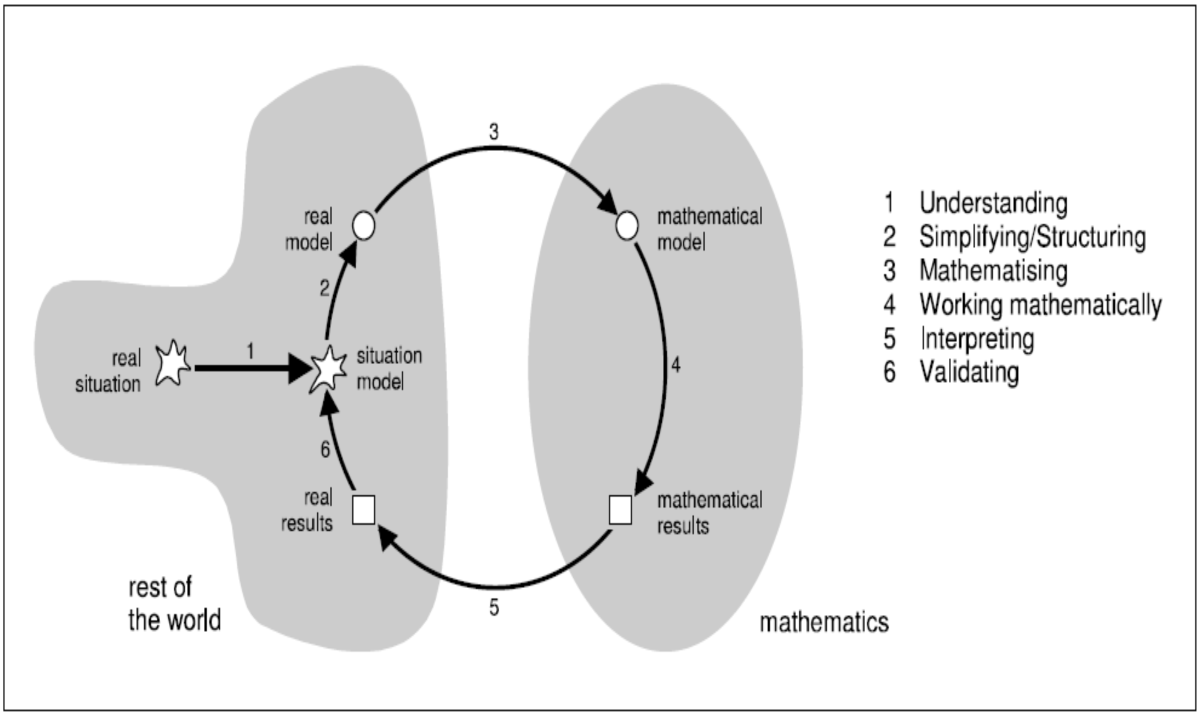

Figure 2. Blum and Leiss modelling cycle (2005).

In this model, derived from the didactics of mathematics, a "real situation" corresponds to a contextualized situation associated with everyday life. It can be, for example, a photo, a text, a video or a mixture of all three. The step corresponding to the "situation model" is also described by Borromeo Ferri (2006) as the "mental representation of the situation". It corresponds to a step in which the students understand the task to a greater or lesser degree and carry out a mental reconstruction of the situation. It is not only the description of the situation encountered, since elements of knowledge begin to be mobilized by the students. The "real model", which can rather be considered as an "idealized model", is obtained by idealizing and simplifying the data from the problem. This step has a strong connection with the "situation model", which explains why it is mostly constructed at an internal level in the individual. A simplified representation of the situation in a diagram, for example, corresponds to an external representation. Here the "real situation" would correspond to the experimental dosage with the observed colour change. The "situation model" would be associated with the understanding of the existence of a chemical reaction during this dosage. The "real model" would be associated with understanding the chemical equation of the dosage, the chemical species reacting and the pertinent parameters to be considered. This is the mathematical step usually involving an algebraic register that we propose to modify using a geometric register.

Two research questions guided this work: 1) How does the extended MWS framework allow the analysis of the sets of rationality frameworks between mathematics and chemistry, during a sequence with students in the final year of secondary school via a geometric approach? 2) To what extent does the analysis of the use of dynamic geometry software by the extended MWS framework, show that it promotes a conceptualization in students?

RESULTS

Students should check the mass percentage of diiodine in a newly manufactured bottle of betadine. In fact, diiodine molecules form a complex with the polyvidone molecule. It is the percentage of iodinated polyvidone that is determined in the betadine solution. Students must perform a determination with a sodium thiosulfate solution and use GeoGebra to automate the determination of the mass titter. Two additional documents are given. They provide information on betadine and reminders on titrations and equivalence. The chemical reaction equation of the titration is also provided. The instruction given to the students is described in the following. A first session takes place in the chemistry laboratory where the students concretely perform the studied dosage in groups of two. They collect the value of the equivalent volume without having had time to evaluate their measurements. A second session takes place in the computer room in groups also to answer three questions.

You are part of a control laboratory in a pharmaceutical manufacturing plant and you must check the mass titter in iodinated polyvidone in a newly manufactured betadine bottle. To do this, you must make a dosage with a sodium thiosulphate solution 2 Na^+, $S_2O_3^{2-}$. You must use software to automate the determination of this mass titter.

1. Represent the quantities of matter of the reactants that have reacted at any time as a function of a reaction quantity. Use GeoGebra to represent the corresponding graphics.
2. Using GeoGebra's "cursor" tool, locate the quantity of sodium thiosulfate solution matter introduced at equivalence and then display on the software the molar concentration in diiodine of the diluted betadine extract.

3. Display on the software the mass titter in iodinated polyvidone of the analysed betadine, conclude.

On GeoGebra, the line of the equation $y = 2.x$ is associated with the amount of thiosulphate mater $S_2O_3^{2-}$ and the line of the equation $y = x$ is associated with the amount of diiodine matter I_2. Cursors are used to identify on the graph, using a horizontal line, the amount of thiosulphate matter added to the equivalence and then to deduce the unknown concentration of diiodine (figure 3). The construction of graphs makes it possible to work on the notion of stoichiometry by graphically observing the relationship between the quantities of matter of the reagents. The GeoGebra file of the activity is available for download using the hypertext link below:

https://drive.google.com/file/d/1DmeAGKjXWUHeWFJ3Gn17mS5QmSu2Ry0F/view?usp=sharing

The a priori analysis is carried out using the ATD theoretical framework and is compared with the recently developed extended MWS framework to test its pertinence. We will then analyse only the work to be done by the students in the computer room. The tasks T, the techniques used τ, technology θ and theory Θ will be detailed for each question.

The various tasks performed are described below. $T_{1\text{-}1}$: It is necessary to know how to use the reaction progress; $T_{1\text{-}2}$: It is necessary to know how to use the graphical representation of the quantities of reagents matter that have been consumed; $T_{2\text{-}1}$: Students must identify the amount of $S_2O_3^{2-}$ matter; $T_{2\text{-}2}$: Students must graphically deduce the amount of diiodine matter and then the diluted concentration of betadine is calculated; T_3: Students should use the dilution to display the iodinated polyvidone mass titter.

The various techniques used are described below. $\tau_{1\text{-}1}$: Students must use the reaction progress $x(t)$; $\tau_{1\text{-}2}$: Students must construct with GeoGebra the lines $x(t)$ and $2.x(t)$ corresponding to the quantities of I_2 and $S_2O_3^{2-}$ matter; $\tau_{2\text{-}1}$: Students must construct a cursor to locate the quantities of $S_2O_3^{2-}$ matter introduced using a horizontal segment cutting the line $y=2.x(t)$; $\tau_{2\text{-}2}$: Students must construct a vertical segment and then a horizontal segment cutting the line $x(t)$ to identify the quantities of diiodine matter. They then deduce the diluted diiodine concentration by dividing the amount of matter by the volume and displaying it on GeoGebra; τ_3: Students deduce the concentration of diiodine by considering the dilution factor and then display the mass titter of iodinated polyvidone on GeoGebra.

The technology uses the graphical representation of the reaction progress as a function of time, the use of cursors and display with GeoGebra. Finally, it is the theory of chemical equilibrium in aqueous solution that is mobilized each time.

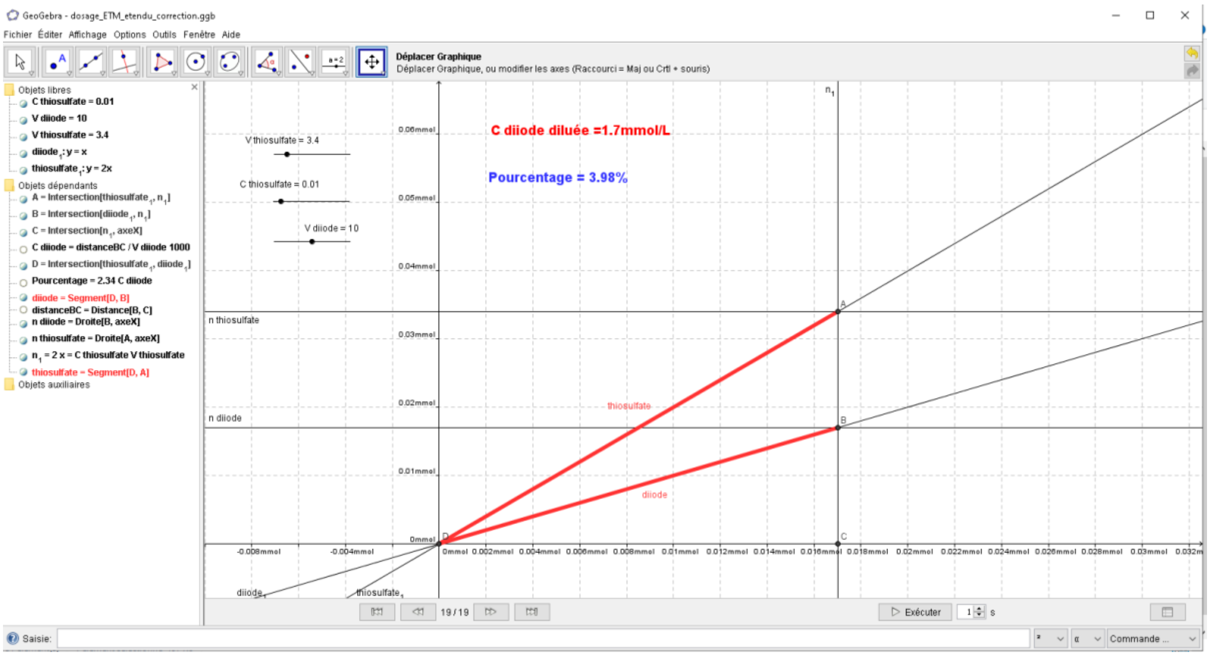

Figure 3. GeoGebra file screenshot.

We use the MWS extended model with an epistemological plane of chemistry (figure 4). The black arrows describe the different genesis on the extended MWS diagram when performing the tasks necessary to solve the problem.

The epistemological plane of chemistry and the cognitive plane are mobilized during the beginning of the resolution of the first question because students must use the reaction progress $x(t)$. A semiotic genesis (use of the symbol of advancement) and a discursive genesis (theoretical knowledge of reaction advancement) are mobilized.

In the second part of the first question, the students must then construct with GeoGebra the lines $x(t)$ and $2.x(t)$ corresponding to the quantities of I_2 and $S_2O_3^{2-}$ matter. The construction of these two lines requires a semiotic genesis and an instrumental genesis between the epistemological plane of mathematics and the cognitive plane. The meaning of these two lines requires genesis (semiotic and discursive) between the epistemological plane of chemistry and the cognitive plane.

In the second question, students must construct a cursor to locate the quantities of $S_2O_3^{2-}$ matter introduced using a horizontal segment cutting the line $y=2.x(t)$. The construction of the cursor requires a semiotic genesis and an instrumental genesis between the epistemological plane of mathematics and the cognitive plane. The epistemological planes of chemistry and the cognitive plane are used when calculating the quantity of $S_2O_3^{2-}$ matter and displaying it graphically (semiotic and discursive genesis).

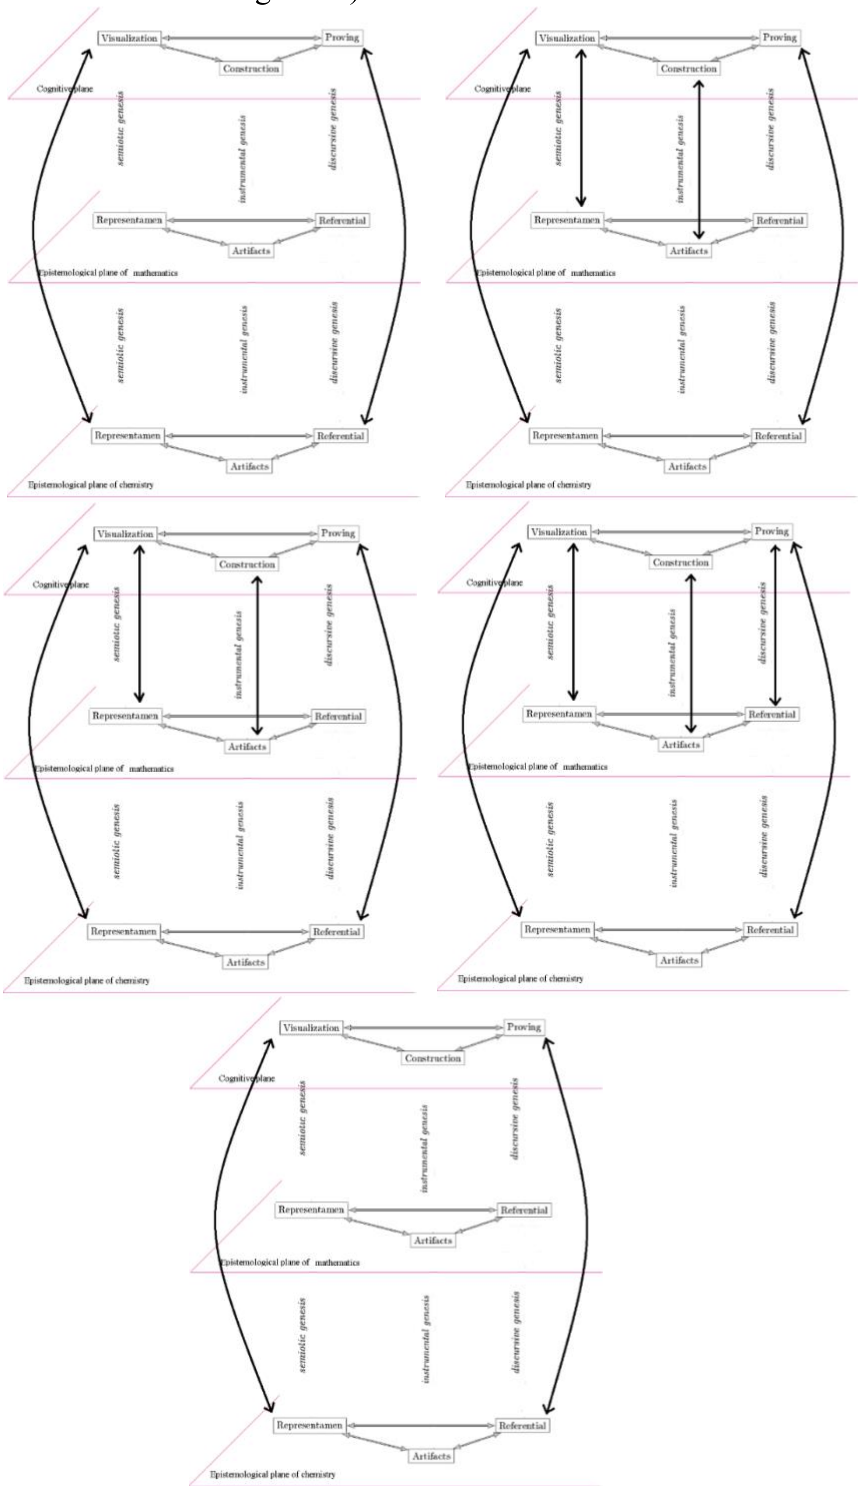

Figure 4. A priori analysis of the tasks with extended MWS.

At the end of the second question, the students graphically deduce the quantity of diiodine matter (semiotic, instrumental and discursive genesis between the epistemological planes of mathematics and the cognitive plane) and then the diluted concentration of diiodine in betadine is calculated (semiotic and discursive genesis between the epistemological planes of chemistry and the cognitive plane).

In the last question, students must use the dilution to display the iodinated polyvidone titter in betadine. It is the epistemological planes of chemistry and the cognitive plane that are involved (semiotic and discursive genesis).

DISCUSSION

We have seen that the ATD makes it possible to analyse the different types of tasks that students must perform during the teaching sequence. However, the rationality frameworks involved are not well clarified. The theoretical framework of the extended MWS allows the same description of tasks and consider the rationality frameworks of mathematics or chemistry as well as the cognitive plane. The interactions between two planes are also described by three types of genesis (semiotic, instrumental or discursive).

Then, the extended MWS framework allows to analyse the tasks assigned to the students and those carried out by them. This study makes it possible to highlight the sets of rationality frameworks when solving problems in chemistry treated by a geometric approach. The GeoGebra dynamic geometry software allows to implement here an additional semiotic genesis with its dynamic aspect. The cursor favours the change of the equivalent volume measured during the dosage and students see the result directly on the screen. An instrumental genesis different from the paper-pencil activity is also involved when constructing graphs representing the quantity of reactants matters as a function of time. Finally, we hypothesize that GeoGebra, by making it easier to draw conclusions on the stoichiometric relationships of a chemical reaction, allows the activation of an original discursive genesis.

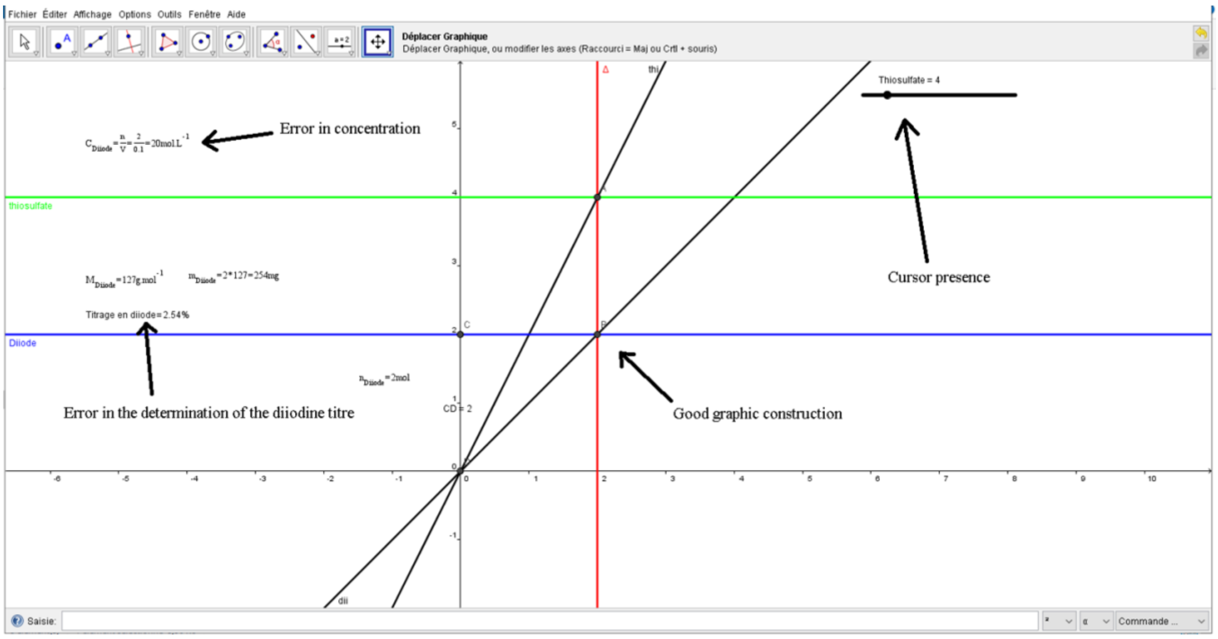

Figure 5. Analysis of a student's work.

The GeoGebra file of the work of a group of students in trouble is available for download using the hypertext link below:

https://drive.google.com/open?id=1I8CQux45Af9brSRBhn_cWH6uUauyY9hB

The black arrows describe a genesis on the extended MWS corresponding to a correctly performed task, the black arrows crossed out an incorrectly performed task and the dotted arrows, a partially successful task. We see that the work required is imperfectly done (figure 6). The group of students represents on GeoGebra the lines $x(t)$ and $2.x(t)$ and the line to identify the amount of thiosulphate matter added to the equivalence. Students incorrectly calculate the amount of material by using mL instead of L (dotted arrow representing the discursive genesis associated with the task at the beginning of the second question).

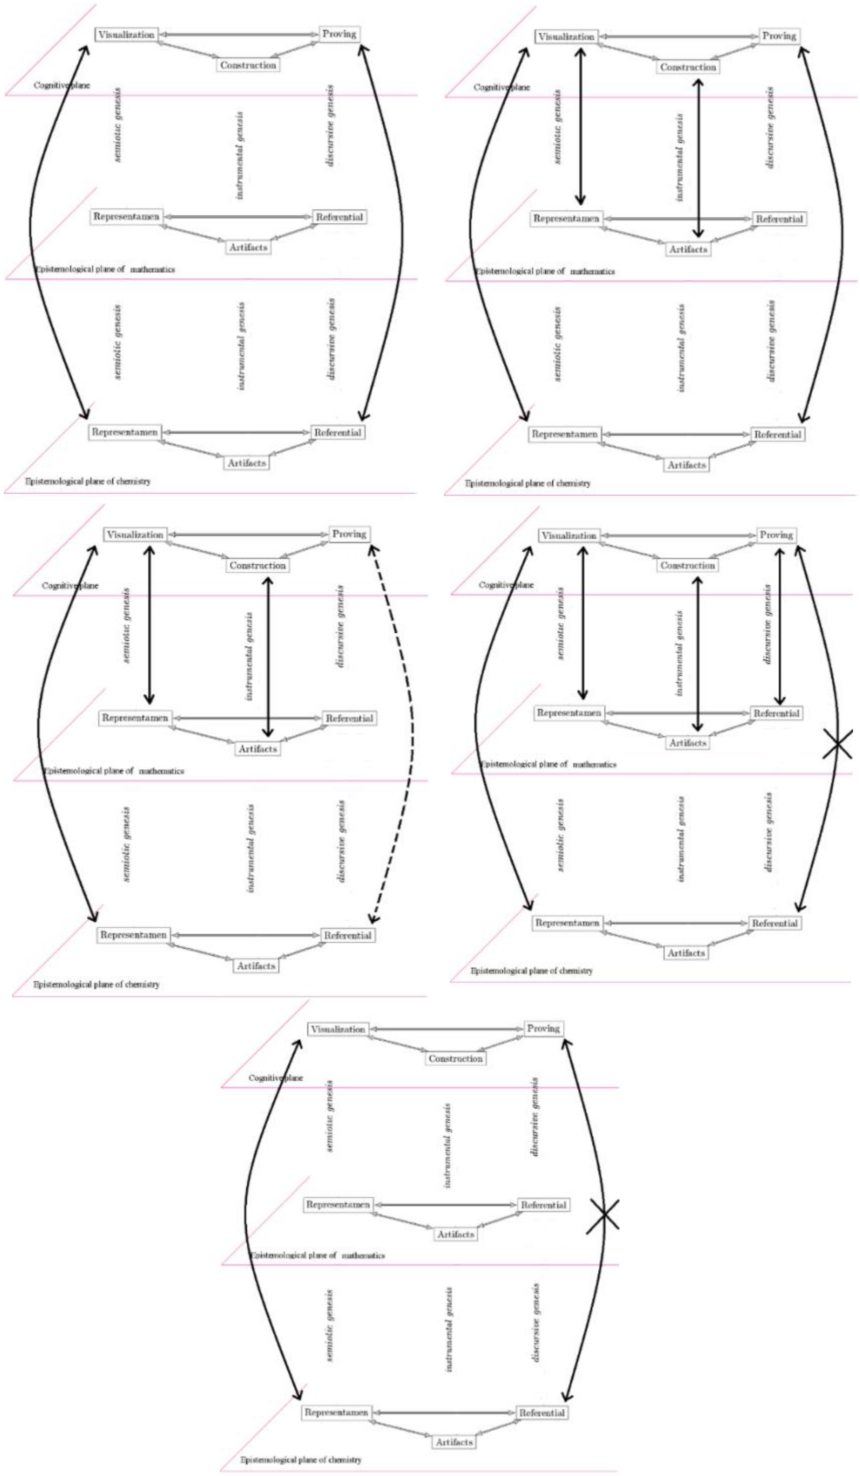

Figure 6. Post-analysis of the tasks performed by a student.

Then the geometrical reasoning is correctly carried out but the calculation of the diluted concentration of diiodine and the mass titter of iodinated polyvidone are incorrect (black arrows crossed out representing the discursive genesis associated with the task at the end of the second question and the task of the last question). Stoichiometry, on the other hand, is correctly established between the reagents by graphical construction.

CONCLUSIONS

The extended MWS framework allowed us to perform a more complete analysis, and assessment of the types of tasks associated with certain stages of the modelling cycle than ATD, during a problem involving chemistry of aqueous solutions. It considers the mobilization of the epistemological planes of mathematics and chemistry for each of the tasks requested with three geneses (semiotic, instrumental and discursive). It also led us to show that GeoGebra develops specific geneses in relation to a paper-pencil activity. It's also possible to propose new strategies when using of GeoGebra with another register of semiotic representation when working with problems solving. Unfortunately, this does not allow all students to succeed even if the work on stoichiometry that was the goal here seems to be well done.

INSTRUCTING SECONDARY SCHOOL STUDENTS IN 'TRIPLET' CONCEPT MAPPING FOR CHEMISTRY

Ylva Hamnell-Pamment[1]
[1]Department of Educational Sciences, Lund University, Lund, Sweden

A sociocultural perspective was utilized to explore if concept mapping using macroscopic, symbolic and submicroscopic aspects (often referred to as the 'chemistry triplet') can be used to promote development of expert knowledge in secondary school chemistry students by facilitating multilevel thinking. An additional aim was to explore the possibilities of using sociocultural theory to study the development of conceptual meaning and its contextual influences. The method was well received by students, and all students produced acceptable maps. Students with difficulties defining symbolic concepts as representations found participation in the study particularly useful. The method appeared to be suitable for studying both the effect of social roles and communication practices in the classroom, suggesting that triplet concept mapping can be utilized to study the contextual influences on the development of conceptual meaning, as well as to promote knowledge integration in chemistry at secondary school level.

Keywords: concept mapping, instructional strategies, conceptual understanding

INTRODUCTION

It has been well established within chemistry education research that students have difficulties emulating what Johnstone (1991) calls the 'multilevel' thinking within the chemistry domain (see for instance Becker, Stanford, Towns, & Cole, 2015; Kozma & Russell, 2005; Stieff, Ryu, & Yip, 2013), namely the ability to think and work with chemical symbols, the tangible world of chemistry and the theoretical, particulate models that are used to explain it. These three aspects of chemistry reasoning known as the 'macroscopic', 'symbolic' and 'submicroscopic' – jointly named the 'chemistry triplet' – have been the focus of several interpretations by chemistry researchers (Talanquer, 2011). Originally proposed as levels of thinking leading to working memory overload (Johnstone, 2006), the model has also been interpreted as levels of representation and utilized for the development of representational competence (Gilbert & Treagust, 2009), or as a mixture of conceptual and representational domains, where the focus has been on the representational, symbolic domain working as a communicative and facilitating resource (Taber, 2013). Depending on the interpretation of what the chemistry triplet entails, suggestions on how to further student reasoning within chemistry could entail teachers being explicit about the meanings of models, representations, analogies and their limitations (Taber, 2017) or encouraging students to develop their representational skills (such as in the study by Thomas, 2017). The development of this type of 'expert' knowledge in chemistry has been described by Anderson and Schönborn (2008) as knowledge integration, an essential aspect of deep learning.

So far, however, a sociocultural perspective on the chemistry triplet and how this may be utilized in chemistry teaching is missing in the research literature. From a sociocultural perspective, the idea of the triplet can be viewed as a way of utilizing models for reasoning about macroscopic or sub-microscopic perspectives of events, where the models used for thinking about these perspectives have both limits and affordances for thinking (Vygotsky, 1934/1987; Wertsch, 1991) Through the use of these models learnt through social interaction, students develop the meanings or words and symbols carried within a community (Davydov, 1995), often referred to as 'concepts' (Clarà, 2017). It is important to note that, although symbolic representations such as graphs or equations play an important part as facilitators for thought, words and their perceived meanings also function in the same way (Vygotsky, 1934/1987). As a sociocultural perspective can focus on social context and the development of meanings, this theoretical framework facilitates the study of contextual influences on chemistry teaching and learning. This in turn can facilitate the study of how sociocultural factors, such as communicative classroom practices, can influence conceptual development. The study of contextual influences on the development of conceptual understanding has been suggested to be an important aspect of furthering research in science education (Duit & Treagust, 2012).

The purpose of the primary study presented in this paper was to explore from a sociocultural perspective how secondary school students relate to the triplet concept, and whether triplet concept mapping is a feasible tool for developing knowledge integration in chemistry at secondary school level. First introduced by Novak & Gowin (1984), concept maps are metacognitive tools used for learning and assessment (ibid.; Novak, 2002). Their construction are based on Ausubel's assimilation theory of learning, which states that meaningful learning of a concept means establishment of the concept's relationship to other, to the student already known, concepts, as a result of school instruction (Ausubel, Novak, & Hanesian, 1978; Novak & Gowin, 1984). Hence, the construction of concept maps has the potential to show the learner's current conceptualisation of an idea within instruction. Within concept maps, the propositions (the statement constructed by connecting two or more concepts using linking words) are regarded essential aspects of the maps (Cañas, Novak & Reiska, 2012), and are crucial for meaningful knowledge comparisons between individuals (Ruiz-Primo, Schultz, Li & Shavelson, 2001). A concept map can therefore be used to elucidate how students think about for instance chemical processes through their choice of words or models expressed in the map. If the idea of the triplet has been presented as a scaffold in this process, triplet concept mapping can be used to elucidate how students engage in dialogue between their personal understandings embodied by words and symbols in the concept map, and the knowledge integration aspect of expert knowledge (Anderson & Schönborn, 2008) represented by the triplet scaffold. Concept maps have been proposed by Schwendimann (2015) to be effective tools for promoting knowledge integration, and knowledge integration maps across knowledge domains in biology have been shown previously to be effective in visualizing complex knowledge connections (Schwendimann & Linn, 2016).

For this paper, triplet concept mapping was taught to a class studying chemistry at the International Baccalaureate Diploma Programme. The concept of the triplet was adapted for upper secondary school according to the framework presented by Thomas (2017). The research questions posed were: 1. 'How do the students in this class relate to the triplet concept when utilizing some common chemistry concepts to define a neutralization reaction?', and 2. 'How can triplet concept mapping, when introduced through a 60-minute class, be feasible exercise to stimulate knowledge integration in chemistry at upper secondary school?'

METHODS

From sociocultural perspective, concept maps can be seen as a type of dialogue with the instructor or knowledge domain, where students utilize models and words (i.e. mediational means; Wertsch, 1991), and appropriating them ('making one's own'; Bakhtin, 1935/1981, p. 294; Wertsch, 1991) to engage in this dialogue in various ways depending on the type of dialogue they perceive is taking place. For instance, an authoritarian discourse, such as the study of an expert concept map, can induce passivity because it does not allow for expression of the personal voice, whereas an *expert skeleton concept map*, that gives some initial concepts that function as a scaffold for student understanding (Cañas, Novak, & Reiska, 2012), can be seen as an exercise that invites dialogue. Each concept map can from the same sociocultural perspective also be said to be expressed within a certain speech genre, for instance the speech genre of physics, biology or chemistry, where each genre includes a certain set of models for reasoning around the subject matter (Wertsch, 1991). Therefore two decisions were made: firstly, to use an expert skeleton of the triplet concept to invite dialogue during the concept mapping exercise in this study, and secondly, also to communicate the speech genre clearly while teaching concept mapping to the students.

For the study, concept mapping was taught during a 60-minute lesson by the researcher to 12 students at the International Baccalaureate Diploma Programme at a school in Sweden according to the previously established method by Ruiz-Primo (2001), but modified according to the above rationale to contain only chemistry examples and practice maps. In addition, due to time limitations, only one concept map was constructed collectively (on the topic of atoms), and questions regarding concept mapping were dealt with in the classroom as they arose while the students constructed individual scaffolded triplet maps with five given concepts and two optional concepts (on the topic of exothermic reactions). Purely theoretical questions were not answered, but for the practice map, the students were allowed to discuss the topic with their neighbors. As previously mentioned, the triplet scaffold (see figure 1) was constructed according to the template developed for upper secondary school level by Thomas (2017). This framework divides the triplet domains into observational/tangible/macroscopic, communicative/symbolic, and theoretical/particulate, which means it is an interpretation close to the original framework presented by Johnstone (1991). The exercise was introduced as a way of learning about the theory of knowledge of chemistry (which is part of the Diploma Programme curriculum).

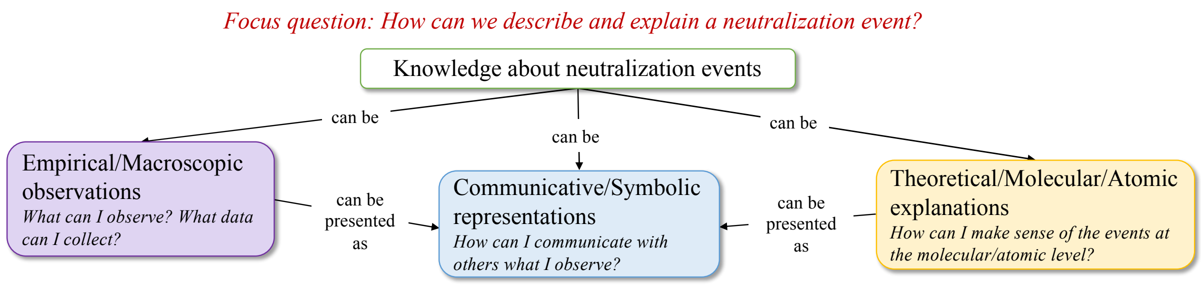

Figure 1. The triplet scaffold used for the concept mapping exercise in the study, adapted from Thomas (2017).

The final scaffolded map on neutralization reactions was constructed individually and in silence, also using five given concepts ('proton transfer', 'acid particles', 'base particles', 'pH' and 'color change'), but where students were encouraged to add two or more concepts. In the instructions given, students were asked to first place the concepts in the appropriate region of the map using Post-its^{TM}, and then to connect the concepts and connect to the top using linking arrows and linking words (according to the procedures outlined by Novak & Cañas, 2008; Novak & Gowin, 1984). An example map showing examples of what type of concepts belonged to each region of the concept map was also given out. The maps produced were according to the class teacher representative of the students' knowledge of neutralization reactions. The concept mapping session was regarded effective as 11/12 students used all concepts provided, and all students used labelled lines and provided one or more valid propositions (Ruiz-Primo, Schultz, & Shavelson, 1997).

In the analysis of how the concepts were placed in relation to the triplet, an interpretive stance was taken on the analysis placement of the concepts, where pH could be viewed as both a macroscopic and a symbolic concept depending on the context, and consideration was given to both how the concepts were linked to the scaffold in terms of linking arrows and how the concepts were placed spatially. This avoided misinterpretation of spatially skewed maps.

During the second part of the study, the students participated in a mandatory 90-minute practical on acid-base titration. This practical took place during the next chemistry lesson the day after the concept mapping class. The ordinary teacher held the practical, which was started by only a very brief introduction to the neutralization reaction (involving acetic acid solution and sodium hydroxide solution), with no mention of the aim of the lab. After the practical the students (N=11) filled in a survey concerning their experiences with concept mapping and their perception of the aim of the lab. In the survey, the students also gave their gender, whether they spoke the school language at home, their achievement level (although some wished to withhold this piece of information), and whether they had constructed concept maps previously. These factors have previously been shown to impact achievement in science or chemistry (Chandran, Treagust and Tobin, 1987; Lopez et al., 2014; van Laere, Aesert & van Braak, 2014).

The concept maps and the survey responses were coded using NVivo software. Descriptive coding and process coding was used, and the codes and categories were then explored in terms of dimensions and variables (Miles, Huberman & Saldana, 2014). For the analysis of the definition of concepts as being macroscopic (observational), symbolic, or submicroscopic (theoretical/particulate), interpretive analysis was necessary rather than spatial analysis, as quite a few maps were skewed in terms of disposition, and the use of the concept pH depended on the context (as an expression connected to concentration, or as a measured variable).

RESULTS AND DISCUSSION

Examining sociocultural dimensions of triplet interactivity

When examining the data from the concept maps, it was clear even from this small data set that it was possible to examine sociocultural effects on degrees of student dialogue with the idea of the triplet. The two dimensions that emerged from the data in this particular study in terms of triplet dialogue were *dialogic interaction with the triplet scaffold*, which was categorized into five levels of interactivity (see table 1 and examples in figure 2) and *degrees of defined symbolic meaning*, which was categorized into five levels of specificity (see table 2).

Table 1. Categories used for differentiating varying degrees of dialogic interaction with the triplet scaffold for the two concept maps (exothermic reaction/neutralization) with degree of interaction divided by gender.

Dialogic interaction with triplet	Female (n=5)	Male (n=7)	Total (n=12)
Dialogue with scaffold concepts	0/0	4/3	4/3
Partial dialogue with scaffold concepts	1/1	2/2	3/3
Example-based concept map	3/3	1/1	4/4
Scaffold connection as afterthought	0/1	0/1	0/2
No dialogue with top	1/0	0/0	1/0
Total individuals	5	7	12

Increasing interaction

Concepts cohesively linked with all three scaffold concepts were regarded as the highest dialogic interaction, links to one or two scaffold concepts in a cohesive concept map were regarded as partial dialogic interaction, concept maps based on the example given out to the class were regarded as passively interactive, and non-cohesive concept maps with unlabeled arrows connecting to the triplet scaffold were regarded as the least dialogic. As seen in table 1, there appeared in this sample to be a gender difference in types of dialogue with the triplet scaffold. This could be interpreted as female and male students taking on more passive and active roles, respectively, in the dialogue with the triplet concept, although more data would be needed to confirm this tendency.

The dimensions of specificity of symbolic meaning were derived from how symbolic concepts were placed in the concept maps. Meanings varied from well defined (no mixed meanings), to one double (macroscopic/symbolic) meaning being given through a double scaffold connection, to symbolic concepts being placed as either macroscopic observations or particles, and finally to poorly defined (symbolic concepts being placed as both macroscopic observations and as particles in relation to the triplet scaffold) in the concept maps.

Although four of the students were aware of not understanding the differences in meaning between observational concepts, symbolic concepts and particulate model concepts, the students showing the most confusion regarding symbolic meaning in their concept maps were unaware of their difficulty (see table 2).

Table 2. Differences in symbolic meaning expressed in the students' concept maps, divided by perceived difficulties of different aspects of concept mapping reported in the student survey (N=11).

Degrees of defined symbolic meaning	**What students found difficult to understand during concept mapping**					
	All parts of mapping	Observations/ Symbols/ Models	What concepts are	What linking words are	How to make a proposition	Nothing
Well defined		X			X	
One double meaning		X				
Symbols as observations		X				
Particles as symbols	X	X		X		X
Poorly defined			X	X		X
Total individuals	1	4	1	2	1	2

Meaning increasingly specific

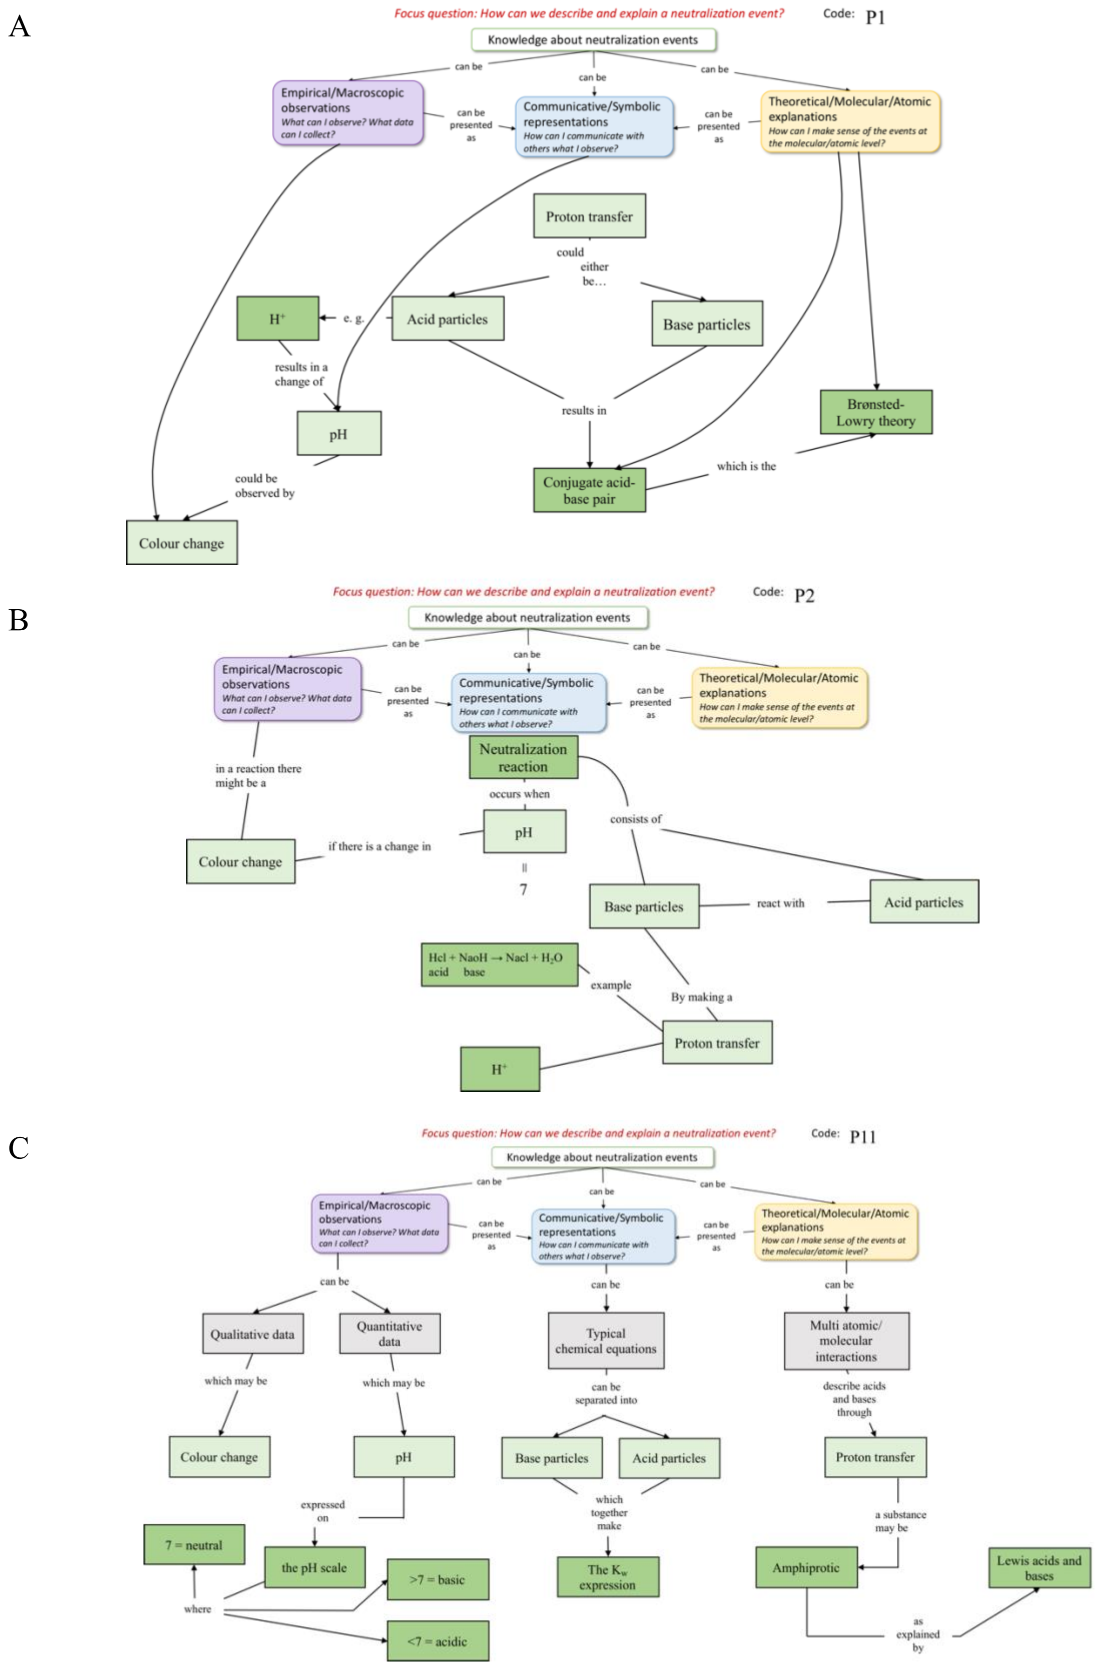

Figure 3. Examples of different degrees of dialogic interaction in the triplet concept maps produced by the students. A. Scaffold connection as afterthought (lowest degree of dialogic interaction); B. Partial dialogue; C. Model-based map (second lowest degree of dialogic interaction). Color key: grey concepts = copied from the example; light green concepts = starting concepts; dark green concepts = student's own added concepts.

In conclusion, the sociocultural framework utilized to examine how the students interacted with the triplet concept was able to detect both a variability in dialogic interaction in terms of passive and active voice, as well as a variability in definition of meaning of the symbolic representations used by the students. From a sociocultural perspective, both dialogic agency and the development of word meaning are dependent on the contextual factors surrounding social interactions (Vygotsky, 1987; Wertsch, 1991).

Examining the utility of triplet concept mapping for knowledge integration

Although the concept mapping class of 60-minutes was effective in teaching the techniques of concept mapping according to established definitions found in the literature (see Ruiz-Primo, Schultz, Li, & Shavelson, 2001; Ruiz-Primo et al., 1997), there was a slight change in how the students related to the triplet scaffold between the two concept maps produced (see table 1). This could be a sign of students having more difficulty relating to the triplet model as they are learning a new topic, but also that triplet concept mapping can improve knowledge integration for some students. With regard to how the students perceived the usefulness of concept mapping, most students (10/11) found participating in the study useful. The students having the most difficulty in defining symbolic meaning also found the concept mapping exercise the most useful (see table 3).

Table 3. Differences in symbolic meaning expressed in the students' concept maps, divided by the perceived usefulness of participating in the concept mapping class prior to an acid-base titration practical as reported in the student survey (N=11).

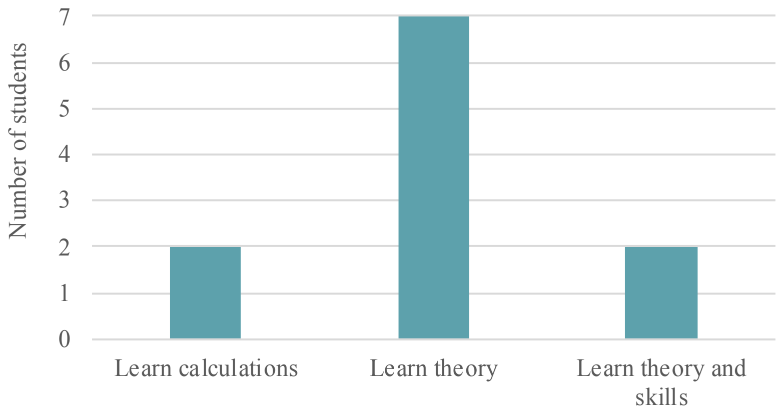
Meaning increasingly specific

Degrees of defined symbolic meaning	**Perceived usefulness of participating in the study** Quite a lot	A little	Very little
Well defined	0	1	1
One double meaning	0	1	0
Symbols as observations	1	0	0
Particles as symbols	1	3	0
Poorly defined	3	0	0
Total individuals	5	5	1

The aim of the practical undertaken the day after the concept-mapping class was perceived as mostly theoretical by the students (see figure 4), which was surprising considering the technical focus of the lab (finding the acetic acid concentration of common household vinegar through multiple titrations). This could be interpreted as a sign of knowledge integration taking place, as a high amount of theoretical thinking is unusual for students participating in science practicals (Lunetta, Hofstein, & Clough, 2007).

It would appear from this study that triplet concept mapping is a feasible method for knowledge integration that students find useful, even if they do not immediately perceive difficulties in differentiating between the three types of concepts in the study. However, it is suggested that triplet concept mapping is accompanied by social dialogue between both peers and teachers to increase meaningful understanding of the triplet model as well as dialogic interactivity.

Figure 4. Categories of students' answers to the question 'What do you think was the goal of today's laboratory exercise?' in the student survey (N=11).



CONCLUSIONS

From a sociocultural perspective, the development of student thinking occurs through reasoning utilizing cultural tools of social origin (Davydov, 1995). Hence, if students are to learn to master expert-like thinking through knowledge integration (Anderson & Schönborn, 2008) in terms of the different meanings represented by the chemistry triplet, this thinking needs to be actively encouraged through social interaction and meaningful class practices. The study presented in this paper successfully utilized a sociocultural perspective to explore the possibilities of studying contextual influences on concept development through triplet concept mapping. From this theoretical perspective, the teacher and the classroom culture can be seen as intimately connected to the students' learning, which can be defined as appropriation of cultural tools within a certain social context (Wertsch, 1991). Within this context, differences in dialogic agency and how language is used to convey meaning become important markers for how differences in language background, social class, gender or achievement level affect learning pathways within the same classroom. With its possibilities of capturing precisely these aspects of classroom learning, triplet concept mapping appears to be a useful tool for the study of conceptual development in chemistry in relation to the learning environment.

In this paper a plausible set-up for teaching triplet concept maps for knowledge integration in 60 minutes was also demonstrated, although more extensive peer and teacher dialogue is recommended to improve student agency and communication of meanings in the classroom. Indeed, previous concept-mapping knowledge integration attempts in biology has shown that high peer interactivity through dialogue produces better results than the studying of expert concept maps (Schwendimann & Linn, 2016). Previous research utilizing long-term efforts of integrating the idea of the triplet in teaching practice long-term has also shown that students can find the idea of triplet levels in chemistry initially difficult and may need time to work with the idea to appreciate it fully (Thomas, 2017). Further comparative studies would be needed to assess triplet concept mapping as a pre-lab exercise, although this study shows great promise for future research in this area as the students had a high focus on theoretical learning during the practical.

In the particular student group studied, differences were found with regard to dialogic interaction with the triplet concept, as well as how symbolic representations were defined in the classroom. However, given the small scale of this study, a larger qualitative study would be needed to fully explore differences in how students relate to chemistry triplet, taking into account classroom aspects such as social roles and how language is used to reason around chemical processes. As differences in classroom dialogic agency between genders has been well established previously (Howe & Abedin, 2013), it would be particularly interesting to study how differences in classroom dialogic agency can influence students' internal dialogic relationship with the knowledge domain of chemistry.

THE NECESSITY OF BEING AWARE OF ANOMALOUS DATA – CONCEPTUAL DEVELOPMENT WITHIN PEER COLLABORATION

Sarah Hundertmark[1], Julian Heeg[1], Johanna Kanne[1] and Sascha Schanze[1]
[1] Leibniz Universität Hannover, Hannover, Germany

The purpose of this paper is to shed light on the impact of discursive processes on conceptual development in a collaborative learning situation in chemistry. Conceptual development is seen as the process of constructing new conceptions or reorganise existing ones (Duit et al., 2012) which can be promoted by instructed peer collaboration (Schraw et al., 2006). We see following factors as influencing: a) adequate cognitive differences of the prior knowledge, b) argumentative complexity of the students' discursive processes, c) awareness of each other's conceptions and d) an appropriate quality of response to productively draw conclusions from each other's conceptions.

In this paper, we present a 4-step qualitative analysis, which was applied to two groups. The approach systematically revealed different dependencies of successful collaboration. We found deep insights into the quality of discursive processes as well as into the students' engagement in discussing diverse ideas (see Hundertmark, 2012). The results showed that conflicting conceptions and a complex structure of the conversation were predictive for a deep collaborative process. Comparing the two groups, a higher complexity of the conversational structure interrelates to the higher awareness of the partners' conceptual understanding as well as to more fruitful response regarding the conceptual development. So far, awareness and the quality of the students' response to each other's conceptions seem to be one relevant aspect regarding the success of collaboration.

Keywords: Conceptual Development, Collaborative Discourse, Qualitative Analysis

INTRODUCTION AND THEORETICAL BACKGROUND

The purpose of this paper is to shed light on the impact of discursive processes on conceptual development in a collaborative learning situation in chemistry. According to Taber (2001) and Duit, Gropengießer, Kattmann, Komorek, and Parchmann (2012) conceptual development is seen as the process of constructing new conceptions or reorganise existing ones that are based on learners' everyday experiences. Peer collaboration can additionally be used to promote conceptual development among students as they discuss and compare their conceptional understanding (e.g. Schraw, Crippen, & Hartley, 2006). It is assumed that reflection on one's own as well as on one's partners' understanding can foster effective conceptual reorganisation (Land & Zembal-Saul, 2003). These processes could be supported by methods or tools that help to make conceptions visible (Fischer, Bruhn, Gräsel, & Mandl, 2002; Linn, 2000; Roth & Roychoudhury, 1992). For a goal-oriented and instructed collaborative peer-to-peer collaboration process that leads to fruitful conceptual development, following factors are relevant:

a) Adequate cognitive difference: To have a reason for discussion and subsequent argumentation processes, the students need a particular conflict potential regarding their prior knowledge (e.g. Howe & Zachariou, 2019). Nevertheless, it is argued that the degree of difference requires to be appropriate, which means that students' conceptions should not be too similar or too different (Webb et al 1996). In the first case, there would be no need for discussion. In the second case, it would either be too challenging to create mutual understanding, or the group will rather accept a solution of one of the group members.

b) Argumentative complexity: The degree of engagement in discursive argumentation is associated with the depth of the responses to different concepts and further discursive development of the shared conceptions. Complex structures, where students argumentatively construct their common conceptions, are of higher collaborative quality. Whereas conversation, mainly characterised by mutually naming of initial ideas, are less structured and of lower collaborative quality (Hundertmark, 2012).

c) Awareness: In order to effectively talk about each other's conceptions and to agree upon a shared solution, the students need to be aware of differences between of their own and the partners' conceptions (Howe, Tolmie, Greer, & Mackenzie, 1995). In our study, we use the terms congruent or anomalous conceptions to express similarity or difference of conceptions.

d) Quality of response: At least, differences in learners' conceptions are necessary but not sufficient for fruitful discursive processes. Collaborative conceptual development also depends on the way how students productively draw conclusions from each other's (anomalous or congruent) conceptions (Howe & Zachariou, 2019). Responses vary in terms of different qualities and aims. A simple agreement or rejection of a partners' statement without evidence is of less quality than a chain of (conceptual) arguments that goes back and forth. In addition to b) that rather focus on a structural level this aspect takes also a conceptual dimension into account.

Within our study, the four aspects a – d serve as framework for analysing discursive processes in a collaborative learning situation. We used pre-structured worksheets that ask students to explicate their ideas multimodally through short texts, symbolic representations and drawings. Within a previous individual phase (IP), the students work on the tasks for themselves, which means, that they externalise and reflect their ideas individually. In a subsequent collaborative phase (CP), all individual solutions are presented to each other to collaboratively agree on one shared solution, which the groups fixed on an additional worksheet. The collaboration processes are supported by a collaboration script (Kollar, Fischer, & Hesse, 2006) in which learners are guided in sharing their knowledge and achieving a shared solution. The combination of an individual and a collaborative phase is seen as essential to ensure students active involvement in conceptual development processes (Heeg, Hundertmark, & Schanze, in press; Olsen, Rummel, & Aleven, 2019) and gives the students a frame to consciously reflect on each other's understanding (e.g Fellows, 1994).

RESEARCH QUESTIONS

To what extend are the following factors influencing successful collaboration: a) differences in prior knowledge, b) degree of engagement in discursive argumentation, c) awareness of anomalous data, d) reactions while confronting anomalous data?

METHOD

Data collection and participants

The study took place in different grammar schools (Gymnasium) in Germany. Negotiation processes of 30 dyads (grade 8 to 9, age 13 to 15) were audiotaped. The underlying phenomenon of the task is the combustion of carbon in a closed system (e.g. Özmen & Ayas, 2003). This topic had been covered in class prior to study.

The focusses of this paper are on the presentation of the instruments and the methodological approach. To demonstrate our procedures, results of two dyads are presented in detail. These two groups serve as exemplary types: they both start on a comparable level as they bring comparable prerequisites into the CP, based on their IP results. However, they show a distinctive progression, which can be traced back to the discursive process.

Data analysis

We used an in-depth qualitative analysis to take the process-related effects with collaborative learning into account. Differences of students' conceptions from each other and in comparison, to their shared solution have been quantitatively evaluated. Regarding aspects a-d of the RQ, the process of successful collaboration is described based on a four-step coding scheme

a) Adequate cognitive difference: For analysing the differences in students' prior knowledge, we took the answers of the IP worksheets into account and assign students' answers to a category scheme of students' conceptions (based on a literature review). This analysis took the adequateness of the content (adequate - partly adequate - inadequate) as well as the level of representation (macroscopic to submicroscopic) into account. A significant difference is given, e,g, if one student shows few adequacies on a content level as well as individual representations only on the macroscopic level whereas the partners' solution is of high adequacy on a sub-microscopic level. The potential of conflict that leads to a fruitful argumentative discussion about the students' conceptions is considered as high, if the students of one group show many strikingly different ideas that are conflictive to the partners' ideas. (e.g. coal is destroyed vs coal becomes gaseous).

b) Argumentative complexity: In a first step, we analysed the transcripts from the CP in order to find typical elements of argumentative structures like *Claim, Reason, Description/Explanation, Question, Assumption or Acceptance*. Therefore, a coding scheme developed by Hundertmark (2012) was adapted. These elements were arrayed chronologically within a flow chart, each side for one student. References to statements that was made in earlier parts of the discussion were displayed by arrows (see Fig. 1-3). Within these prepared transcripts, typical conversational patterns were analysed and categorised. A total of 14 different conversational patterns like *Monologue* (see Fig. 1), *Acknowledgement* (see Fig. 2), *Elaborative Conversation* (see Fig. 3) were identified and assigned to three different levels of complexity (low, medium and high complexity of conversational pattern). The *Monologue* has the lowest complexity as there are no references to statements of the partner. The pattern *Elaborative Conversation* is an example of higher structural complexity as it highlights that both students are involved in more in-depth content related discourse.

Figure 1. Conversational Pattern "Monoloque"

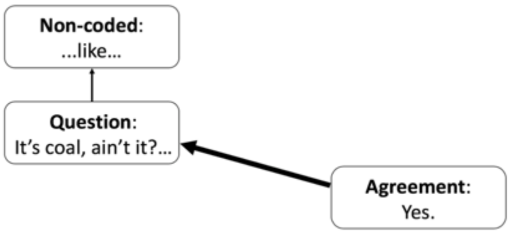

Figure 2. Conversational Pattern "Acknowledgement"

c) Awareness: Students' single statements were examined in detail regarding their awareness of equality or differences. Categories were built inductively based on Maying (2015). Different types of comments are obtained and assigned to different groups of awareness. For the analysis, we classified, whether awareness to anomalous or congruent conceptions was found or not. For our study, it was only relevant whether there is any indication of awareness of abnormality or normality. To illustrate the procedure, we refer to an example from Fig. 3, where students 1 questioned: *"…but it won't turn into ashes, will it?"*. The response of student 2 *"…I thought it was going to turn into ashes…"* point out his / her awareness of Inequality between the two statements.

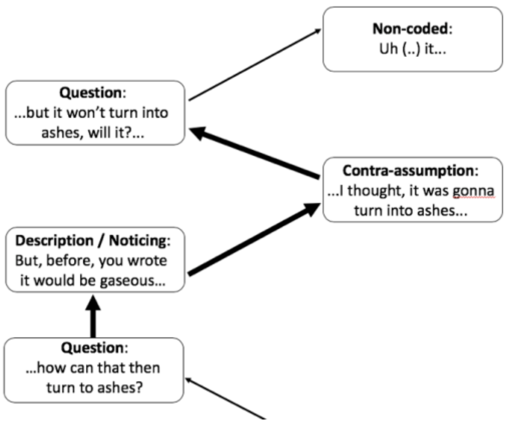

**Figure 3. Conversational Pattern "Elaborative Conversation.
Arrows highlighted in bold represent awareness of anomalous/congruent conceptions.**

d) Quality of response: This step of analysis evaluated in-depth these students' conversations, that followed a coded awareness of anomalous or congruent conceptions. As an example in the conversation part presented in Fig. 3 the statement *"…I thought, it was gonna turn into ashes…"* was interpreted as a conflicting response to the partners' conception (awareness of anomalous data) and therefore categorized as *a confrontation of opposing ideas*. These categories then were assigned according the complexity of content related argumentation in three different levels. Level-I-Responses are of low complexity and show little content relation (e.g. *statement of unknowing, acceptance of a comment*). In contrast, Level-III-Responses have a high complexity and a content-related argumentative character (e.g. *search for common ground, naming an argument for s.o. own idea*). Level-III-Responses are seen to have a higher potential for conceptual development within the discursive process.

In our study, the *success of collaboration* was determined by a positive development in student solutions when comparing worksheet results from the IP with the CP.

RESULTS

In Table 1 relevant data is aggregated from the two selected dyads. We present the results again following the four aspects of the framework.

a) The first line of Table 1 shows the degree of differences between the students' individual conceptions and its potential for a conflict. It is classified high for both groups and build a sound basis for a possible subsequent discursive process.

b) For both groups, the conversational patterns were mostly structured by type II (Group 1: 22, Group 2: 4) and III (Group 1: 16, Group 2: 4). Though, the amount of single conversational patterns differed significantly between the groups (Group 1: 42, Group2: 9), which leads to the conclusion that the argumentative process of Group 1 was more complex and more back and forth than for Group 2.

c) During the conversation, the students of Group 1 perceived 68 times anomalous conceptions of each other. 12 times congruent conceptions were noticed. For Group 2, the awareness of anomalous conceptions was counted 7 times and 2 times for congruent conceptions. In conclusion, the awareness of the partners' conceptions was rated very high for Group 1 and low for Group 2.

d) Most of the responses were classified as Level-III-Responses (50,9%) and Level-II-Responses (44,9%) in Group 1, which represented a high potential for further development of the students' conceptual understanding due to the discursive processes. In contrast in Group 2 half of the responses were classified as Level-II-Responses and the other half were evenly distributed between Level I and II. Overall, the responses of the Group 2 students represent a medium potential for further development of conceptual understanding.

At least, the overall results show differences between the groups regarding the success of collaboration (ranking of students' solution in the worksheets from IP compared to CP). The shared solution (CP) of Group 1 improved (showed higher scientific accuracy) than each individual (IP) solution, though, the shared solution was still not entirely correct. Also, the CP results of Group 2 are different to the IP results. However, regarding the adequacy (partly adequate in the CP) one student partly improved compared to his IP results, while the partner remains on the same level.

Table 1. Overview of the condensed results with regard to the analysis scheme a.-d. Interpretation of the results are summarised symbolically: high rated: +, medium rated: o, low rated:-.

	Group 1 (BP-TK)	Group 2 AA-OK
a) Differences in Prior Knowledge:		
Difference between Individuals' Conceptions	**Medium** differences in prior conceptions	**Medium** differences in prior conceptions
Probability of Conflict	**high probability** of conflict regarding discursive processes	**high probability** of conflict in regard to discursive processes
Interpretation	+	+
b) Degree of Discursive Argumentation:		
Absolute Number of Conversational Pattern	**42** single patterns	9 single patterns
Classification of Conversational structures	Type I = 2, **Type II = 22** **Type III = 16**	Type I = 1 **Type II = 4** **Type III = 4**
Rating of Complexity	Medium to high complexity of argumentative structure	medium complexity of argumentative structure
Interpretation	+	o
c) Awareness		
Perception of Anomalous Conceptions (absolute number)	68	7
Perception of Congruent Conceptions (absolute number)	12	2
Interpretation	+	-
d) Quality of Response		
Assignment to Levels of Response	Level 1: 4,05% Level 2: **44,9** % Level 3: **50,9** %	Level 1: 25% Level 2: **50**% Level 3: 25%
Probability for Development of the Conceptions	Both high	Medium
Interpretation	+	o
Success of Collaboration		
Improvement from IP to CP	Both improved	Partly improvement or constant results.

CONCLUSIONS

For a fruitful discursive collaboration aiming at conceptual development, an appropriate diversity of their conceptional understanding seems to be a sound basis. Students' conceptual understanding neither should be too similar nor too varied regarding the technical correctness. Furthermore, discursive conversations are triggered when conflicting ideas collide (e.g. mass is destroyed vs. mass cannot be destroyed). Nevertheless, all conceptions should be made explicit within a group, which highlights the need for instructed externalisation practices.

In our study we compare two dyads discussing tasks about the concept of combustion. Both groups show similar prior knowledge regarding their differences in individual conceptions about combustion, which indicates a potential conflict resulting in an intensive discursive conversation. Nevertheless, our data show that conflicting conceptions and a complex structure of the conversation alone are not predictive for the overall collaborative success, as both groups perform differently. This calls for deeper analysing the engagement on a content level. In this respect, however, there are significant differences between the groups. The argumentative processes of the groups profoundly differ concerning their complexity. Also, qualitative differences between the groups are evident in terms of awareness and response: the group with higher complexity of conversation more often show awareness of the partners' conceptual understanding as well as more fruitful response regarding the conceptual development. This leads to an interrelation between the quality of discursive collaboration and conceptual development (success of the collaboration on the level of CP results compared to IP results in the worksheets). Consequently, it is required to analyse more systematically, if the frequency of awareness and the quality of response to the partners' expressed conceptual understanding are predictive for a successful collaborative process, which is being proven by analysing further groups.

In this study, we associated the conceptual development facing the group performance by comparing the individual solutions and the collaborative solution. Next, we need to ask for the transfer of these results to the individual level, which requires an evaluation of the individual students' improvement after collaboration.

So far, our findings point to a promising methodical procedure. We used a 4-step analysis that systematically reveals different dependencies of successful collaboration. The analysis of the conversational structures is complex but useful as it gives deep insights into the quality of discursive processes as well as into the students' engagement in discussing diverse ideas (see Hundertmark, 2012). Nevertheless, the analysis of the conversation shows that taking the argumentative processes on the content level into account is necessary. So far, awareness and the quality of the students' response to each other's ideas and conceptions seem to be one relevant aspect regarding the success of collaboration.

ACKNOWLEDGEMENT

The authors would like to thank all students and teachers involved in the study for their contribution to this project.

USING THE PEER-INTERACTION-METHOD TO DIAGNOSE AND FOSTER STUDENTS' CONCEPTIONS ABOUT COMBUSTION - AN IN-DEPTH ANALYSIS ON PROMINENT STUDENTS' CONCEPTIONS AND THEIR DEVELOPMENT

Julian Heeg[1], Sarah Hundertmark and Sascha Schanze

[1]Leibniz University of Hannover – Institute for Science Education, Hannover, Germany

Learners show a multitude of (alternative) conceptions about many chemistry topics like processes of combustion that determine further learning processes. Teachers, therefore, need methods to diagnose these (alternative) conceptions in their classroom and to support their students' development towards scientifically adequate conceptions. Collaboration is one possible and fruitful method for supporting conceptual change processes among learners. The Peer Interaction Method (PIM) is a collaborative teaching-learning setting that helps to diagnose and foster students' conceptions at the same time. The PIM is a two-stepped method, consisting of a previous individual (IP) and a subsequent collaborative phase (CP). Currently, however, little is known about the extent to which students develop their conceptions as a result of collaborative processes. This paper aims at introducing the peer interaction method (PIM) as an instructional design to support the identification of prominent students' conceptions and their development as a result of this intervention.

Therefore, completed working sheets (N=136 students grade 8-9, grouped in 68 dyads) from one implementation were collected and analysed using a manual, consisting of 55 different conceptions about combustion. This analysis serves to identify students' conceptions before and after the collaboration. 14 different alternative conceptions can be identified, which are addressed at least five times in total by the students in their IP and CP worksheets. Six of these conceptions can be assigned to two broader content categories (e.g., "coal is destroyed"). Solely conceptions from the type "coal is destroyed" can be significantly less diagnosed in the worksheets after the CP. This finding does not apply to the other prominent alternative conceptions. Possible reasons and implications for teaching and research are discussed.

Keywords: Learners' conceptions, processes of burning and combustion, collaborative learning

INTRODUCTION AND THEORETICAL BACKGROUND

Learners have a multitude of everyday conceptions about many chemistry topics that determine further learning processes (e.g. Taber, 2019). Referring to the process of combustion, some of these conceptions are considered as being of central importance for the conceptual development, as reported in the literature (Özmen & Ayas, 2003; Prieto, Watson, & Dillon, 1992). It has been a consensus for decades that learners' conceptions are resistant even if students are instructed to change (e.g. Wandersee, Mintzes, & Novak, 1994). There is, however, no general agreement on the reasons for this resistance (e.g. Özdemir & Clark, 2007). In some cases, a firm anchoring of individual conceptions, due to students' everyday experiences, is named to be a possible reason (Amin, 2009; Niebert & Gropengiesser, 2015). Following Wandersee et al. (1994), we define those learners' conceptions, which are not congruent with a subject-related reference frame, as learners' alternative conceptions.

To support students' conceptual development towards scientifically adequate conceptions, teachers need methods to diagnose students' alternative explanations in their classroom. The first step in the evaluation process is to make them externally accessible (Driver, Asoko, Leach, Scott, & Mortimer, 1994). In general, learners are rarely aware of their conceptions, and they show difficulties in expressing them for several reasons. Therefore, reflection and externalization processes need to be supported by reasonable instructions to multimodally represent their ideas (e.g., text, drawing) (Prain, Tytler, & Peterson, 2009; Treagust, Chittleborough, & Mamiala, 2003). Also, mutual negotiation processes within collaborative learning scenarios are seen as being helpful (Hundertmark, 2012) if a previous individual confrontation and externalization processes occurred (Driver et al., 1994). However, only a few studies explicitly consider a previous and extensive individual phase (e.g. van Boxtel, van der Linden, & Kanselaar, 2000).

Collaboration is seen as fruitful for students to jointly (re)construct their conceptual knowledge (Schraw, Crippen, & Hartley, 2006; Tao & Gunstone, 1999) and to support a conceptual change among learners (e.g. Howe, Tolmie, Greer, & Mackenzie, 1995). Successful collaboration requires that all learners actively participate in the learning process and take responsibility for a common goal (e.g. van Boxtel et al., 2000). In order to structure a complex collaborative learning processes, Kollar, Fischer, and Hesse (2006) suggest the implementation of specific collaboration scripts.

Based on these essential features, we developed the Peer-Interaction-Method (PIM) as a two-stepped collaborative teaching-learning format (Heeg, Hundertmark, & Schanze, submitted), which can be used to simultaneously diagnose and foster students' individual conceptions (see Figure 1). The PIM consist of a previous individual (IP) and a subsequent collaborative phase (CP).

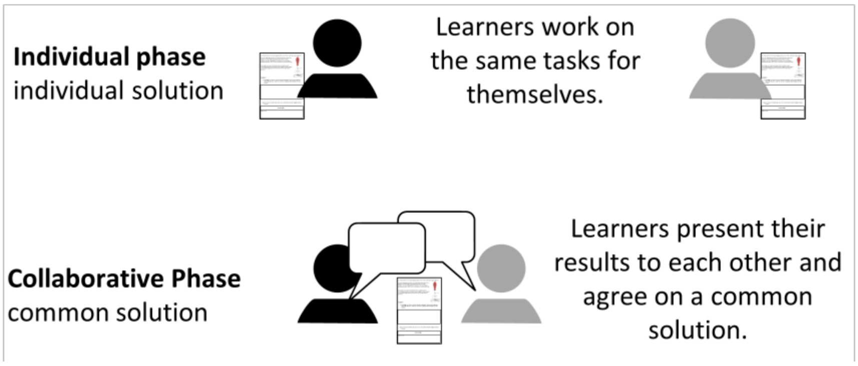

Figure 1. The two phases of the PIM illustrated here for dyads.

This paper aims at introducing the peer interaction method (PIM) as an instructional design to support the identification of prominent students' conceptions and their development as a result of this intervention. Currently, in the field of chemical education, little is known about the extent to which students develop their conceptions due to collaborative processes. Regarding this desideratum, this paper gives insights into students’ conceptual development due to collaborative negotiation processes.

RESEARCH QUESTIONS

RQ1: To what extent are learners encouraged by the PIM to externalize their individual conceptions, and which of these alternative conceptions can be identified as prominent ones?

RQ2: To what extent are the prominent learners' alternative conceptions developing as a result of the collaborative phase?

METHOD

Participants, data collection and analysis

The study took place in several high schools (Gymnasium) in Germany. IP and CP worksheets of 136 students (55.1% female, grade 8-9 and grouped in 68 dyads) were collected and analysed by two raters (κ = .83) using a coding manual which consists of 55 already published scientifically adequate as well as alternative conceptions about combustion (Heeg, Hundertmark, & Schanze, in press). The students who participated in this study were recruited voluntarily by their teachers and free to choose their partner. All students were familiar with the underlying phenomena; accordingly, the conceptions were raised after instruction. The worksheets consist of four different tasks (T1: multiple-choice with T2: open ended second tier question, T3: reaction scheme, and T4: drawing task see Figure 2). All tasks include the combustion of (char-)coal in a closed system (Heeg, Hundertmark, & Schanze, in press).

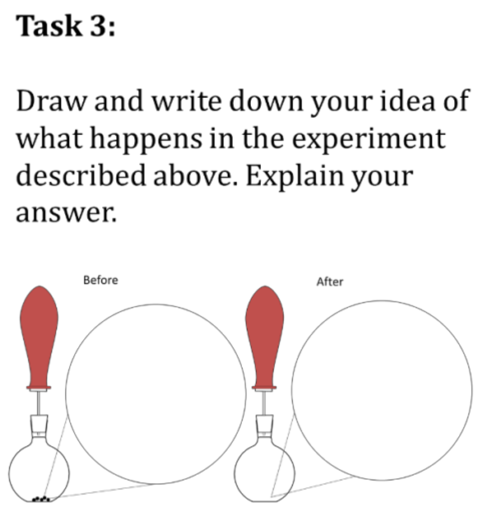

Figure 2. The drawing task (task 3).

RESULTS

RQ1: Externalization of (prominent) learners' conceptions

In total, 14 out of these 23 alternative conceptions are diagnosed minimum five times in the learners' worksheet (IP and CP) and are defined here as prominent learners' alternative conceptions (see table 1). These 14 prominent conceptions have been diagnosed a total of 539 times in across the worksheets.

The result of an exploratory factor analysis (KMO=.612, oblimin rotation) shows that only two factors (categories), each with three variables (conceptions), can be found, in which the eigenvalue of the factors is greater than 1 and the factor loadings greater 0.4 (Stevens, 2012). Subsequently, these six prominent alternative conceptions can be assigned to the two different categories *coal is destroyed*, and *coal becomes gaseous*. Reliability analysis using Cronbach' s-Alpha show values of .76 for category 1 and .74 for category 2. This does not apply to the remaining eight students' conceptions which, for example, relate to aspects like *gases weigh less than solids* (C3) or *ash is a product* (C26). The results in table 1 also show that category 2 conceptions can be found in more than half of all worksheets.

Table 1. Overview over the 14 prominent learners' conceptions.

Conception	N	% (N=204)
Category 1: Coal is destroyed		
Coal atoms are destroyed / Coal is destroyed *without* mentioning the emergence of new substances (C15a)	33	16.18
Carbon dissolves and there is no substance left (C19)	32	15.69
Submicroscopic entities (e.g. atoms) are destroyed / macroscopic entities (e.g. substances) are destroyed without mentioning the emergence of new entities (C1)	22	10.78
Category 2: Coal becomes gaseous		
The appearance or properties of some reactant have changed, the substance (e.g. coal) still exists (C14)	121	59.31
Coal changes its condition of aggregation (e.g. it evaporates) (C11)	110	53.92
The product is a different gas than carbon dioxide (C30)	110	53.92
Category 3: Other prominent conceptions		
Gases weigh less than solids (C3)	33	16.18
The product mixes with the oxygen (C36)	19	9.31
Due to the buoyancy of gases, the flask weighs less (C5)	15	7.35
Carbon monoxide is the only product (C27)	14	6.86
Due to another modification of the substance, the flask weighs less (C6)	10	4.9
Ash is a product (C26)	8	3.92
Gases weigh nothing (C4)	7	3.43
Oxygen molecules are destroyed / Oxygen is destroyed *without* mentioning the emergence of new substances (C16a)	5	2.45

Additionally, the six prominent conceptions (conceptions from categories 1 and 2) are distributed over three tasks within the worksheets (T2-T4). Concerning the residual eight conceptions (category 3), only C5 and C26 were frequently represented. Out of the 14 prominent alternative conceptions, a maximum of 8 conceptions can be diagnosed simultaneously in the worksheets (see Figure 2). In most worksheets (24%), three different alternative conceptions can be identified parallelly. But, in about 22 percent, none of the 14 prominent alternative conceptions can be found in the worksheets.

RQ2: Development of (prominent) conceptions

The total number of prominent alternative conceptions per worksheet decreases significantly from IP to CP (see figure 3) when tested with Wilcoxon Signed Rank test ($z = 3{,}76$, $p < .000$). Besides, conceptions from the category *coal are destroyed* can be significantly less diagnosed in the worksheets after the CP (see table 3) with medium effect sizes. These results have not been confirmed for the other prominent conceptions.

Table 3. Development of some prominent learners' conceptions.

Conception	Wilcoxon test	IP (N=136) %	CP (N=68) %
Category 1: Coal is destroyed			
Submicroscopic entities (e.g. atoms) are destroyed / macroscopic entities (e.g. substances) are destroyed without mentioning the emergence of new entities (C1)	z = 2.35, p = .019, d = .41	11.76 %	5.88 %
Coal atoms are destroyed / Coal is destroyed *without* mentioning the emergence of new substances (C15a)	z = 2.60, p = .009, d = .46	20.59 %	7.35 %
Carbon dissolves and there is no substance left (C19)	z = 2.88, p = .004, d = .51	16.91 %	8.82 %

Concerning conceptions of category 2 a positive development is found. Among other factors, this development is interrelated to the extent to which the learners already showed these conceptions in the individual phase (see table 4). Overall, medium size connections between these factors can be found for conceptions from the category 2 (for the other prominent conceptions see Appendix 1).

Table 4. Occurrence of conceptions from category 2 in the CP in dependence of the IP results.

	C11 (%)		**C14 (%)**		**C30 (%)**	
	Not diagnosed in the CP	**Diagnosed in the CP**	**Not diagnosed in the CP**	**Diagnosed in the CP**	**Not diagnosed in the CP**	**Diagnosed in the CP**
Not diagnosed in the IP	90	10	95	5	91	9
Diagnosed in only one IP	45	55	40	60	56	44
Diagnosed in both IP	43	57	22	78	29	71
Cramér's V	V = .43, p = .002		V = .53, p < .0001		V = .42, p = .003	

The results from Table 4 show that if only in one learners' IP worksheet a specific conception can be found, this conception cannot be diagnosed in the common product in between 40 (C14) to 56 percent (C30) of the cases.

DISCUSSION AND OUTLINE

Previously published scientifically accepted as well as alternative conceptions build the basis for the development of this coding manual (Heeg, Hundertmark, & Schanze, in press). Hence, the coding manuals' purpose was to evaluate students' conceptions deductively, which helped to ensure the validity of the survey.

Analysis of the data shows that 14 different alternative conceptions occur more frequently than other conceptions in the context of this study. Six of these 14 prominent alternative conceptions can additionally grouped into two major content categories (factors). However, the explained variance by these two factors is only about 29 percent. Based on this and due to the small sample size, these results have to be replicated in further studies.

The results of this study also illustrate that the learners' IP worksheets show, on average, only in one about 20 percent no indication for prominent alternative learners' conceptions. This is even more remarkable since the entire survey took place after instruction. In addition, the results indicate a co-existence of diverse conceptions on the same topics and at the same time for the same students which is consistent with Taber (2019).

As previously mentioned, some conceptions (C1, C15a, C19) developed positively due to the PIM. However, this study did not investigate whether and to what extent this is a sustainable effect. Chinn and Brewer (1993) were able to show that learners, when confronted with different conceptions (anomalous data), use different coping strategies. Part of these strategies can, for example, be a superficial acceptance. In this context, Tao and Gunstone (1999) show that learners must recognize a meaning in the new conceptions in order for a long-term change to take place.

Regarding all prominent alternative conceptions, however, it has to be stated that they do not significantly change. When planing their lessons, teachers should take these results into account. In general, instructions need to build upon those prominent conceptions to help students' conceptual development. The data also indicates that some learners' conceptions (e.g. C11, C14, C30) do hardly develop within this intervention and the instruction before. One possible reason for this could be that these everyday conceptions are firmly anchored in the students' daily world (Amin, 2009; Niebert & Gropengiesser, 2015). Consequently, the students hold on using these conceptions instead of the scientifically adequate ones (see also Andersson, 1990; Prieto et al., 1992). Therefore, more theory-based learning offers should be developed and evaluated, especially for these conceptions to support learning processes as these conceptions do not change without tailormade external learning prompts.

The study leaves open how the processes of collaboration and negotiation influence the students' conceptual development. However, the results indicate that there are positive conceptual developments, even if both learners have shown indicators for a specific prominent alternative conception on their individual worksheets. Yet, we do not know the reason for this. Therefore, we analyse audiotapes of the collaborative phase from 30 (out of the 68) dyads. The question of this analysis refers to the collaborative and discursive conditions that promote the development of specific conceptions. We currently assume that willingness to reach an agreement, the awareness of different or comparable conceptions between the learners as well as the quality of response to the partners' conceptions are predictive.

FOSTERING DIVERSITY AND CULTURAL AWARENESS EMANATED FROM LEARNING ONE'S CONTEXT

Lamprini Chartofylaka[1], Thomas Forissier2
[1,2]CRREF (EA-4538), INSPE de Guadeloupe, Université des Antilles,
Les Abymes, Guadeloupe, France Outre-Mer

In recent years, technology - enhanced learning environments bring parts of the world into the classroom. This paper values the importance of integrating cultural elements into the construction of scientific knowledge through educational practices, especially during the first school years of an individual. The evidence is drawn from a research project based on the implementation of a context effect-innovative learning strategy involving the use of technology to facilitate exchanges between learners around the globe. In our study case, putting synchronous and asynchronous forms of communication into practice between students in Guadeloupe and in Quebec, we identify the extent of children's active construction of scientific and global knowledge nurtured within intercultural experiences. Participants were asked to supply answers (during the post-test questionnaire phase) related to their impressions and the milestones acquired during communication with diverse cultures -peoples and contexts. As a result, the intricate world of their understanding inspired by their intercultural exchanges has been qualitatively classified into different categories and presented in this article for further exploration.

Keywords: Culture, Context-effects, Collaborative Online Learning

INTRODUCTION

Societal and cultural factors have an important impact on children's development, in particular when they form their identity and when they shape their mental representations of the world. As one's cognitive development is built upon the interpretation of different schemas (Piaget, 1926), children tend to interpret their environment by elucidating information within the intellectual experiences they undergo. In a social-constructivist approach, young children construct actively their own learning and making sense of the world when interacting and collaborating with others (Vygotski & Sève, 1985). Alongside, cultural artifacts -as means of society's values, events, symbols- provide a vital framework for individuals to collect units of knowledge of other people's way of living and share meanings with them. In the realm of education, the intercultural dimension is portrayed as one of the more important objectives of learning procedure: one's decentration from their own cultural-based assumptions by reconceptualizing their worldviews in consistency with appreciating other people's contexts (Scarino et al., 2009). Regarding scientific thinking, learners can reflect on and investigate their natural environment by making inquiries (Cariou, 2009) which will then help them to answer specific questions leading to the development of a general and worldwide content (Gauch, 2009). Considering all the aforementioned, the outpouring of scientific interest and work of people is enhanced by the implementation of learning experiences putting them in collaboration - a procedure whose communication is undoubtedly nurtured when one creates and exchanges meanings across cultures, across contexts. Acknowledging the huge potential of new technologies into teaching and learning practices, it is now possible for learners around the world to maintain ties with their peers and to construct their knowledge and views in a computer-supported collaborative environment. The advances in virtual collaboration reveal many opportunities for connecting online learners in the spirit of real-world and authentic learning situations (Bonk & Cunningham, 1998). In some respects, exploiting the collaborative aspect of learning and meaning making mediated by technology (Baker, 2003; Dillenbourg, 1999) children are prone to develop a positive aspect towards community participation and as an extension towards the concept of global citizenship for civil society.

THEORETICAL FRAMEWORK

General theoretical model and context-effects

This study is a part of a larger project, under the name "Technologies Éducatives pour l' Enseignement en Contexte -TEEC" (in French), "Educational Technologies for Teaching in Context" (in English). It is funded by the French National Research Agency (ANR) and the Quebec Research Funding for society and culture (FRQSC). Its objectives entail the development and implementation of a learning approach based on context-effects between learners in Guadeloupe and in Quebec (Forissier et al., 2017). In essence, students from different contexts collaborate together in short-term research projects, linked to different scientific disciplines: geothermal energy, sustainable development, linguistics, socio-history. Their exchanges (oral or written) flourish through synchronous and asynchronous communication environments. In each experimentation, students who are normally in small groups, they are asked to investigate a particular aspect of a given object of study strongly related to their enriched context. During their inquiry process, they interpret information of their context by exchanging and discussing on diverse topics with their peers. In this way, they relate their findings to the findings of others, and they enrich their knowledge by situating their unit of knowledge in respect of relevance and meanings. Throughout students' exchanges during these research practices, a conceptual change is expected by grounding a clash between students' perceptions in those particular contexts, hereby an emergence of a context effect, in the study of the same object or concept (Merlo-Leurette & Forissier, 2009).

Review on cultural competences

Online interactions and collaborations offer huge potentials for developing students' skills. The work of Marope et al. (2017) states that future curricula (4.0) will be based upon learners' competencies such as social and cultural awareness but the need of understanding the demands of learner's context is essential. Having learners from Guadeloupe and Quebec as participants in these experimentations has raised our interest, among other things, in investigating the perspectives of cultural competences issued of their exchanges. For defining the latter, we cite the work of Cross et al. (1989) which refers to cultural competence as "a set of congruent behaviors, attitudes, and policies that come together in a system (..) and enable that system (..) to work effectively in cross-cultural situations". According to Jason (2014) , this is "an ongoing process by which individuals and systems respond respectfully and effectively to people of all cultures, languages, classes, races, sexes, ethnic backgrounds, religions, sexual orientations, abilities and other diversity factors". Undergoing this process means that an individual should go through different phases, known as a cultural continuum (Cross, 2012), from cultural destructiveness to cultural proficiency. Some phases in between those two extremes refer to cultural incapacity, to cultural blindness or to cultural pre-competence. In essence, according to Hall (1989). "In its many forms, culture (..) designates what we pay attention to and what we ignore". As a result, individuals tend to adopt different communication strategies into a process which is called "contexting' by which they filter and evaluate the kind of information they would like to obtain or share with others (Zakaria & Cogburn, 2010). The same work adds that when individuals from diverse cultural backgrounds communicate, the understanding of this process is what helps on overcoming or minimizing cultural differences.

RESEARCH METHOD & DESIGN

The general methodology of the TEEC project is the one of Design-Based Research – DBR (Bourdeau, 2017). Data concerning the influence of context-effects on participants' learning outcomes were collected by pre-test and post-test questionnaires.

Study's focus and research questions

This work focuses in particular on two in-situ experimentations that took place in primary schools: one focusing on linguistics (object of study: folktales of Antilles, of Québec) and the other one on education for sustainable development (object of study: sugarcane, maple syrup). Following the iterative feature of DBR (Akker, 2006), when designing the post-test questionnaire, we added a number of questions in order to measure validly children's' feedback and retain their impressions emphasizing on their own context and the context of their peer team. The general content of additional questions is displayed in the Figure 1 and they are further explained in detail later on this article (cf. Content analysis approach).

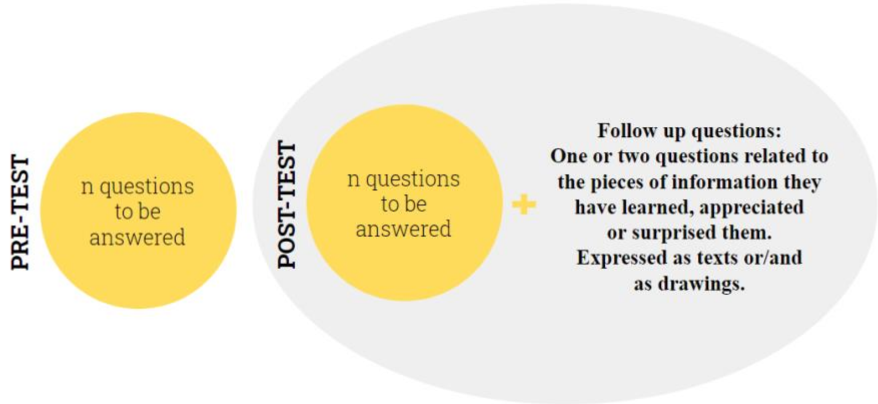

Figure 1. Additional questions in post-test questionnaires for each experimentation.

The main research questions addressed in this study are summarized as follows:

RQ1: Which kind of context is elaborated during the scientific learning and understanding of young learners from different contexts?

RQ2: What type of elements of cultural understanding emerge after the completion of a didactic and collaborative experience between young learners from different contexts?

Content analysis approach

First of all, we provide an overview of the questions asked to the participants of this study. For the experimentation "Linguistics" the question was the following:

- Write in a few words or/and draw what impressed (or surprised) you during the exchanges with the students of the other class.

For the experimentation in "Education for Sustainable Development" the questions were the following:

- What did you learn during the exchanges with the students of the other class?
- Write in a few words or/and draw what impressed you (in our context, in the other context).

These are considered as open questions and the drawing task was proposed as in some cases is an effective communication tool for young children (Farokhi & Hashemi, 2011). For the purpose of examining the RQ1, we perform an inductive content analysis (Bengtsson, 2016) of the answers provided. For each participant, written texts or/and drawings in response to one follow-up question were processed as a single unit of analysis. For the RQ2, our analysis is inspired by the framework on cultural dimensions proposed by (Overall, 2009) which was in fact designed for library and information science (LIS) scholars.

FINDINGS

This study involves children aged 10-12 years old from Guadeloupe and Quebec who participated in the two aforementioned experimentations. The data retrieved from their answers (N=43 from Guadeloupe, N=46 from Quebec) in the questions mentioned before during their post-test questionnaires. Their replies were formed after participating in learning situations, involving verbal and nonverbal communication during synchronous sessions (regular videoconferences) and information shared respectively in an asynchronous communication platform, in our case the social learning platform called Edmodo (www.edmodo.com).
In respect of our exploratory research design, our analysis focuses on identifying patterns and characterized the elements emerged during their intercultural exchanges.

Highlighting the context-effects

When examining the answers given, distinctions are drawn between three different scales (micro, meso, macro). We highlight that these effects have been categorized upon the ideas expressed in their replies. More specifically, we investigate if the content was demonstrating a concept embodied either by observing their real environment or by exchanging with the learners from the other context. The categories are the following:

1. Related to *didactic context (course)*: elements representing the subject content learning and teaching, content knowledge related to the object of study (folktales, sugarcane/maple syrup) of the experimentations they have participated
2. Related to *educational context (institutional settings)*: elements representing the existing conditions and the culture of the school, educational practices and strategies occurring in the school environment
3. Related to the *socio-cultural context (society)*: elements representing climate, language, habits, traditions and lifestyle in the outside world

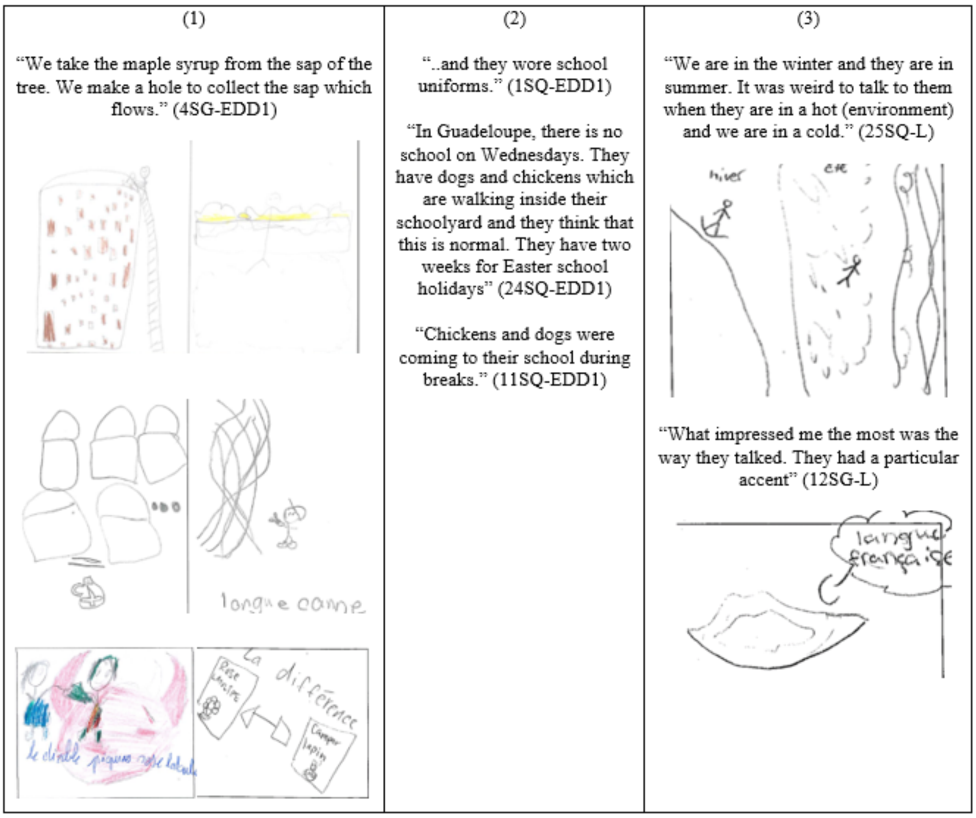

Figure 2. Examples of didactic (1), educational (2), socio-cultural (3) context.

Figure 2 depicts a small sample of the answers provided from the student of the two contexts for each category. We need to note that in general children illustrate examples of things they saw during the videoconferences, information communicated to them from their peers via verbal or non-verbal cues, aspects they observed during their field trips with their classmates.

Cultural competences in perspective

As mentioned before for investigating the presence of cultural competences stemming from the exchanges between learners from Guadeloupe and Quebec, our work is inspired by the framework proposed by (Overall, 2009). According to this article, cultural competences encompass three dimensions: the cognitive, the interpersonal and the environmental one. Along with the classification we performed during the previous section, we believe that most answers included in the third category (cf. socio-cultural context) could be further analyzed into the perspective of cultural competence as those elements exhibit a form of cultural understanding and awareness. Hence, in this section we present a sample of examples that demonstrate cultural competences in the following categories:

1. *Cognitive dimension*: Elements showing individual perceptions for their culture in the alignment with the culture of others, their general knowledge about the culture of others.
2. *Interpersonal dimension:* Elements showing emotions and abilities to collaborate and communicate with others.
3. *Environmental dimension:* Elements showing the understanding of different conditions of a culture (environment, language, natural resources)
4. *Not classified:* Examples that could not be classified in the dimensions mentioned before.

To illustrate these dimensions, in the Figure 3 we present a sample of the answers provided by learners from both contexts.

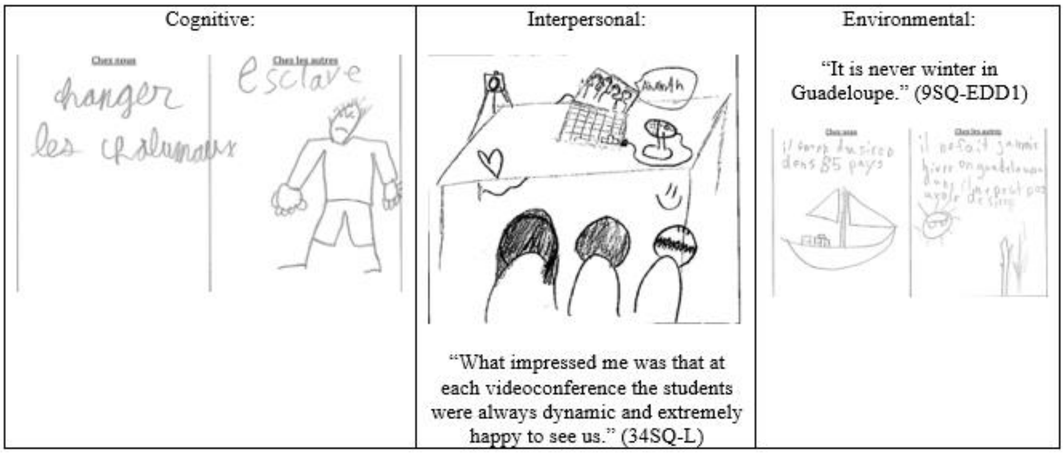

Figure 3. Examples of dimensions of cultural competences.

DISCUSSION

This study demonstrates some preliminary results on the different types of context that can be found in an evaluation phase of a learning experience involving an international audience, in our case students from Guadeloupe and Quebec. However, it is important to highlight some of the limits of this study:

a) In this case study we have a small sample size.
b) Our contexts are Guadeloupe and Quebec, so we cannot generalize all findings for other contexts in interaction.
c) No post-interviews were conducted after the completion of the post-questionnaires.

It provides an insight on the context-effects that can be evoked during this procedure and additionally on the use of these data to further investigate the cultural competences introduced to young learners. The analysis on cultural competences need to be further explored.

CONCLUSION

As child expression is in their nature, there is a huge need of providing them more exciting pedagogical opportunities which will enable them to co-create their worldwide perceptions and build their knowledge in collaboration and in a creative way. Interpreting and revealing elements of their feedback on a research project which supports their intercultural development in practice validates the identification of all these artifacts promoting cultural diversity awareness among them. Sfard (1998) points out the importance for a learner to participate in various social-meditated activities (participation metaphor in learning theories) within a community of knowledge. Transforming learning in the era of computer-mediated environments into making-meaning events rich in discussions and intercultural exchanges is a challenging task for the future. Up to this point, the advances in technological tools can instill empowerment to children regarding the exciting adventure that they will face in the future. The development of learning practices such the one described can embrace innovation in education, more specifically in scientific investigations, along with opening a channel of communication with others. To conclude, as Byram et al. (2001) highlights: "it is not the purpose of teaching to try to change learners' values, but to make them explicit and conscious in any evaluative response to others".

ACKNOWLEDGEMENT

This work has been supported by the project ANR-FRQSC no 2017-QF-210862. QUESTIONING STRATEGIES TO PROMOTE AND ASSESS, COGNITION METACOGNITION AND CONCEPTUAL UNDERSTANDING IN CHEMISTRY: AN ANALYSIS

James Trimble[1], James Lovatt[2] and Odilla E. Finlayson[2]
[1] CASTeL, School of Chemical Sciences, Dublin City University
[2]CASTeL, School of STEM Education, Innovation & Global Studies, Dublin City University

This study focuses on how various types, styles and sources of questions can be used to facilitate higher levels of cognition, metacognition and conceptual understanding in chemistry. This is achieved by analysing in-class questioning and inquiry based activities to determine how they influence a student's metacognitive awareness and approach to conceptional understanding in chemistry. The participants in the current study are two classes of 28 students who participated in an 8-week module of chemistry before deciding to take it as a subject of study for the last two years in upper secondary school. Participants in the study completed pre and post surveys on both their approach to learning chemistry and their metacognitive awareness. The data collected consisted of in-class audio recordings which were backed up for contextual reasons by visual recordings, and also the written work generated by students during inquiry based tasks. The questions and responses which occur during the lessons and evidence of any resulting cognition and metacognition on the part of the students were analysed during the data collection period. The relationship between the students' metacognitive levels and their approach to learning is analysed in the study, both before and after the data collection period. The range of questions posed by the teacher (also the research-practitioner) was analysed and categorised. In this pilot study, the need for a greater range of in-class questions was identified and also the need to be not bound by curriculum in terms of allowing students to develop their own ideas.

Keywords: questioning, cognitive development, metacognition

INTRODUCTION

Metacognition consists of both metacognitive knowledge - knowledge about cognitive processes as well as metacognitive skills – the cognitive processes that regulate and oversee learning (Flavell, 1979). While cognition is necessary to perform a task, metacognition is key to understanding how a task is performed (Schraw, 2001). Although metacognition can be interpreted simply as thinking about one's own thinking, metacognition is a complex construct central to theories of conceptual change (Rickey & Stacy, 2000).

The contribution of metacognition to scientific understanding has become a central area of research (Zohar & Barzilai, 2013). This is perhaps unsurprising, given that science is a quintessentially metacognitive activity: it continually questions itself, probing and testing the robustness of accumulated knowledge (Fleming, Dolan & Frith 2012). Teaching strategies that encourage metacognition and metaconceptual understanding should be fundamental in chemical education as they are the key to more durable and transferable learning and are needed to achieve mastery of the subject (Rickey and Stacey, 2000; Tsai, 2001). In keeping with this, metacognitive skills have been shown to have a significant impact on problem-solving success (Flavell, 1979).

Despite the importance of metacognition and metaconceptual understanding in chemical education, it is an area which is often neglected in teachers' practice (Thomas, 2012). It is crucial, of course, for chemical educators to understand metacognition in order to be able to teach using a metacognitive approach.

This study is particularly interested in the role of questioning in promoting metacognition. Elder and Paul (1998) argue that thinking is not driven by answers but by questions, and to think through or rethink anything, one must ask questions that stimulate thought. Most teachers are not themselves generators of questions and answers of their own, that is, they are not seriously engaged in thinking through or rethinking through their own subjects. Rather, they are purveyors of the questions and answers of others-usually those of a textbook (Elder & Paul, 1998). If teachers want to engage students in thinking through content they must stimulate their thinking with questions that lead them to further questions.

This study examines how teacher questions influence student awareness of their cognition (metacognitive knowledge) and regulation of their cognition (metacognitive skills) in a second level chemistry context.

Objectives

The three primary objectives of this study were (i) to develop teaching and learning strategies which increase higher levels of teacher questioning and student responses associated with metacognition in chemistry, (ii) to determine the students' metacognitive behaviours in response to teacher questioning and (iii) To evaluate the overall impact of metacognitive questioning on students' levels of metacognitive awareness.

METHODOLOGY

An interpretive methodology is used in this research project, as it is concernted with theory building rather than hypothesis testing. Interpretive methodology in an educational context involves classroom observation, interviewing of students and teachers, and the construction of case studies. Some quantitative data is also incorporated into this methodology.

Approach

A pre-pilot study was carried out, which identified relatively low level of metacognitive questioning by the teacher (Figure 1 below). A metacognitive teaching plan was developed, which involved adapting teaching and learning strategies focused on promoting metacognition (see below) for use with the chemistry classroom.

A pilot study was then carried out, which involved implementing the metacognitive teaching plan during an eight week introductory chemistry module. The participants were a group of 28 students aged 15-16 years in a suburban second level school in Dublin, Ireland.

The metacognitive teaching plan

The teaching and learning strategies adapted and included in the metacognitive teaching plan include:

- Explicit Instruction in metacognition. – to promote general awareness of the importance of metacognition in chemistry.
- Regulatory Checklist (RC) – to promote metacognitive skills (King 1991)
- Strategic Evaluation Matrix (SEM) – to promote metacognitive knowledge (Schraw, 1998) Metacognitive curriculum and guided inquiry experiments – to promote metacognitive skills (McGarry et al., 2015)
- Metacognitive Modelling – by students and the teacher to promote metacognitive knowledge and skills (Schraw, 1998)

Recording and analysis of questions, responses and behaviours

All lessons were recorded in order to be able to evaluate student behaviours and responses to questions. Teacher questions were categorised based on knowledge dimensions (Anderson et al., 2001). Metacognitive student behaviours resulting from teachers questions were categorised using Cambridgeshire Independent Learning (C.Ind.Le) framework (Whitebread et al., 2009).

Evaluating metacognitive awareness

The lesson recordings also allowed for an evaluation of teacher questioning and its impact on metacognitive behaviours. Student metacognitive awareness was determined pre and post pilot using the Metacognitive Awareness Inventory (MAI, adapted from Schraw and Dennison, 1994). The MAI is an instrument that measures students' metacognitive knowledge and skills, and also their component subcategories.

RESULTS

The results from this study are outlined below in

(i) Impact of the metacognitive teaching plan on teacher questioning

The inclusion of the use of teaching and learning strategies which explicitly addressed metacognition in the pilot study greatly increased the level of metacognitive questioning occurring during lessons relative to the pre pilot (Figure 1).

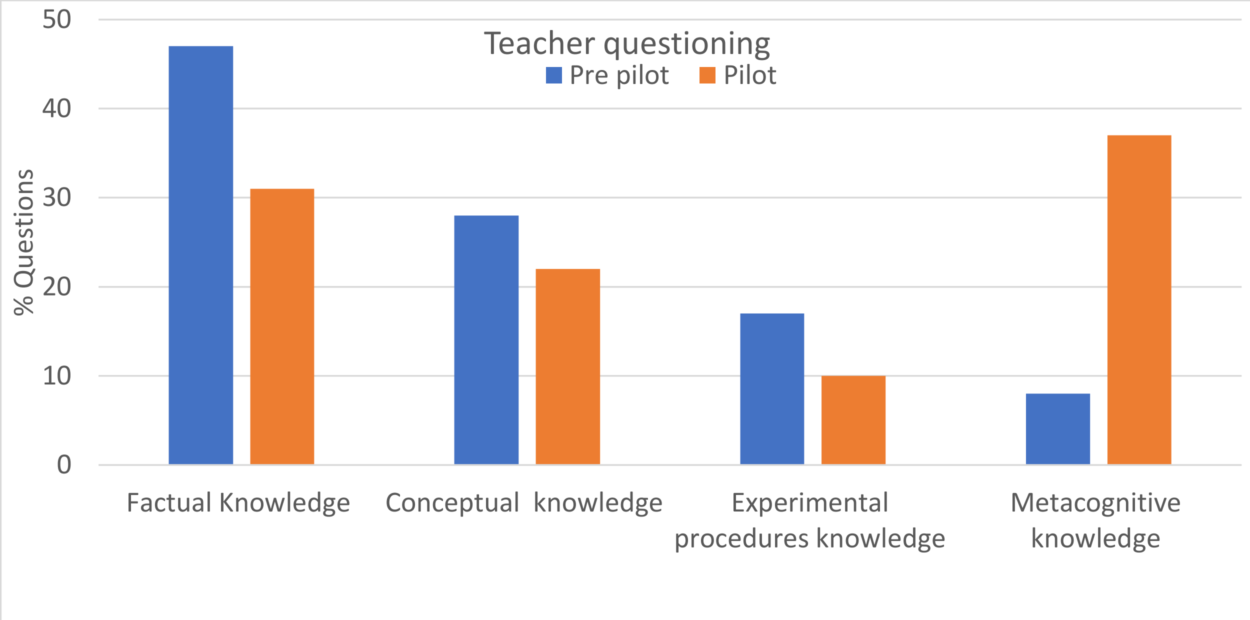

Figure 1 Impact of metacognitive teaching plan on teacher questioning

(ii) Metacognitive student behaviours resulting from teacher questions

The number of incidents of metacognitive student behaviours resulting from teacher questions is shown in Figure 2. It is evident that teacher questioning promoted metacognitive behaviours in the students, particularly the metacognitive skills of control and evaluation.

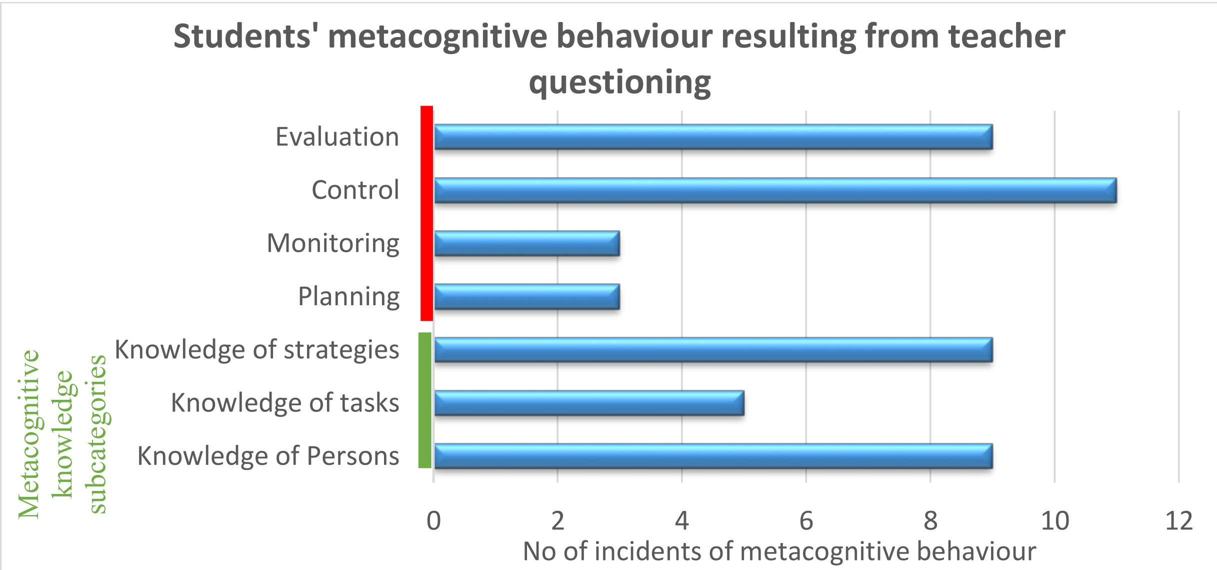

Figure 2 Students' metacognitive behaviour resulting from teacher questioning

(iii) Pre and post-test metacognitive awareness

The pre and post average student scores for metacognitive knowledge and metacognitive skills are shown in Figure 3, together with the scores for the component subcategories. The increase in metacognitive knowledge was primarily due to an increase in procedural knowledge. While the increase in metacognitive skills was primarily due to evaluation, comprehension monitoring and planning. Interestingly, debugging strategies (process of analysing and removing error) scored highly in both pre and post surveys.

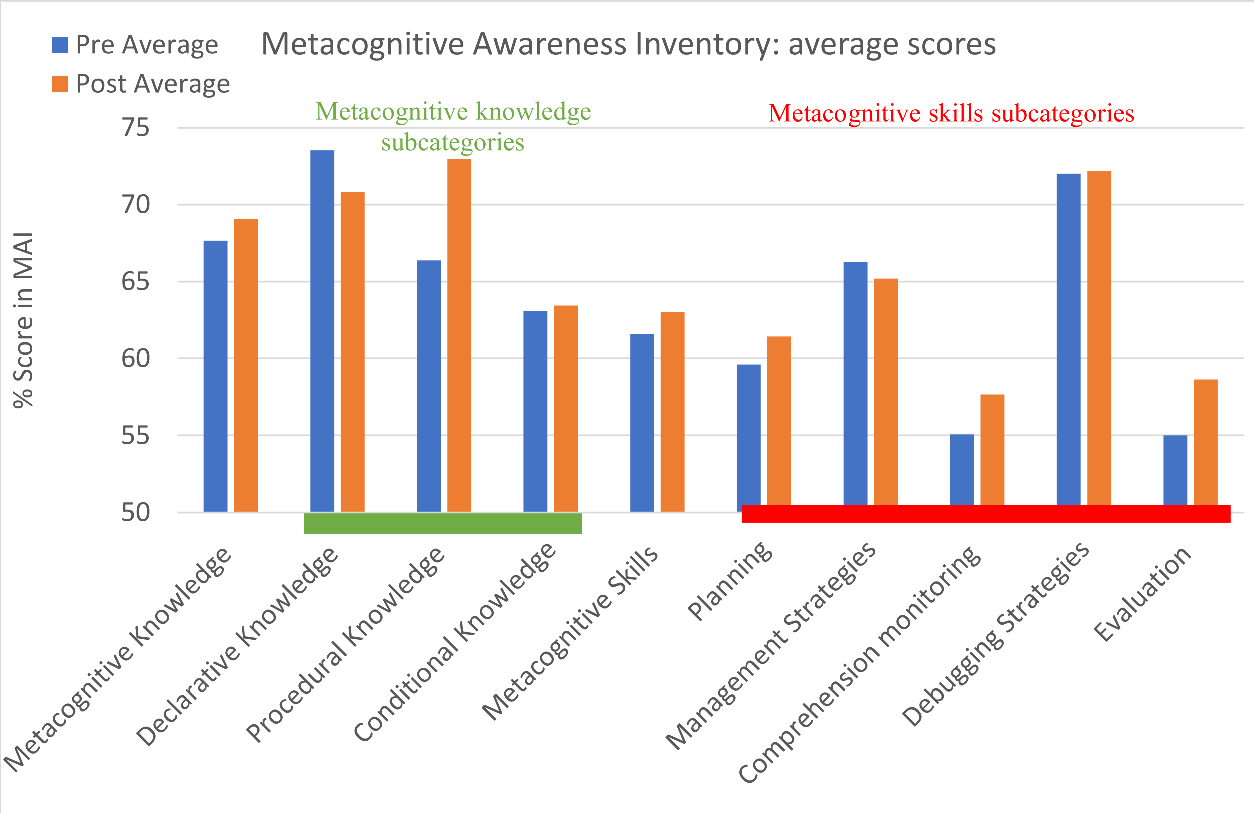

Figure 3 Average student scores: Metacognitive Awareness Inventory

DISCUSSION

The metacognitive teaching plan, which incorporated teaching and learning strategies which explicitly addressed metacognition, let to increased levels of metacognitive questioning by the teacher in chemistry lessons. In this regard, the metacognitive teaching plan was effective.

Students exhibited metacognitive behaviours as a result of teacher questioning, particularly in the metacognitive skills of evaluation and control. Evaluation relates to refers to appraising the outcomes and regulatory process of learning (Schraw., 2006). Control relates to beliefs held by learners, since internal control is effectively achieved when individuals take responsibility for critically assessing what they are doing during learning and why they are doing it (Tsai 2001). In terms of metacognitive knowledge, knowledge of strategies and persons were also frequently exhibited. Knowledge of strategies refers to knowledge about thinking, learning and problem-solving strategies that students might use in order to achieve goals, and knowledge of persons refers to refers to self-knowledge of the variables that influence the individual's cognitive activity, knowledge of the cognition of others and knowledge of the universals of people's cognition (Kuhn, 1999; Kuhn & Pearsall, 1998; Flavell et al., 2002). Implications

It is evident from the pre- and post-MAI surveys that there was a small increase in the average student scores on metacognitive knowledge and metacognitive skills. The increase in metacognitive knowledge is largely due to the increase in procedural knowledge. There was a small decrease in declarative knowledge. In terms of metacognitive skills, there was an increase in the average student score in each subcategory with the exception of management strategies.

One of most important outcomes of the pilot study was the refinement of the metacognitive teaching plan. The teaching and learning strategies which influenced metacognition within the introductory chemistry classroom will be developed and expanded upon. The challenge is now to embed these strategies in chemistry within a year long chemistry course while also determining their effect on student conceptual understanding in chemistry.

This will be the next stage of this research project which is examining (i) metacognitive approaches to teaching, learning and curriculum development in chemistry (ii) metaconceptual understanding and assessment in chemistry, and (iii) the relationship between metacognition and motivation in chemistry education

ACKNOWLEDGEMENT

We would like to thank all the students who took part in the study.

CONTENTS

STRAND 2: INTRODUCTION

LEARNING SCIENCE: COGNITIVE, AFFECTIVE, AND SOCIAL ASPECTS

The number and quality of the proposals in this strand show the research's breadth focusing on cognitive, affective and social aspects. In this ESERA 2019 proceedings edition, 17 papers are included and can be grouped in four themes.

A first theme, bringing together 6 papers focus on the dimensions of motivation, interests, emotions and attitudes in science learning. Stiller and Wild investigate whether the provision of autonomy in combination with prompts during experimentation influences students' motivation and knowledge gain. They show that young students did not seem to be able to cope with the demands of a more open learning environment and discuss possible learning conditions to improve this. Cetin-Dindar reveals that students' constructing educational games, including science concepts, increase their motivation to learn science. Two papers explore the role of emotions in science learning: Contini and colleagues aim to deepen the role that the feeling of pleasure can play in science education experiences in which metaphors and narratives are used systematically. They argue that a strict connection exists between aesthetic pleasure and cognitive processes. Drawing on scientific literature, they claim that science-learning shows more relevant results when it is connected to aesthetic experiences. Watts presents concrete methods that can be used to increase student receptivity by reducing negative emotions and showing how these methods can support content learning in the science classroom. Castro and colleagues map three different dimensions about biodiversity values of secondary school student, "ecological", "symbolic and ethical" and "economic", showing a close relationship with those found in the scientific literature. Moreover, Chu and colleagues investigate students' engagement and participation in science classrooms. Their study indicates some factors that could be used by classrooms teachers to support students' preferred participation practices. In particular, preliminary findings suggest that science educators should think more critically about the role of non-verbal participatory practices for supporting learning and should conduct more classroom-situated research focusing on understanding students with non-verbal participation preferences.

A second theme deals with socio-cultural, gender issues and the diversity of students. Hönig and colleagues investigate how young people of different gender and cultural backgrounds living in Germany differ in their vocational orientation in the sciences. Their results show that not all students prefer the same sources in vocational orientation in science. It differs according to the gender and migration background and involves rethinking strategies to improve vocational orientation in science. In the same vein, Brinkmann and colleagues present and discuss the development and evaluation of tools for gender- and diversity-sensitive career orientation in chemistry. Kirstein and colleagues aim to examine students' individual activities and difficulties while working on collaborative hands-on inquiry learning tasks considering different topic areas in a heterogeneous chemistry classroom, as they consider it is crucial to be aware of possible obstacles and to know in which way they are related to students' individual prerequisites. Guttierrez and Blanchard investigate the experiences of families who took part in STEM activities in their homes and give insight into ways to bridge formal school STEM content standards into learning settings within student homes. Kjelsberg investigates what the lived experience of Bildung in university level education is. The results show that physics students today do have experience of going through a process of Bildung during their time at university. The most common experience is one of increased scepticism. His study also supports the notion of Bildung as a social process.

The contributions included in the third theme focus on language and reasoning. Marialva and colleagues use inquiry-based learning methodologies and experimentation as a tool to promote science and language integrated learning. In a word-level analysis of learners decoding with minimal comprehension English second language science text, Stott and Beelders show that these learners fixate longer on the scientific terms than the others did, and suggest that the degree of linguistic cognitive demand of scientific terms is not the primary factor determining the degree of difficulty they experience during reading. Sin and Chang show that students have different academic self-concepts of different topics of a subject such as a wave and mechanics in physics and ascribe the differences to the use of different reasoning styles in mechanics and wave.

Finally, the fourth theme gathers three contributions focusing on innovative projects. Smit and colleagues implement industry–science projects aiming to foster secondary school students' interest in science-based technology careers. Their results demonstrate that factory visits combined with embedded tasks are one way to overcome fixed self-concepts and allow the students to reconsider a career in the technology and engineering industry towards the end of secondary school. Osman and Hamdan provide secondary school students the opportunity to experience hands-on and minds-on project-based authentic interdisciplinary modules stemming from their interests and designed by seniors and graduate students. This innovative approach attempted to foster student conceptual understanding, increase their motivation towards learning science, and promote their growth as they prepare to take on post-secondary education. In their study, Forissier and colleagues show that contexts effects learning appears as an innovative method based on intercultural collaboration during comparison of the natural contexts of the students involved.

EXPERIMENTING WITH PROMPTS VS. RECIPE-STYLE EXPERIMENTING:

IMPACT ON MOTIVATION AND ACHIEVEMENT

Cornelia Stiller[1] & Matthias Wilde[1]
[1]Bielefeld University, Biology Didactics (zoology & human biology), Bielefeld, Germany

Experimentation is one of the most important scientific working methods in biology. However, on the one hand, students can perceive experimentation as very complex, especially when students were offered a high degree of autonomy. On the other hand, fully structured recipe-style inquiry processes seem to be inappropriate to promote the development of students' scientific reasoning skills. Consequently, to support experimentation optimally and foster an autonomous working practice a combination of instructional support and open inquiry is needed. Prompts provide a high degree of freedom and give instructional guidance by offering hints. Accordingly, prompts allow students to work on a task autonomously and with an appropriate degree of support. The research question in this study focusses on, whether the provision of autonomy in combination with support by prompts during experimentation influences motivation and knowledge gain. In the quasi-experimental study (N=151) students in grades 5 and 6 were randomly assigned to two treatment conditions: recipe-style experimentation and experimentation supported by prompt-cards. The results showed that the students of the 'prompt-group" reported significant lower values in basic need satisfaction (subscale 'competence' and 'autonomy') and in motivation (subscales 'perceived choice', 'perceived competence' and 'interest/enjoyment'). Likewise, the students did not benefit from prompts in the knowledge gain. Summarizing, for young students, experimenting with strong guidance seems to be more beneficial than using prompts. The fulfilment of the need for competence as well as the perceived competence was lower in the 'prompt-group' than in the 'full-structured group'. Thus, these students did not seem to be able to cope with the demands of a more open learning environment. Presumably, it is necessary to improve the students' competence, e.g. by gradually increasing the degree of autonomy in experimenting, in order to enable students to perceive themselves as competent.

Keywords: instructional strategies, motivation, science inquiry

INTRODUCTION

In the German biology curriculum, experimentation is considered to play an important role as a central method of the natural sciences (KMK, 2005). Experimentation is described as a problem-solving process, in which students need to generate questions and hypotheses, design and run experiments and evaluate data (Abd-El-Khalick et al., 2004). Students can perceive experimentation as very complex (Harlen, 1999), which can lead to high cognitive demands, especially when students are offered a high degree of autonomy. One way of avoiding excessive demands and guiding learners during experimentation is to use instructional support (Fretz et al., 2002). For science experiments in schools, recipe-style tasks are often applied. However, fully structured recipe-style inquiry processes seem to be inappropriate to promote the development of students' scientific reasoning skills (Sadeh & Zion, 2012), as these structuring elements often do not involve an understanding of the experimental process (Hofstein & Lunetta, 2004). In addition, experimenting in this way implies that students work through instructions and have no option to decide how to plan or analyse the experiment. This way of experimenting reduces the degree of freedom and thus the autonomy of the students. Consequently, to support experimentation optimally and foster an autonomous working practice, a combination of instructional support and open inquiry is needed (Mayer, 2004). Using prompts during experimentation is a possibility to provide a higher degree of freedom and give instructional guidance by offering hints and allowing students to work on a task autonomously (Ge & Land, 2003) and with an appropriate degree of support. Accordingly, tasks supported by prompts may more easily match students' skills and thus increase their perceived competence. Perceived autonomy and perceived competence are regarded as predictors for intrinsic motivation (Ryan & Deci, 2017).

Our research question focusses on whether the provision of autonomy in combination with support by prompts during experimentation influences students' motivation and knowledge gain in contrast to full-structured experiments.

THEORETICAL BACKGROUND

Motivation: Self-Determination Theory

Learning processes at school depend on motivational conditions. According to self-determination theory, a requirement for motivated action is that the three basic psychological needs for autonomy (the need of individuals to experience personal accountability and empowerment for their actions), competence (experiencing possibilities and backup in performing actions), and social relatedness (feelings of being connected and belonging to others) are satisfied (Deci & Ryan, 2000; Ryan & Deci, 2017). In the school context, the satisfaction of these basic psychological needs yields higher engagement with the learning objects and good performance (Niemic & Ryan, 2009; Reeve, 2015). Furthermore, it can be differentiated between various forms of motivation, intrinsic and extrinsic motivation (Ryan & Deci, 2000; Ryan & Deci, 2017). In terms of the learning process, intrinsic motivation means that learning proceeds as it is associated with a positive experience. An intrinsically motivated student learns for the sake of the subject. Extrinsically motivated learning is based on the desire for positive consequences or avoiding negative ones. An extrinsically motivated student does not learn for reasons of learning or because he is interested in the subject but because of an external reward, such as grades. The reasons for motivated behaviour can be arranged on a continuum of regulatory styles that ranges from the purely controlled form of regulation, the external regulated behaviour to the purely autonomous form of regulation, that underlies intrinsically motivated behaviour (Ryan & Deci, 2000; Ryan & Deci, 2017).

Experimentation

Scientific inquiry indicates the execution and understanding of scientific work and thought (NRC, 2000). Experimentation represents one method of scientific inquiry (Lederman, 2009; Mayer, 2007; Paul, Lederman, & Groß, 2016) and can be described as a problem-solving process (Abd-El-Khalick et al., 2004; Gott & Roberts, 2008; Klahr, 2000; Mayer, 2007). The steps in Klahr's (2000) Scientific Discovery as Dual Search model are related to the steps and phases of experimentation (Abd-El-Khalick et al., 2004; Mayer, 2007) (see also Stiller, Stockey, & Wilde, 2018; Figure 1).

In science lessons, experimentation is supposed to facilitate the understanding of a scientific inquiry process, and provide an understanding of scientific thought and work (Wirth et al. 2008). Prompts are one possibility to support this learning processes. They are defined as hints or questions in order to activate knowledge, strategies or skills (Wirth, 2009) and can be used in experimentation to structure students' thinking (Wichmann & Leutner, 2009).

HYPOTHESES

Students using prompts may perceive more choices than students experimenting in a recipe-style. Since students can choose prompts related to their difficulties with the experiment, their perceived competence can also be supported. From this, the following hypotheses can be derived:

> H1: Students who experiment with prompts for experimental support perceive themselves as more autonomous than students who experiment in a recipe-style.

> H2: Students who experiment with prompts for experimental support perceive themselves as more competent than students who experiment in a recipe-style.

Intrinsic motivation relies on the perception of autonomy (Reeve, 2015; Ryan & Deci, 2017) and competence (Ryan & Deci, 2017). Autonomy-supportive learning environments are beneficial in terms of intrinsic motivation, engagement, and learning (Reeve, 2015). Not satisfying the need for competence or autonomy results in lower performance and commitment (Miserandino, 1996). Learning environments that satisfy the basic psychological needs support intrinsic motivation and foster student engagement during learning activities as well as their learning performance (Niemiec & Ryan, 2009).

> H3: Students who experiment with prompts for experimental support are more intrinsically motivated than students who experiment in a recipe-style.

> H4: Students who experiment with prompts for experimental support learn more than students who experiment in a recipe-style.

METHOD

Sample and study design

In order to answer the question of whether support of experimentation by using prompt-cards is worthwhile for students in terms of motivation and knowledge gain, this study was conducted as a quasi-experimental intervention study with a pretest-posttest comparison group design (Figure 1). In the study, 151 students in grades 5 and 6 (11.28±0.69 years) from two German grammar schools participated. The classes were randomly assigned to two treatment conditions: ‘full-structured experimentation’ (n = 75) and ‘prompt-card group’ (n = 76). Both groups differed in instructional support during experimentation. In the “full-structured group”, a full-structured experimentation guide determined the procedure while the students of the ‘prompt-card group’ received a reduced protocol template and prompt-cards that they could use as support.
The study was embedded in a four-lessons-teaching unit dealing with the behaviour of isopods. Before and at the end of the intervention, the students completed a questionnaire concerning motivation and knowledge.

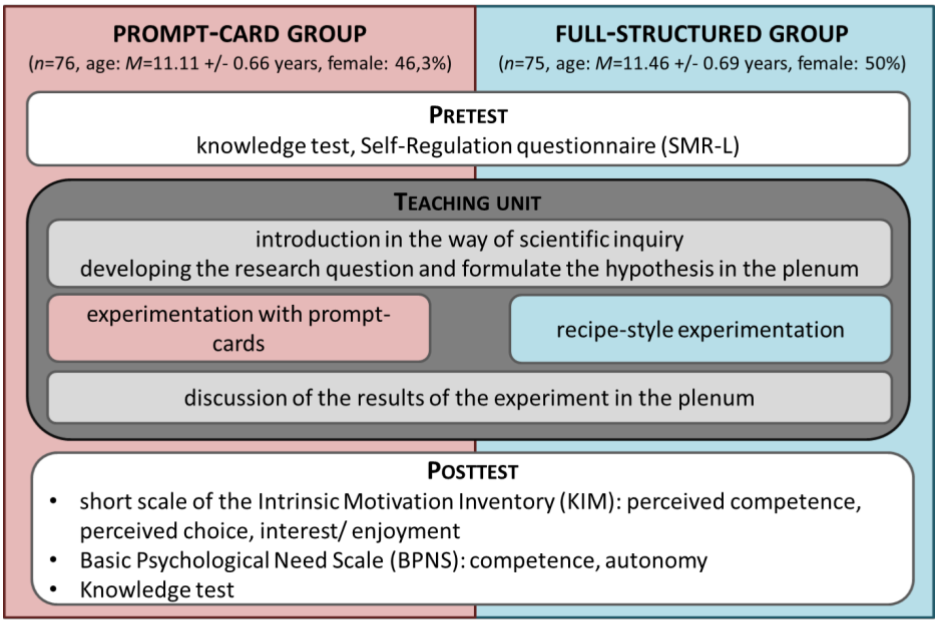

Figure 1. Study design.

Treatments and lessons

The teaching unit started with a short introduction into the way of scientific inquiry. In the following, the students carried out the experiment, recorded their observations and results, and interpreted the data (Figure 2).

Before experimentation, the research question and the hypotheses were developed in both groups in the plenum. Afterwards, the students plan and analyse the experiment in small groups of three to four students. This practical experimentation was divided into six steps for the students: 1. planning: experimental setup, 2. planning: experimental procedure, 3. analysing the observations: calculation of mean, 4. analysing the observations: description of the results, 5. discussion of the results: interpretation and 6. discussion of the results: conclusion. These steps are used to structure the experimentation process on the protocol template. At the end of the lesson, the students discussed the results in the plenum.

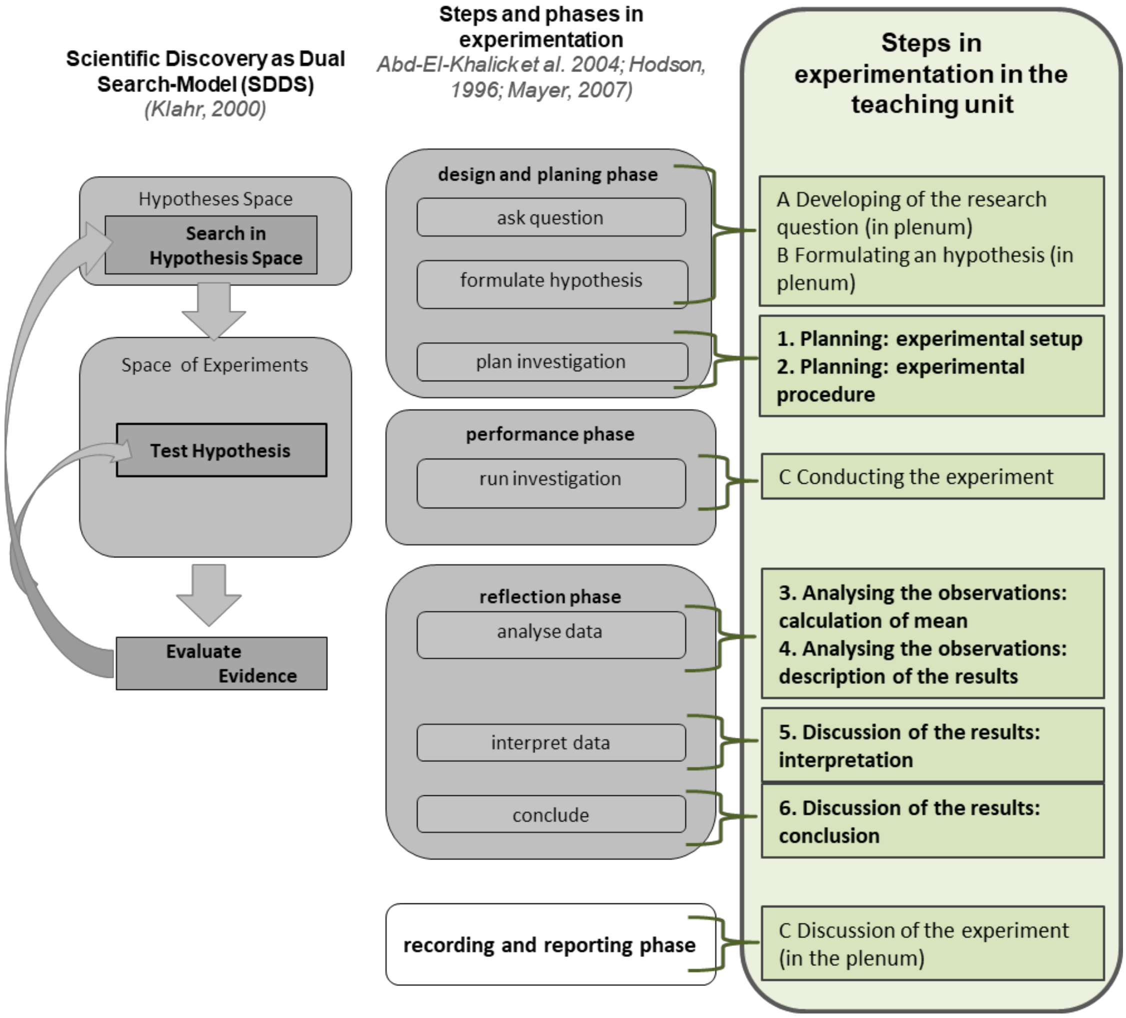

Figure 2. Overview of steps in experimentation in the teaching unit based on the SDDS model and the steps and phases of experimentation (see also Stiller, Stockey & Wilde, 2018). The experimental steps that were supported by prompt-cards in the prompt-card group are marked in bold.

Both groups differed in the planning and analysis of the experiment. The students of the 'full structured group' experimented in a recipe-style and received full-structured experimentation guides. In addition to structuring through the six steps of experimentation, the protocol template of the full-structured group also contained detailed instructions on how the students should perform these steps. Thus, the students in this group had no possibilities to decide anything in the experimental process for themselves. They had to follow the step-by-step instructions in the experimentation guide. The students in the prompt-card group investigated the same research question, but in contrast to the 'full structured group', they experimented independently. The protocol template of this group included merely the structuring by the six steps and at the appropriate places a hint which prompt-card can be used. The students received 14 prompt-cards that they could use as support to manage experimentation. For each step in the process of experimentation, a set of 2-3 cards was provided for the students. The cards of a set differ in their level of support, from a few general hints on the first card (a) to a concrete solution proposal on the last card (c). The general hints in card (a) provide support on a basic level and emphasize experimentation in general without specifically focusing on the lesson's experiment. Prompts are given in the form of questions such as *'Consider how you will conduct the experiment and how you will notice your observations: How's the experiment going? What do you have to pay attention for? What do you count and how often do you count?'*. At the end of the prompt-card followed the question of whether it helped the students and advised otherwise to use the next card for the experimental step. The second prompt-card (b) includes some specific questions that relate more to the experiment in this lesson and are no longer limited to experimentation in general, e.g. *'Consider the following aspects: How often and when do you want to count the isopods? How is an isopod on the centerline counted? What does the columns and the rows of your raw data table contain?'*. In the end, the question of whether the card helped was raised again, but this time, if not, the students had to contact the teacher to pick up the last card. The last prompt (c) card includes the same concrete solution proposal as the one in the full-structured experimentation guide in the other intervention group. These cards were only provided for the two steps of planning an experiment (experimental setup, experimental procedure), but not for analysing and interpreting the results. For these steps, the second card corresponds to the full-structured intervention guide.

Before starting with experimentation, the students were introduced to the use of the prompt-cards. Besides, the teachers emphasized that the use of the cards is helpful and that it is essential to use them if the students are stuck. Nevertheless, while experimenting, the students decided on their own which of the help cards they need and want to use.

Measuring instruments and statistical analysis

To get some information about students' general learning motivation in biology, an adapted version of the Self-Regulation Questionnaire (SRQ) from Thomas and Müller (2016) with the four subscales 'external', 'introjected', 'identified' and 'intrinsic' regulation was used in the pretest. To make statements about students' perceived degree of autonomy, the Relative Autonomy Index (RAI; min.: -12, max.: 12) was calculated with these four subscales (Vallerand & Ratelle, 2002). The more positive this value is, the more autonomous is the student regulated and the more negative it is, the more controlled he or she is.

After the lessons, an adapted and translated version of the subscales 'autonomy' (Cronbachs α = .70) and 'competence' (Cronbachs α = .71) from the Basic Psychological Need Scale (BPNS, Decy & Ryan, 2000) as well as the subscales 'perceived choice' (Cronbachs α = .65), 'perceived competence' (Cronbachs α = .80) and 'interest/enjoyment' (Cronbachs α = .86) of the short scale of motivation (KIM, Wilde, Bätz, Kovaleva & Urhahne, 2009) were applied in the posttest. The scales 'autonomy' and 'perceived choice' were evaluated in order to provide findings on perceived autonomy during teaching (hypothesis 1). 'Competence' and 'perceived competence' indicate the fulfilment of the need for competence (hypothesis 2). The subscale 'interest/enjoyment' is considered as a measure of intrinsic motivation (hypothesis 3). To measure the knowledge gain (hypothesis 4), a knowledge test including nine lessons related open-ended questions concerning the process of experimentation (inquiry knowledge) was used in the pre- and posttest (2 points per question, maximum 18 points).

Analyses of Variance (ANOVAs) were conducted to check whether both groups differed in the motivational scales and in the knowledge gain. To test hypotheses 1 to 3 one-factorial ANOVAs were carried out and for hypotheses 4 a mixed-ANOVA was applied.

RESULTS

The students of both groups differed significantly in the Relative Autonomy Index in the pretest (F(1; 148) = 3.96, p <.05, partial η^2 = .03). The RAI is higher in the 'full-structured group' (M = 5.19, SD = 3.71) than in the prompt-card group (M = 3.91, SD = 4.13). The 'full structured group' was significantly more autonomous regulated than the prompt-card group already at the beginning of the study.

The results of the motivational scales of the post-test, are presented in the following (Figure 3). At the end of the lessons, students of the prompt-card group showed significantly lower values in the subscale 'autonomy' of the BPNS ($M = 2.40$, $SD = 0.76$) ($F(1; 149) = 8.05$, $p < .01$, partial $\eta^2 = .05$) as well as in the subscale 'perceived choice' of the KIM ($M = 2.25$, $SD = 0.85$) ($F(1; 149) = 7.69$, $p < .01$, partial $\eta^2 = .05$) than students in the full structured group (BPNS: $M = 2.70$, $SD = 0.51$; KIM: $M = 2.61$, $SD = 0.75$). Consequently, the first hypothesis cannot be supported. Also, there were significant differences in the subscale 'competence' of the BPNS ($F(1; 149) = 16.59$, $p < .001$, partial $\eta^2 = .10$) and the subscale 'perceived competence' of the KIM ($F(1; 149) = 33.70$, $p < .001$, partial $\eta^2 = .14$) in favour of the full structured group (*full structured group*: BPNS: $M = 2.74$, $SD = 0.68$, KIM: $M = 2.61$, $SD = 0.75$; *prompt-card group*: BPNS: $M = 2.29$, $SD = 0.69$, KIM: $M = 2.25$, $SD = 0.85$). So, the second hypothesis cannot be confirmed, too. In addition, students of the full-structured group were intrinsically more motivated ($M = 3.10$, $SD = 0.84$) than students in the prompt-card group ($M = 2.65$, $SD = 1.05$) ('interest/enjoyment': $F(1; 149) = 8.38$, $p < .01$, partial $\eta^2 = .05$). Concluding, the third hypothesis also cannot be confirmed. In summary, the results concerning the motivational scales showed, contrary to expectations, a motivational benefit for the full-structured group.

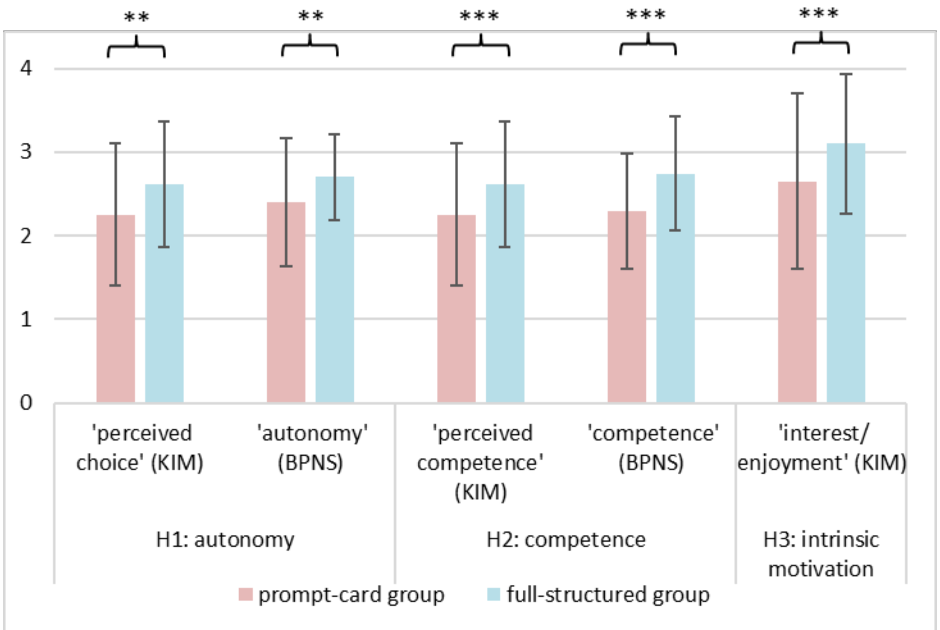

Figure 3. Results for the hypotheses 1 - 3. ** p < .01 ***p < .001

The results of the mixed-ANOVA showed a significant effect of the lessons concerning the knowledge gain ($F(1; 141) = 176.31$, $p < .001$, partial $\eta^2 = .56$), but no significant interaction effect ($F(1; 139) = .08$, p = ns, partial $\eta^2 = .00$). In conclusion, the prompt-card group did not learn more than the full-structured group. So, the last hypothesis could not be supported, too.

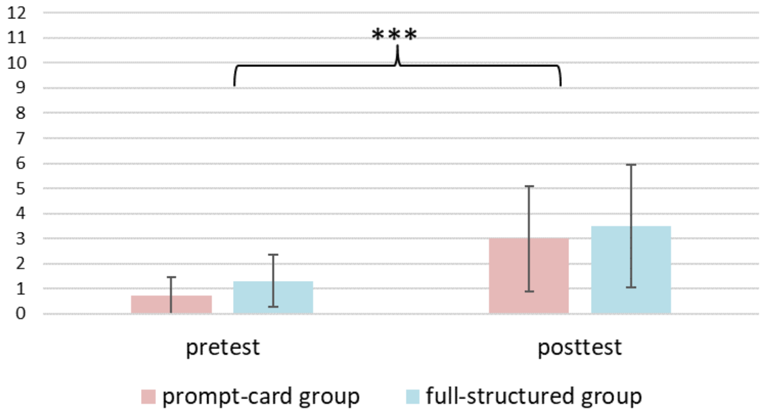

Figure 4. Results for the hypothesis 4. ***p < .001

Summarizing, the results of the ANOVAs for the comparison of the two groups showed that the students did not benefit from the guided experimentation in their basic need satisfaction, their motivation, and their knowledge gain.

DISCUSSION AND CONCLUSION

In this study, the hypotheses could not be supported. The students who were guided by prompts, when experimenting, didn't perceive themselves as more autonomous, more competent and were not more intrinsically motivated than students who experimented in a recipe-style. Besides, the students with prompts during experimenting did not learn more than the students experimenting in a recipe-style way. In conclusion, the results show that students do not benefit from prompt-cards regarding their motivation and knowledge gain. Accordingly, guiding with prompt-cards does not seem to be more suitable to support students of a lower level in experimentation.

Even if the findings from this study are limited by the differences in the motivational prerequisites of both groups, the results indicate that experimenting with strong guidance seems to be more beneficial than the provision of autonomy by using prompts. Although the learning environment with full-structured experimentation objectively offers fewer opportunities for experiencing autonomy, younger students seem to perceive it differently. Students can only use and appreciate the possibilities of an open learning environment if they feel competent enough to cope with the demands (Krapp, 2005). The fulfilment of the need for competence as well as the perceived competence were lower in the 'prompt-card group' than in the 'full-structured'-group. Thus, these students did not seem to be able to cope with the demands of a more open learning environment. For students with low competencies in self-regulation and problems to work focused on a task, open learning environments are not very useful (Dohn, 2013). Consequently, students' inquiry learning should be supported by e.g. scaffolds, which structuring the process of inquiry for the students (Dohn, 2013; Krajcik et al., 1998). The prompt-cards in this study do not seem to be sufficient to support the young students, perhaps because the young students perceived these prompt-cards as to complex. Presumably, especially if the students are young and with little or no experience in experimentation first, it is necessary to improve students' competence and provide more structure, e.g. by gradually increasing the degree of autonomy in experimenting in addition to the prompt cards, in order to enable the students to perceive themselves as competent. In consequence, it can be assumed that this also results in intrinsic motivational qualities and better learning.

However, the results of the study have some limitations. The students in both groups differ in their general learning motivation in biology. Following, it's possible that the full-structured group in this study showed higher values in the motivational scales after the intervention because of their more self-determined motivation in general. Additionally, the quasi-experimental study was conducted with a small sample size and with students of one school type. Furthermore, it might be possible that the prompt-cards were not used by the students to a large extent as it would have been appropriate. It is possible that students needed the prompt-cards, but they did not use them because they have the tendency to avoid help-seeking. In order to secure the findings, the study should be replicated on a larger scale with students of different school types and in different grades. Besides, further studies should take the actual use of the prompt-cards into account, for example by focusing on the conditions for using them or by giving the students the chance to get more familiar with the prompt-cards over a longer period. In addition, the use of regression analyses could be useful in order to gain further insights, e.g. how motivational preconditions mediate the effect of learning support through prompts.

To summarize, it seems that support with prompt-cards might not be sufficient for younger students with low experience in experimentation. However, experimenting in a recipe-style is not adequate to enhance the development of students' scientific inquiry skills (Sadeh & Zion, 2012). Consequently, further studies are needed to investigate how prompt-cards or other formats for younger students can be used successfully in order to promote motivation and learning. Actually, it seems that younger students do not only need support during experimentation, but they should also be supported during the use of support.

THE EFFECT OF EDUCATIONAL GAMES ON STUDENT MOTIVATION IN SCIENCE

Ayla Cetin-Dindar
Bartin University, Bartin, Turkey

For educators, the important goal is to figure out the way how students learn effectively and retain knowledge. Because of this goal constructivist teaching strategies are used for meaningful understanding. These strategies engage students to learning process and they experience by active participation, which also increase student motivation. Educational games, which create active learning environment, enable students to use their scientific conceptions, and create friendly classroom environment, are entertaining and increase engagement in classroom environment, hence could promote motivation in science learning. Considering this theory the purpose of the current study was to investigate whether there was a significant effect of educational games on student motivation and achievement in science education. Twenty-one elementary level students participated in the current study. The science teacher encouraged them to construct educational games related to curriculum subjects. The students constructed educational games and played the games afterwards altogether. The Wilcoxon Signed Rank Test was used to analyze the student motivation on two occasions, before and after the intervention. The difference between the two scores on the motivation was statistically significant. The results of this study revealed that constructing educational games by the students including science concepts increased their motivation to learn science. The instructional strategies that increase student motivation in science should be investigated in larger samples.

Keywords: Educational games, Motivation, Elementary level

INRODUCTION

For educators, the important goal is to figure out the way how students learn effectively and retain knowledge. Many studies in various branches of science reported that student-centered approaches are more effective in meaningful learning to be occurred and student understanding of scientific concepts are more enduring compared to traditional teacher-centered methods (such as Bektas, 2011; Calik, Ayas, & Coll, 2009; Uzuntiryaki, Çakır & Geban, 2001). While students construct the new knowledge, they are active through tasks through self-talk, inner speech, guided-participation, scaffolding, apprenticeships, and peer-interaction. Studies in science education (Zusho, Pintrich, & Coppalo, 2003; Singh, Granville, & Dika, 2002; Pintrich, Marx, & Boyle, 1993, Schunk, 1991) reveal that motivation positively affects students' performance in learning science. Educational games are entertaining and increase engagement in classroom environment, hence could promote motivation in science learning (Foster, 2008). Salen and Zimmerman's (2004) defined games a "system in which players engage in artificial conflict, defined by rules, that results in a quantifiable outcome" (p. 80). In line with this definition considering constructivist theory, educational games were used in this current study for emphasize learning, create active learning environment, enable students to use their scientific conceptions, and create friendly classroom environment. In addition to cognitive perspective of learning process, affective perspective of learning process should also be taken into account such as attitudinal or motivational process (Pintrich, Marx, & Boyle, 1993). Involving and participation in learning process give students motivation to learn, enjoyment, and satisfaction. Constructivist teaching strategies engage students to learning process and they experience by active participation, which increase student motivation (Britner & Pajares, 2006; Pintrich, 2003; Schunk & Pajares, 2002).

Therefore, in this current study, the purpose was to investigate whether there was a significant change on student motivation to learn science when students constructing and developing educational games.

METHOD

Four parts are presented in this method section, which are participants, instrument, design of the study and intervention.

Participants

Twenty-one seventh grade students took part into the study. Eleven female and ten male students were in the group. The previous (fall) semester GPA mean of the students was 73.48 (out of 100) (SD=14.30). The minimum GPA was 52 and maximum GPA was 98.

Instrument

The measuring tool used in the study was Motivated Strategies for Learning Questionnaire (MSLQ) and used to measure students' motivation in science learning (Pintrich, Smith, Garcia, & McKeachie, 1991), consisting of 44 items on a 7-point Likert-type scale, from 1 (not at all true of me) to 7 (very true of me). This questionnaire aims to measure students' motivational orientations and their use of different learning strategies. The translated and adapted version was used in this study (Sungur, 2004). The researcher tested the questionnaire and reasonable fit indices were found via Confirmatory Factor Analysis using LISREL. Besides the MSLQ items, the students were asked to complete their gender and their previous semester science grades.

Design of the Study

The one-group pretest-posttest design (Fraenkel & Wallen, 2003, p. 278) is used as a poor experimental design in this study (see Table 1 for research design details).

Table 1. Research Design.

Group	Pre-test	Intervention	Post-test
One-group	Pre-motivation scores	Constructing and developing educational games and playing	Post-motivation scores

Intervention

The science teacher followed the science curriculum during the study and continued to teach science in the traditional manner. The main difference during the intervention was the students constructed and developed educational games and playing the games afterwards altogether. In addition, the students were actively involved in the process and the teacher was a facilitator and guided them and give feedback during the process. After the teacher explained the scientific topics, the students constructed and developed their own educational games in groups (some students preferred to develop games indıvidually and some in groups) considering and including scientific concepts during the whole spring semester. Design and developing educational games are consisting of following stages: brainstorming stage, researching stage, designing stage, testing stage and re-designing stage. The teacher asked the following sample questions in each stage to the groups:

- *Brainstorming stage*: What game do you think to design? What do you think about the materials that can be used? Which objectives do you think to include to your game? etc.
- *Researching stage*: What sort of games do you like to play, card or board games? You can also adapt your favorite game or create your own game with your rules? What do you what to search? Which materials can be the best for this game? etc.
- *Designing stage*: Design your game and write the materials used. Do you think the number of questions are enough? Which material can you use for your game to be more durable? etc.
- *Testing stage*: What are your class mates' opinions about your game? Do you think your game is appropriate to the objectives? What can your classmates learn from this game? What can be done to improve your game?
- *Re-designing stage*: Based on your initial design and revisions made, redesign your game.

Figure 1. Sample Games.

During this process, the teacher encouraged the students to think about games they could developed related to objectives. The students were free to use any materials or designs (existing games or creating new games with rules). The main point was to develop games using recycled, obtained easily, and inexpensive materials. During the designing stage, the students searched internet and books for scientific content, related questions and design of the games. The next stage was constructing and testing the games, during this stage they tested the durability of the materials and the rules of the games. The last stage was fixing the games based on the peer's opinions and feedbacks from the previous stage (see sample games in Figure 1). The teacher encouraged the students during these stages and often checked the reliability and validity of the questions used in the educational games.

RESULTS

The first research question was whether there was a change in the scores on student motivation from Time 1 (initial-MSLQ) to Time 2 (pre-MSLQ). A Wilcoxon Signed Rank Test (Pallant, 2010) was conducted to compare the two different motivation scores on two different conditions. The Wilcoxon Signed Rank Test does not revealed a statistically significant increase on the student motivation to learn science after theoretical explanation of the subject, $z= -1.339$, $p=.181$. The median score on the student motivations just increased from initial-MSLQ (Md= 220) to pre-MSLQ (Md= 222), but this difference is not statistically significant.

The second research question was whether there was a change in the scores on students' motivation from Time 2 (pre-MSLQ) to Time 3 (post-MSLQ). The research question was to check whether there was a change in the scores in the student motivation to learn science from the beginning and end of the semester (Table 2). The Wilcoxon Signed Rank Test revealed a statistically significant increase in the student motivation to learn science after constructing and developing educational games, $z= -2.312$, $p<.05$, with a large effect size ($r=.50$) (Cohen, 1988). The median score on the student motivations increased from pre-motivation (Md= 222) to post-motivation (Md= 231). The Figure 2 shows the students' motivation change during the semester.

Table 2. Descriptive Statistics.

Time	N	Min.	Max.	Median	Mean	50% Trimmed Mean	Skewness	Kurtosis
Initial-MSLQ	21	115	270	220,00	216,95	219,524	-1,227	2,925
Pre-MSLQ	21	113	277	222,00	217,71	220,101	-1,136	2,805
Post-MSLQ	21	138	294	231,00	229,00	230,410	-,654	,402

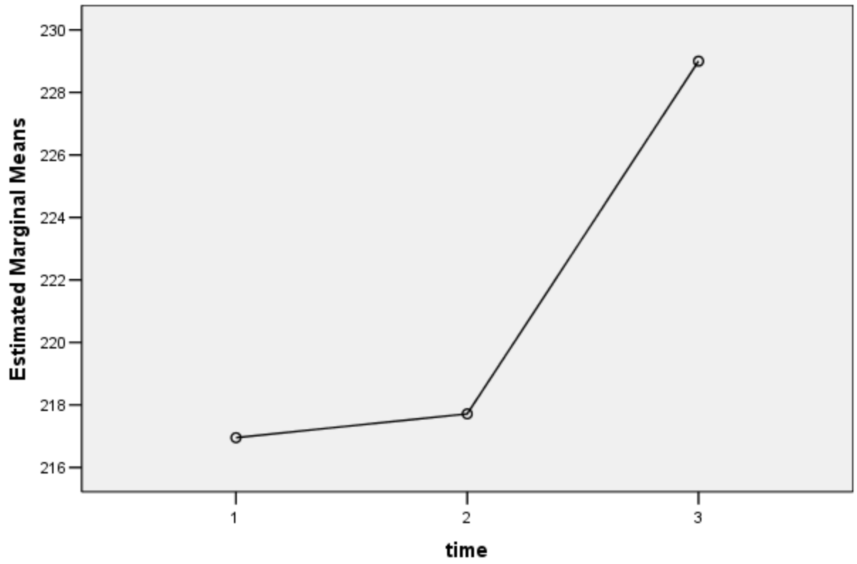

Figure 2. The Change of Students' Motivation Scores during the Semester.

DISCUSSION AND CONCLUSIONS

The results of this study revealed that constructing and developing educational games was effective on student motivation in science. As Brophy (1998) stated the students in the current study were focused on the developing and constructing educational games, they were more motivated in the process rather than being successful in the course. While developing the educational games, the teacher acted as a facilitator and the students were free to express their concerns during the process, the students interacted with each other, and the classroom environment were at the control of the students at the every stage. Ryan and Grolnick (1986) expressed that when students have more autonomy in class, they have higher self-worth and mastery motivation. Furthermore, the motivational theories promoted constructivist learning environment in science teaching and learning (Pintrich, Marx, & Boyle, 1993; Pintrich & Schunk, 2002); and, this study extends the effectiveness of constructivist learning environments on student motivation in science.

Student motivation can change from course to course; therefore, different educational and instructional technologies can be constructed considering student motivation to learn. Investigating the nature of student motivation can help teachers and instructors to understand student motivation within a given course since student motivation affect students learning and their course achievement. During the developing the educational games, the students re-considered the subjects they had learnt and in the future studies the conceptual effect of educational games could be also investigated. In addition, other instructional strategies that increase student motivation in science should be also investigated. Small sample size was the limitation of this study. To increase the generalization, the study should be replicated in various school types, grade levels, over a longer period of time, and environmental conditions.

STORIES ABOUT NATURE AS AESTHETIC EXPERIENCE IN SCIENCE EDUCATION

Annamaria Contini[1], Alice Giuliani[2] and Lorenzo Manera[3]
[1]Department of Education and Human Sciences, University of Modena and Reggio Emilia, Italy.
[2] Department of Education and Human Sciences, University of Modena and Reggio Emilia, Italy.
[3] Department of Education and Human Sciences, University of Modena and Reggio Emilia, Italy.

In recent decades, constructivist and cognitivist research recognized the important role played by imagination in science education. In particular, the potential of imaginative approaches to attract students to the scientific contents has been highlighted, in addition to the importance of routinely engaging learners' imagination in everyday learning experiences. The function performed by emotions and, in particular, by the feeling of pleasure appears to be less investigated in scientific literature: it is still not clearly defined how it is possible to facilitate learning processes related to the scientific contents by making them more enjoyable.
A branch of research is exploring the possibility of using metaphors and narratives for this purpose: to mobilize the emotional and affective dimension, integrating it with the logical one. This contribution aims to deepen the role that the feeling of pleasure can play in science education experiences in which metaphors and narratives are used systematically.
There is an area in which the feeling of pleasure is intertwined in a paradigmatic way with the knowledge of peculiar elements: in the aesthetic experience, we consider an object (artistic or natural) to be beautiful to the extent that we perceive a feeling of pleasure aroused by it.
In this regard, the more pleasant stories about nature are to read, the more effective they are in terms of educational effectiveness.
Stories need to be not only clear, precise, explanatory; stories need in fact not only to be understood, but also aesthetically enjoyed.
By taking "The Winter Story" as example (Fuchs, 2011), the paper focuses on the characters that make stories enjoyable. The pleasure of the text is indeed an essential ingredient in the narrative understanding of natural phenomena: the presence of metaphors, personifications, of a "grammar of stories", meaning the elements that are involved in the cognitive value of the narration.

Keywords: Aesthetic Experience, Science Education, Evaluation.

AESTHETIC PLEASURE AND SCIENCE EDUCATION

Aesthetic experience, pleasure and beauty

The Aesthetic experience's foundational characteristics have been recently discussed in the scientific literature (Desideri, 2018, p.13), where it has been defined "an experience with the characteristics of a dense, memorable and joyful synthesis, an experience that comes from the fusion of perceiver and perceived previous to their distinction. It is an experience without a subject and without an object". Such definition finds strong roots in the philosophical tradition, as the meaning of *aesthetic experience* oscillates between three main different aspects: the feeling of something radically "close", immediately present; a sort of intuition, the possibility of grasping something indeterminate, yet essential; the experience of beauty, which generates a feeling of specific pleasure. A particularly relevant resonance with the latter element can be traced in Kant's analysis of the aesthetic experience, as he discussed the *feeling of the beautiful* expressed in the *judgment of taste* (Kant, 1952). The judgment of taste, in Kant, is defined as a reflection based on the "free agreement" between the object and the need for finality of the intellect, which arouses a feeling of delight. The object of the feeling of beauty appears to be "made for" the needs of the subject, and oriented to arouse aesthetic emotions and a sense of harmony. Kant established a connection between pleasure and beauty, specifically declined in two definitions proposed in his analytic of the beautiful. In the former, Kant affirms "the beautiful is that which, apart from a concept, pleases universally". In this case, the judgement of taste belongs to the subjective experience, which appears individual and non-objective. Nonetheless, it demands consent and sharing, as it implies the claim of a common validity, related to a common sense that all men share. Universality can therefore be conceived as subjective, since it refers to a common sentiment of the judging subjects that resides in them. For this very reason, it remains without proof. However, universality itself becomes the foundation of shared meanings: taste can be formed, educated, it can be an index of a cultural identity. In the second definition, Kant states "the beautiful is that which, apart from a concept, is cognized as object of a necessary delight". In this case, beauty is not an element determined by a concept, but an evidence perceived by the subject. However, in order to happen, the recognition of beauty needs to be connected with pleasure aroused by beauty itself. In other words, the feeling of beauty exists only if the object in question is considered as a source of pleasure. Considering the elements underlined, it is possible to claim that Kant's view suggests that the experience of beauty and pleasure can be considered as the oscillation between a sense of intimacy and, at the same time, a sense of distance from the object. As proposed by Givone (2003), we can call it an experience of "enchantment".

Intimacy and distance of the beautiful

Intimacy and distance are both relevant elements to be taken into account in the analysis of the role played by pleasure in the experience of beauty. Regarding *intimacy* we can affirm, following Kant (1952), that beauty is the object of a free and immediate feeling: the judgment on beauty is neither conditioned by other judgments on the object nor the result of a deductive argument. Instead, the beautiful appears to be experienced on the basis of the needs of the subject. For example, a beautiful natural landscape may seem to be formed in order to allow a subject to admire and appreciate it. Moreover, the regularity of a composition of shapes and lines, or the logic in the proportions of a portrait or a statue, can generate a feeling of correspondence with a subject's need for harmony. For Bergson (2001), the sense of beauty can be identified in the arousing of a peculiar psychic state in the subject, meaning the identification of a high degree of continuity with our own experiences. On the other hand, *distance* plays a relevant role in in the experience of beauty, given how it appears as something we cannot completely explain as a defined concept. It comprehends irreducible elements, almost showing an autonomous subjectivity. For example, in Leonardo's Mona Lisa we can recognize the technique of the composition, but the smile remains an ineffable and indeterminate aspect. Similarly, a beautiful musical composition that follows a regular trend draws attention on the details that determine its variations, or the pleasure in the sense of grace is generated by a movement that looks regular and free at once, as something that cannot be determined by a preceding calculation. Given these elements we can affirm that pleasure, in the experience of beauty, can be considered as the immediate contact with something intimate and, at the same time, a feeling fostered by the search for something, which cannot be immediately grasped.

Beauty, aesthetic pleasure and cognition

In order to understand the strict relation that connects beauty, pleasure and cognition, we can once again refer to Kant's understanding of the aesthetic pleasure. In his view, the aesthetic pleasure corresponds to the experience of beauty and, at the same time, the aesthetic pleasure maintains a strong connection with the "understanding". When he defines the aesthetic experience, Kant used in fact the expression ″free play″ between the cognitive power of imagination and understanding (1952). Drawing on this premise, it is possible to recognize a "free agreement" between the object and the intellect in the judgement of taste. Such judgment is in fact a-conceptual but, at the same time, it is not entirely independent from the intellect. In other words, imagination functions in a rule-governed way, but without being governed by any rule in particular (Ginsborg, 2019). This peculiarity explains the mediating role played by the judgement of taste between the sensible dimension and the conceptual one. The experience of beauty shows an "originating" aspect, as it lays the foundation for knowledge itself. It invites to renew acquired rules, to identify affinities between different contexts, to give shape to new aspects of reality, to desire and anticipate hidden configurations of the world.

THE KANTIAN RELATIONSHIP BETWEEN THE AESTHETIC PLEASURE AND THE COGNITIVE ACTIVITY OF JUDGING FINDS SUPPORT IN RYLE AND GALLIE'S DEFINITION OF PLEASURE (1954). IN THEIR VIEW, PLEASURE IS A PECULIAR STATE THAT OSCILLATES BETWEEN EMOTIONS AND COGNITIVE FACULTIES. IN THE SAME VEIN, LEVINSON AND MATRAVERS (2005) STATED THAT THE AESTHETIC PLEASURE REQUIRES THE ATTENTION OF THE SUBJECT FIRSTLY ON THE CONTENT OF THE OBJECT, SECONDLY ON ITS MEANING, AND FINALLY ON ITS FORM.

By referring to the distinction previously made between the categories of intimacy and discontinuity, we can state that the aesthetic experience establishes a special continuity between our faculties and, at the same time, it rises a clear discontinuity in the ordinary flow of experience.

Aesthetic pleasure and Science Education

The strict connection, or even partial correspondence, between aesthetic pleasure and cognitive processes entails relevant consequences not only for reflections related to the Aaesthetic field, but also for other ones, such as pedagogy (Contini, 2019; Manera, 2019) and Science Education. In regard with the former, Egan (1990) - drawing on Vygotsky's conception of imagination (Vygotsky, 2004) - has defined imagination as an ability that allows to think in terms of possibilities (Egan, 1990). As for the latter, Wickman (2006) has argued, drawing on empirical data, that the processes of understanding and learning scientific contents show more relevant results when is connected to aesthetic experiences. Jakobson and Wickman (2008), by analyzing the use made by primary school children of the category of pleasing/displeasing, have highlighted its relevant role in engaging children in learning science. Milne (2010) argued that a careful exploration of all the qualities inherent in sense experience helps to generate a sense of wonder and interest in science. Finally, Stapleton (2018), Caiman and Lundegård (2018) have provided evidences of the importance of the role played by imagination in learning scientific contents. Drawing on these studies, we can state that educators should put more efforts in providing aesthetic experiences when presenting scientific contents. As argued by Hadzigeorgiou (2016, p. 53), activities that include the use of narrative in science education enhance "the aesthetic experience of pleasure". Similarly, Egan (2019) underlined the narratives' potential to involve students in everyday classroom activities and attract them to the world of science. In regard with the most relevant elements that narratives need to present in order to be effective, some Authors (Altman, 2008; Klassen, 2009) have underlined the importance of including elements such as metaphors, narrative coherence, characterization, conflicts, problems' resolution, and elements challenging previous knowledge. With particular regard to metaphorical devices, an innovative line of research (Fuchs, Contini, Dumont, Landini and Corni, 2019) recently explored how metaphors give formal content to stories of forces of nature, and how - at the same time - stories inform about the meaning of the metaphors in narrative, arousing a feeling of pleasure. By analyzing the example of the Winter Story (stories of forces of nature), and how - at the same time - stories inform about the meaning of the metaphors in narrative, arousing a feeling of pleasure.

Fostering aesthetic pleasure in storytelling trough continuity and discontinuity

Drawing on the discussed ambivalence of the aesthetic experience in terms of intimacy-continuity and distance-discontinuity, we argue that certain narrative elements are particularly effective in order to promote aesthetic pleasure.

With regard to the sense of continuity, we refer an example where metaphors of personification are used, as often happens in science stories for children that present scientific contents. A first explanation lies in the fact that personification can foster empathy, even in the specific terms of an *embodied simulation* (Gallese & Fredberg, 2007). Secondly, we argue that metaphors establish two kinds of continuity. On the one hand, we find continuity among different concepts, because metaphors condense many information in a single semantic element. On the other, we experience the continuity of our faculties, since metaphors bind pleasure and learning by making the latter faster. Thirdly, in order to understand metaphors we need to activate our imagination, as they require to go beyond the objective similarities immediately recognized (Johnson, 1981).

Concerning the sense of discontinuity, a first explanatory example can be found in the narrative scheme of the reversal. In Aristoteles' *Poetics* (1962), the reversal schema constituted the basis of the cathartic experience and the condition of a complex narrative plot. In relevant twentieth-century studies on narratives it was considered as an essential element for the construction of a narrative (Bruner, 1992). More recently, (Passalacqua & Pinzola, 2016), narrative has been studied for its relevant communicative function. A second relevant element related to the importance of the sense of discontinuity can be traced in metaphor. The effect of discontinuity in metaphor is related to its cognitive power, since metaphors tend to organize experience in an innovative way, which cannot be anticipated and determined by any prepared concept. Thirdly, a link between metaphor, discontinuity and pleasure can be related to the fact that the process of metaphors' understanding can trigger a rewarding cognitive research for elements that were not previously determined (Forceville, 1996).

Narrative and personification of scientific facts: the example of the Winter Story

A relevant example of a narrative realized in order to present macroscopic physical science and, more specifically, the concepts of heat and cold can be found in the *Winter Story* (Fuchs, 2010), here summarized.

As the last of the warmth of late Fall left the plain surrounding Little Hollow, cold found its way into the area and spread out. [...] The cold of winter knew a good place where it could do its job of making everything and everybody cold [...] It could flow into the hollow where the town had been built. It could collect there and it knew it would not be driven out so easily by a little bit of wind [...] The people of Little Hollow [...] knew that the cold would find its way into their homes if they were not careful to close windows and doors. The cold could even sneak in through tiny cracks between walls and windows, so the people had learned to build their homes well to make it hard for cold to flow in. [...] At times when much cold had collected in their town, the fires in the furnaces had to work very hard to fight the cold. The people in their homes made sure that the heat produced by the furnaces would always balance the cold so that their homes felt comfortably warm.

From a first analysis, we can notice that through the conceptual metaphor of "cold as a fluid substance", we necessarily and ordinarily think of the cold (Fuchs, 2013, p. 16). Furthermore, the metaphors proposed in the story are the same that are used in the formal scientific description of such phenomena. The expressions "[...] the cold would find a way to enter their homes" and "[...] the people had learned to build their homes well to make it hard for cold to flow in", are at the same time used ordinarily and scientifically correct (Fuchs, 2006).

From a deeper analysis, we can notice that the metaphoric projections elicited by the story lead to a process of personification. The projection frames cold in terms of a force of Nature, meaning a *powerful agent*. In this personification, the cold performs actions, behaves like an agent who has the power to affect reality. If the cold is framed as an agent, we can conceive natural scenes in which it lives adventures and interacts with objects in the world. By acting as a force of nature, cold creates an event that takes place over time and changes things in the world. In this personification, the cold performs actions, behaves like an agent who has the power to affect reality. Acting as a force of nature, it therefore creates an event that takes place over time and changes things in the world. This is the kind of event we call a “story”. In our view, the supported ambivalence of aesthetic experience requires that personification makes the phenomenon "familiar", but for the “estrangement” effect, it must also be evident that we have the encounter between diverse meanings. For example, in this case, rather than saying "the cold gathered in one place", we could speak of a "cold army" as a "collective" agent, separated from the semantic domain of natural phenomena; in this way we could favor the already present sense of confrontation, battle, strategy, without losing scientific coherence. This could also distribute the personification on other "agents": for example, the wind in the phrase "It could accumulate there and knew that it would not be chased away so easily from a little wind as it could happen on the plain".

Beauty in narrative about Darwin’s evolution theory

It is possible to emphasize the importance of narrative’s aesthetic experience in learning processes that involve scientific concepts by referring to an example related to Darwin’s evolution theory.

In this case, the narrative strategy and the personification can help on the one hand to make the evolutionary logic intelligible and familiar, on the other to generate wonder. For example, the spontaneous instinct of bees could be focused in the construction of the perfect hexagons of their hives, as if they were conscious architects. In the evolutionary history of the whale, the unexpected majesty of the contemporary animal could be compared with the less pleasant and significant aspect of its ancestors.

The same ambivalence emerge in narrative schemes related with the evolution. They favor identification (sense of continuity) and, at the same time, exceed expectations (sense of discontinuity). For example, stories of marginalization and redemption, in which an apparent defect becomes an evolutionary resource.

Aesthetic pleasure in stories about evolution and natural selection

To synthetize the aforementioned aspects, we could conceive a narrative about the evolution of a whale, inspired by the book “When the wales walked” (Dixon, 2018). We know that in the skeleton of a whale it is possible to observe tiny hind limbs and pelvic bones disconnected from the rest of the skeleton. These bones demonstrate the connection of cetaceans with ancestors who lived on Earth. If a whale were to discover the existence of these “vestiges”, the story could become a journey aimed to investigate his own past. In such fictional time travel, the whale could meet its own ancestors, who could exhibit and speak about some of their determining features as members of a specie. This element can encourage identification as an aspect of continuity: for example, if the story is addressed to children, they could be stimulated to reflect on their roots and origins, especially in multicultural contexts. At the end of the journey, we could imagine that the whale "encountered" its own species and learned to look at their qualities from a different perspective (e.g., it could see some of its defects as resources), thus declining the aspect of surprise-discontinuity. Furthermore, the encounters with the ancestors taking place during the journey should favor two main elements. On the hand, the idea of continuity with the past (e.g., by highlighting the similarity of some distant ancestors' qualities). On the other hand, the awareness that there are ruptures and discontinuities (e.g., an odd feature that becomes an evolutionary advantage, setting the conditions for a renewal of the species).

The beauty of the phenomenon

We claim that closeness and difference can be thought of as immediately blended in the experience of a primary perception of the object. The primary perception conceived in the phenomenological approach is careful to all the qualities of sensory experience before the intervention of the cognitive filter. In fact, it includes conceptual schemes, and meanings already acquired. By referring to Merleau Ponty, Dahlin (2001) states that the *presence* of the subject when the object is constituted is the characteristic of a radical insight and the condition of a "profound, convincing and satisfying" learning. This perceptive experience appears as "nascent *logos* (intended meaning, order, knowledge)" and condition of objectivity itself.

Conclusive remarks

By referring to the Kantian tradition, we have argued that a strict connection exists between aesthetic pleasure and cognitive processes. Drawing on scientific literature, we have shown how science-learning shows more relevant results when is connected to aesthetic experiences. This connection entails relevant consequences for Science Education. Teachers and educators should in fact put more efforts in providing aesthetic experiences when presenting scientific contents. Our argument is that a viable way to enhance the aesthetic experience of pleasure in Science Education is the use of narrative. Through the analysis of aesthetic experiences' ambivalence, in terms of intimacy-continuity and distance-discontinuity, we argued that certain narrative elements such as metaphors of personification and the reversal scheme, are particularly effective in promoting aesthetic pleasure. To be effective, narratives need as well to possess elements such as coherence, characterization, conflicts, problems' resolution, and elements challenging previous knowledge. By analyzing the example of the "Winter Story", we have shown how metaphors give formal content to stories of forces of nature, and how such stories inform about the meaning of the metaphors in narrative, arousing a feeling of pleasure. Finally, by proposing various examples, we have argued that it is possible to emphasize the importance of narrative's aesthetic experiences in learning processes that involve concepts related to the evolution theory.

SUPPORTING CONCEPTUAL CHANGE - THE HOW AND WHY OF MINDFULNESS IN BIOLOGY EDUCATION

Elizabeth Marie Watts[1]

[1]Friedrich-Schiller Universität Jena, Institute for Zoology and Evolutionary Research, Biology Education Research Group, Jena, Germany

Science learning and scientific literacy are dependent upon a student's ability to understand and process the concepts presented to them in the classroom. When students enter the classroom with pre-existing concepts, they often go through the process of conceptual change in order to integrate the newly presented material into their existing conceptual structures or to rework these structures. Yet, this natural learning process is sometimes hindered due to the emotional attachments to these pre-existing thought schemas. To increase the efficacy of educational interventions, this emotional aspect of learning needs to be recognized and addressed because these emotional states can otherwise lead to conceptual conservatism or even a boomerang effect. One possible means of addressing negative emotional states that arise in response to lessons that contradict with students' worldviews is the introduction of stress-reduction tools such as mindfulness, which has already proven to be effective in supporting an individual's ability to regulate their emotional responses and to access higher cognitive function. In fact, in this way, mindfulness can even be seen as analogous to intentional conceptual change and thus presents an integral means of supporting science learning. In this paper, I will briefly discuss the role of emotions in science learning and then present concrete methods that can be used to increase student receptivity through the reduction of negative emotions and how these methods can support content learning in the science classroom.

Keywords: Mindfulness, Learning, Emotion

Introduction

Research has shown that emotions are not only present in the science classroom but that they have a significant impact on learning outcomes (Alsop & Watts, 2003; Laukenmann et al., 2003; Pekrun & Stephens, 2012; Santos & Mortimer, 2003; Watts & Walsh, 1997; Zembylas, 2002, 2004, 2005). Learning about science can invoke a full-range of emotions from joy, wonder and surprise to anxiety, anger, fear and hopelessness (Sinatra, Broughton, & Lombardi, 2014), yet it has been shown that negative emotions, such as frustration or anger, may foster student resistance towards learning as they perceive the incoming scientific information as a threat (Gregoire, 2003; Linnenbrink & Pintrich, 2004) and this is particularly true when students ideas are challenged or in conflict with the scientific data presented in the classroom (Sinatra, Broughton, et al., 2014). There are a number of topics in the science classroom which could cause this type of conflict such as stem cell research, biological evolution and anthropogenic climate change (Griffith & Brem, 2004). Thus, understanding the role of emotions and addressing these emotional states in the context of science learning is important as there is a clear relationship between emotions and cognitive ability, in which positive emotional states are associated to an increase in cognitive functioning, while negative emotional states are associated with a narrowing of the cognitive functioning (Powietrzynska & Tobin, 2015). Most importantly, in terms of potential scientific literacy, findings have shown that emotions may support or impede conceptual change in science classrooms (Demastes-Southerland, Good, & Peebles, 1995; Duit, 1999; Duit & Treagust, 2003; Rhöneck, Grob, Schnaitmann, & Völker, 1999) as Sinatra et al. found that the processes of attitude change and conceptual modification are significantly impacted by student motivation and their emotional state and that the presentation of facts is not likely to be enough to cause students to relinquish their preconceptions in order to accept newly presented evidence (Sinatra, Kienhues, & Hofer, 2014; Sinatra & Seyranian, 2015).

How mindfulness supports science learning

Data on the effect of emotions on cognitive functions necessitates new teaching strategies that address and mitigate negative emotional states in order to support learning in the sciences. For this purpose, I propose the use of contemplative methods, specifically mindfulness practices, as a means of addressing extreme emotional states. Mindfulness practices have been well-integrated and successful in medical field for multiple decades and is finding increasing application in educational settings. Mindful practices can provide crucial support in addressing the emotional states in the classroom as it encourages the development of self-regulatory skills associated with the ability to be aware of emotions and consciously choose how to react to those emotions. Mindfulness in the classroom can thus be seen as a tool to monitor and ease emotional states so that cognitive functions remain intact (E. M. Watts, 2019).

From an educational perspective mindfulness offers teachers a means of addressing both the cognitive and affective dimensions of student experience in the classroom and "mindfulness training has been linked to a range of cognitive, social and psychological benefits to students and teachers" (Powietrzynska & Tobin, 2015, p. 2). As Tobin points out, this type of reflexivity is crucially important for individuals such as teachers and students as much of social life occurs without conscious awareness and such practices allow actors to better identify the way in which they are affected by their environment and how they affect other players in this environment and offers these actors a means by which they can rationally change aspects of their behaviour to benefit the collective group (2012). Most importantly when considering the positive effects that mindfulness can have in developing scientific literacy potential, it has been shown that mindfulness is in many ways analogous to intentional conceptual change as it reflects a voluntary state of mind that connects motivation, cognition and learning (Duit & Treagust, 2003; Salomon & Globerson, 1987).

Incorporating mindfulness into biology lessons

Mindfulness practices can be introduced into the science classroom in variety of forms and formats. Some school-wide programs involve in-depth training of all school personnel and the involvement of parents, while other interventions can occur at the classroom level through a simple introduction of specific practices from the teacher to a particular class. Powietrynska, Alexakos and Tobin offer an approach to mindfulness in the classroom through the use of heuristics, which encourages students to reflect upon their own thought processes, bodily sensations, emotions, etc. (2014). It is also possible to introduce mindfulness through simple isolated breathing exercises that also encourage students to use their breath as an anchor as they use their higher cognitive structures to observe limbic processes such as the arising of emotions, impulses and sensations.

Connecting mindfulness to classroom content

Although it is possible to introduce mindfulness into the classroom as a self-contained subject, it is also possible to introduce mindfulness in a way that it complements the content presented in the course curricula. Because of the biological effects and basis of mindfulness practices it is possible to introduce these in lessons that discuss anatomy and physiology, human health and even evolution (Table 1).

Table 1. Possible lessons where mindfulness could be incorporated into content.

Lessons Where Mindfulness Can Be Integrated into Science Content	
Anatomy and Physiology	▪ *Lessons on the brain and its anatomy* ▪ *Lessons on neuroplasticity* ▪ *Lessons on the nervous system, particularly about the nervous system(s)*
General Health	▪ *Stress and its effect on the body, in particular a look at the link between stress and certain diseases and ways to counteract stress*
Evolution	▪ *Evolution of stress-responses, threat-response etc.* ▪ *Evolution of various regions of the brain, in particular the difference between the neocortex and the limbic system*

Why mindfulness is useful in biology education

The efficacy of mindfulness in the promotion of increased well-being and decreased suffering has been shown through an extensive amount of studies (Gotink et al., 2015; Holzel et al., 2011; Ireland, 2014; Khoury, Sharma, Rush, & Fournier, 2015; Purser, Forbes, & Burke, 2016; Siegel, 2014; Tabak, Horan, & Green, 2015; Tang, Hölzel, & Posner, 2015; Taren, Creswell, & Gianaros, 2013; Zoogman, Goldberg, Hoyt, & Miller, 2015). The general use in education has also been studied and the results of these studies have highlighted not only on the personal effects for the practitioners but also on the overall improvement of classroom dynamics (Ergas, Hadar, Albelda, & Levit-Binnun, 2018; Felver & Jennings, 2016; Jennings & Greenberg, 2011; Kemeny et al., 2012; Kuyken et al., 2013; Mendelson et al., 2010; Napoli, Krech, & Holley, 2005; Powietrzyńska & Noble, 2018; Schonert-Reichl & Roeser, 2016; Sheinman & Hadar, 2016; Weare, 2012; Zajonc, 2016; Zenner, Herrnleben-Kurz, & Walach, 2014). More recently, studies have also began to examine the specific advantages that it offers for science learning (Powietrzynska & Tobin, 2015).

Supports conceptual change

Studies have shown that simply learning about evolution or climate change does not change an individual's stance on the issue. In other words, those who deny climate change, continue to do so regardless of the amount of factual data that is presented to them (E. Watts, 2019). This phenomenon of conceptual conservatism is rooted in the emotional nature of humans. Without addressing the emotional aspect of issues such as human origins or human|environment interactions, many educational interventions remain fruitless.

Mindfulness offers a means of addressing this emotional aspect and encourages practitioners to access the rational|logical thinking organs rather than basing reactions and judgements on limbic processes (Figure 1).

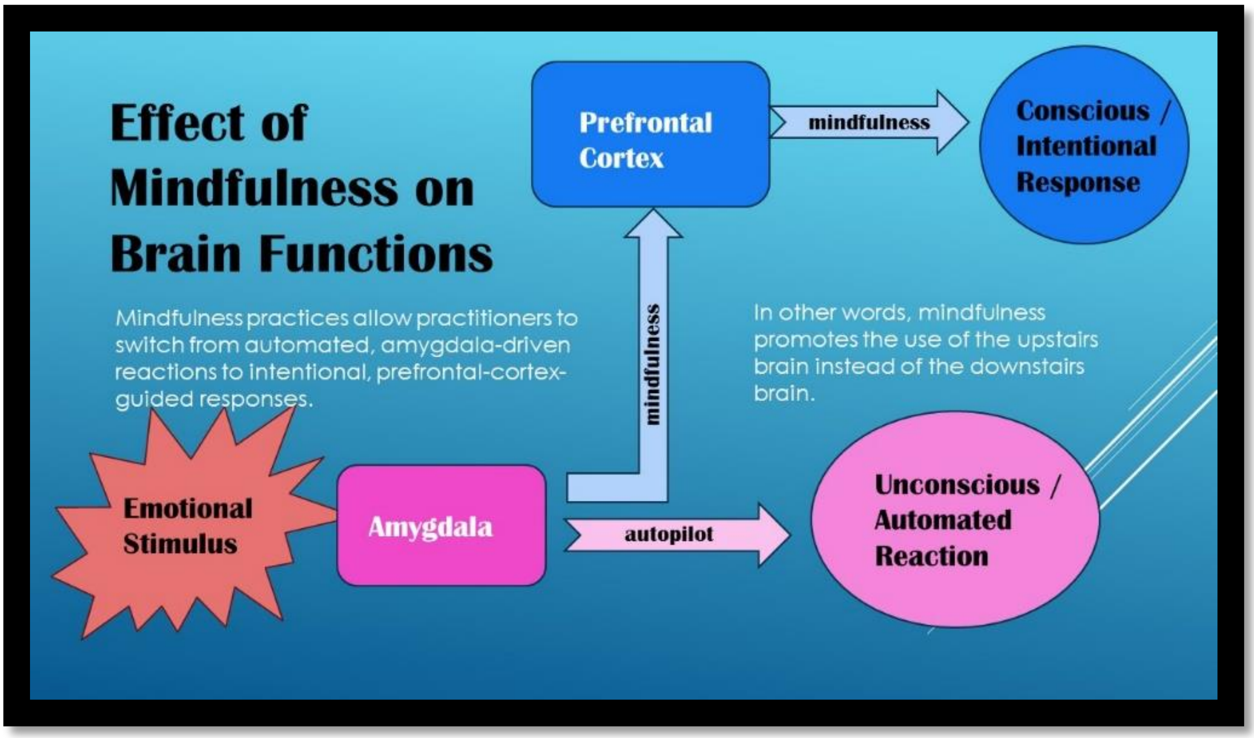

Figure 1. Effects of mindfulness on brain functions (E. M. Watts, 2019).

Makes classroom content more personal

In addition to ameliorating emotional states that can lead to conceptual conservatism, mindfulness practices can also make learning about biology more personal and thus more relevant and interesting. Learning about concepts such as the nervous system or about the circulation system or even the interplay between the parasympathetic system and sympathetic system are no longer abstract concepts that are limited to the pages of textbook but become concepts that students are able to understand and experiment with. These concepts become personal and thus more interesting as they learn how they can observe changes in these systems and even affect these systems through conscious choice. Likewise, learning about the change possible through mindfulness practices can awake a greater interest in the anatomy and physiology of the brain. The idea of neural plasticity becomes one of wonder and excitement once one realizes how this process can be actively guided. We are thereby able to help students better learn about scientific principles as they simultaneously learn about themselves. Moreover, we are awaking an interest in science and associating science learning with positive emotional states which in turn has effects on a student's future relationship to science and thus their overall scientific literacy potential.

Development of a Sample Lesson Plan

Based on these studies, I have begun to develop lesson plans that introduce students to mindfulness while also teaching core concepts of biology such as evolution and physiology

(Figure 2). The lesson plans are designed to be used consecutively as the information in one supports the content of the subsequent lesson.

The first lesson plan focuses on human evolution, particularly the evolution of the fight-or-flight modus. Here the emphasis is placed on understanding the advantages of 'stress' as a means of warning us about potential dangers, and also discusses the health problems associated with chronic stress in modern society as this ancient neurological system often 'overreacts' to stimuli in our current environment, e.g. deadlines. The second lesson plan takes a closer look at our anatomy and physiology, particularly in the differences between sympathetic and parasympathetic nervous systems and how these systems are involved in stress responses and how the balance between these systems can be influenced through conscious, mindful breathing exercises. The lesson was concluded by having the students engage in a five-minute mindful breathing activity.

Sample Lesson Plan for Teaching Mindfulness as Part of Biology Class on Evolution and Anatomy of the Nervous System
Class objectives: At the end of class students will be able to identify how stress reactions are related to evolution of the fight-flight-freeze system and the activation of the sympathetic nervous system. They should furthermore be able to identify the survival advantage that this system offered prehistoric humans and the disadvantages of the over activation of this system in modern society.
Connection to course goals: NGSS: HS-LS4-4 Biological Evolution: Unity and Diversity Builds upon: MS. Structure, Function, and Information Processing and 4-LS1-2 From Molecules to Organisms: Structures and Processes;
Anticipatory set: (*Goal*: Students should become acquainted with the idea of the physiological process of stress) • Open class discussion: When do you feel stressed? What physical attributes do you associate with feelings of stress?
Part 1: Evolution of Stress and the Effects on Our Modern Bodies and Minds
Introduction: (*Goal:* Students should begin to examine the evolutionary roots of stress) • Open class discussion: Is feeling stressed a pleasant feeling? Why or why not? Why have we evolved to feel stressed? • Student discussion: In small groups have students discuss the following questions: o What is stress? o What is the evolutionary advantage of stress? o How does the fight-flight-freeze system help animals survive in the wild? How did this system help primitive humans survive? o Does stress offer more advantages or disadvantages for modern man? *Optional expansion*: This time could be used to discuss the fight-flight-freeze system in greater detail.

Figure 2. Sample lesson plan.

While the direct learning goal for these lesson plans is to increase the students' understanding of the content knowledge by making the lessons more relatable and personal, the secondary goal is to introduce mindfulness within the context of understanding the effects of stress on the body. By understanding the potential to influence our own physiology through mindfulness activities in order to counter the harmful effects of stress students also become more generally aware of their ability to regulate negative emotional states, e.g. anxiety, anger, etc. This increased understanding of emotional regulation is one of the core reasons why mindfulness has the potential to improve classroom dynamics and thus lead to the development of more pro-social classrooms (Jennings & Greenberg, 2011; Kemeny et al., 2012).

Pre-service teachers' analysis of the lesson plan

To test the efficacy of these lesson plans and the willingness on the part of teachers to use such lesson plans in their classrooms, both lesson plans were presented to forty-five students currently enrolled in the biology education program at the Friedrich-Schiller University in Jena, Germany. Based on pre-post questionnaires, we found that the students were already aware of the importance of emotions in science classrooms with 6% of the students stating that emotions were *very important* and 76% reporting that they were *important* on the pre-questionnaire. They were also concerned about how negative emotions in the classroom could impair a teacher's ability to teach and a student's ability to learn.

After the conclusion of the trial of the lesson plans, the students were asked to rate the efficacy of the lesson plan. The results of the post-questionnaire showed that the majority of the students who participated found that the lesson plans had increased both their knowledge of the content material and increased their overall interest in mindfulness practices – with the majority of them stating that they would be interested in using mindfulness both in their personal and professional lives. In fact, the most frequent suggestion for improvement of the lesson was a call for an increased amount of time for mindfulness activities, rather than only five minutes at the conclusion of the lesson. The lesson plan will be updated according to this feedback and further testing is planned for the upcoming semester.

Conclusion

There is neurobiological evidence that emotional processes have a profound effect on learning, attention, memory, decision making and social functioning – all of which are crucial aspects of cognition that are relevant for learning in school settings (Immordino-Yang & Damasio, 2007; King, Ritchie, Sandhu, & Henderson, 2015), which means that it is necessary to develop new strategies to address emotions in the classroom in order to create the best learning conditions possible. Mindfulness presents a means of addressing these emotional processes in order to support learning while also increasing a sense of well-being in the classroom. The lesson plans developed for this purpose showed that biology content can be taught in combination with the basics of mindfulness and that students showed an increased understanding of content knowledge while also developing an increased interest in mindfulness practices.

Acknowledgements

My sincerest thanks to Clemens Hoffmann for his assistance in running the experiments with the pre-service teachers and to all of the pre-service teachers who participated in the analysis of the lesson plan.

BIODIVERSITY VALUES OF SECONDARY SCHOOL STUDENTS

Rafael Gil de Castro[1], *Caio Castro Freire*[2], *Marcelo Tadeu Motokane*[2]
[1, 2]University of São Paulo, Ribeirão Preto, Brazil

Biodiversity is an important and complex concept that involves three hierarchical levels, comprising from genes to ecosystems in an integrated manner with biological evolution as a structure main axis. The values of biodiversity emerge in conflicts between different social interests related to the use and preservation of environment. This study aimed to investigate biodiversity values of secondary school students. Thus, we created and validated a 5-point Likert scale questionnaire about biodiversity values. Then it was applied to 73 secondary school students. The factorial analysis of data allowed us to map three different dimensions about biodiversity values of students: "ecological", "symbolic and ethical" and "economic". These values showed a close relationship with those found in the scientific literature. The differences found among them are due to particularities of the micro social context. Thus, biodiversity plays a central role in biology curriculum and the comprehension of these values provides a wide vision about the human interference on environment and a critical perspective of biodiversity. It is important to clarify in science teaching the values of complex concepts in order to help teachers to understand students and improve pedagogical material.

Keywords: values in science education, biodiversity, secondary school

INTRODUCTION

Biodiversity is a main concept to understand biology and which includes three hierarchical levels (or dimensions), comprising from genes to ecosystems (Wilson, 1997; Lévêque & Mounolou, 2004). This concept has been occupied human mind since the beginning of humanity. Nowadays, there are complex scientific classification systems for all this biological diversity. For Lévêque (1999), biodiversity is not only a catalogue of genes, species or environments. This concept goes beyond of a fragmented approach of the three dimensions and must be seen as a dynamic/interactive set of those different levels of biological hierarchy. In this sense, biological evolution works as a main axis of biodiversity:

> "According to current theories of evolution, it is due to the existence of genetic diversity within species that they can adapt to changes in the environment. It always marked Earth's history. Conversely, the genetic diversity of species evolves over time, in response to these changes in environment, as well as due to mutations. The same occurs with plant and animal communities, which constitute ecosystems and responds by means of qualitative and quantitative changes to fluctuations in the environment in which they live. This dynamic of biological systems and ecological conditions, to which they are confronted, explains that species evolve and diversify and that ecosystems host more or less rich floras and faunas" (Lévêque, 1999, p. 18).

The biodiversity values emerge from a conflict between different social interests related to the use and preservation of environment. In this sense, the values make up the reasons why people are interested in that. Unlike the biological definition of the concept, experts in social sciences have been using the values of biodiversity in different manners. (Wiegleb, 2002). For Lévêque and Mounolou (2004), the biodiversity values occupy three dimensions: I) Economic: values related to the supply of raw materials for human development, in relation to industry, medicines, agricultural production, biotechnology and tourism; II) Ecological: values aimed to maintain life on the planet; III) Ethics and patrimony: values focused on the moral duty to protect all other forms of life. In this work we create a fourth dimension of values, "symbolic and ethical", which is related to the well-being of the humans in relation to nature.

Science education plays an important role in this context. By understanding the concept of biodiversity and its values, students can rethink the use of environmental resources and perceive more critically at how our society organizes itself. The decision-making power of students is strengthened, helping to build a reflective education on environmental issues. However, to understand biodiversity it is necessary for teachers to develop activities that go beyond simply memorizing the concept. It is important that teachers know which values their students have linked to biodiversity. Without access to these values, any activity prepared for teaching biodiversity is decontextualized and meaningless. In this scenario, the present study aimed to characterise the biodiversity values of secondary school students.

METHOD

The work was conducted in three phases. The first involved the creation and validation of a 5-point Likert scale questionnaire about biodiversity values. We did a bibliographical research about biodiversity values in literature. Then, we categorized the values in three dimensions and formulated 27 questions (9 questions for each value). Science teachers, graduate students in science education and academic professors analysed the questions in the process of validation. They judge the contend and form of the questions, verifying if the questionnaire had conceptual errors or were ambiguous. The second phase was the application of the questionnaire in October 2017. Then, in the third phase we analysed the data generated.

The work had a qualitative feature, once it involves the description and categorization of the biodiversity values of chosen students. In addition, the research had also a quantitative feature, once statistical tools were used to obtain the data. The research presented here can be considered a mixed methodological approach (Morais & Neves, 2007).

Participants

The participants of this research were 73 elementary students (between 12 and 14 years old) from a public school at a city in the interior of Brazil. They come from middle and lower economic class families and have little access to cultural assets such as museums or libraries. Their school did not have a science or computer laboratory. However, the science curriculum of this school was very sophisticated. The science teachers of this school based-on the curriculum on science literacy and inquiry-based learning. Therefore, students have classes that strongly stimulates scientific thinking in a constructivist approach.

Questionnaire

Each question proposed a different situation for the respondent to position himself. The scale ranging from 1 to 5 showed the degree of importance and consequently the decision made by the respondent on the proposed situations. Some examples of questions about each value:

Q1 Economic value

In my opinion, one of the main reasons for us to approve extracting plants from an environment is the production of new medicines.

Q8 Ecological value

In my opinion, the main reasons for approving biodiversity conservation is to maintain genetic variability within each species.

Q24 Ethics and patrimony value

In my opinion, one of the main reasons for approving the preservation of a forest is the presence of native people living there.

Validation and Statistical analysis

The first step of validation was the evaluation of the questionnaire by experts consisting of professors and researchers with Biological Sciences background. This validation step allowed removing ambiguous questions, the improvement in vocabulary and the greater precision of the assertions. After application, the internal structure of the questionnaire was validated through exploratory factorial analysis. The assumptions about the suitability of data were tested using the Kaiser-Meyer-Olklin (KMO) and Bartlett tests (Malhotra, 2001; Hair Jr et al, 2009). The factors were extracted according to the main components method and the number of factors was extracted according to Scree test (Cattell, 1966). After extraction, the factors were retained and rotated by the Varimax orthogonal rotation method (Tabachnick & Fidell, 2007). All statistical analyzes were performed in RStudio software version 0.99.902 with the packages "psych", "GPArotation" and "nFactors".

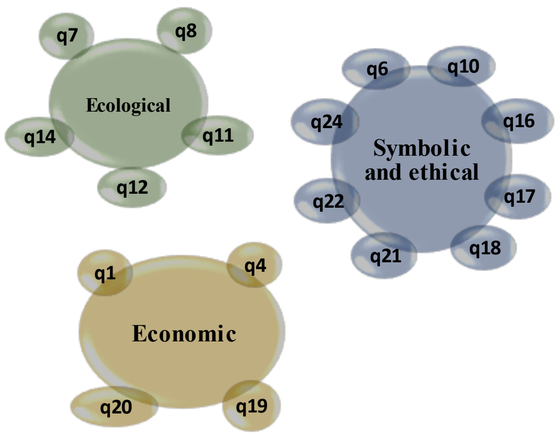
RESULTS

Table 1 presents the factor loads of each question. The loads indicate which variables (questions) were more related to each factor. The symbol "/" represents questions with factor loads whose values were less than 0,10. According to the scree test, it was obtained 3 factors. The next step was the grouping of questions that were more related to each other (figure 1) according to the factorial loads. The first factor was called *Symbolic and ethical* and covered questions 6, 10, 16, 17, 18, 21, 22 and 24. The second factor was called *Economic* and involved questions 1, 4, 19 and 20. Finlay, the last factor was called *Ecological* and grouped questions 7, 8, 11, 12 and 14. The denomination of each factor was given according to the baseline of theoretical reference, the content of the questions and the way in which they interrelate within each factor. Overall and Individual MSA (KMO) must be higher than 0.50. The analyses showed an Overall MSA=0.64 and the individual KMO for each question also showed positive results. Bartlett´s test p-value must be less than 0.05. The analysis showed a p-value= 0.05. Although p-value score of Bartlett´s test was at the limit, the consistency of the other data supported the continuity of the analyses.

Table 1. The factorial loads of questionnaire´s factorial solution.

Factorial solution			
Content of question	**Factor 1**	**Factor 2**	**Factor 3**
q1 - Plants for medicine	\	0.46	\
q4 - Mining	\	0.42	0.12
q6 - Ecotourism	0.5	\	\
q7 - Species extinction	\	\	0.41
q8 - Genetic variability	-0.1	0.4	0.5
q10 - Soil protection	0.43	-0.14	0.2
q11 - River protection	0.14	\	0.55
q12 - Climate regulation	0.18	-0.11	0.38
q14 - Divine nature	0.1	-0.11	0.66
q16 - Welfare	0.35	-0.17	0.35
q17 - Beauty of landscape	0.68	-0.21	0.2
q18 - Good memories	0.63	0.24	\
q19 - Fear or disgust	\	0.52	-0.14
q20 -Living beings that cause problems	-0.14	0.56	\
q21 - Knowledge on biodiversity	0.45	0.11	0.35
q22 - Future generations	0.51	\	\
q24 - Presence of indians	0.43	-0.19	0.29

Figure 1. Categories of biodiversity values generated with data of factorial analysis.



DISCUSSION AND CONCLUSION

The biodiversity values of secondary students found in this work corresponds to the values characterised by Lévêque, Mounolou (2004) and Wiegleb (2002). Factorial solution reveals that students tend to respond (agreeing or disagreeing) those questions that belongs to each factor, according to the factorial loads of each question. So, students evaluated and perceived biodiversity in three dimensions: (i) ecological, (ii) symbolic and ethical, and (iii) economic.

In the ecological dimension, questions treated about the maintenance of biodiversity in order to avoid extinction of species (q7), to maintain genetic variability (q8), to protect rivers (q11) and to regulate climate (q12). All the questions grouped by the factorial loads have strict relation with ecological aspects. It shows inner content coherence of students.

The symbolic and ethical dimension were related to a group of questions about the biodiversity preservation for ecotourism (q6), the protection of the soil (q10), well-being and the beauty of nature (q16 and q17), the memories that this landscape brings (q18), the knowledge (q21), the maintenance of natural resources (22) and the presence of indigenous (q24). This dimension was wider than the previous one and presents aspects of an ethical stance in society. The framework that supports this dimension was subjective, since it relates to the well-being, the memories and the beauty provided by nature. The question about protection of the soil (q10) was initially created to analyse the ecological dimension. However, when students answered this question, it has grouped with questions about the symbolic and ethical dimension. One hypothesis to explain this situation involves the relation of this students with the soil. Most of the students come from rural areas. They need to protect the soil for future generations and to farm, otherwise their families will not have jobs or food.

The last dimension was economic. It involved questions related to the use of biodiversity for mineral exploration and economic development (q4). This dimension showed an anthropocentric view of biodiversity that places nature at the service of human wills (q1, q19 and q20).

Therefore, we concluded that the questionnaire applied and the statistical validation of data contributed to the characterisation of how students relate and articulate reasons to evaluate biodiversity. This is important for science teaching, once it helps the teacher to understand the conceptions of their students and consequently to prepare more efficient pedagogical materials that promotes students' perception of biodiversity from a critical perspective. The next phase of this research is the individual characterization of the students in a cluster analyses, involving the 3 factors. This next step is important to we understand more precisely the characteristics of this group of students about the biodiversity values.

FACTORS ASSOCIATED WITH STUDENTS' ENGAGEMENT AND PARTICIPATION IN YEAR 11 AND YEAR 12 SCIENCE CLASSROOMS

Hye - Eun Chu[1], *Da Yeon Kang*[2], *Faisal* [2] , *Sonya Martin* [2], *Nathaniel Lewis*[1]

[1]Macquarie University, Sydney, Australia
[2] Seoul National University, Seoul, Korea

This study investigated factors associated with students' participatory style in Years 11/12 science classrooms. Students' preferences for verbal or non-verbal engagement and participation practices and what makes some students more verbal while others remain more silent was examined. To measure factors of interest, we developed the Engagement and Participation in Classroom-Science (EPIC-S) questionnaire, consisting of inquiry into four clusters: Expectations, Attitudes, Interaction, and Practices, and which was validated using Rasch Analysis (RA) and Confirmatory Factor Analysis (CFA). A total of 557 students in Australia, Indonesia, South Korea and Taiwan participated. Findings indicated verbal and non-verbal practices were strongly correlated (r=0.6). Factors associated with verbal and non-verbal practices were expectations for classroom engagement and participation practices, peer support, and interest in science. Teacher openness was found to be associated only with students' non-verbal practices and gender was a significant variable for non-verbal practices. While student country was not found to be associated with engagement and participation practices, upon calculating the standard error of the mean (SE) to predict trends among populations in each country using sample mean values, there were differences in verbal and non-verbal engagement and participation practices.

Keywords: Participation and engagement, verbal and non-verbal practices, secondary science classroom

INTRODUCTION

Studies of science education tend to focus on verbal engagement as participation in science classrooms, such as how frequently students ask or answer teachers' questions (Preznel et al, 2012). Students who remain silent may be misinterpreted as being passive and disengaged during science (Chien et al., 2018; Kang, Chu, Martin, 2018) and are consequently described as being "passive" or "non-engaged." However, such participation is too narrowly defined and does not fit well with participatory norms in different contexts as other studies have shown engagement and participation practices to differ in different countries (see Song, 2013). Comparison of engagement and participation preferences from students in different educational contexts has potential to reveal differences in individuals and groups of students that are important for educators to consider. The conceptual framework in this study provided below (See Figure 1).

RESEARCH QUESTIONS

This study was conducted to identify factors associated with students' engagement and participation practices in Year 11 and 12 science classrooms. The specific research questions are: 1) What predictors are associated with students' verbal participation and non-verbal participation practices? 2) How do variables like gender and academic achievement impact on students' participation practices?

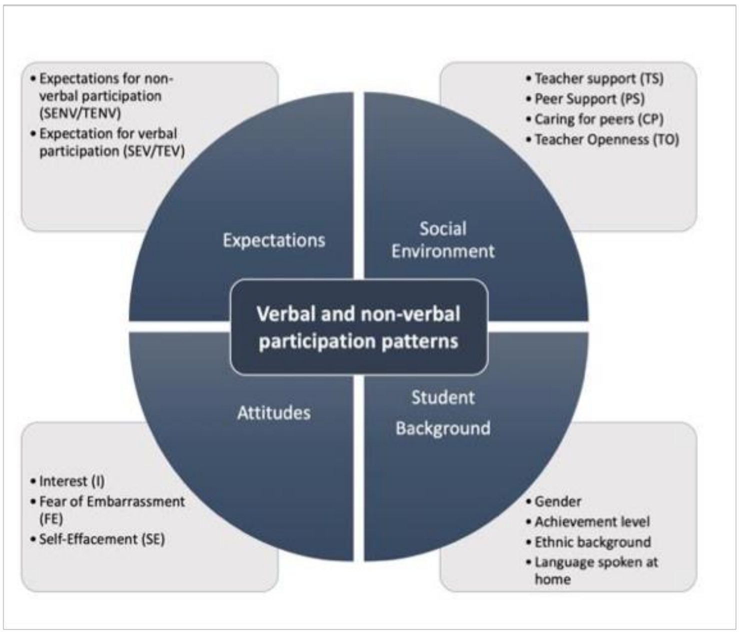

Figure 1. Conceptual framework of this EPIC study

RESEARCH METHOD AND DESIGN

Data Collection

This quantitative survey aimed to predict students' preferred engagement and participation practices in science classrooms. Initial data collection was recently completed, but ongoing data collection is underway to address unequal sample sizes in each country. Thus, data reported here is preliminary. A total of 552 students from four different countries – South Korea, Taiwan, Indonesia, and Australia – participated in this study (see Figure 2). These countries represent a range of achievement data on international science assessments (e.g. TIMSS and PISA), from top groups to middle to well below average. In addition, these countries represent a range of cultural diversity in the classroom from mono- to multi- cultural societies.

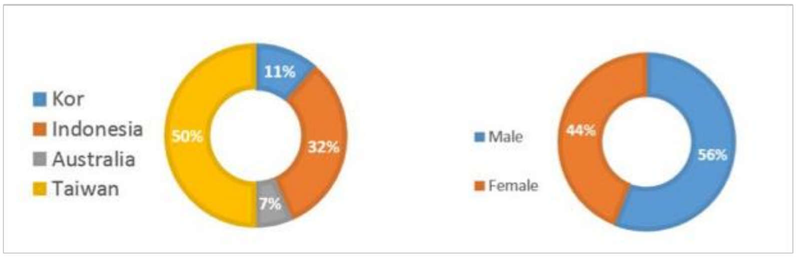

Figure 2. Percentage of participants from Korea, Taiwan, Indonesia, and Australia

Questionnaire and data preparation

Item validation from previous *EPIC-S* studies (Ahn, Chu, Martin, Chien, & Chang, 2016; Chien, Jen, Martin, Chu, & Chang, 2017; 2018) were used. Rasch modelling was used for person and item reliability. In addition, Cronbach's alpha reliability was also calculated.

In Table 1, items in each scale are in acceptable fit. The infit and outfit have the mean square values within the range of 0.7–1.3, and z scores for the infit and outfit have a magnitude less than 2 (i.e. |zinfit| ≤ 2 and |zoutfit| ≤ 2). Scales of 8 show moderate person reliability (0.50 - 0.65) and 5 scales (TEV, FE, TO, RT and CP) show low person reliability (0.24 –0.40). Most scales show high/moderate item difficulty (0.57–0.99), except for the VP scale (0.40). Even though the reliabilities of some scales are moderate/low, items in each scale are within the values range for good fit between the Rasch model and students' responses. To improve the scale reliability in our follow-up study, additional items in each scale will be developed, and more samples, including a wide range of students' tested abilities, will be collected. Cronbach's alpha reliability was also calculated, with results that indicated the items in the scales were well designed to measure accurately the scale developers' focal points of interest. All scales except the CP scale showed reasonably high Cronbach's alpha reliability (> 0.75). The CP scale (a =0.53) was excluded.

Data analysis

After data preparation, 12 scale scores (except for the CP scale) were analysed using multiple-regression analysis to identify predictors associated with the two dependent variables: verbal participation and non-verbal participation. All independent variables that showed as equal/above the 0.4 Pearson correlation coefficient were included in a multiple regression analysis. ANOVA was conducted to investigate the influence of demographic variables and students' study preferences, such as gender and study hours. Due to unequal sample sizes by country, we calculated the standard error of the mean to predict sample population trends for each EPIC-S scale in each country.

FINDINGS

Predictors

When examining Year 11 and 12 students' participatory practices in the science classroom, students' expectations was the largest contributor to both verbal (SEV, beta=.38) and non-verbal practices (SENV, beta=.29). Non-verbal engagement and participation was the second

Country	0.15 A>I/K>T	0.10 A/I>K/T	0.06 T>K/I/A	**0.13** **K>A/I>T**	**0.16** **A/I>T/K**	0.05 A>K/I/T	0.05 T>K>I/A	0.08 I/A/K>T	0.10 A/K>T/I	0.30 A/K/I>T

CONCLUSION and IMPLICATIONS

The study indicates factors that could be helpful in predicting students' classroom engagement and participatory practices. Some factors could be used by classroom teachers to support students' preferred participation practices. For example, the relationship with teachers (RT) is the unique factor in this study influencing students who prefer to engage in non-verbal participation practices. Students from Korea and Taiwan displayed high non-verbal / low-verbal participation practices, but these countries demonstrate high levels of achievement on international assessments (OECD, 2016), suggesting non-verbal science classrooms do not limit learning opportunities. Likewise, Australian and Indonesian students who demonstrate preferences for verbal engagement show lower achievement on the same assessments. Students may show different patterns due to cultural expectations about how to engage in school and learning. Instrument revision and more balanced samples are required, but preliminary findings suggest science educators should think more critically about the role of non-verbal participatory practices for supporting learning and should conduct more classroom-situated research focusing on understanding students with non-verbal participation preferences. Findings will be used for further EPIC-S item revision, to shape interview questions and develop classroom observation protocols.

CULTURE AND GENDER DIFFERENCES IN VOCATIONAL ORIENTATION IN SCIENCE

Marina Hönig[1], Lilith Rüschenpöhler[1], Julian Küsel[1], & Silvija Markic[1]
[1]Ludwigsburg University of Education, Germany

Women and some minorities tend to be underrepresented in science (OECD, 2009). The present research investigates the science aspirations of young people with different gender and cultural backgrounds living in Germany. Further, it tries to establish what kinds of vocational orientation measures in science would appeal to female students with a migration background. The investigation is based on two separate studies: (i) secondary school students (N = 450) were asked about their science aspirations and their preferences in vocational orientation, and (ii) university students (N = 342) were asked to evaluate their vocational orientation in a retrospective view. Study (i) shows that secondary school students in Germany do not differ significantly in their science aspirations when gender and cultural background are taken into consideration. However, they do differ in their preferences in vocational orientation regarding science. The girls with a migration background tend to rely on more institutionalised, professional sources. They wish for more contacts with universities and teacher feedback. In contrast, the boys without a migration background prefer more informal sources such as YouTube videos in vocational orientation. Study (ii) shows that more professional, individual feedback was wished for by university students. The research provides the ground for the design of target group specific measures in vocational orientation in science.

Keywords: cultural diversity in school, gender issues, vocational education

THEORETICAL BACKGROUND

For understanding career choices, two different perspectives can be adopted: a sociological or a psychological lens (van Tuijl & van der Molen, 2016). When taking a psychological perspective, career choices can be explained by variables such as career aspirations or personality traits, for example strengths and weaknesses, extroversion or introversion (e.g. RIASEC (Holland, 1997), expectancy-value model (Eccles & Wang, 2016)). These analyses look at the individuals' dispositions and preferences. When taking a sociological perspective, career choices can be explained by variables belonging to a person's sociocultural environment, such as gender, class and race (e.g. Bourdieusian theory (Bourdieu, 1972) as used by Archer et al. (2015)). In this type of analysis, trends in the society are focused on and the perspective is, therefore, broadened in order to capture context variables that impact individual choices.

In the present study, the main focus is on the influence of gender and cultural background on career choices because women and men of different cultural backgrounds are not equally represented in science (OECD, 2009). Regarding the influence of gender and cultural background on career choices, some important findings have been documented. Female students with a working-class background struggle to develop concrete science aspirations, while this is easier for male, middle-class students (Archer et al., 2010). For example, boys are more likely to choose science subjects (Henderson et al., 2018; OECD, 2009; Riegle-Crumb, Moore, & Ramos-Wada, 2011) and to work in science (Bøe, Henriksen, Lyons, & Schreiner, 2011; OECD, 2008). Boys tend to prefer areas dominated by men such as physics and engineering (Sikora & Pokropek, 2012). Students' cultural background has an impact as well. Students from ethnic minorities choose scientific careers less frequently (Archer et al., 2012b, 2012a; Archer, DeWitt, & Willis, 2014; Carlone, Webb, Archer, & Taylor, 2015) resulting in unequal representation of the gender and culture groups in science. It can thus be assumed that women with a migration background face a double disadvantage in this sector of the job market because being female and belonging to an ethnic minority means that they belong to both groups which are underrepresented in the field of science.

Vocational orientation could play a key role for achieving more equal representation of all gender and cultural groups in science. It serves to both inform students about the range of occupations that are available and to analyse the young peoples' competencies and interests in order to find a good match. Vocational orientation can come in many forms, with a broad range of activities. To date, it is not known which activities are preferred by the different groups of students. We, therefore, do not know how to reach the groups that are currently under-represented in science with appropriate vocational orientation measures that are adapted to their needs.

Some non-culture-specific insights about the effects of vocational orientation measures have been made. Research has shown that activities taking place in school have positive effects on vocational orientation regarding science (Reinhold, Holzberger, & Seidel, 2018). This is especially true for compulsory practical work experiences and well-organised contacts with the local economy. However, not all school interventions have positive effects. Some even discourage students from science careers (Reinhold et al., 2018). Outside school, work experiences and contacts with universities are important factors for choosing a university course in science, with university visits being more important for girls (Robertson, 2000). In the social domain, family members have a greater influence on science course choices than friends. Especially the mother's advice plays an important role in young women's vocational orientation (Esch & Grosche, 2011). Also, more informal sources of information, such as online video platforms as well as TV series with science characters are gaining in importance in vocational orientation (Hoffner et al., 2006).

RESEARCH QUESTIONS

Although we do have knowledge about the effects of some measures employed in vocational orientation in general, we still lack an understanding of the preferences of boys and girls with different cultural backgrounds. The present research, therefore, provides insights into the preferences of young people with different gender and cultural backgrounds for vocational orientation in science. This is investigated from a psychological and a sociological perspective.

In the first part of the study, we investigated how secondary school students of different gender and cultural backgrounds differ in their vocational orientation in sciences. We wanted to know:

(Q1) How do male and female secondary school students with and without a migration background differ in their vocational orientation regarding science?

(Q1a) How do they differ in science aspirations?

(Q1b) How do they differ in their need for more information on jobs in science?

(Q1c) What sources of information do they use in their vocational orientation regarding science?

(Q1d) What sources of information would they like to use more in their vocational orientation regarding science?

In the second part of the study, we were interested in the retrospective view of current university students of science and non-science subjects on their vocational orientation. We wanted to know:

(Q2) How did university students of science and non-science subjects differ in their vocational orientation?

(Q2a) How do the students differ in their reasons for studying their subjects?

(Q2b) What sources of information did they use in their vocational orientation?

(Q2c) What sources of information would they have liked to use more in their vocational orientation?

METHODS

Secondary school students

For the first study, we collected data of 450 secondary school students between 13-19 years (*M* = 15.3) from 8 German schools using a paper-based questionnaire. About 45.8 % (206 students) of the students were female, 49.6 % (223 students) had a migration background, while the target group of girls with a migration background made up for 20.9 % (94 students) of the sample. The analyses were conducted using R (R Core Team, 2017) using the packages car (Fox & Weisberg, 2011), lavaan (Rosseel, 2012), psych (Revelle, 2017), and stats (Lüdecke, 2018).

We measured their science aspirations (DeWitt et al., 2011, translated), their need for information on science jobs (Driesel-Lange & Hany, 2005; Spitzer, 2017, slightly modified), and the sources the students had used and would like to use more in vocational orientation in science (Driesel-Lange & Hany, 2005).

University students

For the second study, we collected data of 342 students between 18-53 years (*M* = 23) from 4 German universities using an online survey. 58.2 % (299 students) were enrolled in at least one science subject, 86.0 % (294 students) were female and 16.4 % (56 students) had a migration background. The analyses were conducted using R (R Core Team, 2017) with the packages car

(Fox & Weisberg, 2011), gmodels (Warnes, Bolker, Lumley, & Johnson, 2018), lavaan (Rosseel, 2012), psych (Revelle, 2017), and stats (Lüdecke, 2018).

We investigated the students' reasons for their choice for a science or a non-science subject (Ellenberger & Ludwig-Mayerhofer, 2005; Hachmeister, Harde, & Langer, 2007, modified). Also, we asked them about the sources they had used in vocational orientation and those they would have liked to use more, just as in the study with secondary school students (Driesel-Lange & Hany, 2005).

RESULTS

Secondary school students

The reliabilities of the scales were good with values for Cronbach's α of .87 for science aspirations (DeWitt et al., 2011, translated, 4 items) and .74 for the need for information scale (Driesel-Lange & Hany, 2005; Spitzer, 2017, slightly modified, 5 items). Confirmatory factor analyses showed acceptable fit (Hu & Bentler, 1999) for the science aspirations scale ($df = 2$; CFI = .964; TLI = .892; SRMR = .029; RMSEA = .193; 90 % CI_{RMSEA} .140, .251). From the need for information scale, we excluded one linguistically difficult item and obtained very good model fit (CFI = .993; TLI = .978; RMSEA = .052; 90 %; CI_{RMSEA} .000, .121; SRMR = .020; Cronbach's $\alpha = .69$).

Two-way ANOVAs showed that the secondary school students do not differ significantly in their science aspirations (gender $F(1, 428) = 0.010$, $p = .919$; cultural background $F(1, 428) = 0.146$, $p = .703$; interaction $F(1, 428) = 0.986$, $p = .321$), and need for information (gender $F(1, 423) = 1.565$, $p = .212$; cultural background $F(1, 423) = 0.004$, $p = .950$; interaction $F(1, 423) = 0.317$, $p = .574$) when gender and cultural background are taken into consideration. In contrast, the students differed in their preferences for vocational orientation measures regarding science. Girls without a migration background ($M = 4.73$) used more sources than the boys ($M = 3.61$), while the inverse was true among the students with a migration background ($M_{girls} = 3.84 < M_{boys} = 4.13$). The interaction effect was significant, $F(1, 438) = 5.870$, $p = .016$.

The students also preferred different types of sources. Multiple logistic regressions showed significant effects for gender: the odds for using online videos were higher for boys than for girls ($b = 0.7$; $SE = 0.19$; $p < .000$). The odds were higher for girls for talking to a female family member ($b = 0.57$; $SE = 0.21$; $p = .007$), for attending a career fair ($b = 0.56$; $SE = 0.22$; $p = .011$) and for wishing for open days at university ($b = 0.71$; $SE = 0.32$; $p = .027$). For students with a migration background, the odds were lower for consulting a male family member ($b = -0.52$; $SE = 0.21$; $p = .012$) and wishing for online videos in vocational orientation in science ($b = -0.74$; $SE = 0.36$; $p = .038$) while the odds were higher for wishing for teacher advice ($b = 0.96$; $SE = 0.36$; $p = .008$) and for university visits ($b = 1.38$; $SE = 0.42$; $p < .001$). These sources were particularly interesting for girls with a migration background: 17 % wished for teacher advice and 16 % for open days at university. It seems like girls with a migration background tend to rely on more institutionalised, professional sources.

University students

The reliabilities of the 5 subscales of the reasons for course choices scale were good with values for Cronbach's α ranging between .70 and .83. Confirmatory factor analysis showed good model fit (Hu & Bentler, 1999) for the model of the reasons for course choices scale when it was assumed that 5 subscales exist (df = 80; CFI = .935; TLI = .915; SRMR = .053; RMSEA = .174; 90 % CI_{RMSEA} .063, .085).

The data showed that the non-science students scored higher on all subscales regarding the reasons for their course choices. The two groups seemed to differ in the overall strength of reasons or in response behaviour, rather than in the types of reasons. We, therefore, assume that the response patterns did not differ in quality but rather in intensity.

However, regarding the sources the science and non-science students had used in vocational orientation, we found significant differences. Significantly more science students had consulted a teacher ($\chi^2(1) = 6.50$; $p = .011$; $OR = 1.76$; $CI_{95\,\%}$ 1.11, 2.81), gone to fairs ($\chi^2(1) = 22.82$; $p < .000$; $OR = 4.40$; $CI_{95\,\%}$ 2.26, 9.16), and participated in Girls'/Boys' Days ($\chi^2(1) = 12.15$; $p < .000$; $OR = 3.44$; $CI_{95\,\%}$ 1.62, 8.00). A smaller number of science than non-science students had used homepages ($\chi^2(1) = 5.74$; $p = .017$; $OR = 0.59$; $CI_{95\,\%}$ 0.37, 0.93), consulted friends ($\chi^2(1) = 8.98$; $p = .003$; $OR = 0.52$; $CI_{95\,\%}$ 0.32, 0.82), female family members ($\chi^2(1) = 18.14$; $p < .000$; $OR = 0.39$; $CI_{95\,\%}$ 0.24, 0.62), and completed a work placement ($\chi^2(1) = 39.38$; $p < .000$; $OR = 0.24$; $CI_{95\,\%}$ 0.15, 0.39). Significantly more science students would have wished for more orientation via homepages ($\chi^2(1) = 4.22$; $p = .040$; $OR = 7.17$; $CI_{95\,\%}$ 0.98, 5.20), company tours ($\chi^2(1) = 7.63$; $p = .006$; OR=3.17; $CI_{95\,\%}$ 1.30, 8.87), and work placements ($\chi^2(1) = 4.83$; $p = .028$; $OR = 1.99$; $CI_{95\,\%}$ 1.03, 4.00). A smaller number of science students wished for more orientation through teachers ($\chi^2(1) = 5.70$; $p = .017$; $OR = -0.49$; $CI_{95\,\%}$ 0.26, 0.92) and fairs ($\chi^2(1) = 4.73$; $p = .030$; OR = 0.50; $CI_{95\,\%}$ 0.25, 0.99). In summary, we assume that more professional, individual feedback was wished for in a retrospective view of university students.

DISCUSSION AND CONCLUSION

The study shows that not all students prefer the same sources in vocational orientation in science. Boys without a migration background seem to like online videos in vocational orientation in science more than girls. This could be due to the range of videos that are currently available on social media. For instance, many YouTube channels present a 'nerdy' science identity which appeals more to boys than to girls (Archer et al., 2013). In contrast, for girls, the range of science channels that would allow for identification with a female science identity is much smaller. To improve vocational orientation in science for girls with a migration background, one strategy could be to diversify the range of YouTube channels covering science and to present a variety of science identities, including girls with a migration background working in science to enhance their presence as role models on social media. First attempts have been made in the project Diversity Sensitive Support (DiSenSu; www.disensu.de) in which short film portraits of girls with a migration background working in science were shot and published on Instagram. These girls reported very impressively on their personal experiences in their scientific careers.

For girls with a migration background, face-to-face conversations with family members or experts such as teachers or career counsellors are interesting. Also, they wish for more university visits. Therefore, another idea would be to make young women with a migration background available for the target group at career fairs as role models and counsellors. Also, regular science workshops at universities for selected girls could be helpful. Teachers could suggest especially shy girls with a migration background to participate in these workshops. In addition, individual feedback from experts and interventions taking place at university could be a key to successful vocational orientation for women with a migration background.

Based on this study, we designed an intervention for vocational orientation in science with which we aim to reach young women with a migration background to support them in their way into careers in science. In the project DiSenSu, we designed an intervention based on face-to-face coaching conducted by female university students who are currently enrolled in a science subject. The university students provide a professional yet personal feedback and could function as potential role models for young women. The coaching takes place in public space to build connections with science outside school. Here, the young women's parents could potentially be reached as well. We assume that the professional feedback of female university students, as well as the interweaving of science with the young women's lives outside school, could appeal especially to young women with a migration background.

DEVELOPMENT AND EVALUATION OF TOOLS FOR GENDER- AND DIVERSITY-SENSITIVE CAREER ORIENTATION IN CHEMISTRY

Ute Brinkmann, Tatjana Jesserich, Ulla Stubbe and Markus Prechtl
Technische Universität Darmstadt, Darmstadt, Germany

Various studies show, that the interest in choosing a scientific career path seems low. This is especially true in chemistry among female students with migration background. The project DiSenSu focuses on this group of students. With the help of a digital vocational orientation program, with different tools, a comic and an interview, students will get a first glance into their competences for a STEM-profession. This vocational orientation program will be presented and discussed in detail. For the evaluation of the tool, a Mixed-Methods approach was used. The quantitative study is based on a computer-aided test of the digital tools. In a pre-study, for example, the levels of difficulty of the tasks related to the spatial visualization ability were tested. The qualitative study is based on the focus group research method for creating a suitable gender-sensitive comic. The outcome of the focus group research led to a full-scale modification of the original comic.

Keywords: Vocational Education, Gender Issues, Cultural Diversity in School

INTRODUCTION

The PISA-Study in 2015 for Germany shows a gender difference in students` interest for science at the age of 15 (Schiepe-Tiska, Simm & Schmidtner, 2016). Furthermore, there is a significant lower self-efficacy expectation among female students than among male students (Schiepe-Tiska et al., 2016). Further focusing on Germany, according to the *MINT-Nachwuchsbarometer*, a nationwide trend report with data of the situation of young talents in STEM domains, chemistry is a study program with a remarkably low growth rate for women, unlike other study programs with a traditionally low proportion of women such as physics and (electrical) engineering (Acatech/Körber-Stiftung, 2017). Many people consider chemistry being abstract, complicated and dominated by men. This stereotypical view influences young people of both genders but especially girls and may even prevent them from choosing a chemistry-related career (Cheryan, Ziegler, Montoya & Jiang, 2017; Wang & Degol, 2017; Prechtl, 2018). For women with a migration background, this difference is even more drastic. Several studies show that being female and having a migration background can be a "double disadvantage" in terms of career (Färber, Arslan, Köhnen & Parlar, 2008). The range of vocational choices of this group is compared to females without a migration background narrower with a clear focus on following four, less well paid, jobs: dental assistant, medical assistant, retail sales woman and hairdresser. Their participation in study programs for high paid professions like chemistry is also lower (Färber et al., 2008).

DESCRIPTION OF THE PROJECT & RESEARCH QUESTIONS

To close this gender gap and to promote chemistry careers among female students specially with migration background, the intention of the project DiSenSu (Diversity Sensitive Support; www.disensu.de) is the implementation of innovative gender- and diversity-sensitive digital vocational oriented events in schools and other educational organisations (Markic et al., 2018). Furthermore, the idea of Science in Public is followed as well. While other vocational orientation approaches focus on interests, in our project typical skills, competences and capabilities for a chemistry career (e.g. spatial ability, haptic skills) as well as students` self-efficacy are considered. Additionally, students read and analyse a comic focusing on female prototypes with a migration background in the laboratory. Female coaches with a background in chemistry assist the students during their work with the tools. After that, individual reflection of the results and personal coaching is offered. Figure 1 presents the foci and tools of the whole program, which takes, all in all, a full hour.

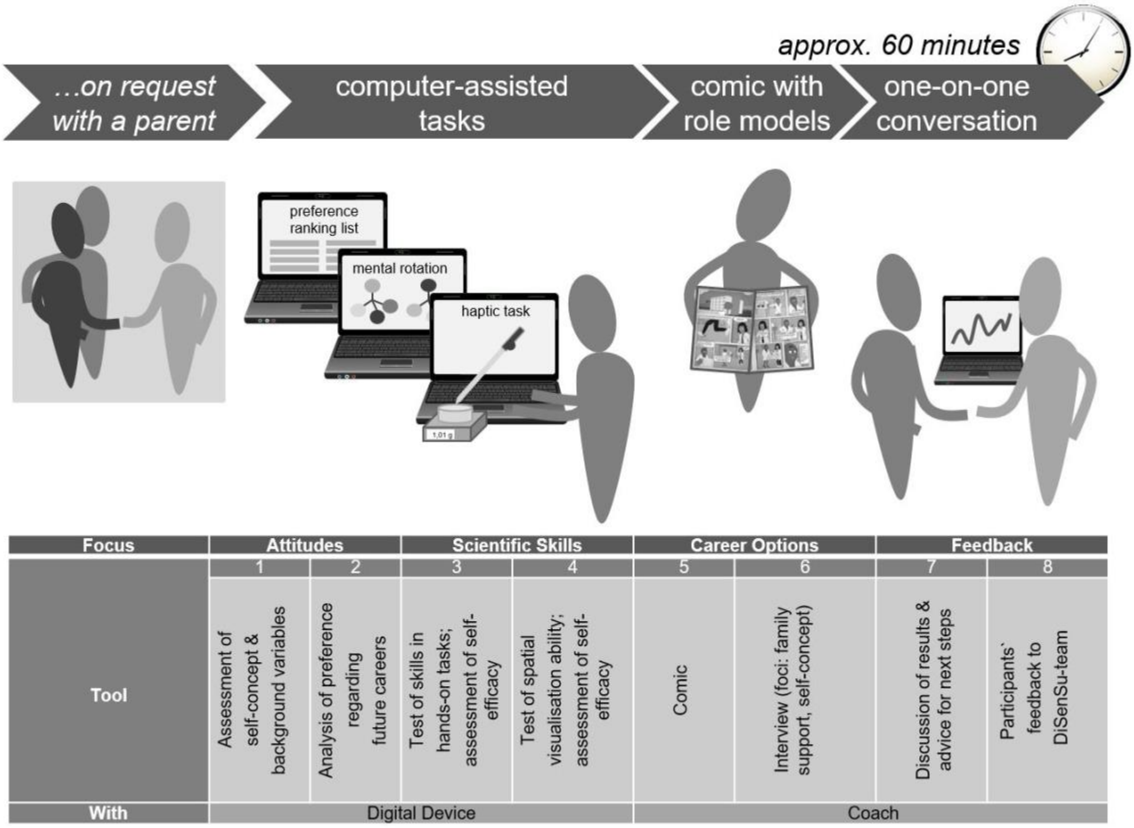

Figure 1. Short overview of the vocational orientation program

In the first phase of the project, the digital tool and the single phases will be tested. Following research questions have to be answered: Which potentials and limits arise for the gender-/diversity-sensitive tools with regard to the quality of the measures? How do the subject-related self-concepts, self-efficacy expectations and ideas of prototypes in science relate to the tasks offered? To answer the research questions a Mixed-Methods approach is used (Teddlie & Tashakkori, 2006). The main quantitative study is currently in progress.

Hereby established scales and completely new conceived designs are used. In this article we present two selected sub-studies.

QUANTITATIVE PRE-STUDY – TOOL 4: TEST OF SPATIAL VISUALIZATION ABILITY

Method

The mental rotation of molecules was chosen as a task to identify a competence typical for a chemistry profession in these girls (Prechtl, 2016). The most adequate tasks were identified in this pre-study. Therefor the difficulty of nine tasks were examined by two different student groups: 30 school students in the age of 13 to 16 years (M = 13.63 yr., SD = 0.84 yr.; 17 girls and 13 boys) and 29 undergraduates in the age of 19 to 32 years (M = 24.31 yr., SD = 3.00 yr.; 13 women and 16 men). They rated the tasks according to five different levels – from level 1, equals easy to level 5, equals hard. The results of this assessment of the two groups were compared with each other using the Mann-Whitney-U-test and the results within the groups were analysed with the Wilcoxon-Test. Aside from that, it was examined whether the levels of the tasks were assessed differently depending on previously being answered correctly or incorrectly.

Results

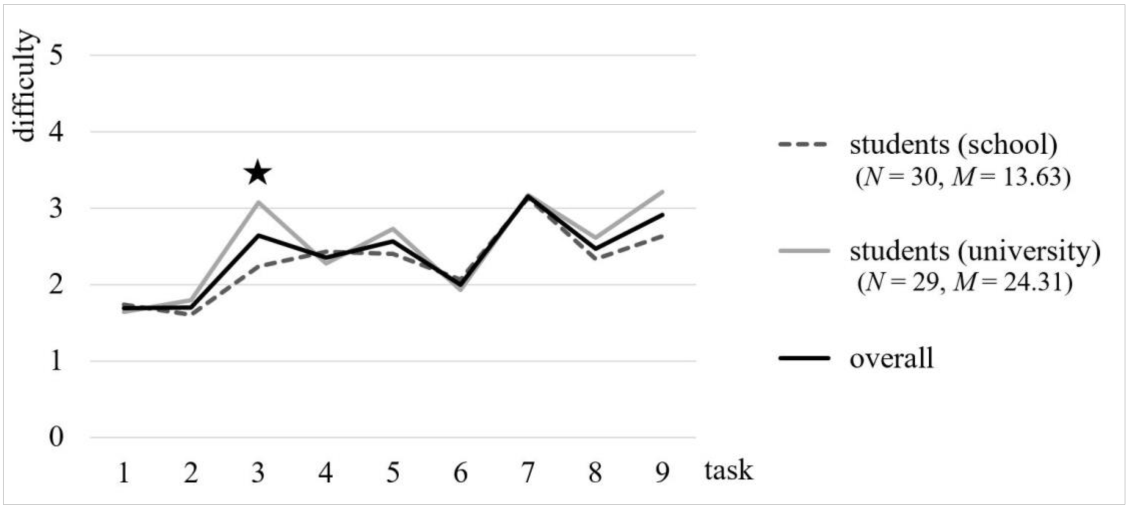

Figure 2. Average values of the degree of difficulty of nine tasks of mental rotation of molecules, completed by two different groups of students

Both groups, school and university students, identified the level of difficulty in the same way, the exception is task 3 as can be seen in figure 2. School students (M = 2.23, SD = 1.01) rated task 3 significantly easier than university students (M = 3.07, SD = 1.25; U = 271.00, p = .01). Task 3 was excluded. Looking at the results of the ranking of the different tasks depending on having solved the task correctly or incorrectly beforehand, there is a difference between university and school students. The university students ranked the level of difficulty of the tasks independently of being answered correctly or incorrectly, whereas the school students ranked the tasks 1, 2, 4 and 7 significantly lower after solving them correctly.

Table 1. Comparison of the perceived difficulty of the tasks of mental rotation of a molecule using the Wilcoxon-Test

Task	1	2	3	4	5	6	7	8	9
1		-0.22	-5.04***	-4.12***	-4.56***	-2.55*	-5.43***	-4.29***	-5.61***
2			-5.07***	-3.93***	-4.25***	-2.43*	-5.61***	-4.14***	-5.41***
3				-1.65	-0.38	-3.50***	-2.40*	-0.76	-1.54
4					-1.23	-2.40*	-4.01***	-0.91	-3.58***
5						-3.74***	-2.85**	-0.67	-1.71
6							-5.12***	-2.87**	-5.10***
7								-3.55***	-1.29
8									-2.93**
9									

Note: Shown are z-values of the Wilcoxon-test and their significance * = p < .05, ** = p < .01, *** = p < .001

The Wilcoxon-test was used to show differences between the tasks' perceived difficulties. The results are shown in table 1. Tasks 1 and 2 were ranked similar difficult but lower then all others. Tasks 4, 5 and 8 were ranked similar difficult and different to all others. Tasks 7 and 9 were ranked similar difficult and higher then all others. These findings showed, that the tasks could be arranged into the categories easy, medium and hard. In that way the series of tasks in the DiSenSu coaching tool was optimized. Taking all these results in consideration three tasks with different level of difficulty and with similar ranking after being answered correctly or incorrectly were identified.

QUALITATIVE STUDY – TOOL 5: COMIC

Background and theory

Within the context of the gender and diversity sensitive vocational orientation the female students get a comic with role models in STEM in which persuasive messages are embedded (Prechtl & Spitzer, 2019). The messages transport a connection between competence and diversity. They shall encourage girls to self-confidently measure their performance and consider a vocation in STEM accordingly. The project is accompanied by a research, which focuses on the question, whether story line and depiction style of the comic are suitable to motivate female students to work in a STEM field.

The chosen media format is a comic, so image sequences are used for presenting role models, who deal with attribution styles and positive self-efficacy. It is shown by studies of Ziegler & Schober (2001) or Perry & Penner (1990) that the effect of such modeling techniques is remarkable. Both groups have used short videos in which people address desired attribution patterns. The students who had seen the video had an improvement in school grades and participation at educational processes.

Method

The qualitative DiSenSu-study analyses two comics, which were created successively. To investigate the research question, the first comic was discussed with the method of group discussions in two focus groups (s. Bogner, Littig & Menz, 2014; Loos Schäfer, 2001). The participants of these focus groups differed from each other. Focus group 1 consisted of experts for diversity and focus group 2 consisted of experts for chemistry. To evaluate the group discussions, the interviews were transcribed. Then they were prepared and analysed with MAXQDA. Afterwards those transcripts were analysed comparatively. Based on the findings of the first study a second comic was created. While (re)designing the comic, the concepts to increase self-efficacy were integrated. Following this, the second comic was evaluated accordingly in the same way. Hereafter both results were compared and lead to the following conclusion.

Results of the discussions on the first comic

The analysis of the first comic produced following findings. Figure 3 presents the shares of the various topics of the overall conversation.

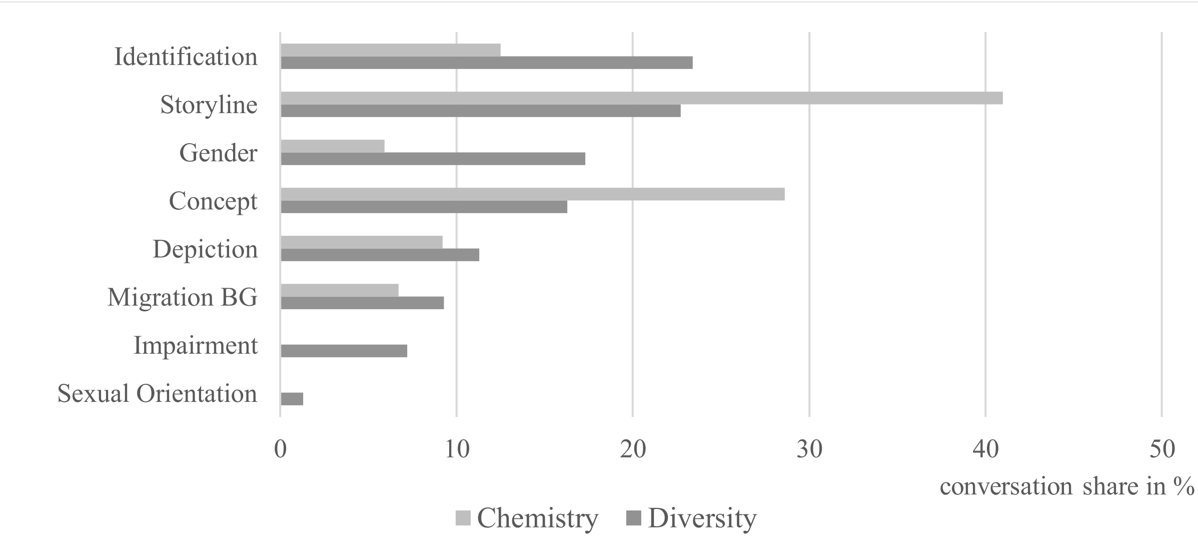

Figure 3. Percentage of conversation share of the various topics discussed by the experts for chemistry and experts for diversity about the first comic

The diversity experts talked about the ability of the female students with migration background to identify themselves with the protagonists of the comic. At 23.4 percent, this topic accounted for a large part of the overall discussion. All following percentage values refer to percentage of the total discussion time. Also the storyline (22.7 %), gender (17.3 %) and concept of the story (16.3 %) were discussed a lot. Besides the depiction of gender and laboratory (11.3 %), the migration background of the protagonists (9.3 %) and the option of depicting mental or physical impairment (7.2 %) were discussed. The option of depicting sexual orientation (1.3 %) was addressed briefly. The chemistry experts focussed on the comics' storyline (41.0 %) and its concept (28.6 %). Further they discussed the ability of the female students with migration background to identify themselves with the protagonists of the comic (12.5 %), the depiction of gender and laboratory (9.2 %), the migration background (6.7 %), and gender (5.9 %). The comic was complimented for illustrating females with a migration background in STEM field. But it was also criticised a lot. According to the participants of the discussion, the story line had a lot of flaws. The message was presented kind of awkwardly and the topics, gender and migration background, appeared enforced. The depiction of the protagonists and the laboratory was also criticised a lot. Laboratory coats were missing, the laboratory was in a “dangerous” state, the female bodies were depicted very “Barbie” like. Furthermore, most remarkable in this context is, that both groups mentioned that it seemed unrealistic to see only two females in the laboratory. It was said, that another man was missing to appear more realistic. Also interesting is, that skin colour was linked to competence. With the least competent person having a light skin tone and the most competent having a dark skin tone in this comic, it contradicts common prejudices.

Statements of the experts for diversity and for chemistry about the first comic, translated from German into English:

- *“Well, the more realistic the depiction is, the more I identify myself. (...) But I would (...) not really be able to identify myself with this doll-like person.”*
- *“For me, of course, it takes a little getting used to, so unrealistic, a bit artificial. Um, if there were other people, maybe a man in between would make the thing, that also not so umm unrealistic.”*
- “*By the way, I also noticed that different skin colours are used there. The darker the skin colour, the greater the expertise.”*
- *“The brighter, the more clueless at this moment. But um, um, I could do it a little bit contrary to what you normally see, because it's often the other way round from a feeling point of view.”*

Results of the discussions on the second comic

The diversity experts particularly discussed the depiction of the laboratory and characters (35.3 %), the comics’ storyline (33.8 %) and its concept (24.8 %). The migration background (3.7 %), the ability for identification (3.2 %) and gender (1.2 %) were discussed quite shortly. The chemistry experts focussed on the depiction of the laboratory and characters (34.9 %) and the comics’ storyline (33.1 %). The comics’ concept (8.7 %), the migration background of the protagonists (8.3 %) and gender (6.0 %) were discussed shorter. Figure 4 presents the shares of the various topics of the entire conversation.

The appearance of the protagonists, the depiction of competent females with character and the positive presentation of people with migration background were for example highly praised. The worker in a headscarf, as another example, was perceived as empathetic and therefore sympathetic. It was no longer mentioned as a problem, that there were only females in the workplace due to a small text passage, which said they are part of a larger team without using gender. Now the focal point of attention were the illustrations of processes and operations. It seemed that they were not shown detailed enough. Another concern was whether the comic was too difficult to comprehend for school students.

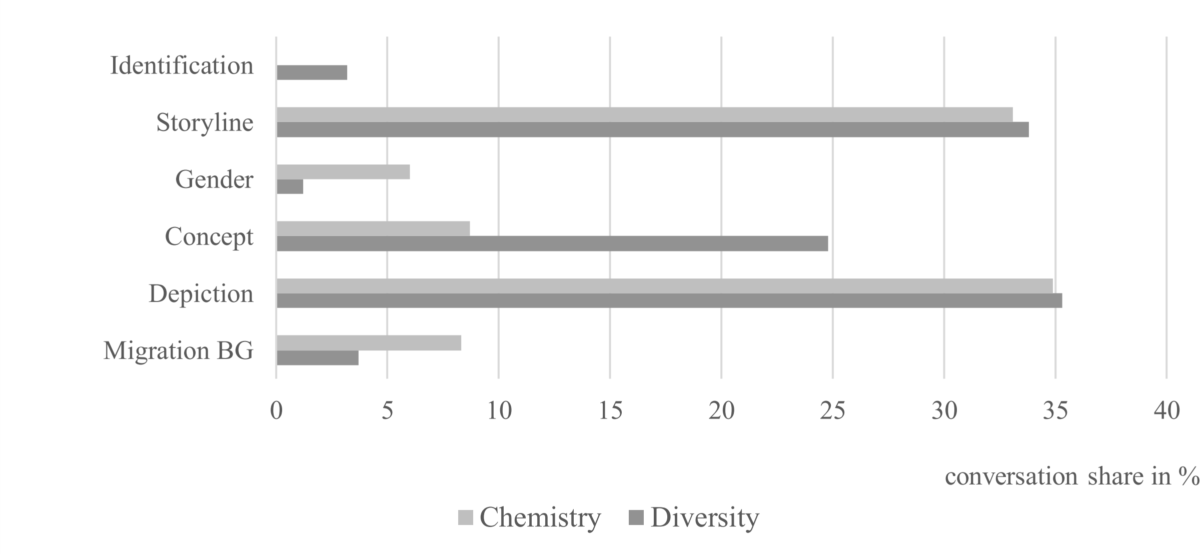

Figure 4. Percentage of conversation share of the various topics discussed by the experts for chemistry and experts for diversity about the second comic

Statements of the experts for diversity and for chemistry about the second comic, translated from German into English:

- *“What I liked on the first - um here at the first picture: "part of a research group". It takes the whole thing with this female/male and who is in this group now - and why are there only two of them now - takes it completely away.”*
- *“I wanted to address that, um - apart from the presentation - I really like the fact that the researcher with the headscarf appears so self-evidently. So there is no question at all whether she is competent or not. But that one is there - that one is the researcher - that one leads the way - that one has the knowledge - so and um that comes across so subtly. So there isn't a big-big barrel opened now - hello I'm the researcher. I know about everything' - but, um, it just comes across in the dialogue. I think, uh, it's very well done. The umm - there's no doubt about it - the one with the headscarf, if she knows that' - no - no - the one knows that. And Leyla can also teach them that.“*
- *“I think it's cool with the centrifuge. I think it's beautifully presented, only what I notice when we talk about correctness. A centrifuge would never be open. Never ever. And um, I don't know how to represent that now, so you - maybe a box. Because the problem is, it's a mega blatant security thing. Um that's definitely um um that wouldn't exist just because of all the friction and stuff.”*

Comparison of the two comics and conclusion

In all discussions, the focus laid on the comics’ storyline and concept. In comparison to the discussions about the first comic, which emphasis was on identification, the discussions about the second comic centred on the way of depiction.

According to this analysis there are certain quality criteria to consider while creating supplementary material which addresses young females with migration background who shall be encouraged to a STEM vocation. First of all, the level of study line and language has to be adequate for students. An accurate depiction of processes and operations in this context is important. In concern of the depiction of migration background, it is useful to present them positively. In the depiction of females, it is important to use quite realistic body types although it is a comic. For both, depiction of migration background and females, it is crucial not to use stereotypes but a variation in appearance. Competent professionals should be shown in an authentic context. In conclusion, taking the described recommendation for creating corresponding supplementary material into account, comics are able to encourage female students to consider a vocation in a STEM field.

SUMMARY AND OUTLOOK

With the first described sub-study three tasks of mental rotation of molecules could be selected specifically with just the right level of difficulty to test the spatial visualisation ability of the female students, i. e. an important competence for a job in the chemistry field. Furthermore, as a result of the main qualitative study, a totally new designed comic was created and evaluated to enrich the vocational orientation coaching to motivate young female students to not only think about a career in the chemistry field, but also to be able to see themselves actively in such a chemistry profession (s. https://www.disensu.de/comics/). The next big step in the project DiSenSu is the quantitative analysis of all recorded coaching data.

It should also be mentioned that this vocational orientation program is very well perceived by school students, parents and teachers. Feedback given directly after the coaching or in writing later, points out how helpful and special the vocational orientation coaching is. The students praise the duration of one hour, enjoy reading the comic, which was designed especially for them, see the different tasks as very helpful and mention how much they learn about the diversity of career opportunities within STEM and what job descriptions in this field actually look like. They leave the program motivated and encouraged.

ACKNOWLEDGEMENT

The project "DiversitySensitiveSupport: STEM vocational orientation for female adolescents with a migration background in daughter-parent dyads (DiSenSu)" is funded by the German Federal Ministry of Education and Research under the funding codes 01FP1725 and 01FP1726.

DIVERSE STUDENTS, DIVERSE INQUIRY? HANDS-ON INQUIRY LEARNING IN HETEROGENEOUS CHEMISTRY CLASSROOMS

Dennis Kirstein, Sebastian Habig & Maik Walpuski
University of Duisburg-Essen, Essen, Germany

Hands-on inquiry-learning tasks provide many opportunities for chemistry learning in heterogeneous groups. Commonly, students with various cognitive and affective preconditions work autonomously on those tasks and face individual difficulties and challenges. To be aware of possible obstacles and to know in which way they are related to students' individual prerequisites is crucial to create appropriate learning settings which take students' individual prerequisites into account. Against this background, the purpose of this study is to examine students' individual activities and difficulties while working on collaborative hands-on inquiry learning tasks considering different topic areas. In a qualitative study with 16-year-old students from different school types in Germany we used test data and video data from small-groups working on tasks on different topics. The results show that inquiry activities are quite individual as no correlation between a small-group' composition and activities during the inquiry-process could be found. Concurrently, high achieving small-groups show more activities that are necessary to gain knowledge from the inquiry learning task.

Keywords: Inquiry-oriented Learning, Differentiation, Video Analysis

PURPOSE OF THE STUDY

Inquiry learning in science education has become a widely used approach in recent years. A proven approach for inquiry learning in context of chemistry education is using collaborative hands-on inquiry learning tasks (Walpuski et al., 2008). Since students differ with regard to their competences in science (OECD, 2016) hands-on inquiry learning tasks have to be adjusted to students' individual prerequisites. Therefore, different individual prerequisites are important just as the way they are composed in small-groups. However, studies about the interaction of both students' individual prerequisites and effects of composing them in small-groups in context of hands-on inquiry learning in chemistry are still missing. As most of the studies focus on test data, there are barely qualitative insights about students' learning process. Therefore, the aim of our study is to gain insights into the use of hands-on inquiry learning tasks in heterogeneous chemistry classrooms across different topics. For this purpose, we analyse small-groups' individual ways of dealing with various hands-on inquiry learning tasks and investigate the correlation between small-groups' composition and inquiry activities and emerging difficulties in context of hands-on inquiry learning tasks.

THEORETICAL FRAMEWORK

Scientific Literacy as a part of education is an important learning outcome for every student in our modern society. There is international agreement that chemistry education as part of science education has to focus on educational aims, which are necessary to develop a general understanding of important scientific ideas and concepts as well as typical scientific practices and knowledge about science itself (AAAS, 1990; in Germany: KMK, 2004). By conducting experiments within inquiry learning tasks, students not only gain knowledge about chemical ideas, but also knowledge about science practices and the nature of science (Lederman et al., 2013). As doing so, students' prerequisites play an important role and affect their achievement (e.g. van Riesen et al., 2018). Prior content knowledge (van Riesen et al., 2018) and procedural knowledge (e.g. Stender et al., 2018; Ben-David & Zohar, 2009) have proven to be particularly relevant for successful inquiry learning in science education. Although students use similar activities when processing inquiry learning tasks low prior knowledge seems to determine a rather ineffective process structure (Mulder et al., 2010). Moreover, there are some insights about difficulties students have when working on hands-on inquiry learning tasks for single topics (e.g. Kechel, 2016). Overall, it seems that both, structure of inquiry activities the students use to structure the process and occurring difficulties have to be considered in investigations that focus on students' individual success while learning in a hands-on inquiry setting. For collaborative hands-on inquiry learning tasks the learning groups' composition also has to be considered for individual learning achievement (Lou et al., 2000). For example, general educational research has already stated out that low performing students profit most from heterogeneous small-groups whereas higher performing students tend to profit most from homogeneous small-groups (e.g. Lou et al., 2000).

DESIGN OF THE STUDY

In this study test data and video data of 16-year-old students from different school types in Germany processing hands-on inquiry tasks on different topics ('batteries', 'ocean acidification' and 'mineral water') has been analysed. Each topic involves the processing of two learning tasks that build on each other. Students' content knowledge has been assessed one week before and directly after the intervention by using multiple-choice single-select items. These tests consist of items relating to the contents of the learning tasks and items relating to general core ideas in chemistry (Celik & Walpuski, 2018). The items to general core ideas are used as anchor items. The parameters of the anchor items are fixed during scaling so that the tests can be related to each other. Additionally, we used established tests to assess students' cognitive abilities (Heller & Perleth, 2000) and procedural inquiry knowledge (Mannel, 2011) as control variables. In total, 146 students participated in our study working together in small-groups of four students. Furthermore, we selected 25 of these small-groups and videotaped their working processes. Test data have been analysed with unidimensional-IRT-models in R by using Test-Analysis-Modules (TAM) (Robitzsch, Kiefer, & Wu, 2019). Person parameters have been estimated by using WLE based on item parameters from MML-approach. Video data have been analysed using qualitative content analysis (Mayring, 2009) to identify different inquiry activities during the working process. For this purpose, a coding manual has been developed from our current video data, taking into account results from previous studies. Coding itself has been done timebased (10-second-intervals). 25 % of the video data considering different topics and small-group compositions have been analysed by two independent raters to determine the quality of the manual.

RESULTS

Although all items used in this study show sufficient item-fit statistics for the Rasch model, the reliabilities are only acceptable for tests regarding 'cognitive abilities' and 'procedural inquiry knowledge'. The reliabilities for the prior knowledge tests are quite low (Table 1). However, high correlations between all test scales ($r_P \geq .608$) justify the use of the prior knowledge data for further analyses.

Table 1 reliabilities of test scales

t-values	-1.99 - 1.92	-3.00 - 2.86	-3.00 - 1.83	-1.23 - 1.82	-1.30 - 1.40
r_{it} (M(SD))	0.29 (0.18)	0.23 (0.24)	0.28 (0.21)	0.48 (0.09)	0.38 (0.11)

Overall, a significant increase in learning can be observed for all experimental tasks (subject 'batteries': $t(36) = 6.39$, $p < .001$, $d = 1.02$; subject 'ocean acidification': $t(53) = 5.97$, $p < .001$, $d = 1.01$; subject 'mineral water': $t(54) = 13.63$, $p < .001$, $d = 1.92$). Since only average tendencies can be derived from this consideration, the individual learning success was considered in a further step absolute (absolute difference between the abilities at both measuring points) and residual (deviation from the regressed learning increase depending on the abilities at the first measuring point). Of the 146 pupils, 76 learners fell short of expectations and 20 could not improve at all.

In addition to the performance data, the work phases of 23 small groups (93 pupils) were videographed. These learning process data were evaluated as part of a qualitative content analysis (Mayring, 2015). The coding manual is designed to cover all topics and comprises 7 main categories ('students work with the card material', 'students plan an experiment', 'students formulate hypotheses', 'students conduct an experiment', 'students make observations', 'students draw conclusions' and 'students work off-topic') with 16 codes (e.g.

‘students read the task’). The coding was time-based in 10-second intervals with a view to the experimental activities of the small group. In concrete terms, task-specific indicators (directly observable student actions and statements) of superordinate and task-independent activities (phases of experimentation) were coded. The observer agreement for this procedure varies according to the small group ($0.43 < \kappa_{Cohen} < 0.72$) and can be interpreted as acceptable to good (Wirtz & Caspar, 2002). An objective and thus reliable description of the experimental activities does not seem to be equally possible for every small group. For the further analyses, the frequencies of occurrence of the higher-level activities were standardized over the duration of the processing. With regard to heterogeneity within a small group (absolute difference between the most efficient and the least efficient learner), significant correlations can only be found with regard to specialist knowledge. Thus activities for planning ($r = .469$; $p = .024$) and evaluation ($r = .691$; $p = .000$) increase with increasing heterogeneity in a small group, while experimental activities ($r = -.358$; $p = .093$) and observation ($r = -.470$; $p = .024$) become less important for the group process. The performance level of the small group is not taken into account in this context, since heterogeneous small groups with an average high performance level have others than heterogeneous small groups with an average low performance level.

Within the framework of a communicative validation (exchange between the codes via inseparable categories or indicators) after completion of the coding, it was found that the experimental activities of individual pupils within a small group cannot always be clearly assigned to the overarching objective of cooperative task processing. In addition, especially in very heterogeneous small groups, individual pupils seem to dominate the working process.

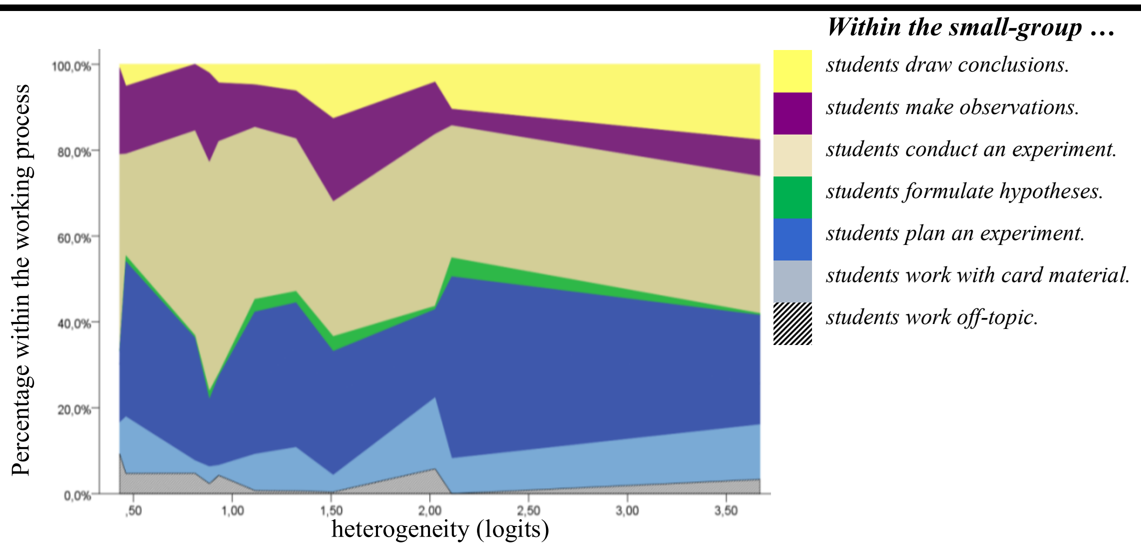

Figure 1 Group-specific activities within the working process

Therefore, in a second approach, the experimental activities at the individual student level were coded. In the course of further analyses, the comprehensive coding manual was revised. For this purpose, the topic-specific characteristics of the codes were worked out from the video material. Additional categories (e.g. ‘students document their results’) were added. Finally, the work phase of each learning task was analysed with the help of specific coding manuals (see Table 1).

Table 1 Characteristics of the coding manuals for the analysis of individual activities

	'batteries'		**'ocean acidification'**		**'mineral water'**	
	task 1	task 2	task 1	task 2	task 1	task 2
categories	8	8	8	8	8	8
codes	57	63	51	71	57	70

In all cases, this method provides significantly better observer agreement ($0.74 < \kappa_{Cohen} < 0.89$), which lies within an ideal range ($\kappa_{Cohen} > 0.70$) for qualitative class observation (Wirtz & Caspar, 2002; Frick & Semmel, 1978). For an initial analysis, the individual activities of twelve students from three different small groups were examined in more detail. In order to analyse the individual participation in the group process, κ_{Fleiss} was determined as the measure of agreement between the individual activities of the pupils. This shows that with increasing heterogeneity within a small group, participation in the group process becomes increasingly individual and different (see Table 2).

Table 2 Group-specific agreement of individual participation

	small group 1	small group 2	small group 3
Average level of performance (logits)	-0.433	-0.236	-0.149
heterogeneity (logits)	0.094	0.386	0.811
κ_{Fleiss}	0.658	0.412	0.362

DISCUSSION AND OUTLOOK

Overall, the results show that an individual-oriented analysis of experimental phases in cooperative settings is much more accurate than at the level of the small group. At the same time, such an approach allows deeper insights into the individual learning process within the framework of cooperative work. These can provide a central basis for the design of individualised and adaptive learning opportunities. The topic-specific coding also suggests that the content of the learning tasks also has an influence on the individual learning processes of the pupils. Due to the small data base, the analyses only provide indications of possible correlations. To what extent the topic on which the experimental task is based has an influence on the processing cannot be answered on the basis of the previous results either. Furthermore, the process data also indicate individual difficulties and mistakes, which seem to have a significant influence on the success of small-group work. In previous research, there have been numerous findings on difficulties and mistakes in experimentation, but these are often limited to specific topics. In addition, the occurrence of difficulties and mistakes has not been related to the learning conditions of students yet. It can be assumed that both individual participation and difficulties and mistakes have an influence on students' learning success.

Therefore, in a final study with 179 16-year-old students we will examine the relationship between individual learning prerequisites, individual processing strategies and difficulties. Analogues to our first study we used tests to assess students' individual prerequisites in first step. Therefore, we optimised those tests with insufficient tests statistics by improving existing items and creating new items. Furthermore, video data from 125 students working in 32 small groups are analysed. The results from the process analyses will be correlated with students' individual prerequisites. These findings can then be used to individualise learning processes during experimentation.

LEADING FAMILIES TO STEM WITH EXTRA SCHOOL LEARNING

Kristie S. Gutierrez[1] *and Margaret R. Blanchard*[2]
[1]Old Dominion University, Norfolk, VA, USA,
[2]North Carolina State University, Raleigh, NC, USA

This mixed methods study investigates the experiences of families who took part in STEM Career Club: Home Edition (SCCHE). Forty-four families at three rural, high poverty middle schools in the Southeastern US participated in SCCHE, receiving all materials necessary to complete up to 4 STEM activities in their homes. Parents generally perceived they had less understanding of STEM content than did their children, pre-activity; however, parents consistently answered more than 50% of content questions correctly on the post-activity survey. Parents and their children described developing or re-learning skills and content knowledge, and they most often noted enjoyment while participating in STEM activities with their families in this extra school learning experience. This study gives insight into ways to bridge formal school STEM content standards into learning settings within student homes to increase content knowledge, enhance home-school partnerships, and provide evidence-based applications for future extra school learning implementations.

Keywords: Parental Involvement, STEM Education, Informal Learning

INTRODUCTION

There has been a decline in the extent to which parents have been involved in their children's educations (Jeynes, 2012). A variety of reasons contribute to this trend: the increase of parents (particularly mothers) in the workforce, the fast-paced nature of society, increasing work hours, and the perceived reduction in the role of family in society (Jeynes, 2006; 2010; 2012; Mapp, Johnson, Strickland, & Meza, 2008). The majority of research on parental involvement is situated in preschool and primary grades contexts, and findings indicate that parental involvement is inversely related to their child's age (Hill, 2015). Hill asserts that it is easier to recruit parents of elementary school students to action, and parents often view their children's adolescent years (middle and high school) as a time for students to explore their identities and figure out who they want to become. Thus, parental roles change to include less involvement in school and academics as they attempt "to prepare them [children] for adult roles and experiences" (Hill, 2015, p. 43). The child's developmental level may dictate the degree to which they are interested in parental involvement; as adolescents mature, they often show more independence and less interest in certain forms of overt parental involvement (Bhargava & Witherspoon, 2015).

Parental involvement with schools during the middle school years is significantly associated with students' academic self-efficacy, academic aspirations, perceptions of academic potential, self-expectations, parental expectations, and teacher expectations (Seitsinger, Felner, Brand, & Burns, 2008).Thus, there is a need to provide opportunities for parents to remain involved in middle school to assist their children in content knowledge gains and planning for post-secondary education and careers (Epstein, 1986; Blanchard, Gutierrez, Hoyle, Painter, & Ragan, 2018). This study investigates the experiences of middle school students and their families who participated in an intervention intended to involve parents [guardians] with their middle-school children in engaging at-home STEM activities.

Theoretical Framework

Epstein (1986) identified six types of parental involvement that enhance student success in school: 1) involvement in basic obligations at home (i.e. securing school supplies, providing a quiet place to work while at home); 2) two-way communication between school and home (e.g., parent teacher conferences and more recently email or text communication); 3) volunteering at school (e.g., class parties, helping in the school cafeteria or library); 4) assisting students to complete at-home learning activities (ranges from high to low involvement and can be categorized into one of five categories); 5) involvement in school level decisions and advocacy (e.g., PTA or PTSO); and, 6) collaboration with community organizations. Epstein (1986) categorized 12 different types of at-home parental involvement activities into five categories: 1) reading books, 2) discussions between parent and child, 3) participation in informal activities (such as games using household materials), 4) implementation of contracts between parents, children, and teacher, and 5) tutoring and teaching the child skills and drills. Most at-home parental involvement programs are multidimensional and include between 3 and 4 of the above main types of involvement (Mattingly, Prislin, McKenzie, Rodriguez, & Kayzar, 2002).

Research Questions

The current research with the *STEM Career Club: Home Edition (SCCHE)* was designed as a vehicle to help parents work with their children in an extra school learning environment to complete up to 4 at-home STEM learning activities meeting Epstein's five categories. The research questions examined in this study are:

1) What are the characteristics of the families who participated in the SCCHE project? To what degree did families participate in the SCCHE project?

2) What content knowledge did participants (parents and children) demonstrate following SCCHE activities?

3) What were family members' perceptions of the SCCHE extra school learning experience?

METHOD

This funded research study (Blanchard & Gutierrez, 2016) builds off of a larger study (Blanchard et al., 2014; Gutierrez, 2016) and investigates the experiences of families who participated in at-home STEM activities using a mixed methods design (Creswell, 2013).

Context/Participants

Thirty-one families participated in this study, of the original forty-four families who initially consented (Total participants: N = 84: Parents/Guardians: n = 30, Children: n = 54). The participants were associated with established after-school STEM Career Clubs in 3 rural, high-poverty (>70% free-and-reduced lunch) middle schools in the southeastern US, as part of a

NSF-funded project (Blanchard et al., 2014). The STEM Career Club student membership for the participating schools was predominantly African American (55%), followed by White (22.5%) and Hispanic (8.1%). Large percentages of students in the four districts *failed* the end-of-grade mathematics (70.9%) and science (36.1%) tests.

STEM Career Club: Home Edition

Forty-four families initially consented to participate in this extra school learning environment, *STEM Career Club: Home Edition*. These families received all the materials required to complete a STEM activity in their homes, one activity at a time. When families returned the data associated with one activity (they kept all the STEM supplies), they were provided with the next activity until they completed a possible maximum of 4 activities throughout the school year. Included in each of the *Home Edition* kits were STEM materials (e.g., Circuit Scribe kit, Meccano robot, Germ Glo and *Achoo! The most interesting book you'll ever read about germs*, Steve Spangler's *Larry's Lab*); snacks, instructions for the activities, information about activity related careers and local post-secondary opportunities.

Data Sources & Analysis

In addition to the *STEM Career Club: Home Edition* materials, families also received pre-& post-activity questions. Each family member completed a pre-activity perceptions of knowledge survey and were asked to report on their affective perceptions and concerns prior to beginning the activity. Following the activity, all family members responded to 4-5 activity-specific content-related questions, and explained any changes in STEM understanding and their affective perceptions through short answer prompts.

Content knowledge questions were answered once families concluded the activities in their homes. These questions were multiple choice and included material that was specifically addressed within the at-home activities, such as: " You may program movement of your Micronoid by rotating its head back and forth in a unique pattern of your choosing through _____ programming. (a) Block-based, (b) Push-button, *(c) Learned Intelligent Movement*, (d) Text-based, and (e) None of the Above." Items were scored and the overall percentage correct for each participant, per activity, was calculated and reported through descriptive statistics.

Short-answer questions assessed family members' affective perceptions of the activity (" How did you feel about participating in today's STEM activity with your family at home?"), what participants learned ("What did you learn from completing today's STEM activity with your family at home?"), what was different than expected, and how STEM conceptual understanding was altered following the activity (" Did anything about the activity surprise you?" "Were there STEM concepts that you didn't know that you now have a better understanding of?"). Responses from each family member were then categorized into Epstein's five categories of at-home parental involvement activities.

RESULTS

RQ1: Characteristics of Families Participating in SCCHE and Degrees of Participation

Out of the 44 families who received materials for activity one, thirty-one families participated and returned data; 30 parents and 54 children participated in at least one *Home Edition* activity. Participants (parents & children) were mostly female (69%); only 30.8% of parent participants were male. Additionally, Caucasian participants comprised 46%, followed by African American (35%). Approximately 23% of parent participants held a high school diploma or less, with the majority of participants having either some technical or 4-year college experience (30.8%), a college degree (30.8%), or graduate degree (15.4%). The average age for participating students was approximately 12 years old and in either 6th or 7th grade. Return rates for data for SCCHE:

- *Activity 1 (Circuit Scribe):* 44 families received materials & 72.5% returned data;
- *Activity 2 (Meccano Switch Robot):* 29 families received materials & 79.3% returned data;
- *Activity 3 (Germ Glo & Achoo book):* 23 families received materials & 73.9% returned data; and
- *Activity 4 (Larry's Lab-A Steve Spangler Lab on super absorbent polymers):* 17 families received materials & 64.7% returned data.

The average return rate for data from participating families was 72.6% following each of the four activities.

RQ2: STEM Content Knowledge Demonstrated by Participants following SCCHE Activities

Parents generally perceived they had less understanding of STEM content than did their children, pre-activity. However, as shown in Table 1, parents consistently answered more than 50% of content questions correctly on the post-activity survey (≈ 47-91% of the time). Children (C) and Parents (P) were least successful in the area of electricity and circuitry (C:17.6%; P: 47.6%), and most successful with robots (C: 82.2%; P: 90.5%) and germs (C: 80.8%; P: 91.6%).

Table 1: ***SCCHE Activities, Participation Numbers, Participant Knowledge Perceptions, and Content Question Accuracy***

Activity	Parent (P)/ Child (C)	*n*	Perceptions of Content Knowledge Pre-Activity *(1 = Almost Nothing - 5 = Almost Everything)*	Percentage of Participants Receiving > 50% Correct Responses Post-Activity
1. Circuit Scribe (electrical circuitry)	P	21	2.1	47.6%
	C	34	3.0	17.6%
2. Meccano Robot (mechanical/ computer engineering)	P	21	1.4	90.5%
	C	28	2.3	82.2%
3. Germ Glo (microbiology and pathology)	P	12	3.8	91.6%
	C	26	3.0	80.8%
4. Steve Spangler's:	P	9	2.1	88.8%

Larry's Lab (absorbent polymers)	C	17	2.7	82.4%

RQ3: Family Member's Perceptions of the Home Edition Experience through Epstein's 5 Categories of Parental Involvement

Parents and children frequently described developing (or re-learning) skills and content knowledge in their written responses, as shown in Table 2. However, participants (both parents and their children) most often noted their enjoyment of time spent with their family members *while* they were learning more about STEM areas.

Table 2. Exemplars of Epstein's (1986) five categories of parental at-home activities (with pseudonyms).

Parental Involvement	Description	Participant Quote(s)
1. Reading books	Parents and children read about germs and discussed the text together as part of Activity #3.	"Reading with critical questions was helpful, and the experiment was really effective to make the point." *-Mr. Smith, Caucasian Father*
2. Discussions between parent and child	Families were encouraged to discuss all content provided and to help one another throughout the activities. (*Note:* Analyses of family conversations not analyzed in this manuscript but is forthcoming.)	"We have definitely had the opportunity to explore & discuss different school/career options for [my son]. I feel better prepared in helping him discover the major he should pursue in college." *- Ms. Floyd, Caucasian Mother*
3. Participation in informal activities	Activities were chosen and designed to be enjoyed, while at the same time, learning STEM content and introducing STEM educational pathways and career options.	"I loved it. Me and my son had fun. I learned that the STEM club is not just a waste of time, and I am glad he is in the club. I felt overjoyed in the fact that my son has found an optional career path." *- Mr. McLean, African American Father*
4. Implementation of contracts between parents, children, and teacher	Parents entered into a voluntary "contract" to participate in *Home Edition* (a partnership with their child, school, families and university partners) with their child via the SCCHE recruitment materials.	"I am a stay at home mom that volunteers a lot in the schools. I feel having had my mind opened to more possibilities I can share, challenge and pass possibilities along to children. Thank you!" *- Ms. Brown, Caucasian Mother*
5. Tutoring and teaching the child skills and drills	Each of the four activities were designed such that both parents and children learned content and skills simultaneously in a collaborative manner with two-way assistance between parent and child.	"I feel that I learned about things I've never heard of. I learned the names of the four main germs." *-Ms. Galindez, Hispanic/Latina Daughter* "I learned that there are different types of bacterias." *-Mrs. Galindez, Mother*

DISCUSSION AND CONCLUSION

In this study, participants of the SCCHE, both parents and children, were more likely to be female and Caucasian than were represented in the larger STEM Career Club project. We wonder if the research aspect of the study was off-putting and would like to try this again without it requiring informed consent in order to benefit.

It was heartening that parents who had less than a college degree (approximately half) were willing to participate. A surprisingly large percentage of participants (over 70%) returned data following the activities with their children. This suggests that the activities and the study were meaningful to these families, and that the mode of delivery (via child and packaged in a vibrant bag or bucket) was well received. However, persistence faded as the activities progressed, despite the families reporting enjoyment of shared family interactions, learning about STEM content, and gaining insight into educational pathways and career opportunities. Some families noted challenges (e.g., time constraints, complexity of activities, lack of confidence) that may have impacted their level of success and persistence.

The majority of the homes in this study were "working-class" homes, whose students received free lunch (97% of the students in these schools), either because individual families qualify or because all students in the school receive free lunch due to the high percentage of poverty in the entire school. Yet, clearly participating parents felt responsible for helping educate and guide their children into the appropriate post-educational pathway and career. This is in contrast to findings by Lareau (1987) and Stanton-Salazar (2011) that "working-class" parents often have a separated view of home and school, in which where schools are solely responsible for educational decisions, not parents, and in contrast to the findings of more 'interconnected' upper-middle class parents (Lareau, 1987, 2000, 2011; Lareau & Horvat, 1999). Therefore, the findings of this study challenge those reported in the literature.

Recommendations

Given our findings, we have several recommendations. First, we recommend that home activities be scaffolded so that activities at the beginning of the year are generally easier/less time intensive and later activities perhaps become a bit more complex/time consuming to increase persistence. Second, we suggest that the learning experiences should take families no more than one hour to complete or should be easily broken down into parts that can be completed over several sessions. Third, we encourage that more invitations are sent to families for participation in-home STEM activities, which was requested by many families in the year following this study. We have strong data indicating the enjoyment of families on school-related projects and want this to increase the home-school connections at all grade levels, particularly for families in low SES areas. Fourth, we encourage more research into the at-home interactions of family members as they work together on academically oriented STEM activities. There is little in the literature documenting these interactions, and it could give us great insight into how to better involve families of students in high poverty settings.

Conclusions

The SCCHE project provided opportunities and resources for families to explore and discuss career pathways, which has been described as especially important for families with low SES, parents without post-secondary education, and minorities (Hill, 2015). The SCCHE intervention provided all the materials needed for all four *Home Edition* activities, thus allowing families to complete the entire experience within their home setting, avoiding transportation and materials concerns that have been described in the literature (Dearing, Sibley, & Nguyen, 2015). We hope that this study provides meaningful ways to enhance home-school partnerships, evidence-based applications, and encouragement for future extra school learning projects to help lead families to STEM.

ACKNOWLEDGEMENT

The authors would like to thank the STEM Career Club teachers, and students and their families, for their participation. We would also like to thank the *STEM Career Club: Home Edition* university team members at NC State University from the College of Sciences and the College of Education. Research reported in this publication was funded by an NSF-ITEST (supplemental) grant under award number 1433747.

THE SKEPTICS - EXPERIENCES OF BILDUNG IN UNIVERSITY LEVEL PHYSICS

Ronny Kjelsberg [1]

[1] Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway

This study seeks to answer the research question "What is the lived experience of Bildung in university level physics education?" by a phenomenological study based on interview data of six Norwegian master level physics students. The results show that the students experience becoming more skeptical and critical in different ways, and while not solely ascribing this to studying in general, or studying physics in particular, they also ascribe their change to their experiences as physics students. The different forms of skepticism are evaluated and compared with forms of skepticism known from literature (e.g. known divisions within the "skeptic's movement") with diverse results. The students process of Bildung is also evaluated, within a theoretical tradition from Humboldt and Klafki, and the results suggest that Bildung is a social process.

Keywords: Cognitive Development, Culture and Education, Values in Science Education

INTRODUCTION

The purpose of university education is not only to qualify young people for work life, but also to see "oneself as a member of a larger community" and in such a societal view to use ones powers for the larger good" (Committee on Yale College Education, 2003), this can be referred to as Bildung. The present study explores Bildung in university level physics by trying to identify effects a physics education has on students outside the area of physics itself, and the processes where this happens, by answering the research question "What is the lived experience of Bildung in university level physics education?"

Science and technology are commonly seen as less relevant to questions of Bildung than other fields of research (Schwanitz, 1999, p. 482; J. Sjöström, Frerichs, Zuin, & Eilks, 2017, p. 166). The validity of such claims are however heavily disputed, and to try to evaluate them, we both have to define Bildung a bit more closely, and evaluate science and science education in view of this definition.

BILDUNG AND SCIENCE

Attempts to define Bildung in any specific sense have been considered futile by many. Max Horkheimer famously declared, "Don't expect me to define it [Bildung]. There are areas in which clear and simple definitions are more than to the purpose, and the role of definitions in knowledge should not be underestimated in any way" (Siljander & Sutinen, 2012, p. 2), arguing that clear boundaries of concepts are not always necessary. Attempts to define have however been made. Liedman describes "The backbone of the concept of Bildung" as "the notion that knowledge, or at least some knowledge, fundamentally changes and develops a human being" (Liedman, 2001, p. 351), translation by Sjöström et.al. (J. Sjöström, et al., 2017). Klafki presents his concept of *categorical* Bildung, in which the individual and the world simultaneously open themselves up for one another (Klafki, 1973). In a university context, Wilhelm van Humboldt is important historically, and to this study also how he (and Klafki) describes Bildung also as a collective process (Klafki, 1991, p. 27).

A useful operative definition of Bildung is as a process making an educated person able to operate within the "the everyday world" and the "everyday language", as opposed to the separation of science into its own world and language (Hellesnes, 1992, p. 84). In a broad sense, Bildung thus connects science to society. This is also similar to the idea of Bildung as a process enabling you to become a *citizen* – an active participant in society, and not simply a vocational practitioner of a craft. This idea is found in both the tradition of classical Bildung and the Anglo-American tradition of liberal education (Adler, 1952, p. 57; Hancock, 1987; Paxson, 1985). This also explains why some see science as relatively less relevant to Bildung, as many other fields, like the humanities and the social sciences, directly research aspects of society.

Bildung and the nature of science

With a view of Bildung as coupling science to society, science education research identifies several relevant aspects of science. We might separate Bildung aspects of science into two parts; elements that can be useful also in society as a whole, like cognitive skills and values of science (Dagher & Erduran, 2014, p. 48) or scientific literacy (Jesper Sjöström & Eilks, 2018, p. 66), and aspects of science that themselves show sciences interconnectedness with society, like elements of the Family Resemblance Approach to Nature of Science, such as Social certifications and dissemination, Scientific ethos, Social Values and Professional activities (Dagher & Erduran, 2014, p. 28).

Norwegian scientists like physicist Svein Sjøberg and biologist Dag O. Hessen, give some examples of the contributions they believe science and technology have to Bildung, like how the natural sciences, not only their products, but also their methods, ideals and values are an important part of our cultural inheritance. Sjøberg explicitly also mentions the belief in rationality and reason, and in critical discussion in connection with these aspects of science (Sjøberg, 2009, p. 200). Hessen points out how "realization and cognizance in a broad sense, about the human being itself, and our place in it all", makes knowledge about the natural world central to both culture and Bildung (Hessen, 2011, p. 458).

This study will attempt to examine students experiences of Bildung in university level physics education qualitatively through interviews with Norwegian master level physics students, and thus answer the research question "What is the lived experience of Bildung in university level physics education?". This question is important to understand the mindset and motivations of physics students and the effect an education in physics can have on the same, and to disclose some of the hidden curriculum in physics.

mETHODology

This study is based on six individual semi-structured interviews with master level physics students (See interview guide in Figure 1) on Bildung-aspects of their physics education, using a phenomenological method. A natural starting point in the process of sorting, has been to be on the lookout for recurring content, and sorting this content thematically (Rennstam & Wästerfors, 2015, p. 69).

1. Open question about physics and the education the student has taken.

2. Of all those who start physics in the first year, some do not go on to a master's thesis. What is your impression of those of your fellow students who quit? When did they quit and why do you think they quit?

3. Transformative experiences - is there anything about physics education that has been a bit "wow" - that has changed you or the way you see things?

4. What about your world view? Is there anything about your education that has influenced how you look at the world beyond physics itself? Are there any areas you have changed views on?

4 B. Elaborative/follow-up questions in specific areas - politics – view of science - ontological/epistemological questions, the view of other disciplines (hard/soft science) etc., depending on the response on previous questions.

5. Is there anything you think physics education should have had more or less of in light of what you have said until now? Does it have the right focus? Had it been more inspiring and exciting if something had been done differently? If so, what? Is there anything you think of as "physics" you wish you had learned more about?

6. Is there anything you wish to say that I have not asked about in this conversation?

Figure 1: Questions from the interview guide.

From a phenomenological perspective this process should be oriented towards larger meaning-units. The researcher should attempt to look at the material as freely as possible from forgiven prepositions and expectations (Rennstam & Wästerfors, 2015, p. 75), or as Giorgi puts it, in a "more naïve, pretheoretical way" (Giorgi, 2009, p. 135). In line with this the present study was undertaken by systematically going through interview transcripts, indentifying such meaning-units, critically re-reading them, and evaluating recurring themes.

After such recurring-meaning units were disclosed, illustrative quotes were identified, and evaluated through meaning condensation (2009, p. 146).

rESULTS and discussion

The most common theme (larger meaning-unit) from the interviews was that all the students described how they during their education had become more skeptical and critical in different ways. Illustrative quotes, meaning condensation and further examples of recurrences can be seen in Table 1.

Is skepticism relevant to Bildung?

Skepticism can be connected to Bildung e.g. through the connection Sjøberg makes with critical discussion and reason (Sjøberg, 2009, p. 200). It also falls within the form of cognitive skills we previously considered relevant to Bildung. It does not in itself necessarily imply interconnectedness with society, but it can be useful in society, and as we can see from the diverse topics the students volunteer in Table 1, they have employed these skills to society. It thus makes sense to see this experience as relevant to Bildung as we have defined it.

Forms of skepticism

To an extent, the forms of skepticism can also be seen in connection with the "international skeptic's movement". Its original goal was to attack forms of pseudoscience like alternative medicine, paranormality and conspiracy theories, such topics were e.g. the focus of Carl Sagans influential "Demon-Haunted World" (Sagan, 1997), termed "classical skepticism" in Table 1. The focus has however shifted over the years. Given the students own descriptions of their development and the examples they give, it gives sense to label their experiences into this framework. This is summed up in Column 4 of Table 1. Two students explicitly mention the popular skeptically oriented Norwegian TV-program "Folkeopplysningen" (Popular Enlightenment) hosted by physicist Andreas Wahl, and many of the subjects of their skepticism correspond with topics the program has raised.

Table 1: Analysis of forms of skepticism from students S1-S6. Column 1: Student, Column 2: quote from interview, Column 3: Meaning condensation from quote. Column 4: Subjects of skepticism gathered from entire interview, Column 5: Short interpretation of "form of skepticism".

Student	Quote	Condensation	(Additional) mentioned subjects for "skepticism"	Interpretation
S1	No, it's much about this – I have learned to think independently. If I am to give an example, I use to get very pissed at alternative treatment and stuff like that. How it is done, how it is being worked with in politics. I think it should be illegal.	S1 states that he has learned to think independently and thinks e.g. alternative treatment should be prohibited.	- alternative treatment - organic food - humanities (money spent on)	Combines elements from "classical skepticism" with skepticism towards not humanities per se, but their priority in society relative to natural sciences.
S2	I perhaps feel that I have become a bit more skeptical. That I in a sense no longer accept something as true, just because. No, I think I want to get more to the bottom of things, and I believe I have become more concerned with being precise.	S2 states that she has become more skeptical. Deeper understanding and precision has become more important.	- tabloid news media - dietary advice - pedagogy and psychology (as science) - homeopathy	Combines elements from "classical skepticism" with skepticism towards the scientific rigor of pedagogy and psychology.
S3	… to be quite critical towards yourself and all the time think «if somebody was to read this, what will they think I did not think of? What could it be here, that is not what I want it to be?».	S3 states that she has become more self-critical, thinks of what a critical outside reader would think.	- climate denial - own preexisting views on abortion - pedagogy and social science (as science) - general lack of skepticism in society	General disapproval of lack of skepticism in society combined with skepticism towards e.g. climate denial.

S4	I look much more at the world, look at things and am more reflected on … everything, I hope. […] A lot of stuff could be solved if only people knew a little more about this one little thing. That enlightenment of masses is very important. And a lot boils down to – as a physicist you get very provoked by these people who believe the world is flat. Seriously – people managed to calculate this 3000 years ago, now we are done with this discussion. Stuff like this naturally provokes extra much.	S4 states that she looks upon the world in a more reflected way, believes in popular enlightenment and is provoked by e.g. flat earthers.	- flat earthers - climate denial - resistance against nuclear technology - gender biases - religion	Combines elements from "classical skepticism" with skepticism towards gender biases.
S5	What I feel with physics is that I have become very realistic, on stuff, so perhaps less feelings in politics, more objective approach to stuff. Sometimes to the extreme that one feels one gets sort of emotionless, that you just see things very black/white, as they perhaps are, but you lose some of the human romantic interpretation of stuff. Like this with organic food and such, genetic manipulation and stuff.	S5 states that he has become more objective and less emotional. Critical towards organic foods, etc.	- organic foods - resistance against genetic technology - emotions in politics	All elements fit into "classical skepticism".
S6	In general that people express themselves with a cocksureness they in no way have a reason to. You understand when you study physics, how very, very difficult it is to figure out even something simple. You have to simplify the situation extremely and then you have to be extremely careful to get real knowledge, and even then you can be wrong. So such cocksureness on subjects is often not in place. […] A usual example now is nuclear power, perhaps that one does not look at rational scientific things there. That public opinion sort of is just based on emotions.	S6 states that he has become more skeptical towards cocksureness and feels discussions about e.g. nuclear power are too emotionally driven.	- resistance against nuclear technology - CERN (money spent on) - lack of scientific rigor in evolutionary psychology, pedagogy and humanities and social sciences in general.	Combines elements of classical skepticism with skepticism towards priorities of expensive parts of physics itself, and the scientific rigor of humanities and social sciences.

Two central divides in the "skeptics movement" has been the view on religion (should it be an area of skepticism or not?) and the view of the humanities and social sciences (are they scientifically sound?). The most common view of religion among the students seems to be one not of personal religiosity but neither one of anti-religion. This is a view more similar to Stephen Jay Gould's "non-overlapping magisteria"(Gould, 2011, p. 269), than Richard Dawkins' "Root of all Evil" (Dawkins, 2006). However, if there was to be a conflict between faith and science, physics comes first. Similarly, some students are skeptical to some aspects of social sciences and the humanities. We can perhaps still see remains of the American "science wars, and the "Sokal affair" from the 1990's (Sokal & Bricmont, 1998), and the students are reluctant against viewing these fields as "science", but on the other hand they also see their importance. See Figure 2 for an illustration of a typical student positioning within this 2D-space of skepticism.

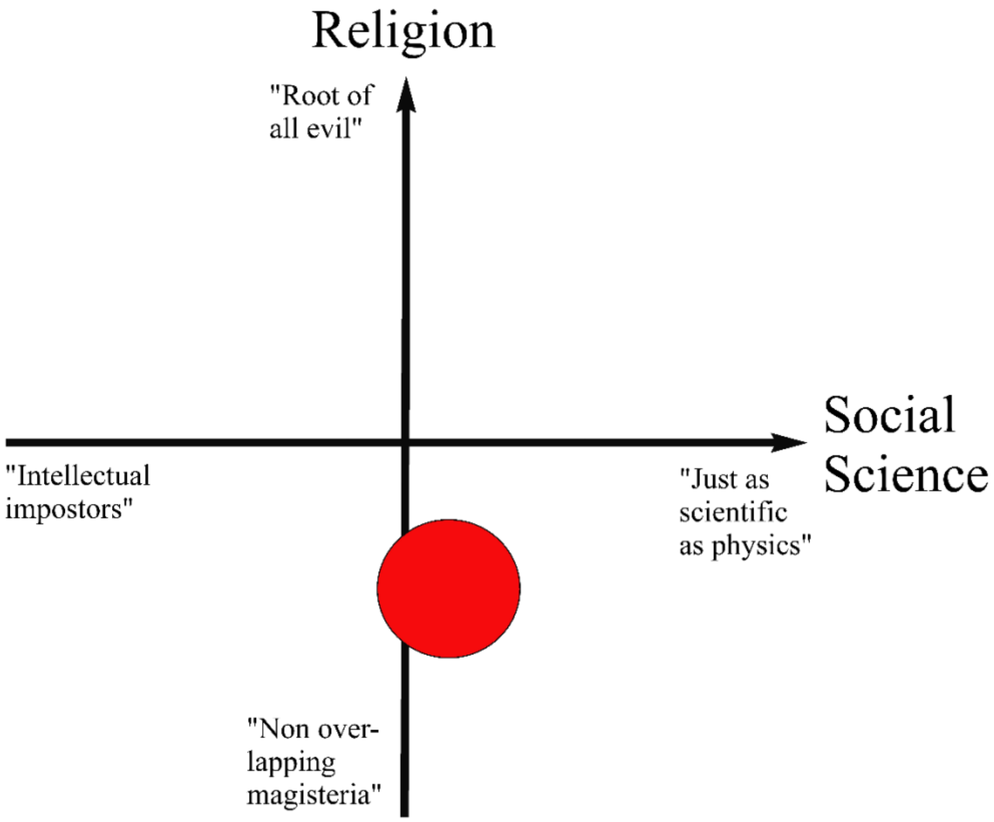

Figure 2: Illustration (not graph based on data) of how a typical student can be placed in a 2D space of "skepticism" where views of social sciences is along the x-axis, spanning from "intellectual impostors" (Alan Sokal's famous diagnosis of some postmodernists), to equating them scientifically with physics. On the y-axis are views on religion, spanning from "Root of all evil" (Richard Dawkins) to "Non overlapping magisteria" (Stephen Jay Gould).

The process of Bildung

The students in general had nuanced views on the reasons of their skepticism. As student S3 puts it:

> I have always liked to be critical, towards myself as well. But I also believe that I've become more like this as a result of studying physics, and also because I've gotten to know other people who are also critical. So I think that has helped quite a lot. The conversations you are having with others, not just about physics, but about politics, for example.

This fits with the idea of university Bildung as a collective endeavor that both Humboldt and Klafki presents. We can glimpse a process of Bildung that happens while physics students are socializing each other into a role as physicists, with a corresponding skeptical attitude.

In physics, you often operate with scales of both time and distance that might seem absurd and unfathomable to most non-physicists. To some students this perspective gave them a motivation to go out and change a world riddled with petty disagreements. To other students however, these vast scales made them numb and indifferent – as student S5 expresses it:

> And in a way, it's a bit so sad that you feel you have no impact on the world. Whatever you do, everything just goes on by itself, and then you die, and the earth continues to rotate.

These latter students do not seem to see themselves as (potential) active agents in the world. Do these reactions signal a missed opportunity for Bildung? The question arises in particular, as these students had expressed not being a part of a scientifically oriented student community.

CONCLUSION

The results show that physics students today do have an experience of going through a process of Bildung during their time at university. The most common experience is one of increased skepticism.

This study also supports the notion of Bildung as a social process, and further study should be undertaken to examine whether lack of student access to an academically oriented student community hinders Bildung.

Acknowledgement

I would like to thank Magnus Strøm Kahrs, Berit Bungum and Einar Sundsdal for important input into the direction of this project.

HANDS-ON SCIENCE TO PROMOTE LANGUAGE LEARNING IN BILINGUAL CONTEXTS

Marta Marialva[1,2], Bahtiyar Yilmaz[2] and Maria de Lurdes Gonçalves[3,4]

The Luso-descendant community in Switzerland represents the third largest emigrant group counting with 39,906 students that attend the regular Swiss education. A closer look at the Swiss education system notes a stigmatizing trait in its relationship with the Portuguese community and we estimate that 2,733 secondary school pupils are victims of a discriminatory system that underrates them. This has important implications in terms of integration into the society and work-related settings. As a consequence, Swiss authorities strongly support initiatives aiming to promote teaching of heritage languages and that together with the regular education system should promote the motivation of students with Portuguese origin to pursue studies while developing their bilingual identity. In this project, we used inquiry-based learning methodologies and experimentation as tool to promote science and language integrated learning. Here, we transformed classrooms into non-formal learning environments and learners into active players in their learning process while diving into the scientific method. Primary and secondary school learners were encouraged to ask questions, formulate hypothesis, design experiments, test ideas, observe results and draw conclusions using their heritage language as an instrument for questioning, communicating and thinking. The success of our hands-on science sessions was evaluated through questionnaires that 106 participants answered before and after the class. The results obtained point to positive implications in terms of acquisition of knowledge, understanding about the scientific process, destruction of prejudices in relation to science, and the broadening of students' expectations for the future. Additionally, surveys addressed to the Portuguese Heritage Language (PHL) teachers so as to classify our sessions as "good" or "very good" with regard to the introduction of new vocabulary, students' ability to expose ideas, and increase in the motivation and enthusiasm to learn the heritage language. In summary, this study shows the benefits of introducing the scientific method through the use of experimentation, and that of practices centred on "learning by doing", in multidisciplinary educational contexts such as in PHL learning. However, a more comprehensive study is necessary to justify the application in a larger scale of such alternative methodologies that, together with the formal education system, should broaden students' future perspectives and increase their understanding and appreciation of the heritage language.

Keywords: Multilingualism, Interdisciplinarity, Inquiry-oriented learning

PROBLEMATIC

The recent acute rise in social media manipulation and fake news phenomena is a global problem that urges for multidisciplinary interventions (Lazer et al. 2018). Empowering individuals with the right amount of skills that allows them to critically evaluate information poses a potential solid way to address the issue. Although the efforts to introduce such strategies in a regular school system have been made (Jones, 2017), the importance of scientific literacy as a route to redesign how the public deals with information is still underappreciated. In addition to this problem, we live today in an age of uncertainty (Bauman, 2007) where students are prepared for a future that may possibly no longer exist. In order to solve an ecosystem of challenges never encountered before, we need to encourage problem-solving attitudes and equip the young generation with deeper and better understanding of scientific method that provides the guiding rules used to answer questions. These contemporary issues place science education at the centre while serving as a safeguard that strives to face global and local problems.

In an era rich of multicultural learning environments, a practice-oriented science classroom can also hold as productive language- and science-learning settings that promote social equity (Cuevas, Lee, Hart, & Deaktor, 2004; Lee, 2005; Lee & Fradd, 1998; Lee, Quinn & Valdés, 2013; Poza, 2016). The application of such methodologies should be global in scope but are particularly urgent in countries with higher prevalence of immigrant communities.

According to the United Nations Department of Economic and Social Affairs (2015), Switzerland is among the ten European countries with most migrant load when compared with total international migrant stock. Amid the almost 200 different nationalities residing in this country, the Luso-descendant community represents the third largest emigrant group counting with 39,906 students that attend the regular Swiss education (Federal Statistical Office, 2018). Here, and regardless of governmental efforts to support initiatives promoting the motivation of students with Portuguese origin, the percentage of Luso-descendant pupils enrolled in advanced secondary school classes with increased chances of pursuing higher education is still 27% lower when compared to that of Swiss students.

The use of innovative practices at the core of PHL teaching, such as the introduction of hands-on science activities in a pedagogical context, can be determinant to change representations and to increase students' self-esteem through the appreciation of their heritage language and culture (especially in multicultural and multilinguistic environments). However, in order to justify the application of such strategies at a large scale, it is important to carry out a research that allows to diagnose changes in several dimensions of students' attitudes. The study presented here arises from this need and seeks to verify the advantages of using science and experimentation in an educational bilingual context.

METHODS

Target group

This study was conducted in four different Swiss cantons and in close collaboration with five PHL teachers. 106 students, 45% boys and 55% girls at the age of 7-16 years old, were involved in the intervention and answered questionnaires.

Questionnaire

In order to estimate how the introduction of hands-on science activities in the classroom influenced students' attitude and ability to respond, all 106 participants in this study answered the questionnaire (before and after class). The inquiry consisted of 23 questions to evaluate the following parameters: 1) declarative knowledge, 2) knowledge about the scientific process, 3) deconstruction of representations or preconceived ideas about what it is to be a scientist, and 4) motivation and students' perspectives for future. To each answer was assigned a score: [-1] for wrong or negative responses in terms of future perspectives, [0] for blank or "do not know" answers, and [1] for correct responses or positive perspectives for the future. Questions in which participants chose more than one option were not considered in the analysis.

To evaluate our sessions regarding the introduction of new vocabulary, students' ability to expose ideas, and increase in their motivation and enthusiasm to learn the language of inheritance, PHL teachers answered a survey containing 15 questions. They were asked to evaluate classes in a scale ranging from 1 ("very bad") to 5 ("very good").

Statistical analysis

To determine the effect of our didactic methodology on the various criteria mentioned above, we used Mann-Whitney test. For each question, the difference in students' scores before and after the experimentation class was assessed. Additionally, for two statements assessing pupil's motivation and perspectives for future ("I love science" and "I would like to be a scientist") we analyzed the difference in scores between Primary School and Middle School pupils. All statistical analyses were performed in R program (R-Core-Team, 2018). The p-value lower than 0.05 was considered significant.

Hierarchical clustering

The heatmap generated using Euclidean clustering of student response scores (vertical) before and after intervention was performed using categorical information such as location, time, school year and gender (horizontal). Location corresponds to participant's residence (Sursee, Brugg, Wohlen, Dubendorf, Sarnen, Luzern or Aarau), and time to the period between before and after questionnaires (0, 7, 14 or 21 days).

RESULTS

Positive implications in student's attitudes for all criteria tested

This research shows that a methodology based on inquiry-oriented learning and hands-on experimentation has positive implications in transforming students' attitudes regarding all criteria tested. In particular, we verified that the use of practices focused on learning-by-doing (Dewey, 1916) can be determinant to learn and understand new concepts, to acquire knowledge about the scientific process, to deconstruct preconceived ideas and to raise students' motivation and perspectives for future (Figure 1). In a more detailed analysis, we observed an effective change and improvement in learners' responsiveness in 83.3% of the questions assessing acquisition of declarative knowledge, in 42.9% of the questions assessing their understanding about the scientific process, in 60% of questions on determining misconceptions about science and in 60% of questions on evaluating their motivations and prospects for future careers. In addition, all PHL teachers involved in the project evaluated our experimental sessions as "very good" regarding the introduction of new vocabulary (average score=4.8), students' oral communication (average score=4.7) and increase in the motivation to learn their heritage language (average score=4.7).

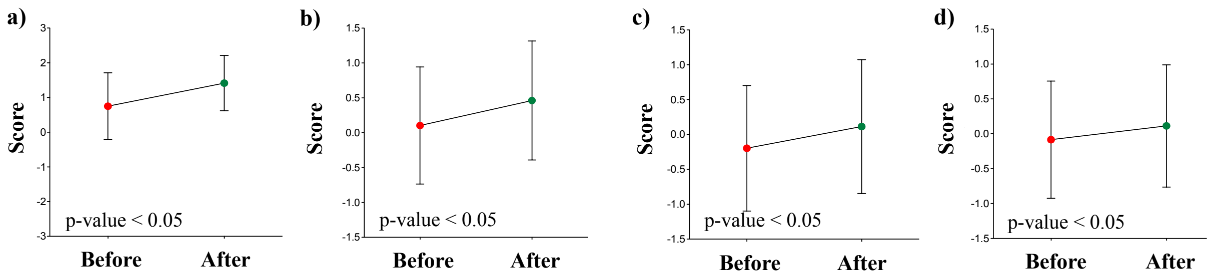

Figure 1. Assessment of hands-on science methodologies success. We evaluated efficacy of using inquiry-based learning techniques and experimentation to improve student's acquisition of knowledge (**a**), understanding of the scientific method (**b**), reduction of pre-concepts related to science (**c**), and expansion of their perspectives for future (**d**). Students (n=106) answered same questionnaire before and after each session. We observed significantly positive effects ($p<0.05$) in 5 out of 6 questions assessing acquisition of knowledge (83.3%), 3 out of 7 questions evaluating their understanding of the scientific method (42.9%), 3 out of 5 questions testing pre-concepts and student's perspectives for future (60%). Each graph represents statistically significant effects observed for one question per evaluated aspect. We used Mann-Whitney test to evaluate the effect of hands-on experiments activities. Each circle in plots represents mean and bars show 95% confidence interval.

Younger students are more interested in science

A deeper analysis to students' attitude towards the statement "I love science" and "I would like to be a scientist" shows that Primary School pupils are more interested in science-related topics and more motivated to pursue a scientific career when compared with Middle Schools pupils (Figure 2). Conversely, none of the further clustering categories (location, time and gender) showed to have statistically significant influence on responses of pupils (Figure 2a and b).

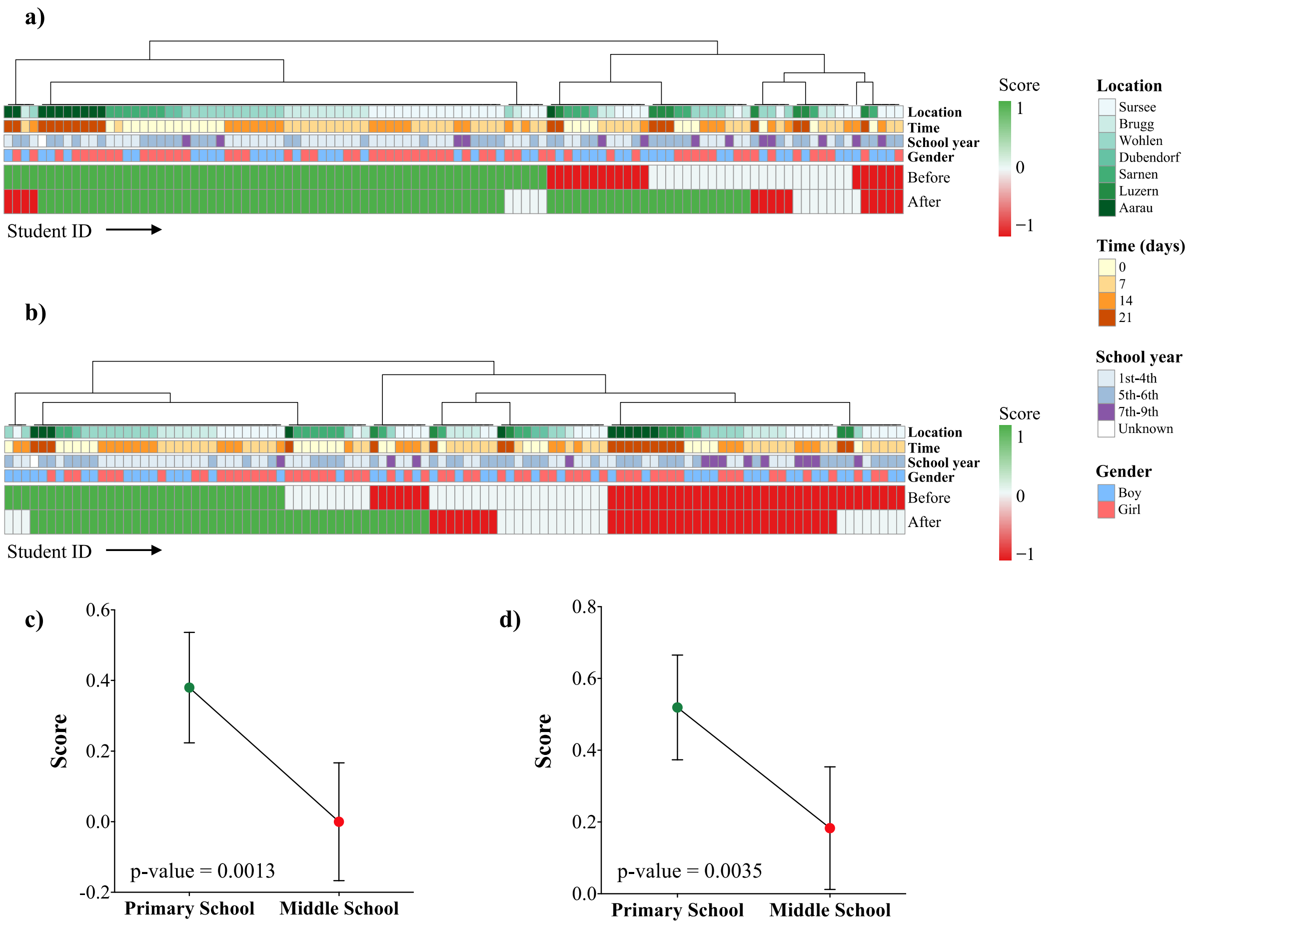

Figure 2. Factors influencing learners' attitude towards "I love science" and "I would like to be scientist". Euclidean clustering of participant position concerning the sentence "I love science" (**a**) and "I would like to be a scientist" (**b**), before and after hands-on science session. Answers were clustered taking into consideration four categorical factors (location, time, school year and gender). Assessment of score differences between Primary and Middle School pupils before (**c**) and after (**d**) intervention by using Mann-Whitney test. Each circle in plots represents mean and bars show 95% confidence interval.

DISCUSSION

In this section we discuss to what extent the use of experimentation in the classroom can be used as a transforming force of the learning process and of the relationship that learners establish with science and with their heritage language. First, it should be noted that although the Luso-descendant community of each Swiss canton has its own social characteristics and establishes different relationships with their heritage language, data obtained in this study point towards positive implications of student-centered practices and learning-by-doing methodologies in all the criteria analyzed here regardless of participants' area of residence. Second, the analysis of learners' behavior in relation to statements such as "I like science" and "I would like to be a scientist" allow us to conclude that our intervention seems to move towards a consolidation of increased interest in science. On the other hand, we also observe an improvement in participants' self-confidence by their changing attitude to statements like "If I want, I can someday become a scientist". However, regardless of our efforts, as learners move from Primary to Middle School, their excitement about science and their ambition to pursue a scientific career are greatly reduced. The idea that learners' attitudes towards science typically decline with age is not new (Murphy and Beggs, 2003; Pell and Jarvis, 2001) and calls for a redesign of the current school ecosystem that should safeguard pupils' curiosity and creativity.

In summary, we conclude that the results are consistent and place the use of science at the forefront of encouraging critical thinking and increasing self-esteem among participants. Hence, we propose the application of alternative methodologies along with the formal education system, that aims at broadening learners' perspectives for the future and increase the understanding and appreciation of their heritage language. Although this research supports the introduction of the scientific method through the use of experimentation, and practices focused on learning-by-doing in multidisciplinary educational contexts (e.g. when science education is combined with PHL learning), there is still a great need for an extended evaluation of different educational interventions in order to proceed with large scale applications.

Final considerations

The recommendations of Delors et al. (1997) in their report to the United Nations for Education, Science and Culture are the driving force for the project presented here. We believe that our teaching strategies are determinant in the empowerment of learners, where science and the scientific process emerge as a foundation in establishing critical spirit, and in transmitting the necessary knowledge and tools for the rebirth of individuals as solvers and creators of their own future. However, in order to apply this teaching methodology integrated with language learning, we propose not only the continuation of the project presented here – where scientists enter the classroom as motivators – but also the development of workshops that aim to empower teachers so that they are able to independently introduce our approach in their classroom. Only in this way, education can take on a multidimensional nature and can provide learners the necessary skills to become active participants in the society and creators of a renewed, more human and healthier world for all (Delors et al., 1997).

AUTHOR CONTRIBUTIONS

M.M. conceived and designed the study; organized and collected the data; wrote the manuscript. B.Y. performed all statistical analysis. M.L.G. supervised the study. All authors read and agreed with the final version of the manuscript.

ACKNOWLEDGEMENT

We thank the PHL teachers that welcomed the project in their classroom: Elisa Aeschimann, Jorge Lopes, Nicole Gomes, Paula Rodrigues and Raquel Rocha. To all the pupils involved in this endeavor, we thank for their enthusiasm and curious spirit. This project was supported by *Coordenação de Ensino de Português na Suíça - Instituto Camões, I.P.*.

A WORD-LEVEL ANALYSIS OF BARKING AT PRINT FOR ENGLISH SECOND LANGUAGE SCIENCE TEXTS

Angela Stott[1], Tanya Beelders[2]
[1]University of the Free State South Campus, Bloemfontein, South Africa
[2]University of the Free State, Bloemfontein, South Africa

The ability to read science texts with comprehension is necessary for development of self-regulation in learning. However, particularly among learners in the developing world, barking at print, i.e. decoding with minimal comprehension, is highly prevalent when reading science texts. Eye-tracking is an effective way of studying reading difficulties such as barking at print. However, in a previous study a whole-text analysis of eye-movement metrics was insufficient to distinguish between the reading behaviour of English second language South African learners who read a science text with comprehension from those who barked at this text, suggesting that a word-level analysis may be necessary to diagnose this difference, and to understand the underlying cognitive engagement differences, from eye-tracking data. In this study we conduct such an analysis using a subset of the same eye-movement data as were used in the previous study. These data were collected from 57 grade 8 and 9 learners, 13 of whom were shown to have been barking at print while reading this text, and 19 of whom appeared to be reading with comprehension. Only the eye fixation durations for the scientific terms were included in this study. These scientific terms were classified, by a panel of experts, according to scientific linguistic cognitive demand. Barkers were found to fixate longer on the scientific terms than the other learners did, but inconsistencies in trends found between the groups and word classification levels suggest that the degree of linguistic cognitive demand of scientific terms is not the primary factor determining the degree of difficulty these learners experience during reading.

Keywords: Eye tracking, comprehension, reading

INTRODUCTION

Poor reading comprehension abilities of South African learners from socioeconomically disadvantaged backgrounds (Spaull & Pretorius, 2019) are certain to contribute to the high dependence such learners display on skilful translanguaging activities of their teachers as they learn science (Probyn, 2015). This dependence limits these learners' opportunities to learn science, particularly beyond the classroom experience, reducing the time learners are likely to spend on science learning and hindering the development of self-regulation in learning, a crucial requirement for meaningful learning of science to occur (Schraw, Crippen, & Hartley, 2006). Gaining an understanding of what such learners do as they engage with science texts is crucial for devising intervention strategies likely to be effective internationally wherever poor science reading comprehension hinders science learning, and particularly in contexts of poverty. Eye-tracking equipment is particularly valuable in aiding the development of such understanding since it exposes otherwise covert behaviour, from which deductions about the cognitive activity of the reader can be made (Alemdag & Cagiltay, 2018). Additionally, intelligent tutoring systems, programmed to make and respond appropriately to these deductions, can customise the learning experience for enhanced effectiveness (e.g. D'Mello, Mills, Bixler, & Bosch, 2017). This can only happen, however, if the relationship between eye movement metrics and particular cognitive activities are understood.

PROBLEM STATEMENT

A reader's reading state is an example of a group of cognitive activities which can be inferred from eye movement metrics. Eye movement metrics have been published for reading states of mindless reading, mind wandering, concentrated reading, scanning and skimming (e.g. Rayner, 1998). This body of literature is, however, largely restricted to studying reading non-scientific texts in the reader's home language. Previous work amongst South African township learners reading science texts in English as a second language (Stott & Beelders, 2019) has alerted us to the high prevalence of another type of reading, namely barking at print (Samuels & Farstrup, 2011), for which we were unable to find literature on eye movement metrics. Barking at print involves engaging in word decoding without developing comprehension beyond the surface level of representation (Cain, 2010).

In an initial investigation to address this gap in the literature (Beelders & Stott, 2018), we found that eye movements during barking at print are distinct from those published for what may be seen as the cognitively similar activities of mindless reading (reading nonsense text) and mind-wandering during reading. We found the distinguishing trait to be the greater variability in eye-fixation times per syllable during barking at print. This is consistent with the view that barking at print, unlike mindless reading and mind-wandering, does involve a degree of comprehension at the surface level of representation. For this to occur cognitive processing must be engaged in at sentence, phrase, or at least word level for at least some of the time. Further, in our initial study (Beelders & Stott, 2018), we found no statistically significant difference between the eye metrics of those learners in the sample who were deduced to have been barking at the science text used and those who were deduced to have been engaging in concentrated reading with comprehension. This led to the need to confirm the supposition that metrics at a word level differ for readers who are barking at print compared to those who are reading with comprehension. Also, there is a need to determine the underlying cognitive processing occurring which can account for the difference in comprehension.

Longer fixations (periods of time that the eye is relatively still) are known to indicate heightened concentration or perhaps a difficulty in understanding the text being read (Rayner & Pollatsek, 1989). Consequently, in this study we examine fixation times more closely at the word level, and we have chosen to do this only for the scientific words in the text used. This is done to better understand the cognitive processes present during the barking process and how these processes can be distinguished from those of concentrated reading with comprehension, with a focus on science text. This is done with the purpose of determining how eye-tracking metrics can validly be used to diagnose engagement in barking at print for science texts. Therefore, this research is guided by the following questions, with reference to reading science texts in a second language: (1) How do fixation durations and counts during reading differ at the word level for scientific words, when barking at print compared to when undergoing concentrated reading with comprehension? (2) What does this analysis suggest about factors affecting cognitive difficulties which result in barking at print?

CONCEPTUAL FRAMEWORK

The Theory of Multimedia Learning (Mayer, 2009) is used to understand cognitive processing. According to this theory, sense-making, which includes higher levels of reading comprehension, can only occur to the extent that the individual has cognitive processing capacity left over to devote to it after deduction of other forms of cognitive processing. These other forms of cognitive processing are extraneous processing, irrelevant to the target learning, and essential processing, which involves selecting relevant information. The extent to which cognitive capacity has to be devoted to essential processing is determined by the difficulty of the medium (including text), as perceived by the learner.

Eye fixation times can be used as indicators of cognitive processing (e.g. Park, Korbach, & Brünken, 2015). It is therefore to be expected that fixation times will be affected by word difficulty and it seems reasonable that barkers may undergo different cognitive processing patterns in response to various levels of word difficulty compared to concentrated readers, in which case it may be possible to diagnose barking based on this. The model of linguistic cognitive demand, created by Rees, Kind, and Newton (2019) for use with chemistry terms, and slightly modified to be applicable to physics terms too, provides a framework for analysing scientific terms according to the amount of cognitive load they are likely to offer to a particular population of people. According to this model, there are four dimensions along which each term should be analysed for linguistic cognitive demand: interpretive, sub-microscopic, similarity and multiple contexts. The interpretive dimension refers to the extent to which the reader is likely to be able to interpret the correct meaning from the sound of the word, with a lower score being assigned the more likely this is. The submicroscopic dimension has to do with whether the concept refers to the more cognitively demanding, abstract, invisible, realm of submicroscopic particles (assigned a higher score) or the more concrete, visible, macroscopic realm. We expanded this dimension from Rees et al.'s (2019) version, to include invisible, abstract concepts other than submicroscopic particles, for example electric fields. This is consistent with Stiller et al.'s (2016) finding that the degree that a word is specialized or abstract affects its readability. The dimensions of similarity and multiple contexts refer to the extents to which the readers are likely to be confused by alternative meanings of similar words or of that word in other contexts.

METHOD

Sample and data collection

The convenience sample used in this study consists of 57 grade 8 and 9 learners from South African schools and low socio-economic backgrounds, who participated in a science intervention hosted by one of the authors and who were willing to participate anonymously in this study. These learners read a science text in English, their second language, on an eye-tracking machine which recorded eye movements and from which standard eye tracking reading metrics were extracted. These learners then answered a comprehension test, on the basis of which they were divided into three reading categories: barkers (n=13), intermediate (n=25) and readers (n=19). Those referred to as readers are considered to have been undergoing concentrated reading with comprehension for most of the observation period and the barkers to have been barking at print for most of this time. We are less certain of the extent to which the intermediate group engaged in each of these types of reading.

Word classification

The scientific terms in the text were classified by an expert group of six science educators and academics who were all familiar with both the learners' contexts and the linguistic dimensions in Rees et al.'s (2019) model. Each member rated each term along each of the four dimensions of this model (each dimension on a scale of 1-10). Thereafter, a composite score was obtained for each term by adding the individual dimensional ratings for each term and for each expert. The terms were then grouped on the basis of this score, into three difficulty categories. Figures 1-3 show the mean ratings along each dimension for each term for these three difficulty categories (least demanding, moderate demand and most demanding).

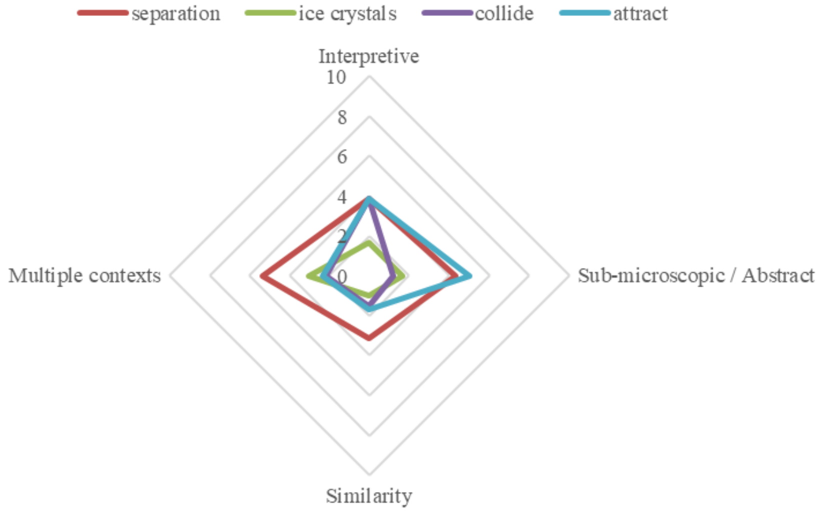

Figure 3: Mean dimensional ratings for the lowest cognitive load terms

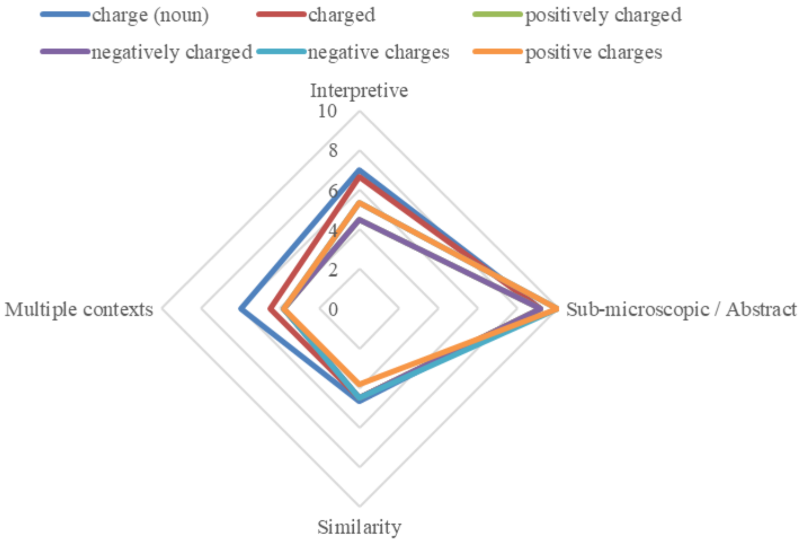

Figure 4: Mean dimensional ratings for the moderate cognitive load terms

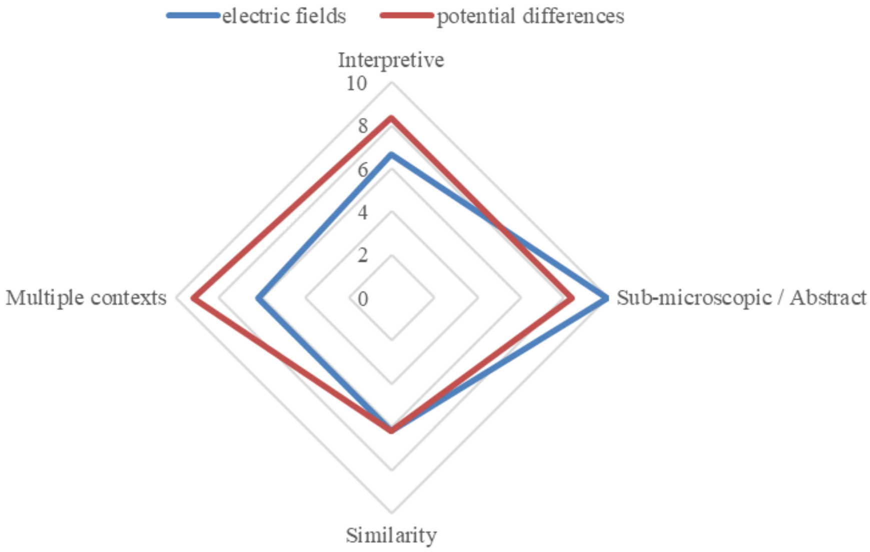

Figure 5: Mean dimensional ratings for the highest cognitive load terms

Data analysis

Qualitative analysis was performed by graphing the averages of the fixation durations and number of fixations for the words of each cognitive demand level for the three comprehension groupings of the learners (barkers, intermediate and readers). First the data for all the words within a cognitive level were grouped together, after which analysis was performed on a per word basis. Since the classification groups are small, statistics were not performed.

FINDINGS

Per cognitive level

Figure 4 shows the mean fixation duration for each comprehension level and for each cognitive demand level. The readers clearly had the shortest fixation durations for all cognitive demand levels and the barkers the highest. Fixation length, therefore, appears to be an indicator of the extent to which these learners experienced difficulty with the words.

All groups except barkers exhibited the longest fixation for the words classified as offering the lowest cognitive demand, suggesting greatest difficulty with these words. An examination of these words (see Figure 1) reveals potential reasons for this anomaly. Learners of this demographic are unlikely to be frequent readers of any type of text. It is therefore to be expected that they should experience difficulty when reading phonetically opaque words such as *crystals*. Although the term *ice crystals* was classified as offering low cognitive demand, and the word *ice* would surely have offered little difficulty to the learners, they may not have realised that they could chunk it with the less familiar word *crystals* to process the term as a unit. Later we examine the data word by word to explore these thoughts further.

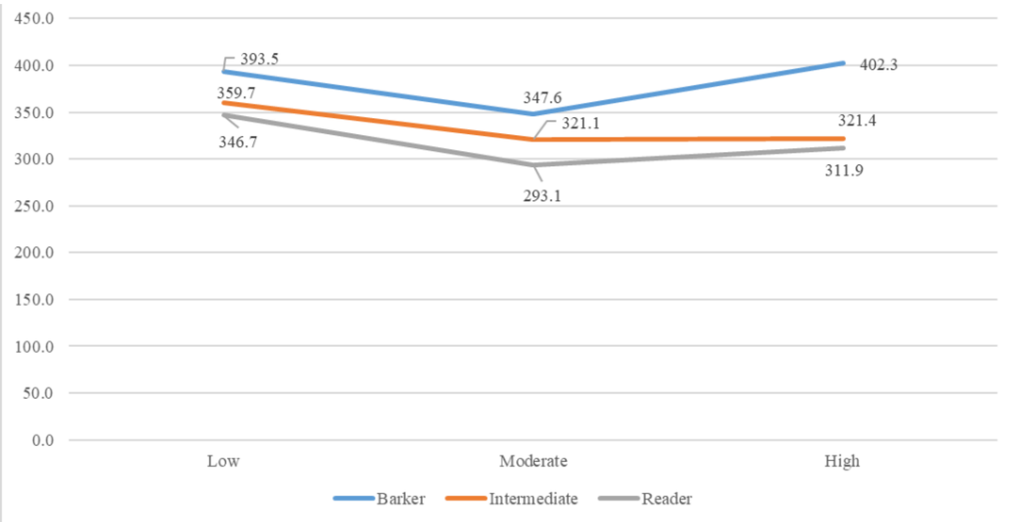

Figure 6: Mean fixation duration per cognitive demand level and per comprehension level

Inspection of the mean number of fixations (Figure 5) per cognitive demand level indicates that the readers and intermediate comprehenders had the most fixations on the moderate mid-level cognitive demand terms while barkers had the most fixations on the high cognitive demand terms. It is unclear what can be deduced from this regarding cognitive processing.

As shown in Table 1, a summary of the findings represented in the two figures above, for barkers the high cognition words caused many long fixations while the low cognition words caused few medium length fixations. Conversely for readers and intermediate comprehenders the high cognition words had few medium length fixations and low cognition words had medium number of long fixations. Moderate cognition words caused many short fixations for these groups. Note that by referring to long and short durations and many and few durations, the reference is relative to their respective mean fixations for the group. The absence of clear trends in this data may suggest that the system used to classify the terms may have little correspondence to the cognitive processing occurring.

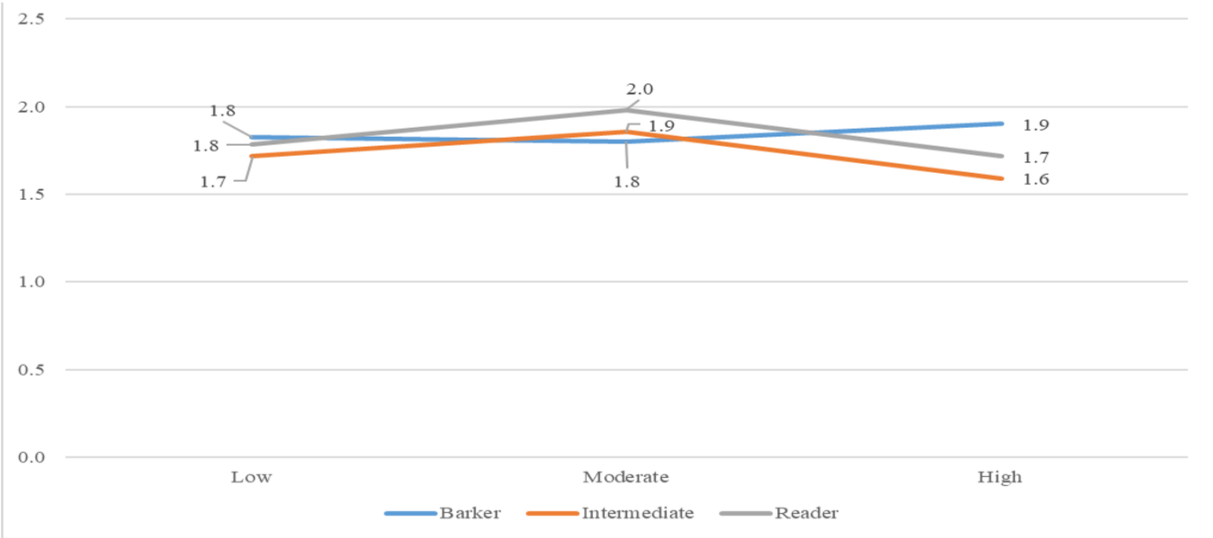

Figure 7: Fixation count per cognitive demand level and per comprehension group

Table 1: Summary of relative fixation counts and durations per cognitive demand level and per comprehension group

	Low cognition	**Moderate cognition**	**High cognition**
Readers	Medium fixations Long duration	Many fixations Short duration	Few fixations Medium duration
Intermediate	Medium fixations Long duration	Many fixations Short duration	Few fixations Medium duration
Barkers	Few fixations Medium duration	Few fixations Short duration	Many fixations Long duration

Per word

Figure 6 shows the mean fixation duration for each comprehension group and for each word for the low cognitive demand terms. The terms are demarcated on the graph using a dashed grey vertical line. On average, when reading fiction in English as a first language, fixations vary between 225 and 250 milliseconds (Rayner and Castelhano, 2007). The red horizontal crosshatch indicates this typical range. It is unsurprising that these learners, who were not only reading in a second language, but also reading scientific text, exhibited longer fixation durations than the published range except for the simple word *ice*. This is consistent with the view that fixation duration can be used as an indicator of the cognitive difficulty these learners experienced with the text.

In some instances the same trend is seen throughout the groups, for example the final occurrence of the term *ice crystals* showed an increase in the mean fixation duration on the word *crystals* for all groups. The variation in the mean fixation duration for repetition of terms is interesting. The higher cognitive load on the first and last occurrence of the term could indicate an increase in processing at the start and conclusion of a segment explaining a concept. The readers fixated longer on the last occurrence of the word *crystals* than they did on any of the other low cognitive demand words. Perhaps this was indeed because the readers were trying to make sense of the context and passage as a whole when they reached the end of the explanation. Although the other two groups showed a similar pattern for this term, their longest mean fixation duration in Figure 6 is found on the word *collide*. These learners are certain to have been unfamiliar with this word. Perhaps it and other unfamiliar words distracted these poorer readers from being able to make sense of the passage as a whole despite their attempts to do so. It should be noted that this discussion suggests that the increased fixation durations for the first and last instances of the word *crystals* indicates at least an attempt at engagement in sense-making cognitive processing, rather than cognitive processing associated with reading difficulty (extraneous) and basic comprehension (essential processing). The difficulty, even possible inability, to distinguish between these discrepant cognitive outcomes from eye-tracking data, makes interpretation of such data difficult.

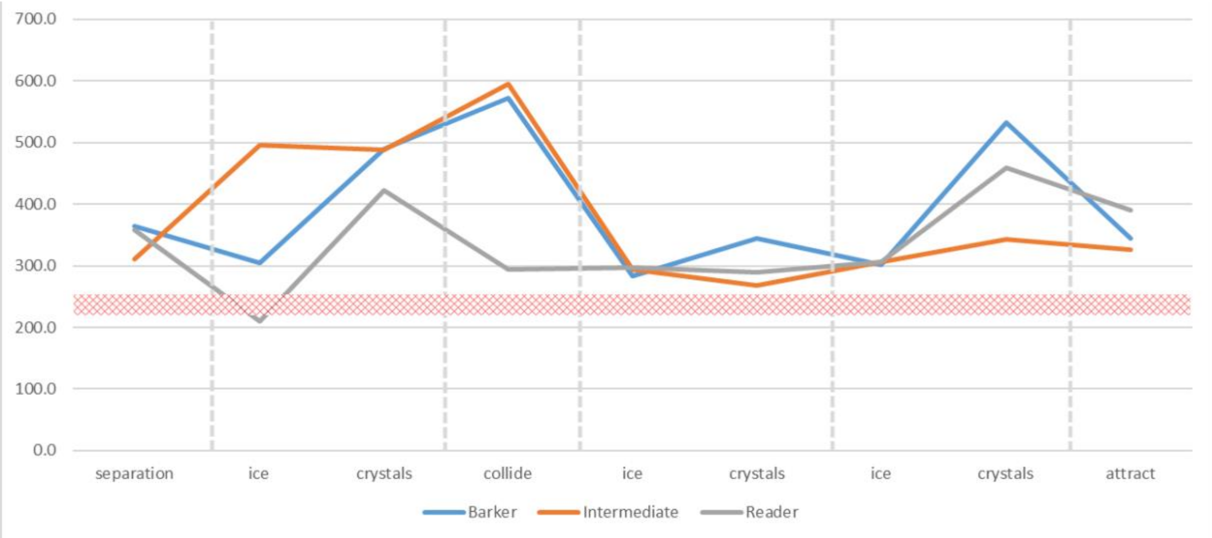

Figure 8: Mean fixation durations for low cognitive load

The fixation count shows that for instance, the barkers had more fixations on the first occurrence of the term *ice crystals* than on the other occurrences (although each occurrence of *crystals* has on average more fixations than the other low cognitive load words). They also, on average, had few fixations on the word *collide* meaning they processed the word in a single fixation and did not regress to the word. The phonetically opaque word *separation* also had a higher number of fixations. The readers had a higher number of fixations on the second occurrence of the word *ice*, as did the intermediate comprehenders. Frequent counts and long durations of fixations, as summarised in Table 1, suggest that the learners experienced difficulty with some words. However, the fixation counts do not shed much light on establishing a trend for the difficulty experienced within the groups and cognition levels.

The moderate cognitive demand terms (Figure 7) show minor fluctuations in the mean fixation durations. Individual words within terms have similar durations for all groups. Readers and barkers had the highest mean fixation duration on the word *positive* while this was the word that had the lowest mean fixation duration for the intermediate comprehenders. The first occurrence of *charged* caused respectively the longest and shortest mean fixation duration for intermediate comprehenders and readers. As with the low cognition words, these all have an average greater than the typical reading range.

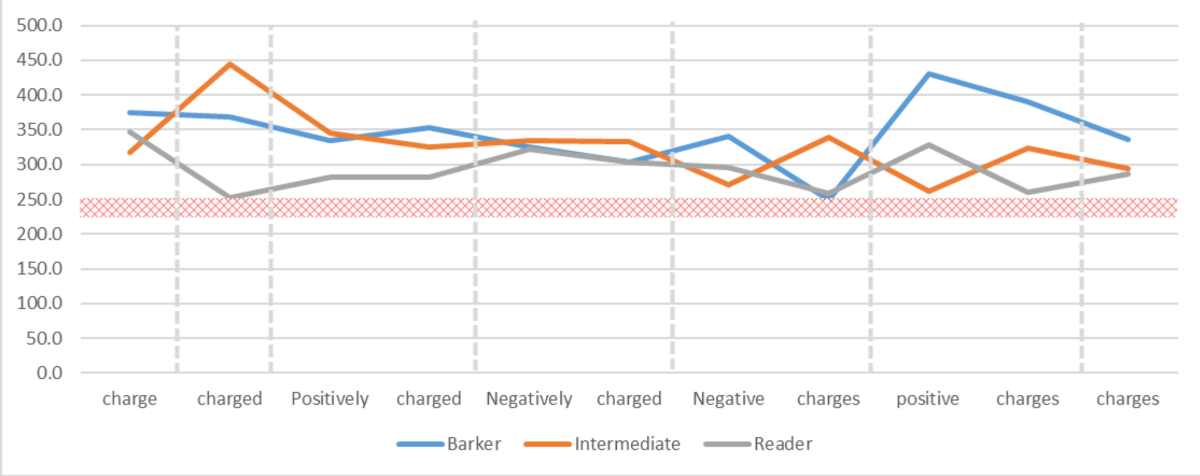

Figure 9: Mean fixation durations for moderate cognitive load

For all groups, the word *negatively* and *charges* had more fixations, on average, than the majority of the other words. All the moderate cognitive demand words had more than one fixation, even though the lengths varied from 5 letter words (*charge*) to 10 letter words (*positively* and *negatively*). Nevertheless, regardless of length they all required multiple fixations, on average.

High cognitive demand terms (Figure 8) show mild variations in the mean averages for individual words. The barkers clearly show longer fixations than the other comprehension groups. The fixation duration for the intermediate comprehenders for the word *electric* is the only word that falls within typical reading durations. Both readers and the intermediate comprehenders exhibited the longest average fixation duration on the word *fields* while for the barkers the word *potential* caused the highest fixation duration. For very poor readers, such as the barkers, the word *potential* can be considered to be a difficult word, given the phonetic opaqueness of its ending, hence it is not unexpected that this word caused some trouble for this group. Conversely, readers had the shortest fixation duration on the word *potential*, while for barkers this was *differences* and for the intermediate comprehenders *electric*. In terms of fixation counts all the words required multiple fixations and all were within the same range for all groups.

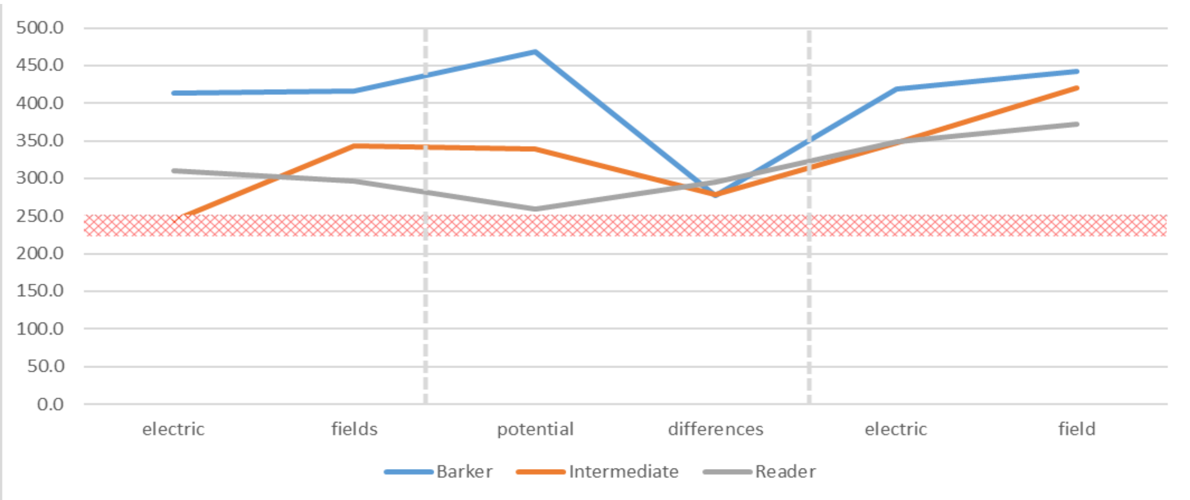

Figure 10: Mean fixation durations for high cognitive load

DISCUSSION

As has been argued above, the findings suggest that the cognitive demand of the scientific terms, according to Reese et al.'s (2019) framework, appears not to be a significant determining factor regarding word difficulty during reading science texts, with word familiarity appearing a stronger determinant. Although Reese et al.'s framework includes word familiarity in its dimensions of interpretation, similarity and multiple contexts, we suggest, below, why it seems to fail to identify cognitive difficulty in the manner used here.

Firstly, our modes of measurement (fixation counts and durations) appear to indicate a different type of cognitive processing (extraneous and essential) to that which Reese et al.'s framework was designed to measure (sense-making). For example, given the finding that the comprehension level of the barkers was so low as to elude our measurement, we deduce that their particularly long fixation durations were not indicative of engagement in sense-making. It is therefore to be expected that a classification of words using Reese et al.'s framework would correspond poorly to the measurement we used. This is because Reese et al.'s framework refers to the extent to which terms offer difficulty during engagement in sense-making while learning their meanings.

Secondly, the very different fixation durations displayed for the individual words within scientific terms, such as for *ice* and *crystals*, suggests that words within terms may have been processed individually, rather than as the unit used in the classification system. For Reese et al.'s framework to indicate the cognitive demand for learning particular concepts, it must be applied to terms according to their scientifically intended meaning, rather than to individual words according to their probably inferred meaning. This discrepancy undermines the value of this framework for interpreting the cognition occurring during reading, particularly in a context where the perceived and intended meanings are very likely to differ and their differences to have opposite cognitive implications. For example, both words in the term *positive charge* have multiple meanings other than those intended in this term, contributing to the term being classed as offering a medium amount of linguistic cognitive load. However, a learner's familiarity with each of these words in everyday usage could decrease the difficulty they experience in reading these words, without the learner comprehending the scientific meaning intended.

Consistent with the view that the word classification system used was inappropriate for the manner in which we used it, we could not discern any trend in the fixation count data we have displayed. Further, in the findings section we have discussed trends we find anomalous. For example, we found similar fluctuations in eye fixations for the three comprehension groups across the successive appearances of the term *ice crystals*. We have provided an explanation for these fluctuations which suggest that all were at least attempting to undergo sense-making, associated with longer fixations. This is inconsistent with the view we generally took in this analysis, i.e. that longer fixations indicate cognitive difficulties which hinder sense-making.

We believe that this discussion displays some of the complexity of reading difficulties and of eye-tracking data. This makes productive use of such data a complex task. This highlights the need for research, such as that reported here, which aims to aid development of diagnoses for barking at print using eye-tracking. Additionally, improving the understanding of cognitive difficulties experienced when reading science texts can help inform intervention programme development and guidelines for writing for greater accessibility.

CONCLUSION

In answer to the research questions, we make the following assertions regarding reading science texts in a second language: (1) Barking at print is associated with longer fixations on scientific words. While fixation counts show variation across the cognitive levels, no discernible trend or conclusion can be drawn from their fluctuations. (2) It appears that factors other than a scientific term's linguistic cognitive demand, as operationalized by Rees et al. (2019), determine the cognitive difficulty experienced by those who bark at print. We suggest that a learner's degree of familiarity with individual words, rather than terms as units, may be a significant contributing factor to the difficulty experienced while reading.

IS MECHANICS OR WAVE MORE CHALLENGING FOR STUDENTS? SELF-CONCEPTS AND STYLES OF SCIENTIFIC REASONING

Roy K.H Sin[1], Maurice M.W. Cheng[2]
[1]Yuen Long Merchants Association Secondary School, HKSAR, China
[2]The University of Waikato, Hamilton, New Zealand

Academic self-concept has long been regarded as an important indicator of students' academic achievement. Different subject's academic self-concepts are independent of each other and they have their own constructs (Bong & Skaalvik, 2003). We suggest that different topics of a subject, such as wave and mechanics in physics, have different styles of reasoning (Kind & Osborne, 2017), and hence students would have different academic self-concepts of these topics. We tested this hypothesis with questionnaires that measured students' academic self-concepts of these topics respectively. 107 Year 11 students (around 17 years old), who have learnt these two topics, from two schools in Hong Kong completed the questionnaires. We found a very week correlation between these two self-concepts (r=0.102). Written responses from 77 of these students revealed some ways that they approached these two topics, which were consistent with the heavy use of mathematical deduction and hypothetical modeling as reasoning styles in mechanics and waves respectively. Both quantitative and qualitative data point to the idea that there were topic-specific self-concepts in physics and that they were related to the use of different styles of scientific reasoning.

Keywords: Physics, Reasoning, Self-efficacy

INTRODUCTION

Scholars have been spending a lot of work investigating self-concept (Byrne, 1984). Students having a different level of self-perception shows different levels of cognitive, social, and emotional engagement in school (Bong & Skaalvik, 2003). Among all elements in self-concept's theory, academic self-concept is the most influential item in the education aspect. Since academic self-concept is defined as how students see their academic ability, the construct has a high correlation with academic performance (Bloom, 1976; Handsford & Hattie, 1982).

Marsh & Shavelson (1988) suggested a hierarchical model based on empirical data, showing the top of the hierarchy is general self-concept and it composes of different subject-particular self-concepts. All subjects' self-concepts are the components of the general self-concept and suggested to be somehow connected to the two major self-concepts, namely mathematical self-concept, and verbal self-concept. For physics, it was agreed to have a stronger linkage with mathematics while a weaker one with verbal self-concept (Marsh & Shavelson, 1988).

Kind & Osborne (2017)'s work in the style of scientific reasoning may give an insight to the educator in revisiting the relationship of physics self-concept with other self-concepts. Science was found to use different styles of reasoning and different types of knowledge use a different style in reasoning. While most of the content in mechanics relies on the mathematical deduction in reasoning, analogical and hypothetical models are commonly used in learning waves (Kind and Osborne, 2017). This difference in the required style of scientific reasoning may post a potential explanation of the difference in subjects' academic self-concepts.

Based on the discussion above, this research focuses on identifying if students could have different self-concepts on different topics. The findings should enrich the idea of self-concepts in the literature (e.g., Marsh & Shavelson, 1988). Furthermore, how students construct their subject's self-concept is going to be investigated to see if students collect different information in constructing their subjects' self-concepts. To frame the research, the following part presents the theoretical framework of the work.

LITERATURE REVIEW

Academic self-concepts

Academic self-concept has been an important indicator of academic achievement. It is defined as how students see their academic ability (e.g., Hansford and Hattie, 1982). It plays an important role in students' intrinsic motivation, positive emotion, and academic performance (Wolters & Pintrich, 1998; Bong & Skaalvik, 2003).

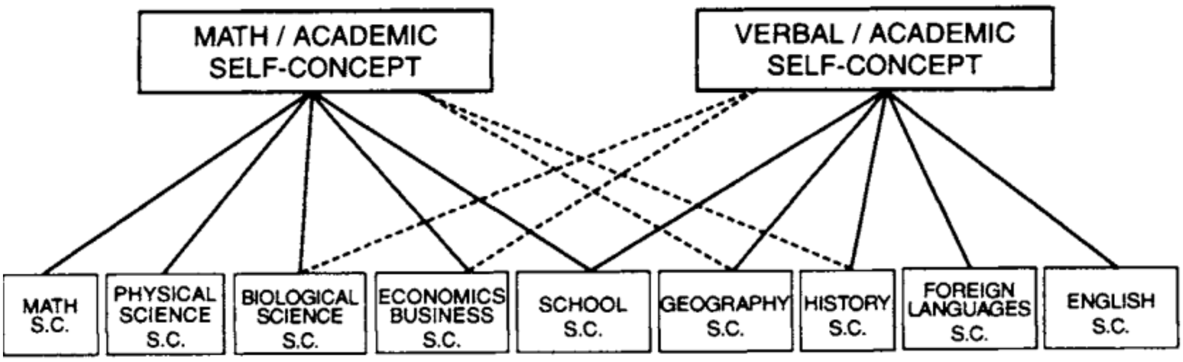

Figure 1: the hierarchical structure of academic self-concept (Marsh & Shavelson, 1988, p.378)

Marsh & Shavelson (1988) suggested a hierarchical model based on empirical data. There was a broad academic self-concept at the top of the hierarchy, which in turn was composed of two general self-concepts (i.e., Math and verbal self-concepts in Figure 1). Different subjects' self-concepts correlate with the two general ones to different degrees, which depend on the nature of the subject. Thus, different subject's self-concepts have their own formula of construction (Bong & Skaalvik, 2003).

The model suggested a relationship between general self-concepts and the subject's self-concept. Nevertheless, different disciplines of science worked rather differently in solving their disciplinary problems. It has been suggested that there are six distinct styles of scientific reasoning, namely (i) mathematical deduction, (ii) experimental evaluation, (iii) hypothetical modeling, (iv) categorization and classification, (v) probabilistic reasoning and (vi) historical-based evolutionary reasoning (Kind & Osborne, 2017). Therefore, there may be factors other than mathematics self-concept and verbal self-concept that correlate with physical science self-concept.

Style of scientific reasoning

How scientists argue and develop their reasoning can always be found in the history of science. Crombie (1994) examine different scientific thought in history and he revealed that scientific reasoning does not only have one style only. In fact, there were six distinct styles of scientific reasoning found, namely (1) Mathematical deduction, (2) Experimental evaluation, (3) Hypothetical modeling, (4) Categorization and Classification, (5)Probabilistic reasoning and (6) Historical-based evolutionary reasoning. These different styles of reasoning exist because they can successfully answer the questions and they become the standard of argument and reasoning now (Hacking, 2012).

Physics consists of several major topics, for example, mechanics, wave, electromagnetism, and atomic physics. Each topic, such as mechanics and wave, uses a different style of scientific reasoning. Most of the content in mechanics adopts Newtonian mechanics and it mainly relies on the mathematical deduction in reasoning (Kind & Osborne, 2017). Most of the ideas discussed in Newtonian mechanics, such as projectile motion and circular motion, are expressed a mathematical form. Such a form informs deductive predictions (Kind and Osborne, 2017). This exemplification by the Greek mathematical science is categorized as mathematics deduction in scientific reasoning. As mechanics mainly involves mathematical deduction as the style of scientific reasoning, there is no surprise that there was a close relationship between students' math self-concept and physical science self-concept (Bong & Skaalvik, 2003).

Science sometimes relies on hypothetical models to represent physical phenomena. These models help make predictions and '[simulating] the possible behavior of the world' (Kind & Osborne, 2017, p.12). By using hypothetical models, scientists are more able to share abstract concepts and do discussions and predictions. This reliance on the use of the hypothetical model is identified as one of the main styles of scientific reasoning. In learning wave, analogical and hypothetical models are commonly used. Since wave is a continuous process and is invisible, visual models are often used to explain related phenomena such as superposition, interference and the formation of a stationary wave. Through visualizing individual waves at different times, scientists can better understand the interaction of waves. Modeling is a key to make sense of phenomena related to waves.

RESEARCH QUESTIONS AND METHODOLOGY

Based on the discussion above, and the classroom observation that some students reported mechanics was more challenging for them while some reported wave, this study aimed at identifying if students could have different self-concepts in different topics. The findings should enrich the idea of self-concepts in the literature (e.g., Marsh & Shavelson, 1988). Our research questions were:

1. Were students' self-concepts of the physics topics 'wave' and 'mechanics' domain-specific?
2. How may students construct their academic self-concept of mechanics and wave respectively?

To answer the first question, we used two questionnaires (based on Bong & Skaalvik, 2003) to measure students' mechanics and wave self-concepts respectively. Correlation analysis was done between these two constructs. 107 physics students from two mixed-gender schools who had finished learning mechanics and waves were invited to complete the questionnaires. To answer the second question, 77 students from 3 classes in a school were invited to answer two follow-up open-ended questions (Comparing mechanics and wave, which topic do you think is easier? Why do you think that?). Through using open-ended questions, the researcher is then more able to probe into their mind and understand the underneath reason for having high/low academic self-concept towards a particular topic in physics (Turner III, 2010). Answers to the open-ended questions were coded by the first author. The coding was based on the styles of scientific reasoning (Kind & Osborne, 2017) and was double confirmed by another researcher in order to maintain its fairness and objectivity.

To minimize distractions when answering, the data collection was held in a closed classroom. This avoidance of distraction can improve students' willingness to disclose and hence research can obtain a more accurate and in-depth data from students (Turner III, 2010).

RESULT & DISCUSSION

All 107 students agreed to participate and completed the questionnaires. The Cronbach alpha reliability coefficient for mechanics self-concept and wave self-concept, using individual students as the unit of analysis, were 0.882 and 0.916 respectively. The correlation between these two constructs was weak and insignificant (r=0.102, p=0.297), meaning that the two constructs have little correlation with each other and they had little or no relationship with each other.

In relation to the second research question, it was found that students tended to have different reasons for choosing wave and mechanics as an easier topic for them. For mechanics, students tended to formulate their academic self-concept based on their perceived competence in mathematics:

Ben: (choosing mechanics as easier)	*…Mechanics mainly uses mathematics to analyze daily life phenomenon. I can use mathematics and calculation to understand the relationships…*
Billy: (choosing mechanics as easier)	*I am studying mathematics (module 2), some of the content such as trigonometry and vectors can improve my understanding of physics.*

It is not surprising for students to construct their mechanic's self-concept based on their perceived competence in mathematics. Mechanics' self-concept may closely link with mathematics self-concept because mechanics has a high reliance on the mathematical deduction in reasoning. This echoes with the finding that the physical science self-concept has a strong correlation with the mathematics one (Bong & Skaalvik, 2003). In mechanics, most of the physical phenomenon is expressed and exemplified by the Greek mathematical sciences and learners usually use mathematical deduction as a main way of argument. This idea is categorized as a mathematical deduction in Kind & Osborne's (2018) work about the style of scientific reasoning. From that, it seems that when students construct their mechanics' self-concept, they collect information about their mathematics ability, which is reported as a distinct nature of the topic. This information not only help construct the mechanics' self-concept in a positive way, but it can also be in a negative way:

Beatrice: (choosing wave as easier)	*Calculation (in questions concerning waves) is easier, I always get wrong in doing calculations about mechanics.*
Benjamin: (choosing wave as easier)	*It is because I don't have to deal with complicated mathematics.*

Even though Beatrice and Benjamin chose wave as an easier topic, they rated their mechanics' self-concept as low through the lens of mathematics. This echos with the finding that the physical science self-concept has a strong correlation with the mathematics one (Bong & Skaalvik, 2003). Students choosing wave as easier, on the other hand, tended to construct their wave self-concept through reviewing their ability in using internal visualization and visual representation:

Betty: (choosing wave as easier)	*...because the wave's waveform is easier to be visualized. On the other hand, vectors in mechanics are hard to imagine.*
Bobby: (choosing wave as easier)	*...because concepts in force and motion are relatively abstract and hard to be understood. However, concepts in wave motion are easier to imagine. Just draw a diagram and you can understand, which is not the case in force and motion.*

The responses showed a biased collection of information on the ability in coping with visual representations. Here, the word visual representation can be interpreted as model manipulation. Models usually use visual representations to show the interactions between entities. Students usually need visual representations to know how a hypothetical model is simulating the science behind in a phenomenon and they generate pictures to manipulate the model in mind. Here, representation is defined as what Hegarty (2004) suggested: 'any display that represents information in a visual-spatial medium' (p.1). Based on this definition, dynamic visualizations are also considered as representation. This idea is coherent to Kind and Osborne (2017) which students tried to understand the world through hypothetical models. Unlike mathematical deduction, hypothetical modeling is another style of reasoning which requires the construction of analogical and hypothetical models to represent the world. In this way of reasoning, models, and representation are taking a central role to reason on the relationships between different entities. Based on what Kind and Osborne (2017) suggested, scientists usually use representations to manipulate models so as to depict some abstract phenomena, and this is the nature of the topic wave and optics. From that, it seems that students also construct their wave self-concept through the lens of hypothetical modeling: they collect information about their perception of whether they can manipulate models and representation. Students who perceive better at producing internal visualization and manipulating models may have a better wave self-concept.

IMPLICATION AND CONCLUSION

In this research, we found a very weak correlation between students' mechanics' self-concept and wave self-concept. That is, students did have different self-concepts in these two topics. We ascribed the differences to the use of different reasoning styles in mechanics and wave (i.e., mathematical deduction and hypothetical modeling respectively). The conjecture was supported by students' written responses about some ways that they approached these two topics.

Based on our findings, we suggest that there may be topic-specific self-concepts among other physics topics. Academic self-concept may not be just a general perception of a subject. It may be determined by several academic self-concepts that are of smaller grain size. This research opens a further discussion on how we should see academic self-concept. Obviously, future work is needed to investigate whether mechanics self-concept and wave self-concept are the components of mechanics self-concept. By extension, there may be topic-specific self-concepts in physics and other subjects.

Apart from the topic-specificity of academic self-concept, this paper also explores the diversity of construction basis of different academic self-concepts. In previous work, physical science academic self-concept is only considered as being root in mathematics. However, the responses from students suggest that students may collect different information from a different aspect. The construction formula of different topics' self-concept may depend on the nature of knowledge: mechanics relies more on mathematical deduction while wave relies more on hypothetical modeling as the main style of reasoning (Kind & Osborne, 2017). The interaction between different constructs in Marsh & Shavelson's (1988) hierarchy can be more complicated than suggested before.

We acknowledge that mechanics also demands hypothetical modeling (and other reasoning styles), and wave demands mathematical deduction etc. Further studies should be conducted to delineate the role of different reasoning styles in different topics/subjects, and how they may explain topic-specific self-concepts.

ACKNOWLEDGMENT

I would like to take this opportunity to express my greatest gratitude to my advisor, Dr. Cheng, Maurice Man Wai. This work would not have been possible without the advice and assistance provided by him. Furthermore, I would like to thank my school principal, Mr. Yau Chi-Leung, for all the assistance and support during data collection. Finally, I sincerely thank my fiancé, Josephina, who listened and share my ups and downs in my journey of life. Without the support from them, this work could not be done smoothly.

INDUSTRY-SCHOOL PROJECTS AS AN AIM TO FOSTER SECONDARY SCHOOL STUDENTS' INTEREST IN SCIENCE-BASED TECHNOLOGY CAREERS

Robbert Smit, Nicolas Robin, Christina de Toffol and Sanja Atanasova
St.Gallen University of Teacher Education, St.Gallen, Switzerland

Industry-school partnerships offer authentic learning opportunities and can support the development of students' interest in a STEM career. The expectancy-value model of achievement-related choice helps to explain how several factors influence career choice. Interest-enjoyment values and attainment values are most important in students' motivation to participate in out-of-school technology and design activities. Our research question is the following: Is there a development in secondary school students' career interests in science-based technology-related professions over time? We employed a longitudinal, mixed-methods research design. The sample consists of 213 secondary school students from 9 classes and 72 students from 4 classes in 4 neighbouring schools who served as a control group. All of the students filled out a questionnaire before and after the visit. The questionnaire items were based on scales relating to an expectancy-value model. Four groups of students were interviewed with respect to the industry visit experiences. Analyses indicated that attitudes for applying technology became relevant for predicting career interest in a technology profession in the project group. However, career interest did not increase over time. In the qualitative analysis, four topics emerged that elucidated why career interest did not increase. Overall, the results demonstrate that factory visits combined with embedded tasks are one way to overcome fixed self-concepts and allow the students to reconsider a career in the technology and engineering industry towards the end of secondary school.

Keywords: science-based technology, expectancy-value model, career interest

INDUSTRY-SCHOOL PARTNERSHIPS

Industry-school partnerships offer authentic learning opportunities (Watters, Pillay, & Flynn, 2016) and can support the development of interest in a STEM career (Sasson, 2018). This is important because multiple research studies register a growing decline of student interest in STEM subjects (Becker, 2010; NGSS Lead States, 2013; Organisation for Economic Co-operation and Development (OECD), 2006b; Xie & Achen, 2009). Effects of out-of-school learning opportunities, such as visits to industry workspaces, museums or science centres, are also found to foster development in science learning, the development of self-efficacy, and even the sense of belonging to a local area (Sasson, 2018). Generally, out-of-school activities have a strong influence on student interest in science over time (Simpkins, Davis-Kean, & Eccles, 2006). For many such events, participants reported that they enjoyed and learned most from hands-on activities (Laine, Veermans, Lahti, & Veermans, 2017; Levine, Serio, Radaram, Chaudhuri, & Talbert, 2015). Examining student attitudes helps to explain the impact that out-of-school activities can generate. The results show that interest-enjoyment values and attainment values are most important to students' motivation to participate in out-of-school technology and design activities (Masson, Klop, & Osseweijer, 2016).

The objective of our industry-school partnership project was twofold. First, the students should experience science-based technology in a local factory. The more specific and long-term target was to induce positive attitudes among students towards a career in the technology and engineering industry. In many countries, technology is not yet a prominent feature of science education. The US National Science Education standards, for instance, integrated technology and engineering in 1996, but despite these early efforts, engineering and technology have not received the same level of attention in science curricula, assessments, or the education of new science teachers in comparison to traditional science disciplines (NGSS Lead States, 2013). Out-of-school experiences can be a promising way to overcome possible shortcomings of the curriculum.

The general public as well as teachers consider technology to be an applied science (Jones, Buntting, & de Vries, 2013). However, this view is somewhat incomplete (Jones, 2012). In school, teachers and students should develop an understanding of technology and science as two areas that can interact but are also distinct in nature. This means that technology is often an applied science. Sometimes, however, there is no interaction when products are created without a proper understanding of the scientific background (De Vries, 2001). For instance, secondary school students could learn to assemble and use a 3-D printer in class without having knowledge of the molecular structure of a thermoplastic. Another ambiguity is that technology education is often confounded with the use of computers in schools. Therefore, in this study we apply the term science-based technology as it is defined in the Programme for International Student Assessment (PISA) (Fensham, 1988; Organisation for Economic Co-operation and Development (OECD), 2006a). In Swiss lower-secondary schools (grades 7-9) the subject of technology has not been a significant part of the curriculum up to now. The new Swiss 'Curriculum 21' describes technology as part of science with respect to being able to talk about the relevance and the sustainability of technological inventions such as genetic engineering, electric engines, or communication technologies. Students should also possess the capability to use and understand everyday tools (hair dryer, loud speaker, LED, etc.), as well as to test and optimize technical devices. The practical implementation of the new Swiss curriculum is still ongoing. Hence, it is reasonable to assume that Swiss science teachers do not put much emphasis on teaching technology in the secondary classroom yet as this was not a topic in earlier curricula. Studies of science teachers' knowledge regarding teaching technology in German-speaking countries do not exist, but research projects, such as that by Goreth, Geißel, and Rehm (2015), aim to close this gap. Research has shown that the early years of secondary education are crucial in terms of the impact a teacher can have on students' views of science and careers involving science (Regan & DeWitt, 2015). Therefore, it is important that Swiss secondary school teachers receive professional training on how to conduct motivating technology lessons in the science classroom.

Our research is embedded within a Swiss-Austrian development project in secondary schools that lasted for two years. According to Archer et al. (2010) students' identities, which are largely formed around the age of 13, are responsible for their career choices in secondary school. Therefore, it is sensible to create projects for that age group, which help students to determine what career possibilities the science-based technology field has to offer. The expectancy-value model of achievement-related choice demonstrates how several factors influence career choice. The model also explains how constructs and processes such as self-schema, short- and long-term goals, and identity formation change over time in part in response to the accumulation of new experiences and the acquisition of new information (Eccles, 2011). Based on this model, we investigated the development in the students' career interests in technology-related professions over the duration of the project. We examined the following questions:

1. Are there differences in the development of career interest between the intervention and control groups?
2. Which factors explain the development of career interest in the science-based technology field?
3. Are there differences in the relationship of the predicting factors between the intervention and control groups?

Method

Our longitudinal research design was embedded within a bi-national STEM implementation project. The fully mixed concurrent equal status design (Schoonenboom & Johnson, 2017) combines QUAN + QUAL student data. The project started in 2016 and ended in 2018. The principal aim was to network industry and school and to motivate secondary school students regarding science-based technology topics and career aspirations. As part of the project, secondary school students visited a local company with a STEM background and worked on STEM tasks related to the company's products. Each local industry-school part of the project was designed by teachers and industry partners according to their requirements.

The sample for this study consists of 213 Swiss secondary school students (grades 7-9) from 9 classes who took part in the 3 industry-school projects and 72 from 4 classes in 4 neighbouring schools as a control group. The age range lies between 12 and 17 years. In addition, we conducted group interviews in four schools from the project group, N = 16 students (4 x 2 female, 2 male).

The student questionnaire consists of 85 items on students' attitudes towards mathematics and science-based technology, and of some variables related to the students' background, e.g., gender, father or mother's job, and importance of technology at home. Our items refer to the expectancy value model of achievement by Eccles and Wigfield (2002).

The interview followed a structured guideline. After questions relating to technology and science at school, the students had to report about the factory visit, including what they had liked and disliked. Then, they were asked about their perceptions of technology and whether their interest in technology had increased. Finally, a section on each student's career choice followed, which explored their intentions at the moment and explanations for their choice, including whether they would consider an apprenticeship with the company that they visited.

RESULTS AND DISCUSSION

A CFA was used to check whether the scales would load on the expected two factors expectancy and values. However, it showed that the scales had to be arranged differently. One factor comprises expectancy, costs and attainment values, while the other factor includes interest values e.g. enjoyment of the activity (Fig 1). Measurement invariance over time was tested and scalar invariance was reached. For the first factor (expectancy) F-Tests showed no difference over time and group. The second factor (applying) showed a significant small decline over time for the intervention group (Eta2 = .02) compared to the control group. Career choice declined a little too in the intervention group and also with a similar small effect compared to the control group.

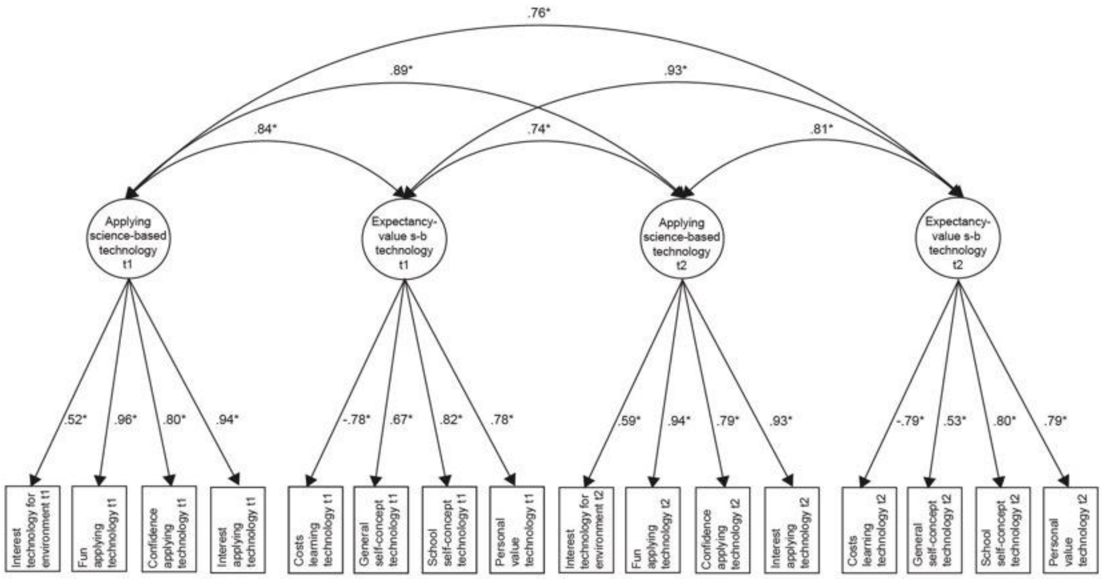

Figure 1: Longitudinal CFA-Model for expectancy-value and applying science-based technology attitudes

Our first question relates to the effect of our project on the students' career interests. To answer this question, expectancy-value and application of technology attitudes were compared over time in two groups with no effect for expectancy-value and with very little effect for application attitudes (Smit, Robin, De Toffol, & Atanasova, 2019). Unexpectedly, we found also no effects of the industry-school project on the development of the students' career interests. Second, we investigated which of the variables explained career interest. From the context variables, gender was the strongest predictor, having a negative effect on career choice. The other context variables showed only indirect effects mediated by expectancy or applying technology. Overall, career choice proved to be of medium stability over time. The two main factors in our research model to explain career choice need to be explained for each group separately. With respect to the third question, interesting differences resulted between the two groups regarding the prediction of career choice over time (Fig. 2). In the control group career choice is predicted solely by expectancy while in the intervention group expectancy and applying technology explain career interest over time. This result might indicate that the industry-school project leads to a change of students' perception of science-based technology professions. Applying science has become a more salient feature of such jobs.

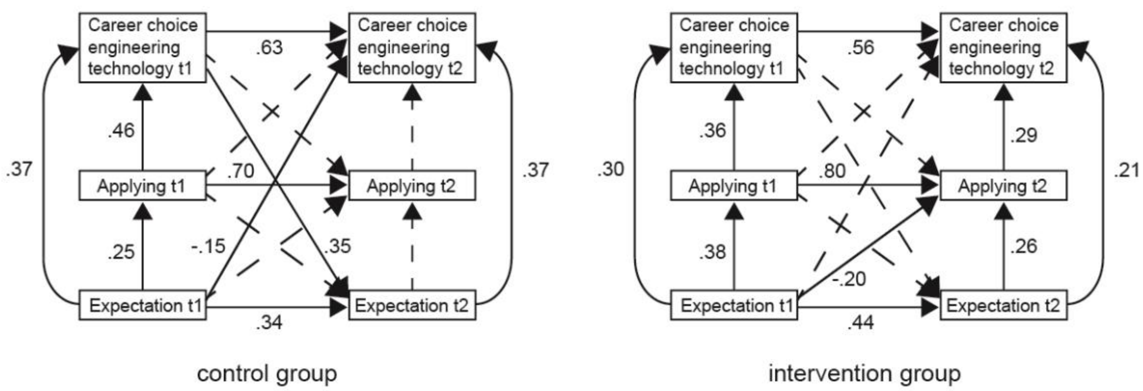

Figure 2: Two-group model for explaining development of STEM career choice

The qualitative results point out that the growth of career interest as part of an industry-school visit with accompanying preparation and reflection in school faces some obstacles. Is the visit at the right time of the students' career planning? Is the student open to considering a job in the technology field? Additionally, the image of the company is of importance as well as the working conditions. Finally, the activities must appeal to the student. As the students can choose among many apprenticeships, one of these factors can prevent students from continuing further inquiries about the job. Hence, the chance for a company to reach an applicant through an industry visit is not very high; however, very often in small to medium companies, there are not more than two apprenticeships available per year anyway.

Overall, our results show that factory visits combined with embedded tasks could be one way to overcome fixed self-concepts based on school science experiences. Even if career interest did not increase for the class as a whole, the insight into job-related science-based technology and working on practical tasks allowed the students to reconsider a career in the engineering industry towards the end of secondary school. Finally, it should be considered for further research that because of the specific orientation of technology towards application, more studies are needed that explore differences between science and science-based technology attitudes and knowledge and how they interact in developing career interest in technology professions.

AN INNOVATIVE DESIGN IN RESEARCH, EDUCATION, AND PRE-COLLEGE MENTORING PROGRAM

Enja Osman[1]*, Hiba Hamdan*[2]

[1]American University of Beirut, Beirut, Lebanon
[2]University of Cambridge, Cambridge, United Kingdom

In an increasingly complex world, there is limited research that focus on designing rigorous school counseling programs that meet students' needs, enhance their learning, and increase their motivation to pursue tertiary education. As a result, a group of experts gathered minds and experience to tackle this significant issue of career guidance and pre-college counseling. In this case study, 24 grade 10 students were provided with the opportunity of experiencing hands-on and minds-on project-based authentic interdisciplinary modules stemming from their interests and designed by seniors and graduate students. This innovative approach attempted to foster student conceptual understanding, increase their motivation towards learning science, and promote their growth as they prepare to take on post-secondary education. Implications for practice and directions for future research in the context of education and higher education are discussed.

Keywords: higher education, experiential learning, motivation

I. INTRODUCTION

In an increasingly complex world (Osberg & Biesta, 2010), a lot of research and professional development has been done on designing school curricula that match 21st century skills (e.g. Alismail & McGuire, 2015; Care, Kim, Vista, & Anderson, 2018; Partnership for 21st Century Skills, 2009; Schleicher, 2012). However, less focus is on designing rigorous school counseling programs that (a) consider the needs and interests of students, (b) reinforce what they study at schools, and (c) foster decision making and 21st century skills to help students transition smoothly from school into tertiary education (CERD, 2019; OECD, 2012; Yorke, 2000).

In Lebanon, Grade 10 is a common path for all students prior to following the scientific or literary tracks (Loo & Magaziner, 2017; Nuffic, 2016). However, students greatly lack awareness on how to select their majors or align their future path with their interests and abilities (Vlaardingerbroek, Al-Hroub, & Saab, 2017). In fact, career guidance and support programs – if present – are limited and often very theoretical. To further confirm these findings, national meetings and interviews with schoolteachers revealed problems within school curricula and a deficiency in school counseling programs. Both challenges led to the (a) failure of Lebanese science school curricula to cater to students' interests and nurture 21st century knowledgeable and skillful learners, (b) lack of student interest in science, (c) inability of students to apply science concepts to solve real-world problems, (d) prevalence of traditional teaching, limited practical skills and opportunities to engage students in investigations, inquiry, and experiments, and (e) absence of robust school counseling program to help students make informed decisions regarding their future career path (Osman, 2014).

If we are to prepare students for the future, we need to attract their attention by creating an authentic and positive learning environment that develops their problem-solving skills within a meaningful context (Hallissy, Butler, Hurley, & Marshall, 2013; Schleicher, 2010). As a result, we wondered how we could construct a pre-college mentoring program that could (a) support school curricula in reinforcing content, skills, and authenticity, (b) increase student motivation and conceptual understanding, and (c) provide students with life skills to help them select careers related to their fields of study.

Previous research in science education has shown that positive classroom experiences through hands-on engagement result in improved motivation and attitude towards science (Osborne, Simon, & Collins, 2003; Vlaardingerbroek, Taylor, Bale, & Kennedy, 2017). However, whether such a change improves understanding of theoretical science is to be unraveled.

In this study, we discuss a pilot precollege boot camp program, the first initiative of its kind in Lebanon. We worked collaboratively with three university professors and their senior, Masters, and PhD students to design a scaffolded pre-college mentoring program to reinforce concepts taught at school, increase student motivation, enhance learning, provide training on basic life skills and hands-on career counseling to ultimately encourage students to pursue tertiary education. The fields of Cancer Biology, Neuroscience, and Mechanical Engineering (ME) were selected because they are aligned with subsequent secondary school science curricular units (i.e. that of Grades 11 and 12), are difficult to learn at schools (mainly due to the lack of labs and/or lab sessions), and are authentic with genuine problems from students' daily lives; cancer biology is a human-related disease, neuroscience deals with neural stem cells in embryonic and adult brains, and ME addresses energy consumption with emphasis on the solar chimney and cooling systems.

We sought to investigate the effect of the designed pre-college mentoring program on Grade 10 students' (a) conceptual understanding of some basic yet complex theoretical science concepts and (b) motivation towards learning science. We also aimed to explore their perspectives on making educated decisions regarding their future college major and career path.

II. METHODOLOGY

This case study adopted a descriptive mixed-methods design, planned across five phases (Figure 1). Quantitative and qualitative data collection methods were used to explore possible gains in Grade 10 students' understanding of scientific concepts, observe developments of their motivation towards learning science, and obtain an in-depth understanding of their perspectives on engaging in similar projects as means to make informed decisions concerning their post-secondary studies and careers.

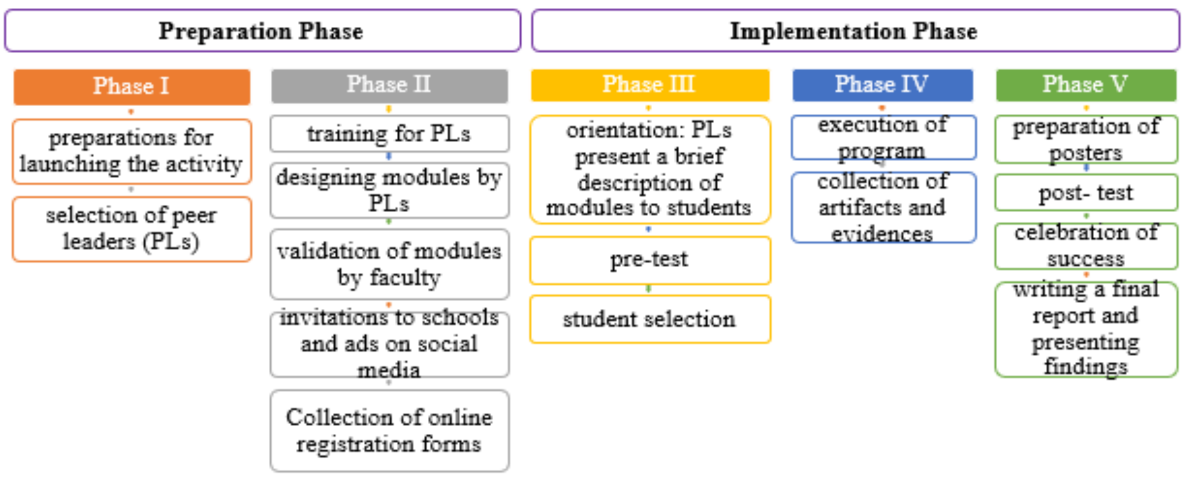

Figure 1. Phases of the study

A. Participants

Two peer leaders (PLs) from each of the three fields were selected according to the following criteria: they are seniors and/or graduates from the American University of Beirut (AUB), exhibit great leadership and communication skills, and are committed. Upon their nomination by faculty, the PLs and their faculty supervisors attended three one-day workshops on active teaching strategies, working with students, and providing constructive feedback to students.

For this study, we targeted Grade 10 students. From a pool of 120 student applicants pertaining to a total of 38 public and private schools across Lebanon, 8 students were selected per field based on results of a subject proficiency test and open-ended questions on interest, purpose, and career motivation. The total of 24 participants who were blindly chosen pertained to 7 private and 1 public schools in 3 governorates.

B. Training Modules – Experiential Learning

The training modules were developed by peer leaders and faculty members, then reviewed by the researchers. Activities included hands-on-minds-on sessions, visits to different facilities of authentic research, discussions with guest speakers and experts in their field, discussion of research studies, and career-related classes (Figure 2). Each module was taught by PLs under faculty supervision over a period of 4 weeks (8 sessions) at AUB labs and classrooms.

The researchers attended different sessions to assess students' motivation level and conceptual understanding, as well as provide constructive feedback to PLs. Then towards the end of the module, students were asked to submit a scientific poster to reflect on their experience.

C. Data Collection Tools

At the start and end of the program, students completed a subject proficiency test and a motivation questionnaire.

Test items were developed by PLs based on the topics to be covered in the modules and validated by 3 university faculty advisors (experts in the field). The final version of the topic proficiency test included 13 open-ended items for ME, 15 open-ended items for Neuroscience, and 16 open-ended items for Cancer Biology. These items assessed students' understanding of the theoretical aspect of their topic of interest as well as laboratory protocol and results.

The motivation questionnaire consisted of (a) 25 items that identified students' motivation towards science using a validated Likert-type scale (Glynn, Brickman, Armstrong, & Taasoobshirazi, 2011) and (b) 3 open-ended questions that explored students' personality and interest in relation to their future.

Both the subject proficiency test and questionnaire were administered during a 1-hour session held at AUB following an orientation that provided an overview of the modules, where students selected one of the three fields: ME, Neuroscience, or Cancer Biology. Final selections of students were objective as peer leaders corrected the assessment papers with reference only to a code identifier for the participants.

Figure 2. Sample activities within the (A) Cancer Biology, (B) Neuroscience, and (C) Mechanical Engineering training modules

By the end of the modules, students also engaged in informal discussions with the researchers and faculty advisors about their opinion of the program. PLs and some students shared their opinions in short testimonies in the closing ceremony. Thoughts and opinion were video recorded.

Lastly, all 24 participants were sent a questionnaire (exit survey) to assess the training module they attended and reflect on their experience. The response rate was 83.33% (20/24).

D. Data Analysis

A summary of data analysis strategy used for each type of question is presented in Table 1. Means and standard deviations were used to analyze students' responses to the knowledge items. Frequencies and percentages were used to analyze students' responses related to motivation. Since the sample size per subject was small, no inferential statistics were computed. Open-ended items were analyzed by the peer leaders based on a defined correction scheme. In general, exams and questionnaires were evaluated and reviewed by two PLs; disagreements in corrections were discussed until consensus was reached.

As for the post-implementation focus group discussions, testimonies, and exit survey, emerging themes and recommendations were identified and analyzed using thematic content analysis.

Table 1. Analysis scheme of items in the topic proficiency test and motivation questionnaire

Category	Target	Type of Items	Analysis
Knowledge items: **Conceptual understanding**	Students' understanding of theory and experiment results	MCQs and short-answer questions	*Descriptive Statistics:* Means and standard deviations for scores
Knowledge items: **Practical skills**	Students' understanding of lab protocol and results *Does this understanding differ between Cancer Biology & Neuroscience students?**	Short-answer questions **The same questions were used to investigate whether one group outperforms the other based on topic taught*	*Descriptive Statistics:* Means and standard deviations for scores *Student t-test*
Student Motivation **(Glynn et al., 2011)**	Level of motivation in learning science based on 5 constructs: • intrinsic motivation • grade motivation • career motivation • self-determination • self-efficacy	25 Likert-type scale items	*Descriptive Statistics:* Frequencies and percentages
Interest & Career Choice	Students' personality and interest in relation to their future	3 Open-ended items	*Thematic content analysis*

III. RESULTS

Data collected showed that – overall – students showed increased understanding of complex concepts and higher motivation towards learning science. They were also better informed on how to select their majors.

A. Conceptual Understanding

A comparison of average scores on the topic proficiency tests pre- and post-program showed a variation across modules (Figure 3). While there was a 5.93% overall increase in performance for Cancer Biology students post-program, both Neuroscience and ME students had scored better on the pre-test on average compared to post-test results; on average, the change in performance for students in Neuroscience was -6.28%, and a greater change (-13.38%) was observed in the scores of Mechanical Engineering students. However, differences in student performance on the pre-test and post-test knowledge items within each group were not statistically significant ($p>0.05$).

Moreover, analysis of post-tests results showed an increase in the average individual percentage change of students' conceptual understanding, practical skills, and overall performance in Cancer Biology, with the change being largest for the practical skills (+16.59%) compared to pre-test performance. However, while Neuroscience students showed a greater change in conceptual understanding compared to students in the Cancer Biology module (+5.25% compared to +2.88% respectively), the average change in performance of ME students was 13.05% lower after the training sessions.

To investigate whether one group outperforms the other in the hands-on items based on topic taught, the same practical exam was used with students from Cancer Biology and Neuroscience. A comparison of student performance indicated statistically significant differences in the pre-test ($p<0.01$) but not in the post-test ($p>0.05$) practical items.

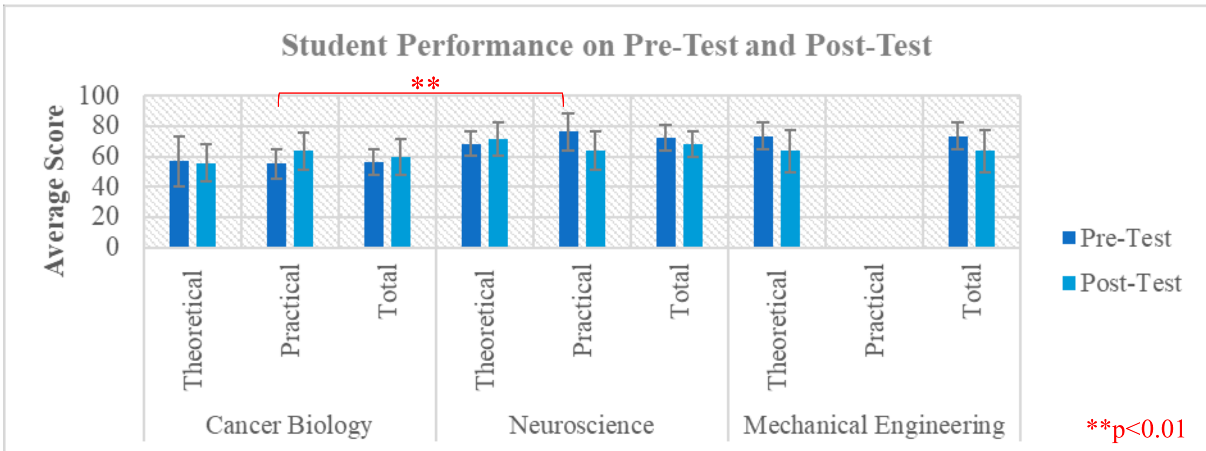

Figure 3. The average student performance on the subject proficiency test administered before and after the Cancer Biology, Neuroscience, and ME training modules

The change in student conceptual understanding was also reflected in focus group discussions, testimonies, and exit surveys. When asked about their opinions, 90% of students believed that the program provided them with an authentic opportunity that favored learning and a better understanding of the subject. As one student stated:

> *"This experience gave me a clear idea of what neuroscience is - besides being a fancy word - and offered me a fresh outlook on biology in general. I realized how much neuroscience contributes to the advance of the medical field!"* Neuroscience Student 5

B. Motivation

For Cancer Biology students, motivation towards learning science increased overall during the post-test. The increase was greatest for s*elf-determination* and *self-efficacy* factors. As for student in the Neuroscience module, motivation also increased overall during the post-test. While the increase was greatest for the *career motivation* and *grade motivation* factors, *self-efficacy*, was lower after the training. Unlike students in the other two modules, ME students showed a lower motivation overall and in all 5 factors after the program, with the decrease being greatest for *grade motivation* and *self-determination* factors (Figure 4).

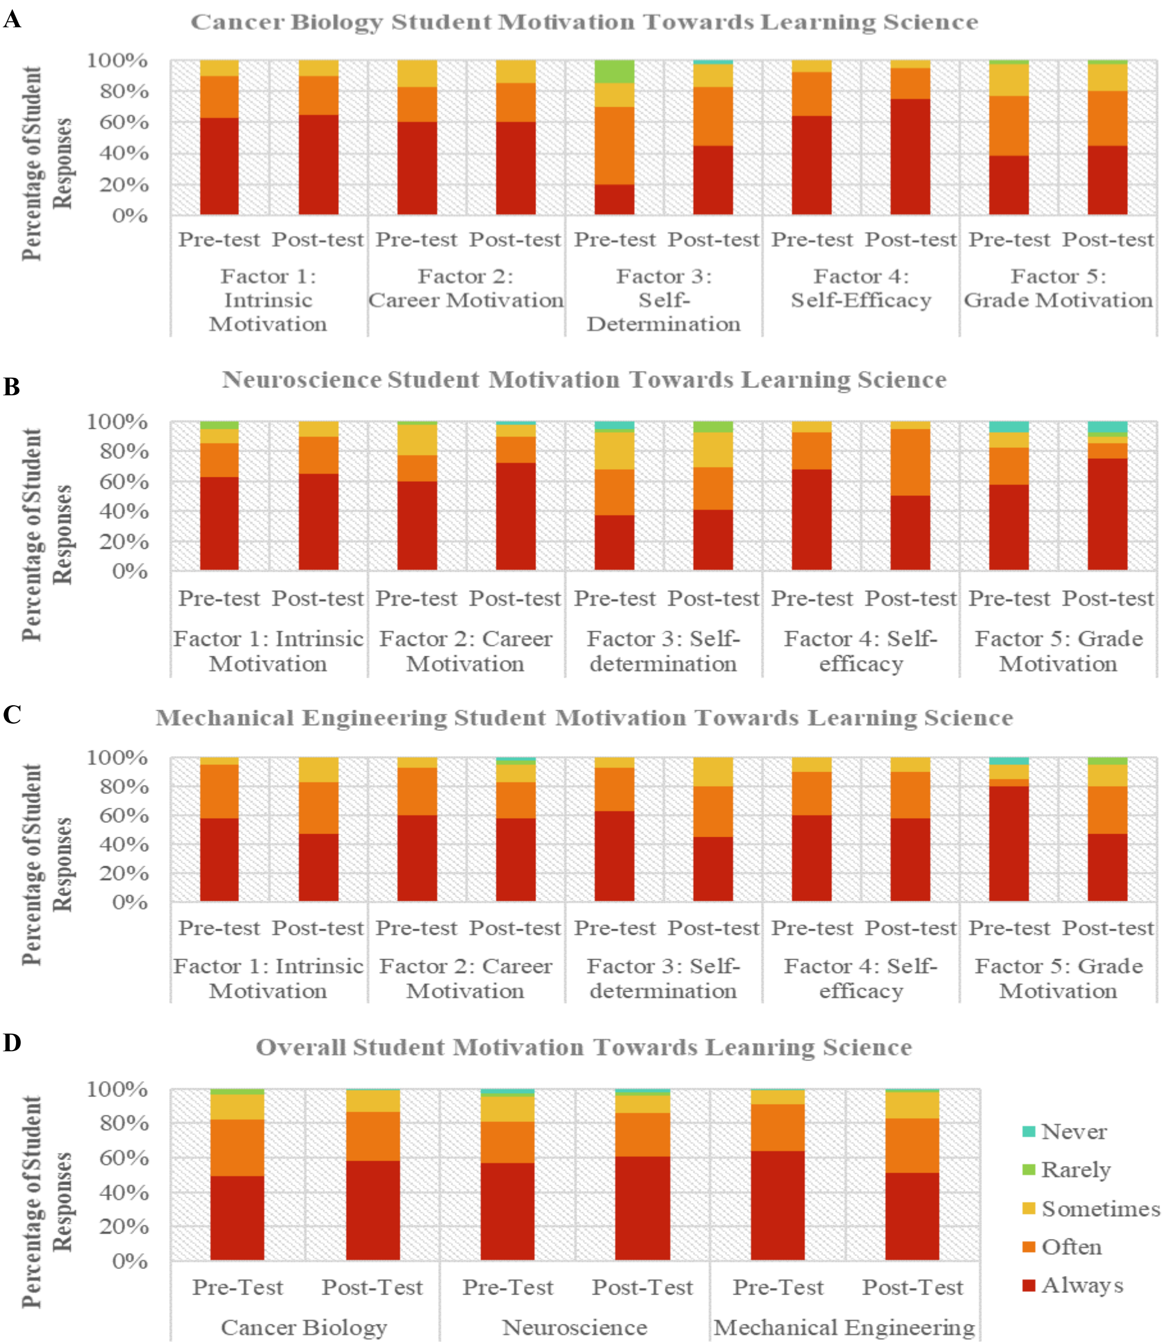

Figure 4. Student motivation levels of Grade 10 student participants before and after the intervention for individual factors in (A) Cancer Biology, (B) Neuroscience, and (C) ME, as well as (D) Overall

Recurring themes of passion and increased awareness constantly emerged, with numerous anecdotes support these findings.

> *"The training made me fall in love all over again with the job…it is possible to become a neurosurgeon!" Neuroscience Student 6*
>
> *"I have a passion for biology and I want to do something that will help cure people in my future career" Cancer Biology Student 4*
>
> *"This program opened my eyes to [Heating, Ventilation, and Air Conditioning] which I didn't know was previously a part of ME. It also made me be curious..." ME Student 3*

Furthermore, discussions with students and PLs revealed that the authentic and practical aspect of the training was key to student motivation towards learning. In fact, the hands-on experiments were unanimously the most engaging aspect of the project, where some students saw a real lab and worked with real tools for the first time.

C. Perceptions and Future Careers

Themes emerging from thematic analysis revolved around two main concepts: increased learning and guidance for future careers.

First, increased learning was illustrated in student responses which reflected how they were able to understand complex ideas.

> *"This experience gave me a clear idea of what neuroscience is - besides being a fancy word - and offered me a fresh outlook on biology in general. I realized how much neuroscience contributes to the advance of the medical field!" Neuroscience Student 5*

Students believed that the knowledge and skills they gained will help them choose their major and future career. Students voiced their interest in such programs that pave the way to a goal-oriented and brighter future.

> *"My choice of major at the university shifted from engineering to the sciences after experiencing what it truly meant to be a scientist." Neuroscience Student 2*
>
> "*It helped me deciding what I want to be in the future." Cancer Biology Students*

Students also expressed that this project allowed them to experience part of college life. They were thrilled to experience how the program can foster social collaboration and offer career guidance; they made new friends and met instructors who might become their supportive mentors as they take their education forward. One student even contacted the Research Science Institute at MIT for a possible follow-up project.

On the other hand, PLs stated that the project was a priceless teaching and learning experience for them as well, as they took on the challenge to design interdisciplinary teaching modules that target real-world problems, acquired pedagogy skills in teaching, and became aware of school students' needs and interests.

Last but not least, common suggestions for improvement included increasing the number of sessions and lab experiments, covering a wider range of topics, supplying complementary teaching resources and home assignments, and strengthening curricula through partnerships with schools.

IV. DISCUSSION & CONCLUSIONS

In this era, high school teachers struggle to motivate their students to learn and continue their education. When activities challenge students to develop knowledge and deep understanding, students are provided with a motivating experience to appreciate the field and related career options (Gregson, 2011). However, when students experience science through a plethora of information to memorize rather than via engaging hands-on laboratory experiences (Danaia, Fitzgerald, & McKinnon, 2013), it is not surprising to notice a decrease in conceptual understanding and motivation similar to our observation with the ME students. In fact, the discrepancy between the engaging planned ME module and observed results may be attributed to prevalence of lecturing rather than authentic workplace science, and to the turnover of PLs due to university exams and a tight schedule. On the other hand, the increased motivation and conceptual understanding of Cancer Biology and Neuroscience students may be due to recent confirmation that students thrive on problem-based, interactive, authentic learning (e.g. Darling-Hammond, Flook, Cook-Harvey, Barron, & Osher, 2019).

In addition to insightful observations from the authors, feedback from student responses to open-ended questions and focus group discussions, PLs, and faculty dictates that precollege programs could be better designed by taking the following features into consideration: (a) containing research-driven activities (complex concepts from school syllabi), (b) engaging students with challenging interdisciplinary real-world problems that promote their motivation and foster better learning, (c) establishing an incentive system to increase commitment of students and PLs, (d) providing an opportunity to explore 2 or more fields, and (e) partnering with schools to develop a well-structured school counseling program that serve both academic and social needs.

As preliminary results were discussed with the Ministry of Education and Higher Education, implications for practice underscore collaborations towards reaping success at the school and university, with a promising integration of high-level innovative thinking in supporting school programs that foster 21st century skills and prepare students to become self-directed citizens.

This case study is of a narrow-scale implementation within a specific context (24 students in 3 majors at one university in Lebanon), so its results are not generalizable. Though we believe we have had a successful attempt, future studies are needed to (a) extrapolate this project to other subject areas, teachers, and a larger number of students, (b) revise the curriculum for authentic learning, and (c) provide genuine opportunities for students to make educated study and career choices. In fact, a scaled-up 2019-2020 project with 106 students (11 schools) and 10 departments (25 faculty) have indicated promising results with improved performance in all majors. Details will be presented in subsequent manuscripts.

In conclusion, we are now more confident of the importance of pre-college mentoring programs. They complement formal school curricula to improve learning, understanding, motivation, and the ability to make better decisions regarding career choices. Instead of abstractly talking about careers or interacting with university counseling websites, pre-college counseling programs should serve two purposes: academic and social. In this regards, partnerships between schools and universities is essential to engage students in authentic learning environments that help them practice a field of interest rather than listen about it, as well as acquire basic life skills that help them choose their careers based on interest and abilities, ultimately meeting the needs of the society they live in.

V. ACKNOWLEDGEMENT

We would like to thank Dr. Hala Gali-Muhtasib, Dr. Kamel Abou Ghali, and Dr. Noël Ghanem for their guidance and for believing in the mission of this project. This work would not have been possible without the project PLs: Dr. Maamoun Fatfat, Mr. Anthony Bejjani, Ms. Rose Marie Akiki, Ms. Rana

Sarieddine, and Ms. Douaa Al-Assaad; their contribution was invaluable for the successful implementation of the modules.

We would also like to acknowledge Dr. Imad Saoud, the Biology Department Chair at AUB in 2018, and the time and support of all faculty, staff, personnel, schools, parents, students, and guest speakers without whom the project would not have been possible.

This project was supported by the Fulbright Program and sponsored by the U.S. Department of State.

Context-based science learning (CBL) creates instances for authentic inquiry pertaining to students' environment. It allows students to build their conceptions through interactions between a scientific model and an observable and specific example. In order to avoid the risk of building their conceptions from paradigmatic examples, this article presents research based on the contexts effects. reflecting the symposium*, principles and experimental modalities will be presented (part 1). One of the main results about context and conception lies in the fact that correspondences between the identified conceptions and the geothermal contexts of students have been established (part 2). In a design-based research, a modeling tool allowing to calculate contexts gap and predict contexts effects have been developed and* described (part 3). *The analysis of interactions and affective dimensions during presents the concept of contexts effect as a complex object both a psycho affective event (eureka effect) and as a constructed sequence of interaction (Contexts effect séquencies, part 4).*

Keywords: context effects, innovation in teaching/learning Modeling, Context gap Calculator, conceptions, geothermal energy, Collaborative Learning, Emotion.

The relationships between the students' natural and technical contexts and scientific learning were investigated in the context based framework context (King 2011). Context effect based learning is a collaborative method involving two groups of learners from different contexts with an inquiry process on a common issue. Each group discusses the involved concepts relating to examples in their context. Thanks to numerous distance collaborations, students work with their counterparts throughout the inquiry thus questioning their own conceptions as they are exposed to the other groups' conceptions. Everyone shares their culture, acquires digital skills and also disciplinary knowledge, of which the limits and possibilities are more precisely identified. The protocol, which has already been put into place during several iterations, is more effective if the contexts show clear differences.

The objective of this paper is to present learning based on the effects of contexts as a learning method but also to present various works related to these teachings.Several questions concerning learning based on the effects of contexts, are addressed. The first is the relationship between scientific conceptions and the contexts of a territory. The concept of context effect was initially defined as a cognitive break. This paper presents results from two different methodologies that centralize the socio-emotional and international dimension in order to show the complexity of this concept. How can we predict the appearance of a context effect? The part named "Development of a Modeling Tool for the Context Effects Based Teaching" presents the development of an external context deviation calculation tool. This tool is built on the assumption that the larger the external context deviations, the greater the chance of a context effect.

CONTEXT EFFECT BASED LEARNING, PRINCIPE AND EXPERIMENTAL MODALITIES

Context in Science Education

The emphasis placed on students' environment is an important factor in the teaching of Natural Sciences. Authentic learning experiences (Schwartz et al 2004) insist on the importance of teaching sciences within a framework of real investigation processes, thereby creating real problem-solving opportunities for students. In 2011, King, Winner and Ginns pursued this work by proposing a context effect based learning approach. The students' natural environment is the context emphasized in this study. It is the framework of their research which also enables the construction of contextual learning that is in close connection to the students' environment. The limit in this approach lies in the risk that students construct representations that are very contextualized, for which they are unaware of. Tardif, (1999) suggests viewing learning as a transfer between contextualized knowledge, de-contextualized knowledge and re-contextualized knowledge. This learning model resituates the relationship between learning and context with respect to the students' representation. Zimmermann & al (2004), links these two types of contexts under the terms internal (links to conceptions) and external (links to environment) and is interested in the relationships that can exist in instances of communication. This article proposes teaching methods in the science field, that will take into consideration external as well as internal contexts, while allowing students carrying out an inquiry in their external context to construct through their exchanges and collaboration on conceptions that are not limited to their contexts. A context effect is an event that arises during a teaching/learning relationship between two actors. If the effects of contexts were first presented as an obstacle to learning, the teachings described in this text aim to provoke them in order to express the different students' conceptions during collaboration.This event is related to the difference between their internal contexts. It may be expressed as different manifestations of emotions (laughter, conflict, incomprehension) and lead built more complex scientific conception.

Principles and design modalities in an iterative approach

Education based on the emergence of context effects has been put in place on several scientific themes. Knowing different observables between Guadeloupe and Quebec: the concept of adaptation of frogs (tropical arboreal or pond), fruit (i.e. apple and banana), agricultural production of sugar (maple syrup and cane sugar) and the exploitation of geothermal energy according to the geological contexts.These interactions have been of 2 or 3 months duration have allowed learners of primary, secondary and higher education to collaborate during scientific investigations. The results show different modes of emergence of context effects.

These effects of contexts differ by the external contexts involved, by the moments of emergences during the inquiry and by the emergence modalities. Numerous learning has also been demonstrated, and expert representations appear.

Methodological issue

Design-Based Research (DBR) is a well-recognized methodology for its relevance in design projects of technological environments in education Anderson & Shattuck (2012). As its name indicates, it is inspired by the science of design, and is oriented towards the design of artifacts; it brings together theoretical concerns and field considerations for the development of solutions.

Inspired by Brown (1992), the founding works (Barab and Squire, 2004, Wang and Hannafin 2005), were quickly adapted to the questions of science education (Sandoval and Bell, 2004). The DBR has been built around two characteristics. The first is the twofold goal: the advancement of theoretical knowledge and the iterative conception of a solution, the two elements being considered as a single whole. The second characteristic is the in situ mode practiced both in terms of collaboration with the actors in the field and for the tests and micro-experiments conducted during the different phases.

The mixed methodology uses to collect data on each iteration include analyzing of texts produced by students, pre-test and post-test interviews, and videoconference recordings. The phenomenon of context effect has been described as a process of cognition expressed during interactive sequence with strong emotional dimension (incomprehension, surprise, satisfaction).

Principles and Learning scenario

In order to bring out a lot of context effect, a number of principles can be proposed: choosing students who can collaborate with each other, maximize external contexts opposition, allow students to develop contextual conceptions, compare its to conceptions build in a different context and then integrate it's to build a more complex conception, dependent on the contexts and more aware of the limits and generalities of the concepts. The modalities of the learning scenarios are based on these principles (table 1).

Table 1. Principles and learning scenario

Learning Scenario	Principles
Objects of scientific study that are observable and part of the students' environment	Different external contexts
A common problem for all students	Collaborative students: levels close but not necessarily identical
Small work teams	
Students who can introduce themselves, meet	
Field investigation	Buid contextual representations
development of a particular methodology	
Writing a response proposal in each context	
Multiplying moments of collaboration	Confronting contextual representations
Alternate working moments in context and synchronous and asynchronous exchange times throughout the project	
Present findings synchronously to peer teams	
Metacognitive phase and explanations of the representations of each other	Build together expert representations

Learning model and contextualized conception

Teaching that is based on the emergence of context effect is an innovative teaching method based on the collaboration between students carrying out field investigations in different contexts. In the examples studied. Many learning opportunities occurred and seem to be structured according to two axes. First, the students acquire specialty competencies while carrying out a study within their own context. Then, after a collaboration with the other teams from the other context, the students build expert responses that are characterized by a more complex approach with respect to concepts (diversity of situations) and a better description of the limits of these concepts. Those experiments also allowed observing and describing in-situ context effects.

The "CLASH" model used in these learning situations is based on a shock of internal contexts and gives a significant place to contexts in learning. This generic model was originally designed to be applied to environment learning. By placing students in inquiry, field observation, data collection, and then confronting them with the results of a peer team in a different context, these students are challenged when faced with differences in context for the same object of study.

In keeping with the concept of situated conception (Clément, 1999) wich is expressed according to the conjunctures, the conceptions in the natural sciences are also contextualized : they are constructed with respect to the observal nature by integrating the diversity studied environments. Hence the question of the uniqueness of a relation between a general model and a particular example derived from the epistemology of physics might not be optimal for understanding naturalistic concepts.

COGNITIVE ELEMENT ANALYSIS IN LEARNERS' DRAWINGS

Specific theoretical framework

Conceptions may correspond to a system of interactions between knowledge structures, value systems and social reference practices of individuals (Clément, 2010). The context-based approaches (King, Winner, & Ginns 2011) emphasize the importance of including learners' environment in teaching, in order to promote a better understanding of the world in which they live and also to improve their motivation. Context effects-based pedagogical approaches therefore insist that contexts and conceptions be an integral part of the learning process. In order to set up these approaches, it is necessary to clearly identify learners' initial conceptions, as well as contextual differences that may exist between various geographical areas, with respect to the studied object. The West Indies are volcanic islands resulting from the subduction of the North and South American plates under the Caribbean plate and they thus have significant geothermal activity. The involvement of local actors in the development of this energy industry presupposes its integration in education. The present study focuses on learners' conceptions in three Caribbean territories, that in spite of a relatively close geological context, present different geothermal contexts and uses of geothermal energy. In Guadeloupe, a geothermal power plant located in Bouillante city produce 8% of the island's electricity. In

Dominica, despite a proven significant geothermal potential, no geothermal power plant exists. However, several boreholes were drilled between 2011 and 2014. Finally, in Martinique, some exploratory studies were carried out, but there is currently no geothermal facility. Our study aims to examine the relationship between learners' conceptions on a geothermal topic and the local contexts in which they are living. Furthermore, the study of geothermal energy is of interest in the field of science teaching since it is related to many general scientific and technological concepts such as energy, geology and technology.

Methods

A questionnaire survey was carried out in three islands of the West Indies (Guadeloupe, Dominica and Martinique) with a representative sample of 14-15 year-old students for a total of 1349 individuals (496 students in Guadeloupe, 372 in Dominica, and 481 in Martinique.) The questionnaire had several open-ended and closed-ended questions. Students were also asked to draw a geothermal power plant. In order to analyze those drawings, an initial list of 18 elements was first established. These elements, although directly referred to concepts related to geothermal energy, were also elements commonly found in drawings, even if they were not directly related to geothermal energy. Sometimes they were easily identifiable objects (volcanoes, crust, mantle or core, thermometer, etc.) or concepts that we believe contribute to a complete understanding of geothermal energy and its industrial production process (transformation, exchange, use or distribution). Coding was done according to the presence or absence of the elements in the drawings and some elements were regrouped, such as those related to renewable energy (wind turbines, solar panels, etc.). To avoid an errroneous analysis, a validation of the coding was carried out (Ehrlén. 2009).

Results

A descriptive analysis of the drawings reveals differences in students' views between the three islands. The most represented elements in the three islands are: ground, heat, tubes, and plants. In addition to these four elements, the most represented element in Martinique is: renewable energies, in Guadeloupe: transformation, and in Dominica: nuisance. Some drawings illustrating these specificities appear in Figure 1.

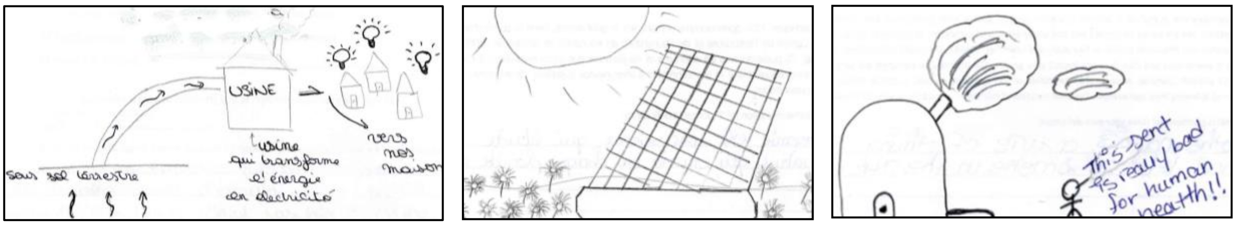

Figure 1. Examples of drawings from each island (from left to right: Guadeloupe, Dominique, Martinique).

Different methods, such as the Multiple Correspondence Analyses (MCA), were used (Figure 2): At the top left (in blue), are the grouped points corresponding to elements referring to renewable energy (wind turbine, solar panel, hydroelectricity…). Martinique is situated in this blue area. It is also very close to the "individual" element which is also represented in the drawings that illustrate individual uses in the form of heat or hot water. Guadeloupe is in the second zone (in orange), which groups together the elements that correspond to a representation of the soil, a plant, heat, nuisance, tubes, groundwater, a turbine, electricity and distribution. Guadeloupe students have a more industrial and technical perception of geothermal energy. They are also the ones who drew the most elements. Finally, the last zone (in green), includes the elements: earth, human, volcano and boreholes, as well as Dominica Island. The idea of human exploitation of a volcanic resource is well established in Dominica. According to this analysis, Martinique students have conceptions related to the environment and renewable energies, whereas Guadeloupe students' conceptions are related to industrial activity and Dominica students' conceptions are related mainly with respect to human exploitation of a volcanism resource.

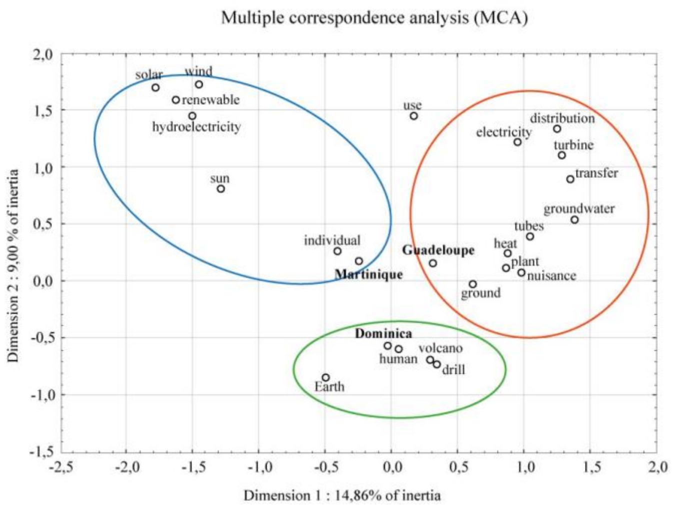

Figure 2 : MCA analysis between Guadeloupe, Martinique and Dominica

Observations from the analyses of the students' drawings highlight three main elements: (1) Very few students were able to include in their drawings more than two elements directly related to geothermal energy. This indicates a lack of knowledge in this area. (2) The MCA analysis reveals that conceptions are different depending on the island. (3) Others MCA analysis show that students from the same island have similar conceptions. In Guadeloupe, the presence of a geothermal power plant is well known by students. Conceptions are thus linked to the industrial aspect of the resource. In Dominica, despite efforts to exploit the resource in recent years, no facilities have been created. In addition, the media setbacks related to exploitation difficulties may have tarnished the image of this industry. The transcribed conceptions are related to the harmful aspect of the resource. Finally, in Martinique, because of the lack of geothermal facilities, students mainly describe the renewable aspect of the resource, and link it to the environment. These differences in learners' prior conceptions of geothermal energy are essential considerations. They can serve as a support for the setting up of pedagogies involving pupils from the three islands, such as those based on context effects.

ELABORATION OF A MODELING TOOL FOR THE CONTEXT EFFECTS BASED TEACHING

This part presents a research project in science education that is positioned at the intersection of computer science and context in learning. The main objective is to create a software tool that will participate, from the inception to the achievement, in the design of a leaning scenario, based on context effects. To this end, the software will allow to compute context differences between two learning environments. Input data include a chosen set of parameters, specific to the phenomenon or object that students are expected to explore in each learning context. The calculator has been elaborated according to the design based research theory. It is to be used in dynamic learning situations, with several iterations including field experiments, in order to collect comparable data in each context.

Specific theoretical framework

Our study focuses on the contextualization of science education involving fieldwork. Context is defined here as everything that surrounds an object and that has connections with it. Our main objective was to create a software tool, in order to support the design and development of context-sensitive tasks, inside a chosen learning scenario, by considering Context Effects (Forissier, Bourdeau, Mazabraud, & Nkambou, 2014). This software allows to provide several external contexts instantiations (Van Wissen, Kamphorst, & Van Eijk, 2013), in relation to the scientific object of study, and to compare them in order to predict the emergence of Context Effects. The software tool compares two geothermal learning contexts modeling, in order to highlight the points or concepts that show differences between the two contexts in that specific field. Using this comparison, one can bring to light significant differences and take advantage of them for the construction of a context-sensitive learning scenario. Learning is expected to happen more efficiently due to the gaps between contexts that may enrich learners' interactions within and between the two contexts. Our position is that context gaps during student's collaboration are what create context effects. Teaching based on context effects is an innovative approach in science education and allows students to develop rich and complete conceptions, and to open their minds to very different world contexts.

Methods

Taking into account contextual sensitivity in science teaching is important, especially if one targets inter-or trans-contextual educational activities. To enable this, we have designed a tool called Mazcalc which can be used when the object of the study is context sensitive. While using Mazcalc, the user is progressively led to model contexts and calculate their differences (context gaps) according to a built-in method. Four user profiles (four access levels) are supported, each related to a specific role: (1) cognitive computer scientist, (2) context and content modeling expert, (3) instructional designer, and (4) teacher. Each role has access to the appropriate tools to produce the resulting artifact: configured system and meta model (ontology), general and specific context models, context gaps and pedagogical scenario, and trans-contextual training activities.

A context is always defined with respect to the object of study. For this study, geothermy was used as the use-case for validating our tool. The object of study is represented by a model of context consisting of a set of parameters to which a variable is assigned, for each context modeled. The parameters have properties, which define the rules that will be applied for the gap calculation. They can be composite, dependent or independent (if they are composite, the parameter value assignation gives rise to a new parameter that, depending on the first one, can give rise to another composite parameter, forming a tree where values by level are weighted). Parameters' variables (ordinal or nominal) are either qualitative (fuzzy) or quantitative (numeric). They can also be continuous or discrete. Usually, a parameter is part of one or several groups of context parameters called, families.

The expert must first specify the relevant set of parameters of the object under study, whatever the context. As previously said, these parameters can be grouped into families and have scales (domain) of values that can be numeric or fuzzy. Once such a general model is specified, it can then be instantiated in one or more contexts (specific models). During the instantiation, the subset of the relevant parameters is determined and their values for the context are specified. It is possible to extend the subset of the parameters by adding new parameters specific to this context. It can follow a resolution that would include these local parameters in the model under certain conditions. The computation of the context gap is a process of alignment between two or more instances of context that highlights the differences between the parameters, and therefore the difference between the models. The calculation rules used vary according to the nature of parameters (variables and their current values). The overall result is viewable in several forms and can also be transmitted to a host system that uses Mazcalc services. The prototype was implemented as a user-friendly Web application leading to the current version of the tool (Psyché et al., 2018). An application programming interface (API) version of the tools is currently under development and will make it easier to connect Mazcalc services with any application where context-gap is to be considered. In the following section, we describe how the tool has been used for 'geothermal energy' as the object of study.

Context gaps computing for geothermal energy

In this section, we discuss how the Mazcal has been used for creating a context model of the geothermal energy concept, in Guadeloupe (French West Indies) and in Montreal (Quebec). The Caribbean Islands are located in a subduction zone, creating a great potential for geothermal energy. In Guadeloupe, this potential is harnessed, in Bouillante, and a geothermal power plant uses the groundwater heat. In northeastern America, the bedrock mainly consists of ancient Precambrian rocks from the Canadian Shield, which does not allow electricity production. There, the geothermal heat is used to regulate the temperature in buildings, to create spas and to grow crops. It is called low temperature geothermy.

We first specify a general context of geothermy by setting a number of relevant parameters into Mazcalc. Two specific context models are then created, making possible to easily compute context gaps between Quebec and Guadeloupe. Variables are assigned to the parameters, related to the expected context model for each context. The contexts gaps' values provided by the calculator can be plotted on a graph and provide a qualitative and quantitative support to teachers about what is different between the two contexts. They can thus be used as a support for the creation of pedagogical scenarios based on contexts effects. In fact context effects are expected to emerge during interactions between students in relation with the parameters for which gaps between the two contexts are important.

CONTEXT EFFECTS IN COLLABORATIVE LEARNING: VERBAL AND NON-VERBAL INDICATORS

In this part, we propose to analyze the interactive dimension of the manifestation of context effects in learning, focusing on both verbal and non-verbal indicators. In the following sections, we mainly analyzed between group verbal exchanges and within group affective dynamics to detect the so called “Eureka effect” happening when contrasting contexts induce debates and understanding.

Verbal indicators

« Collaboration is a coordinated, synchronous activity that is the result of a continued attempt to construct and maintain a shared conception of a problem » (Roschelle & Teasley, 1995, p. 70). Collaborative interactions concern ideas, representations, understanding and grounding (Schwarz & Baker, 2017). From this definition, researches on collaborative learning have investigated the role of communicative interactions to achieve a task and co-elaborate knowledge (Schwarz & Baker, 2017). Studies focus specifically on debate in which argumentation in interaction is engaged in order to answer a specific question by purely verbal means (Baker et al., 2007). Two main processes of creation of knowledge are associated with debate: the production of arguments or counter-arguments and the negotiation of meaning (Baker, 2002). According to this approach, we propose a model to analyze knowledge-building process in collaborative learning based on context effects.

We transcribed and analyzed several moments with a context effect on the TEEC corpus. We identified four steps on how knowledge is co-elaborated between groups in relation with a context effect (Figure 3). The context effect begins with a question asked by the teacher or by a learner (step 1). The question typically concerns knowledge and representations about concepts (e.g. functioning of a heat pump) that are necessary to pursue the common task. The question provokes debate where verbal indicators of context effect can be observed (step 2): comparison between the two contexts (e.g. “we use a heat pomp for that, you use it for that”), negotiation of meaning (e.g. “it is functioning like this because”) or argumentation (e.g. “you are wrong, it is functioning like this”). The debate leads to the understanding of the difference between the two contexts (step 3). We observe a typical verbal expression as “ah, okay” or “ah, I understand” (e.g. “ah okay, it is because the temperature of the water is different”). There may have back and forth between the first three steps if the concept is not totally understood and/or if all the learners did not understand it. In such case, we observe learners who have understood the gap between the two contexts explain it to those who dit not understand it. This leads to the distribution of knowledge between learners and to the mutual understanding (step 4). Verbal indicators for mutual understanding are paraphrases and reformulations as well as expressions of a common approval (e.g. “we all agree to say that...”).

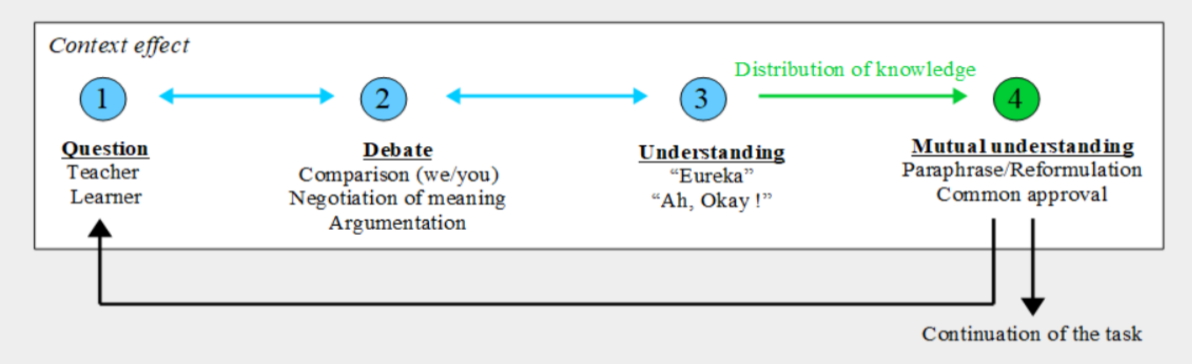

Figure 3. Model of the interactive dimension with context effect.

Non verbal cues

These last decades, affective computing has drawn more and more attention from many research communities: computer science, psychology, neuro-science, etc. It was defined as "computing that relates to, arises from, or influences emotions or other affective phenomena" (Picard, 1997). The general name of "socially aware computing" was introduced later (Pentland, 2005). In fact, there is more than words in social interactions: non-verbal behavior convey information about feelings, mental state, personality, and other traits of people. This happens through a wide spectrum of non-verbal behavioral cues like affective/cognitive states and conversational regulators.

A potential "Eureka effect" seems characterized by several affective states (and their corresponding cognitive states): (a) active listening or lack of understanding/frustration, (b) understanding/surprise followed by happiness and (c) mutual understanding (cognitive and emotional propagation). Figure 4 illustrates these three states. Of course, all these emotional states are more or less subtle due to the extravert/introvert disposition of learners. These information are collected by analyzing the internal dynamic of learner's faces. But other cues (the so-called conversational regulators) can also be meaningful: (a) head pose (when learners turn toward each over) and mouth movements indicate potential turn taking, (b) head nod (resp. shake) indicates that learner agrees (resp. disagrees) with another one and (c) body movements can indicate either surprise or disengagement.

We use the following pipeline to extract low level information (i.e. faces and face poses, facial landmarks) and infer high level indicators (emotions and turn takings). We use *face_recognition* (Geitgey, 2016) to give an Id to each learner in the first image of the sequence. Then, we perform spatial face tracking throughout the sequence. We get 3D facial features, including face pose and facial landmarks using *PRNet* (Feng et al. 2018). We also use the latter to analyze who is talking and when in the video. Finally, we infer emotions using *Emotion-recognition* (Ayman, 2018).

Figure 4. "Eureka" effect. State 1: active listening. State 2: understanding. State 3: cognitive propagation.

At this point, the methods presented in this paper are under development, but several correlations have already appeared. In the next few months, we will use them to treat various corpus of data in order to refine them. We also plan to cross verbal and non-verbal analyses and deliver a global analysis tool.

CONCLUSION

At the end of this paper, contexts effects learning appears as an innovative method based on intercultural collaboration during comparison of the natural contexts of the students involved. It is technologically equipped with a context gap calculator. It provide knowledge on the close relationships between scientific concept and the natural contexts on the example of geothermal energy. The concept of contexts effect, originally defined as an event during conceptual changes, is today conceived through two other dimensions: a psycho-affective event (eureka effect) and a sequence of didactic interactions.

Science Teaching Processes

Co-editors: *Sabine Fechner & Roald Verhoeff*

CONTENTS

STRAND 3: INTRODUCTION

SCIENCE TEACHING PROCESSES

In this chapter the relations between particular teaching practices and students' cognitive and affective development are explored. Inquiry-based teaching receives ongoing attention as an inspiring way of learning science. 4 studies in this chapter focus on designing inquiry-based activities and supporting teachers to guide these:

Moreno, Mas and Skorsepa studied students' understanding, interest and difficulties in Physics within the context of a specific inquiry-based activity using Microcomputer-Based Laboratory. 150 students aged 13 to 18 were asked to model traffic speed detection by a sensor and study the graphs produced. Although students perceived difficulties in working with the sensors and graphs, they did enjoy working with them.

Jimenez, Hamed, Lederman and Lederman present the results of a validated questionnaire measuring Spanish students' and pre-service teachers' understandings of scientific inquiry. The authors emphasize the presence of a positivist perspective of science among middle and high school students and pre-service teachers. They argue that more attention should be paid to student-centered approaches that promote "understanding" of scientific inquiry instead of only "doing" scientific inquiry.

Rivero and Lewis consider science teachers' reflection as a necessary practice for teacher preparation programs and schools to improve teaching through inquiry-based instruction. Their multi-methods qualitative study describes the reflective practices of 15 novice teachers in a Midwestern US city and the factors that support or limit these practices.

Teichrew and Erb focus on modelling as the basis for experimenting and interpreting collected data in scientific inquiry. They present an open online learning environment to prepare students for experiments in optics in which no precise learning steps are specified. The authors show that such open inquiry learning should go hand in hand with an instructional design that engages students in a purposeful experimentation process.

Several studies refer to science as a difficult school topic that may even raise feelings of anxiety among students. 3 studies in this chapter explicitly focus on such affective aspects of science learning:

Kirmizigül and Kaya follow the definition of anxiety as the total of negative experiences such as failing to solve a science problem or failing a science exam. Within the context of the course on "Reflection in Mirrors and Absorption of Light" their quasi-experimental design compared computer-aided instruction with hands-on activities in terms of the effect on students' anxiety levels.

A diagnosis of difficulty-generating characteristics in physical problems is offered by Freese and Winkelmann. For the reader the main difficulties may sound familiar, e.g. an increased share of scientific language, mathematization, modelling or a lack of reference to everyday life. Students themselves were found to experience problems in formulating concrete difficulties and in asking for targeted support.

Energy has also been reported as a difficult and less attractive topic. Toli and Kallery developed an intervention including experimental hands-on activities, outdoor activities, problem solving situations and software to enhance secondary students' interest in the topic of energy. Their efforts paid off as they indicate a strong positive correlation between high levels of interest and levels of engagement and academic achievement.

Teachers face challenges on a daily basis as they try to connect the curriculum requirements with a diversity of individual students' needs and difficulties. studies in this chapter explicitly address a variety of such teacher challenges:

Pawlak and Gross take on the challenge to develop inclusive chemistry classrooms. Creating a safe and supportive environment for all students that do hands-on experiments appears as one of the major concerns that teachers have. From their explorative study, the authors conclude that establishing rules and routines are key to inclusive chemistry lessons.

Thomas argues that teacher professional development can learn from insights in teachers' procedural metacognitive knowledge. Based on interviews with sixteen science teachers and twelve pre-service science teachers the author sketches a varied picture of teachers' metacognitive abilities and stimulates the debate on this understudied area.

Two contributions report on studies that focus on bringing specific science topics into the classroom.

Zloklikovits and Hopf present a teaching-learning sequence to introduce electromagnetic radiation in the eighth grade. They guide the reader through their iterative design cycle of implementation and evaluation that they did with individual students and address difficulties in students' conceptual understanding of 'heat', 'radiation' and 'energy'. Santini, Bloor, Quilio and Sensevy address the issue of teaching and learning a phenomenon that isimpossible to get into classrooms; earthquakes. Based on the Joint Action Theory in Didactics, the authors present a collaborative designing process in which they devised a simulation that confronted students with a genuine aspect of seismology.

The three final studies in this chapter offer a creative perspective on science education and offer insights in narrative-, art- or play-based teaching methods. Canducci and Demartini aim to promote learning of physics by organizing and managing content as narrative structures or 'conceptual stories'. They provide a story on the conservation of energy and the Copernican revolution and analyze and reinterpret the typical elements of narration in such conceptual stories. They conclude that narratives stimulate curiosity and involvement and help students to deeply internalize scientific information, improving long-term scientific literacy.

Mutvei, Tobieson and Mattsson report on a chemistry course for future primary school teachers that included hands-on exercises, group discussions and aesthetic learning processes sessions. Their approach based on intermodal art theory and the philosophy of phenomenology engaged participants in a variety of learning situations, including the making of art. The authors argue that this promoted creative thinking and deepened the students understanding of chemistry, which empowers them for their future

profession as teachers.

Adriana Cardinot and Jessamyn Fairfield provide an overview of their workshop on a play-centric approach to science education. The challenge they present is to design a gameplay in which learners enjoy the play while they also absorb and embrace the science involved, e.g. astronomy. A 7-step design strategy is presented to take up this challenge.

Roald Verhoeff & Sabine Fechner

RESEARCH-BASED PHYSICS USING SENSORS AT SECONDARY: STUDENTS' CHALLENGES AND DIFFICULTIES PERCEIVED

Montserrat Tortosa Moreno[1], Fina Guitart Mas[2], Marek Skorsepa[3]
[1]AIREC Associació per a la Recerca Educativa en Ciències, Sabadell (Barcelona), Spain,
[2]Universitat de Barcelona, Barcelona, Spain
[3]Matej Bel University, Banská Bystrica, Slovakia

The analysis of students understanding and perceptions on interest and difficulties faced in the implementation of an Inquiry Based activity using Microcomputer-Based Laboratory in Physics at secondary school is presented. The activity is contextualized in the traffic and speed of vehicles. The analysis using SPSS software of a perception post questionnaire answered by 150 students of secondary school (aged from 13 to 18) is presented. Conclusions showed students' perceptions on the most engaging parts of the activity, and also revealed difficulties that they have.

Keywords: Inquiry-based teaching, Data Logging, Secondary school

THEORETICAL BACKGROUND

Microcomputer-based laboratory (MBL, Thornton, 1990) allows students to work out many features of science competencies, having a quick and continuous interaction with new learning that they acquire. Since 1980s, a number of benefits of experimenting with sensors and computer devices for science education has been identified. One of them is still considered the most powerful element: simultaneous graphical representation of real-time measuring (Brassell, 1987; Barton, 1997; Beichner, 1990). Moreover, the proposal of MBL instructions presented as an inquiry-guided activity (IBSE) and structured as a learning cycle has revealed to be effective in achieving significant learning (Pintó & Hernández, 2010; Tortosa, 2012; Ye, Lu, & Bi, 2019). There is empirical evidence that with the implementation of inquiry-guided MBL activities, the perceived competence and interest of students and the enjoyment reported by learners are highly correlated (Urban-Woldron, Tortosa, & Skorsepa). Nevertheless, significant differences about its efficiency in the classroom among different laboratory activities, have been detected both on students and on teachers' perceptions. (Guitart, Stratilova-Urvalkova, Smejkal & Tortosa, 2014, Skorsepa & Tortosa, 2014). A fine analysis on single activities is desired to delimit the potential of this methodology.

AIM OF THE STUDY

The context of this study is a European research project finally aiming at supporting science teachers for integrating MBL activities into science classrooms. The purpose of the study was, after performing a Physics activity, to investigate the following research questions:

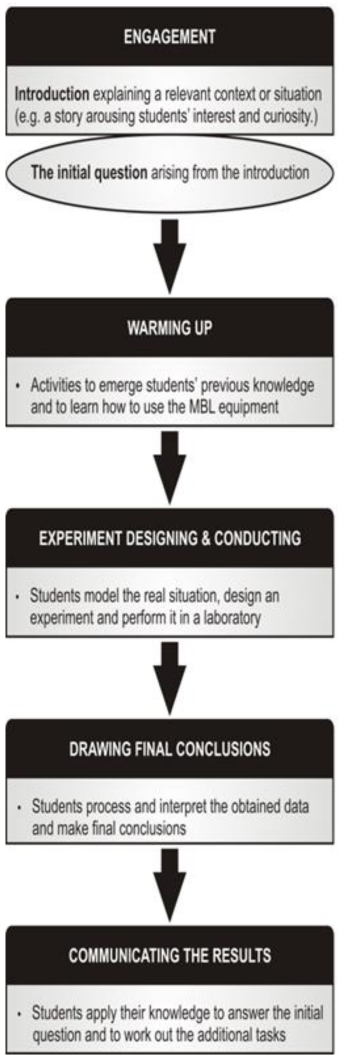
1. Do students identify the objectives of the activity?
2. What parts of the activity do students perceive as the best ones?
3. What kind of difficulties do students perceive in this activity?

METHOD

The activity

The Physics activity reported is contextualized in the traffic and speed of vehicles, students must work to answer the question: How can a radar know the speed of a car? Students are guided to model the situation in the laboratory walking themselves in front of a sensor of distance and studying the graphs produced. From their results students must be able to answer the proposed question. The activity reported is "Average speed control - how to detect the speed of a moving car?" (available at www.comblab.eu , COMBLAB Project, 2012). It was designed with the research-based framework of COMBLAB activities (Tortosa et al, 2013). Figure 1 shows the framework of COMBLAB activities in relation to the Physics activity that students performed in this study.

In the experimental part, the activity has the potential to encourage students to "play" like scientists as they are led by a POE (predict-observe-explain) didactical sequence (White & Gunstone, 1992).



The activity begins in the context of speed control on roads, specifically with a relatively new speed technique called section control, or point-to-point control, that is a control of the average speed. Students are asked to answer the questions "How do policemen find out if somebody drives too fast?" and "Do you have an idea of how it is possible to find out the average speed of an object if the vehicle is detected when enters the section, and when it leaves it?"

Students use a motion detector that plots position-time graphs of their body. They predict the graph in relation to their movement. They perform the movement and realize the difference between they move slowly or quickly, and when they move towards or away from the motion detector. They also get familiarized with the equipment and learn about how to us it.

Students walk and collect data when they walk with different constant speeds. They first predict the shape of graph and then they plot graphs of their motion with sensors. Experiments and data collection are scaffolded for students at lower secondary school and would be less guided for older students.

Students make calculations with the obtained data. They are asked to calculate the average velocity by using the position-time graph registered by the equipment. This part is scaffolded by given tables to fill in with data and calculations. At the end they write an explanation about how the average velocity of an object can be calculated from the position-time graph. They also explain how to walk to match a given graph and finally they draw their conclusions.

Students answer the main questions of this activity in the initial context. They are asked to write an explanation about how the average speed of a car can be found out and what physics magnitudes are required to measure to de detect the average speed of a moving car using the section control or point-to-point control technique.

Figure 1. Research-based framework of the COMBLAB -MBL activities and description of the performed activity

Participants and setting

The activity was implemented with 150 students aged from 13 to 18 (80 males), by their Physics teachers in three secondary schools in the area of Barcelona (Spain). The three secondary teachers received two sessions of teacher training on microcomputer-based laboratories and on Inquiry-based science before implementations Distance sensors were provided to schools if they are not used in their classrooms. A post questionnaire on the activity was answered by students after implementation. Data were collected from these questionnaires that included 19 items. Four items were chosen to be analysed in this article. These 4 items are mentioned in this work as items 1, 2, 3 and 4:

1. I understood the objectives of the activity.
2. List the objectives of the activity
3. What parts of the activity did you like the most?
4. What parts of the activity did you find the most difficult?

In ITEM 1, students chose from a four-level Likert scale ranging from: 1 (strongly agree) to 4 (strongly disagree). Students could add comments if they wished. Questions two, three and four are open questions and data had been analysed by categorizing of the open answers.

In ITEM 2, answers have been categorized from 1 (good content and good context), 2 (good content or good context), 3 (insufficient answer) and 4 (totally erroneous answer). A second order categorization was established for categories 1, 2 and 3, to analyse if students' answers are more related to the Physics content or to the context or they are not related to science.

In ITEM 3, a first order categorization attending the feelings (positive, neutral and negative) expressed by the students has been made, and a subsequent second order categorization was performed to determine the kind of action (making, thinking, observing or other) related to that feeling.

In ITEM 4, a first order categorization has been made to determine the kind of difficulty expressed by students in terms of action (making, thinking, observing or other) and a second categorization for the topic of justification (it includes 12 categories related to MBL, lab work, design of experiments, interpreting the graphs, or filling in the worksheet)

RESULTS AND ANALYSIS

Data were analysed in several statistical ways using IBM SPSS software (IBM Corp., 2010): descriptive statistics, analysis of frequencies and comparative analysis (e.g. gender). Non-parametric Mann-Whitney U test (for ordinal data) and chi-square test (for nominal data) were used in comparative analysis (significant level .05).

Most students (92.1%) perceive that they understand the objectives of the activity (M =1.74; SD = .641; N(valid) = 139) as they totally agree (35.3%) or agree (56.8%) with the statement in ITEM 1 (Figure 2a). Nevertheless, when students were asked to list the objectives of the activity (Figure 2b), most of them (54.6%; M = 2.8; SD = .571; N(valid)=110) provided not sufficient answer. That is, students overrated (or overestimated) their opinion about how they understand the objectives of the activity. In fact, only 24.5% of them reported objectives of a good content or context or both (content and context). Only 1.8% of students reported both, good content and good context at the same time. On the other hand, 22.7% of respondents provided either good content or a good context but not both of them, where about 2/3 of answers were related to good content and 1/3 to good context. It is obvious from the analysis of frequencies that most students answered insufficiently when listing the objectives of the activity (69.1%). The complete second order distribution of responses to ITEM 2 is depicted in Figure 3. Mann-Whitney U test (ITEM 1, $U = 2\ 377$; $z = .139$; $p = .890$) and chi-square test (ITEM 2, $p = .225$) revealed no differences in responses by gender.

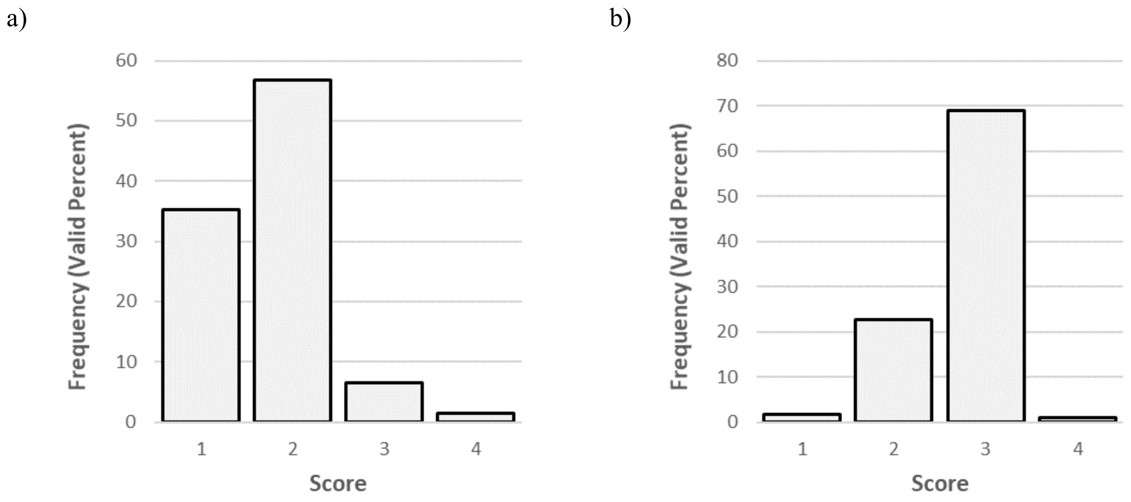


Figure 2. Frequencies of responses to ITEM 1: *I understood the objectives of the activity* (a) and ITEM 2: *List the objectives of the activity* (b)

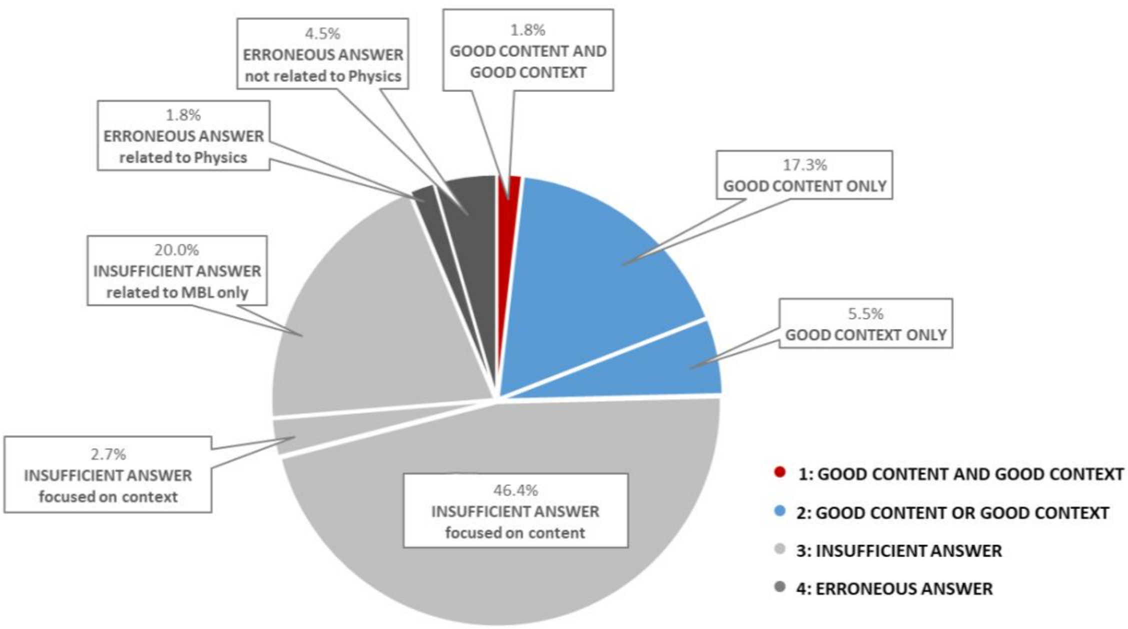

Figure 3. Second order distribution of responses to ITEM 2: *List the objectives of the activity*

It is also important to note that the results mentioned above are based only on valid answers. However, we have accounted 41 respondents (27.2% of total cases) who provided no answer in ITEM 2. During the statistical treatment, these cases were classified as missing values but it is still questionable whether the student with no answer didn't know the answer (to list the objectives) or he/she just ignored answering the item.

In the answers to ITEM 3, most students expressed positive (34.1%) or more or less positive (neutral) (59.3%) feelings. Second order analysis of the responses revealed that students of both groups mainly preferred "making" (88.1% of students with positive feeling and 87.7% of students with neutral feeling). "Thinking" and "observing" where less frequently attractive for the students of both types of feelings expressed (Figure 4).

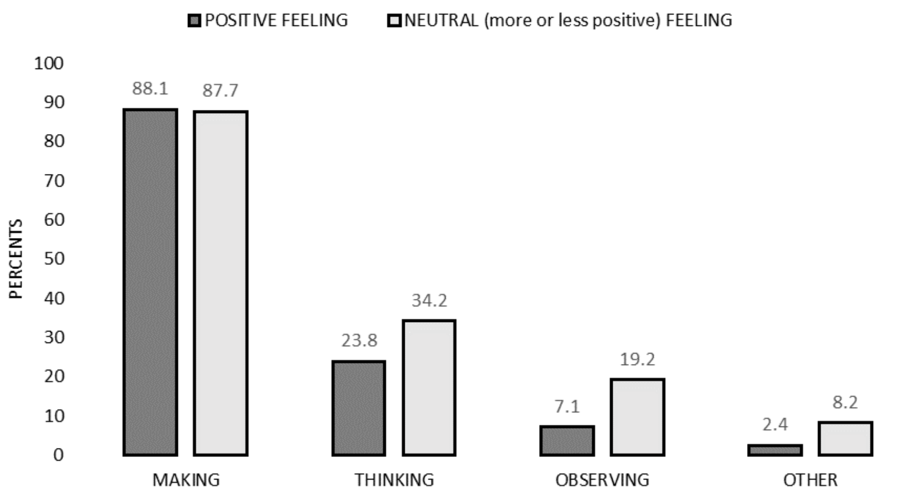

Figure 4. Second order distribution of positive and neutral (more or less positive) students' feelings in ITEM 3: ***What parts of the activity did you like the most?***

Moreover, almost 90% of students with positive and more or less positive (neutral) feeling justified their answer and the analysis shows (Figure 5) that they favoured mostly "working with graphs" (45.0% of students with positive feeling and 58.1% of students with neutral feeling) and "working with sensors of MBL" (37.5% of students with positive feeling and 52.5% of students with neutral feeling). Notice that each student could provide (and mostly provided) more categories of action (making, thinking etc.) and more categories of justification of his/her feeling. This is why the number of responses in second order analysis of students' feeling and its justification extends the number of respondents involved in the study. Again, similarly to ITEM 2, it is still questionable if students who didn't expressed any feeling (28 missing values, almost 1/5 of all cases) didn't want to provide their answer or didn't like anything related to the activity. We have also encountered 8 negative feelings (6.5%). However, none of them was justified, so it is impossible to analyse the reasons.

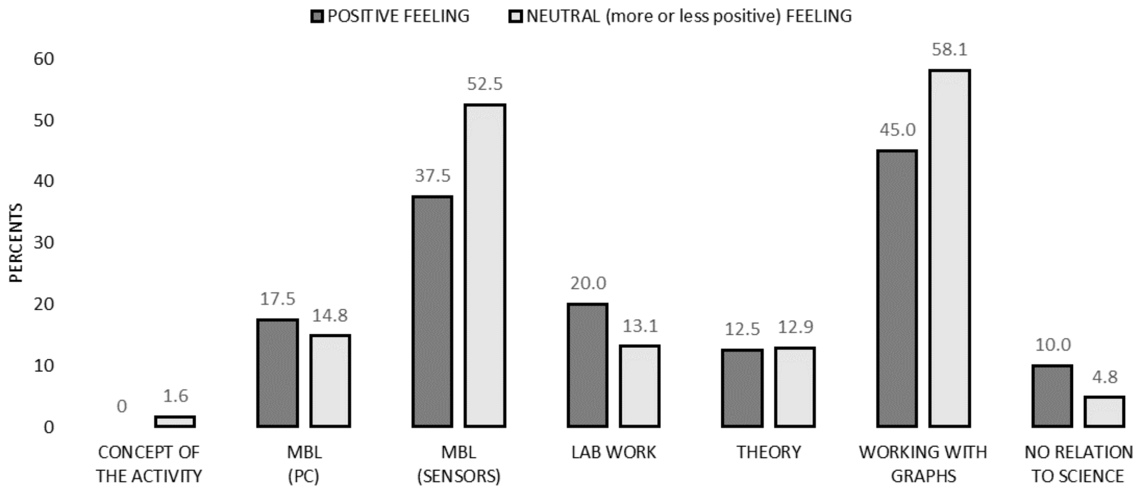

Figure 5. Justification of positive and neutral (more or less positive) students' feelings in ITEM 3

Our records in ITEM 4 show that 89 students (58.9%) reported some difficulties during performing the activity. The analysis of frequencies of difficulties reported (Figure 6) reveals that most of them are related to "thinking" (87.6%). However, more than 1/4 of the valid answers reported difficulties in "making" as well.

The categories in which students reported their difficulties are shown in Figure 7. If we don't take into account that students reported "filling in the questionnaire" as the most difficult thing (the questionnaire for collecting feedback from the respondents), it is interesting to find out that working with graphs was considered difficult in 43.1% of cases. The other difficulties reported were related to the theory (25.0%), explaining and interpreting (19.4%), and only 11.1% working with MBL. Other categories, as designing the experiment, predicting the results, and filling in the worksheets were not reported so frequently. Gender was found a factor not generating the statistically significant difference, as the chi-square test ($p = .151$) revealed no divergence between male and female students in how they perceived potential difficulties.

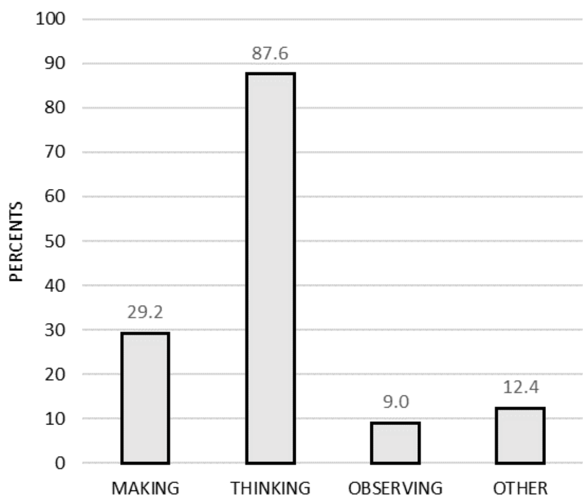

Figure 6. Difficulties of students reported in ITEM 4: ***What parts of the activity did you find the most difficult?***

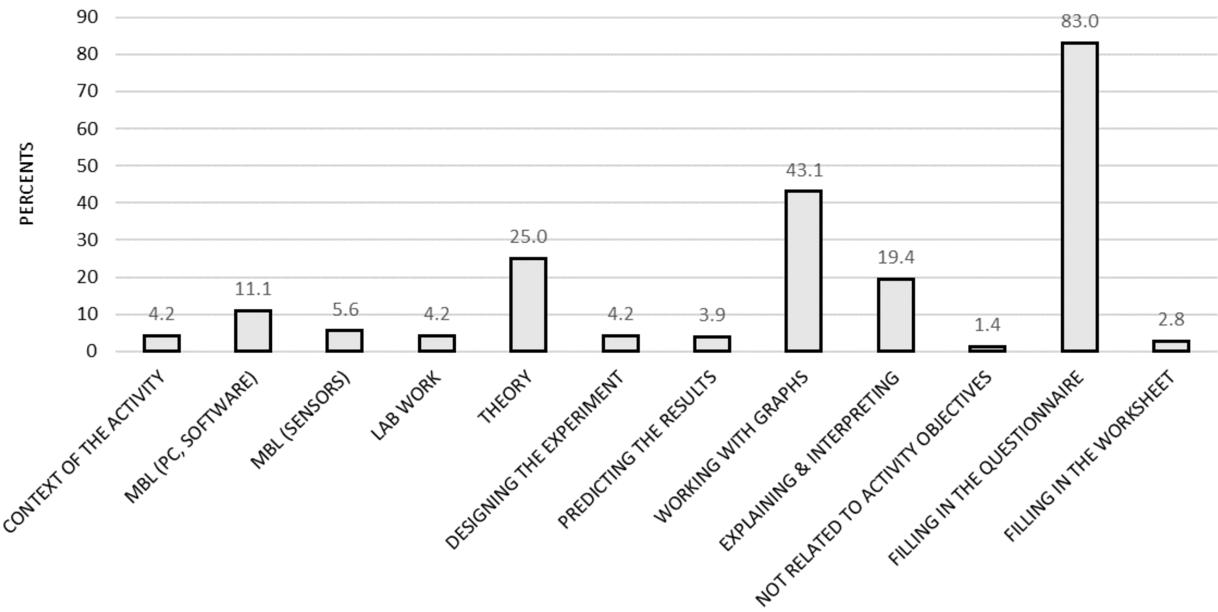

Figure 7. Justification of students' difficulties in ITEM 4

CONCLUSIONS

As regards the first research question - *Do students identify the objectives of the activity*, many of respondents do not express the objectives of the activity at a satisfactory level. Our findings show clearly that the sample of students can be divided into two groups. The first group represents ¾ of students who didn't identify the objectives properly, as 75.4% of them reported insufficient or totally erroneous answers. This fact is worrying even if some of them partially mentioned (but inadequate) ideas related to content, context, MBL, or at least Physics. The other group, representing ¼ of students, provided valid or more or less valid answers. However, it is correct to say that only negligible part of them (less than 2%) provided evidence about comprehending both, content and context of the activity. Most of the students from this group provided either a good content or a good context but not both. Moreover, it is obvious that students who identified the objectives at a satisfactory level perceived them more related to the content than to the context.

In addition, these findings are in contrast with the fact that almost all students (more than 90%) were more or less confident that they understand the objectives of the activity. Linking these findings together, we obtained a strong evidence that students tent to overrate or overestimate their opinion about their own knowledge and their level of understanding. This is why we suppose that there is a couple of new questions arising from our conclusions: (i) *What is the level of students' self-reflection?* and (ii) *Do our findings reflect the general knowledge about the level of students' self-reflection?* However, these questions were not intended to be investigated in this study.

Answering the second research question - *What parts of the activity do students perceive as the best ones*, we can conclude that parts of the activities that students like more are working with sensors and computers (MBL) (62,4%) and working with graphs (53,5%). According to our results, we can resume that students working in the computer-based lab tend to be attracted more by hands-on activities than by thinking or observing. This is a relevant result that highlights the use of MBL and its potential to involve students in working with graphics and measuring equipment.

In response to the third research question - *What kind of difficulties do students perceive in this activity*, it can be summarized that students consider thinking and reasoning the most difficult parts of the activity. One of the interesting outcomes was that more than 40% of students find out difficulties in working with graphs. Paradoxically, they previously reported working with graphs as the part of the activity that they liked the most. However, we suppose that those two perceptions can even coexist because working with graphs can be difficult but attractive for the students at the same time. Our findings also revealed that students really don't have a taste for theory. It was confirmed twice in our study, when students reported "theory" as less attractive part of the activity and also as one of the most difficult part of the activity.

Findings about the difficulties of the identification of the objectives of the activity make us reflect on the activity it-self. COMBLAB activities where reviewed, and refined, but in this case, after results, we consider to include some change in order to enhance the connection between the real situation and what students perform in the lab using MBL equipment, and also to encourage students to design experiments to answer the initial questions.

It should be underlined that these conclusions are related to the analysis of one specific activity, although providing relevant information, the analysis of the results of other activities are needed to allow a deeper understanding before concluding more general outcomes.

EXPLORING VIEWS OF SPANISH MIDDLE, HIGH SCHOOL STUDENTS AND PRE-SERVICE SCIENCE TEACHERS ABOUT SCIENTIFIC INQUIRY

Juan Jimenez[1], Soraya Hamed[2],Judith S. Lederman[1] and Norman G. Lederman[1]
[1]Illinois Intitute of Technology, Chicago, Illinois
[2]University of Seville, Seville, Spain

The aim of this study is to analyze and compare views of Spanish elementary, middle school students and pre-service science teachers about scientific inquiry (SI). A total of 159 elementary school students, 121 middle school students and 100 pre-service teachers from Spain participated in the study. The Views about Scientific Inquiry [VASI] (Lederman et al., 2014) was used to assess participants' scientific inquiry views. The baseline data will provide, on the one hand, information on what students learn about inquiry in middle and high school and, on the other hand, information on what future science teachers know about inquiry when they start with a science method course in the primary education degree

Keywords: Scientific inquiry, Initial Teachers Training, Middle School Students

STATEMENT OF THE PROBLEM

Scientific inquiry (SI) has been a perennial focus of science education for the past century and it generally refers to the combination of general science process skills with traditional science content, creativity, and critical thinking to develop scientific knowledge (Lederman, 2009). At the same time, recent reform documents have emphasized that students should develop the abilities necessary to *do* inquiry as well as have an *understanding* about inquiry (e.g., *Benchmarks for Science Literacy*, AAAS, 1993; *A Framework for K-12 Science Education: Practices, Crosscutting Concepts, and Core Ideas*, National Research Council [NRC], 2011; NGSS; Achieve, Inc., 2013).

In Spain, the Royal Decree 1105/2014, of December 26, regulates the basic curriculum from 7th grade to 12th grade and, for the 11th and 12th grade, this Royal Decree emphasizes the importance of applying the necessary skills for scientific inquiry such as, raising questions, identifying problems, collecting data, designing problem-solving strategies, using models and laws, reviewing the process and obtaining solutions. However, in the classroom few spaces are left to the exploration of phenomena and to the investigation, since teacher performances reflect that teaching is factual and based on the reproduction of concepts (Solbes, Monserrat, & Furió, 2007; Sánchez Cumplido, & Viejo Montesinos, 2012).

On the other hand, scientific inquiry has been introduced in the classroom and in the curriculum through different programs in teacher training and in-service teachers. However, there is no evidence whether, in fact, the students achieve an adequate understanding of the scientific inquiry. The aim of the study was to analyze and compare pre-service teachers and 7th and 12th-grade students' understandings of scientific Inquiry.

SAMPLE, METHOD, DATA COLLECTION AND ANALYSIS

The sample for the middle (MS) and high schools (HS) came from three public middle and high schools in Andalusia and they purposely selected to participate in the international VASI study (two schools from Seville and the other from Granada, Spain provide). The participant sample has been selected keeping in mind its socio-economic level (high, medium and low) and its population representativeness (students from rural, urban and marginal areas). We have contacted teachers who work in schools that present these characteristics by requesting their help on a voluntary basis. The first school is located in a neighborhood next to Seville. The second school from Seville is located in the Eastern District of the city. Finally, the third school from Granada is situated in a rural area halfway between the capital and the coast of Granada. Therefore, we carry out a purposeful sampling that allows us to provide rich and relevant information about the Spanish 7th and 12th-grade students (Patton, 2002). The sample consists of 159 seventh-grade students, 121 twelfth-grade students, and 100 pre-service teachers. The majority were Spanish with, also, students belonging to minority ethnic groups of Gypsies and Muslims. Female and male students were represented is similar proportions in this study. On the other hand, the sample from pre-service teachers (PST) came from a cohort of student teachers from the University of Seville. One hundred preservice teachers consented to participate in the study. The future teachers have a background in science that is a mandatory requirement to become a science teacher in Spain.

The VASI questionnaire was administrated in its paper and pencil version. Most of the students had no difficulties answering the VASI questionnaire. All students had no difficulty in reading, understanding and answering the VASI questions during a period of 60 minutes. After that, two researchers participated during the coding process. Each researcher analyzed each answer in each questionnaire independently and scored each response as naïve (N), mixed (M), and information (I). Blank responses were coded as no- answer (NA). The expected reliability for the VASI study was 80% of the inter-rater coding agreement for each aspect because we were measuring cognitive outcomes and also by typical international convention. After discussing the differences, the values achieve the overall reliability of 90%. Finally, as part of the research protocol, 20% of students were interviewed in order to verify coherency between written answers and thought, and also to confirm that the answers have not been affected by time or other conditions. However, no significant changes were observed.

RESULTS

In general, most of the Spanish students and future teachers show a Naïve or Mixed knowledge of the aspects of Scientific Inquiry (Figure 1). Then, the results are presented describing each aspect of understanding scientific inquiry.

Related, to **Begin with, a Question.** Most of the students 65.4% (MS) and 50.4% (HS) show a naive view about the importance of the questions to begin a scientific investigation and only

12.6% and 17,4% of students show an informed view of this aspect. Some students mentioned that the questions are not important because scientific research can begin with the observation of a phenomenon, problem, experimentation or even testing. 17.6% (MS) and 25.6% (HS) have a mixed view about this aspect and 4.4% (MS) and 6.6% (HS) of students did not answer the question. On the other hand, 30% of the science future teachers (PST) do not mention that the questions are an important aspect to begin an investigation (naive view), 14% expressed a mixed answer about this issue and 54% have an informed view for thi s aspect.

No Single Method: 83.6% of middle school students think that there is just a single scientific method and only 15.7% expressed a mixed response about it. No student expresses that scientists can use more than one method to do science. It seems that students have a reductionist view of the scientific method. Only 0.6% did not answer the question and 84.3% of high school students showed a naïve view for this aspect. In the same way, most future teachers (70%) have a naïve view about this issue, they do not explain the existence of more than one method to do science. 18% have a mixed response and only 12% have an informed view.

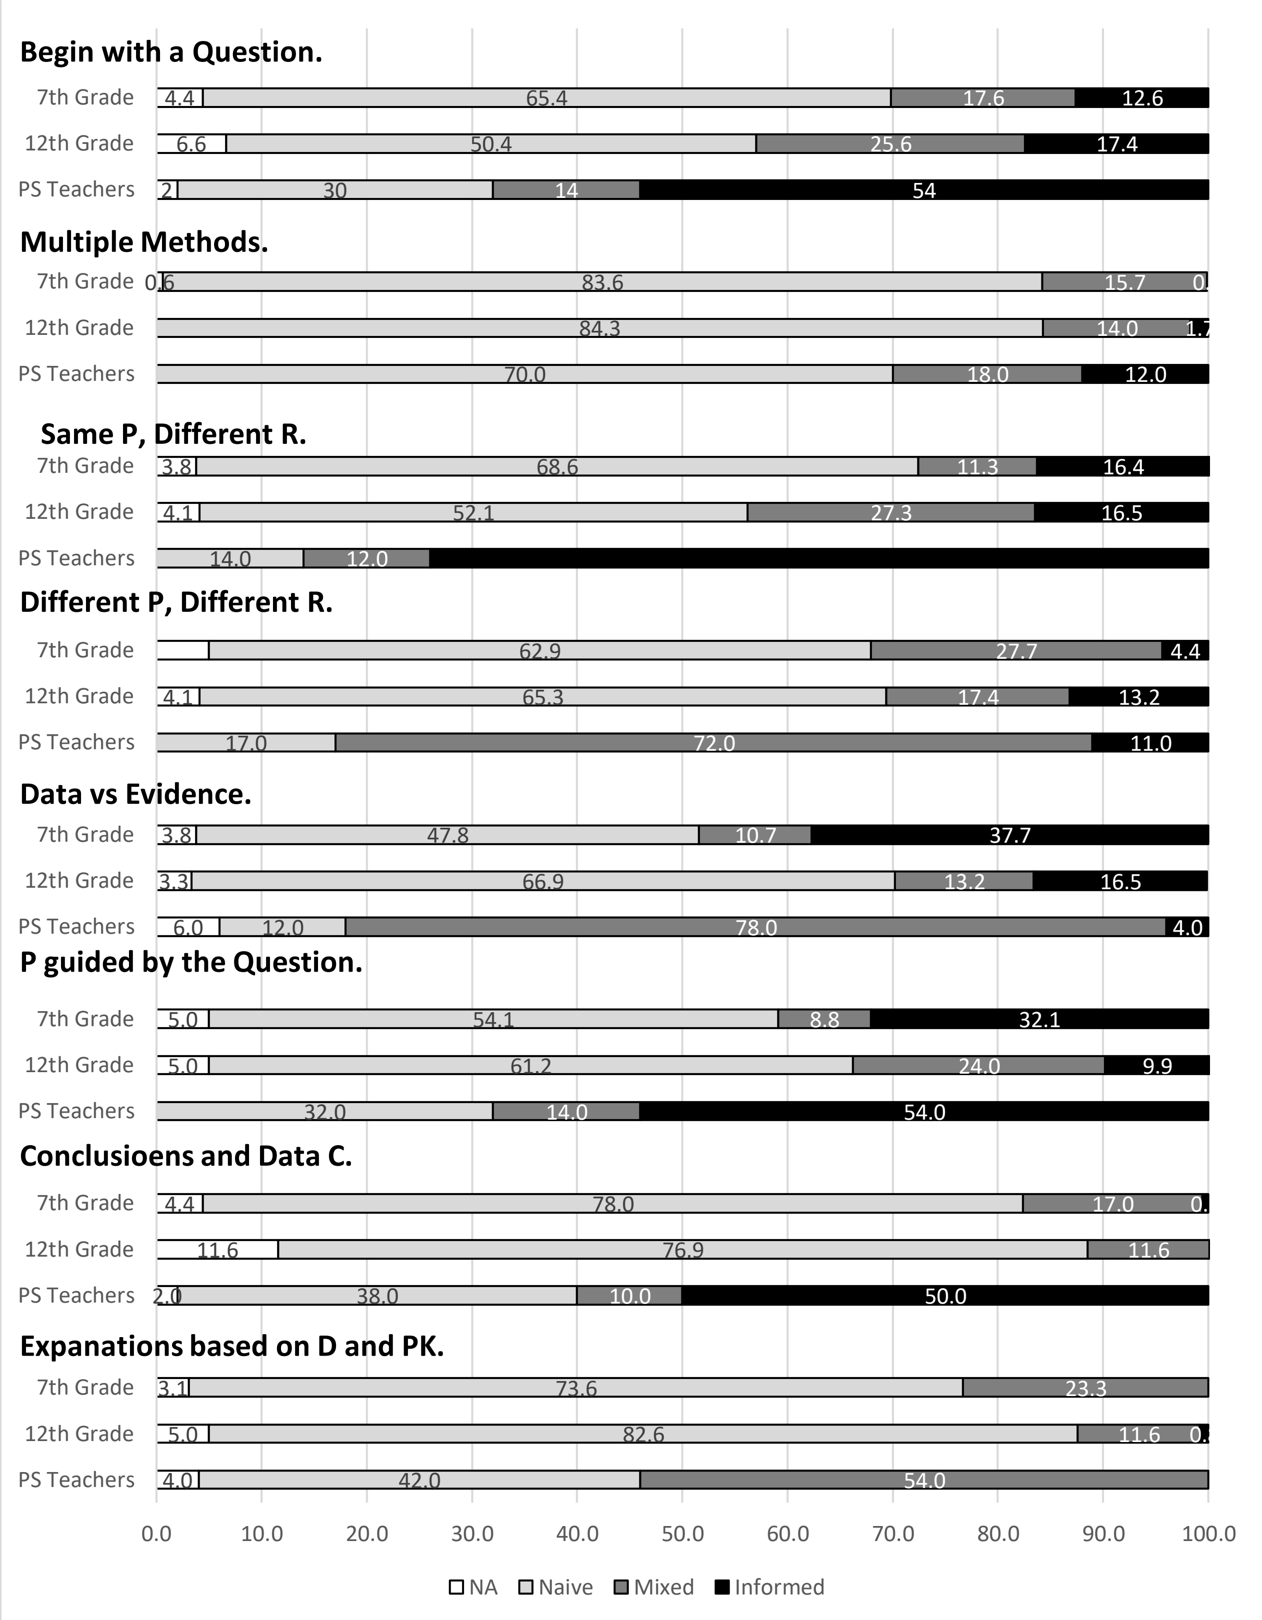

Figure 1. Comparison of Knowledge of SI among 7th grade, 12th grade, and Pre-Service Science Teachers

Procedure guided by Question: 32.1% of the middle school students show an informed view related to procedures are guided by the question asked. On the other hand, 54.1% of the students have a naïve idea about the procedures are designed to answer a question and 8.8% of students showed mixed ideas. Only 5% did not answer this question. Only 9.9% of high school students showed an informed view of this aspect vs 61.2% who showed a naïve view. On the other hand, 54% of future teachers have an informed response about this aspect, 32% have a naïve idea and only 14% express a mixed answer.

Same Procedure, different Results: Only 16.4% of the middle school students think that in from to the same procedures, the researchers can interpret the conclusions differently and get different results because of subjectivity and previous knowledge. On the other hand, 68.6% of the students think that when scientists do the same, they have to get the same results. 11.3% of the students have a mixed view for this aspect and only 3.8% did not answer. For high school students, only 16.5% showed informed views about this aspect and 52.1% exhibited naïve views. Instead, 74% of the future teachers have an informed view about this aspect, 14% a naïve response and 12% a mixed answer.

A different procedure, different results: Only 4% of middle school students showed informed views for this aspect and 62.9% showed naïve views. In high school students, the results are not different, only 13.4% expressed an informed view vs 65.3% with naïve views. Preservice science teachers have similar results than middle and high school students, only 11% of future science teachers are able to show understanding of this aspect and 72% showed mixed views.

Conclusions consistent with Data: 37.7% of the middle school students present an informed answer to this question. However, more than 47.8% still shows a naïve answer. Also, 10.7% show a mixed answer and 3.8% did not answer. This could show little ability of students to critically interpret tables and graphics. On the other hand, most of the high school students showed naïve views for this aspect (76.9%). For the future science teachers, 50% of the future teachers show an informed view, 38% a naïve view, 10% a mixed response. Only 2% did not answer.

Data differ from Evidence: 78% of the middle school students are not able to explain the difference between data and evidence. Showing that, for most of them, data and evidence are the same. 17% have problems to define one or another term. Only one student (0.6%) explain correctly the difference between them, and 4.4% did not answer. In high school students, the panorama is not different, only 16.5% of students showed an informed view and 66.9% showed naïve views for the aspect. In the same line, 78% of the future teachers show a mixed view, 12% a naïve response. Only 4% have an informed view. 6% did not answer.

Explanations developed from Data and existing Knowledge: None middle school students were able to provide an informed answer to this question. Again, more of the half of the students show a naïve answer for this aspect and 74.6% and 23.3% showed a mixed answer for this aspect. Only 3.1% did not answer. Similar to the category Conclusions consistent with data collected, students have difficulty interpreting the information in charts as well as having a naive conception of it. Similar results were obtained for high school students were only one student showed an informed view vs 82.6% who showed naïve views. Finally, 54% of the future teachers have a mixed view, 42% have a naïve response and 4% did not answer.

CONCLUSIONS

More than 50% of high school and high school students show naive responses to all aspects of scientific research. In the case of future teachers, it is distributed among naive, mixed and informed. The analysis of the aspects reveals for the three educational levels the idea that there is a single method for doing science (Lederman, Lederman, & Antik, 2013), the difficulty of differentiating between data and evidence and that the explanations and conclusions are developed from of data and pre-existing knowledge.
It seems that the results emphasize the presence of a positivist perspective of science, conceived as an absolute and true knowledge that is generated and validated whenever we faithfully follow the sequence of steps characteristic of the scientific method (Windschitl, Thompson, & Braaten, 2008; Lederman, Lederman, & Antik, 2013).

The lack of opportunities in the classroom for exploration, the reflection of phenomena and the conduct of research (Sánchez Cumplido & Viejo Montesinos, 2012), the complex and theoretical curriculum and the excessive use of books Text from an early age, maybe reasons that explain the distorted vision of students and future teachers about the aspects analyzed (Senler, 2015).

Developing research activities does not necessarily entail obtaining a sophisticated understanding of the nature of its aspects (Trumbull, Bonney and Grudens-Schuck, 2005). The results obtained provide evidence to the educators of these stages to reflect on the need to explicitly teach the aspects analyzed (Abd-El-Khalick and Lederman, 2000b) and on the strategies that facilitate it.

IMPLICATIONS AND FUTURE RESEARCH

The goal of science education is to develop scientific literacy in every citizen. In order to reach this goal, the citizens need to be able to understand what science is, the process involved in the development of scientific knowledge and also a comprehension of the characteristics of scientific knowledge or nature of science in order to solve daily life problems that have a scientific basis.

Scientific inquiry refers to the process of how science is developed and involved different methods and the development of science skills, but also it is needed to understand the characteristics of scientific inquiry. For that, students, from an early age, must be involved in simple scientific researches that allow them to get an understanding of how science works.

Teachers at schools should include the practice of doing research in the classroom and also help the students to develop an understanding of the aspects of scientific inquiry. Teacher educators should provide a set of strategies and methods to the future teachers that they can apply in their classroom in the future, but also teachers' trainers must provide activities to promote understanding of scientific inquiry. In-service teachers need to modify their current practice at the classrooms from center teacher approaches to student-centered approaches in order that students can show autonomy and be able to carry scientific investigation that allow them to reach an understanding of scientific inquiry.

Finally, this study provide a brief and not generalizable overview about the state of understanding scientific inquiry in Spain classrooms in three levels, middle school, high school, and preservice teacher programs that allows to take some actions in order to improve teaching practices and also promote more active ways of teaching in the classrooms focusing not only in "doing" scientific inquiry but also "understanding" scientific inquiry.

[2]University of Nebraska-Lincoln, Lincoln, United States of America

Science teachers' reflections can be used as an opportunity to improve teaching through inquiry-based instruction (White, Frederiksen, & Collins, 2009), especially during their first years as teachers. Yet more work is still needed to support the development of beginning teachers' reflective practices (Russell & Martin, 2014). The purpose of this exploratory multi-methods study was to describe: (a) beginning secondary science teachers' reflective practices up to 4 years after completing their teacher education program, (b) the factors that might have an effect on these practices for participants, and (c) the connection (if any) between their inquiry-based instruction and reflective practices. We used open-ended interviews to describe the participants' reflective practices, applying Cartwright (2011) levels of reflection, and to determine factors that could support or limit their reflective practices. Additionally, we analyzed classroom observations coded using EQUIP to understand the teachers' inquiry-based teaching. We found that novice teachers can develop all levels of reflection, but they tended to be more unconscious when they teach a new course or teach out-of-field. Teaching experience, collaboration among teachers, and whole-school professional development can support science teachers to engage in higher levels of reflective practices. Finally, higher levels of reflection seemed to have a connection to more proficient use of inquiry-based instruction.

Keywords: Reflection, teacher induction, secondary school

INTRODUCTION AND RATIONALE

Secondary science teachers' reflection could support the process of learning how to teach science using inquiry-based instruction (White, Frederiksen, & Collins, 2009), especially in their first years as teachers (i.e., induction phase). Reflection, in the context of teaching, means to "look back" or "think back" at actions and teaching strategies, being able to assess these strategies for improvement and develop expertise focusing attention on certain elements teachers want to develop (Korthagen & Vasalos, 2005; McGregor, 2011; Marzano, Boogren, Heflebower, Kanold-McIntyre & Pickering, 2012). Moreover, reflection as part of a learning process, has a social component (Lovett, 2013). This is, it might start as an individual internalization, but it is enhanced when it is done in communication with others, such as peers or supervisors.

The purpose of this exploratory multi-methods study was to describe beginning secondary science teachers' reflective practices up to 4 years after completing their teacher preparation program. The research questions for this study were: What are beginning science teachers' reflective practices after finishing their teacher preparation program? What factors may affect beginning science teachers' reflective practices? And, what is the relationship (if any) between reflective practices and inquiry-based instruction?

Theoretical framework

Teachers' first years are full of new experiences and learning. New science teachers come to their classrooms with a set experiences inside (e.g., as students, student teachers) and outside (e.g., personal interests) the school, content and pedagogical knowledge, and many expectations and hopes. As novice science teachers gather new experiences within the specific context of their science classrooms, teachers' reflection may support their process of meaning making (Duffy, Miller, Parsons & Meloth, 2009; Rusell & Martin, 2014). Applying the conceptual change framework, after a higher order cognitive task, such as teaching science as inquiry, teachers' reflection supports the process of accommodation and assimilation of new ideas and experiences (Russell & Martin, 2014). Moreover, teachers' reflection should involve a process of high levels of metacognitive thinking to transform teachers' cognitive conflicts and alternative conceptions into new learning (Duffy et al., 2009). In other words, reflection can enhance, modify, or adapt teachers' initial knowledge about science teaching, into new knowledge to improve their practice. Yet, more work is needed to support and understand beginning science teachers' reflective practices (Russel & Martin, 2014), especially when using high stakes science standards (e.g., NGSS) and inquiry-based instruction.

Teachers' reflection is a broad and complex construct that might involve several elements about science teaching. For example, reflection might involve thinking about teacher's mission, identity, beliefs, competencies, or behaviors (Korthagen & Vasalos, 2005). Therefore, to gain a better understanding of beginning teachers' differences on thinking about and capacity to use reflective practices, some scholars have suggested levels of reflection. Although Collin, Karsenti, and Komis, (2013) stated that reflective practices in all levels could be useful for teaching improvement, depending on the pedagogical circumstances, we found Cartwright's (2011) levels of reflection as a helpful analytic lens to view reflective practices (Table 2) and gain a better understanding of the qualities of reflection and possible connections to inquiry-based teaching.

RESEARCH METHOD AND DESING

We used an multi-methods exploratory research approach to conduct this study about beginning science teachers' reflective practices. We followed the requirements of the university's Institutional Review Board. For this study, the participants were beginning science teachers (0 to 4 years of experience), alumni from a university-based, secondary science education program in a Midwestern city in the United States during August 2016-May 2017. We contacted 64 alumni who graduated from the masters level (MAT) or undergraduate (UG) programs between 2013 - 2017. Fifteen teachers agreed to participate (10 females and 5 males; 12 of Western European descent, one Latino, one African American, and one Middle Eastern; two participants came from the UG, while thirteen from the MAT) (Table 1); all of them were participating or participated in some point in a larger longitudinal study about inquiry-based instruction.

Table 1. Summary of Interviewed Participants.

	Gender		Level			School	
	Male	Female	HS	MS	Both	High SES	Low SES
MAT	5	8	9	3	1	7	6
UG	0	2	2	0	0	1	1
Total	5	10	11	3	1	8	7

We conducted open-ended interviews (average of 50 minutes) from August 2016 to March 2017, and included questions to generate reflection about their concept of effective science teaching and factors that might affect their reflective practices, using a grounded theory approach. This is, the data collection and analysis occurred simultaneously using in-process and analytical memos. We transcribed all the interviews for analysis. For teachers participating in the longitudinal study, we observed their instruction at least four times during the school year 2016-2017, wrote detailed field notes, and coded (after a process of calibration) them using the EQUIP instrument (Marshall, Horton, Smart, & Llewellyn, 2008). This tool (EQUIP) analyzes four specific areas of inquiry-based teaching (i.e., instructional, discourse, assessment, and curriculum factors) in a scale 1 to 4, where 1 is labeled as "pre-inquiry" and 4 as "exemplary inquiry". We used 64 coded lessons from 11 participants.

Table 2. Levels of Reflective Practice Indicators for beginning teachers (Cartwright, 2011).

Unconscious Reflection (UR)	Conscious Informed Reflection (CIR)	Conscious Critical Reflection (CCR)
1. Learning as "transmitter of knowledge."	1. Seeks support from different sources (e.g., readings, colleagues).	1. Recognize different ways of approaching a problem.
2. Trial and error. Getting things done for now.	2. Recognizes his/her own feelings.	2. Use different learning strategies.
3. Little evidence, but the lesson appeared to run "smoothly."	3. Evaluates his/her own practice and modifies instruction.	3. Using theory to inform teaching.
4. Accepting intuition to assess effectiveness.	4. Using data to support teaching.	4. Taking risks, but willing to evaluate the results.
5. Considering only his/her feelings.	5. Experience informs teaching.	5. Comparing with other teachers or ideas.
6. Using generalizations or unsubstantiated statements.	6. Using experience as student with meaning as a teacher.	6. Open to other's ideas and criticism.

To identify the level of reflection used by the participants during the interviews, we analyzed them using protocol coding (Miles, Huberman & Saldana, 2014). In MAXQDA, we identified the descriptors listed by Cartwright (2011) (Table 2) in the interview segments. We tallied the number of descriptors found to classify the interview trending as uncounsious (UR), conscious informed (CIR), or conscious critical reflection (CCR). Because all the participants had coded segments in the three levels, we decided to use the level with the most segments. To find out factors that affected teachers' reflective practices, we used an interactive model (Miles et al., 2014); in MAXQDA first we used open coding to condense the data and then, with the themes that emerged, focused coding to reach conclusions. For trustworthy purposes, we used the classroom observations we conducted from the longitudinal study to confirm our emerging themes. We hypothesized that years of teacher experience might have an influence on the level of reflection used by participants.

To find connections between the levels of reflection and inquiry-based instruction, we used the participants' EQUIP coded lessons. Because EQUIP uses an ordinal scale, we calculated the total mode for each participant, grouping the four tool's inquiry areas. We compared these modes with the level of inquiry practices.

ANALYSIS AND FINDINGS

We used the descriptors developed by Cartwright (2011) to identify segments and tallied these descriptors to identify trends (Table 3). Due to space limitations we provide a few examples of the range of teachers' use of reflective thinking practices.

Table 3. Example of coded segments of Unconscious (UR), Conscious Informed (CIR), and Conscious Critical Reflection (CCR).

Descriptor	Participant	Example of coded segments
Learning as "transmitter of knowledge" (UR-1)	David	*I like to bring something to kids that you can use as an example or applied when, in some point, you would have to lecture or explain things. You know, it's like... I like to have like a concrete example to bring…* (12/03/2016, line 50)
Using data to support teaching (CIR-4)	Frank	*I'll look at the grades and that indicates to me either those skills are or aren't being met.* (11/29/2016, line 27)
Using different learning strategies (CCR-2)	Betty	*I think it should be engaging as far as the kids are asking questions and the kids are trying to gather, collect data, generate data, the kids are doing the thinking where they're figuring out how to solve a problem but also they're talking with each other, they're discussing…* (12/01/2016, line 66)

The coded data showed that almost all of the 2nd-year teachers, the largest group in this study, tended to use CIR or CCR (Table 4). This is, teachers with more than one year of experience demonstrated more conscious reflection. Nevertheless, we found teachers with three and four years of experience using UR as well (e.g., Mary and David). Therefore, it seemed years of teaching experience might have an influence but be insufficient to explain the development or lack of change in how teachers engaged with reflective practices.

After each interview, we had a general sense of some participants' overall level of reflection. These teachers' interview analysis showed a strong trend in their number coded segments in one level of reflection. For example, Frank, a 2nd-year teacher, had 77% of his coded segments as CIR; or Jean, a 5th-year teacher, had 72% as CCR. Therefore, we could identify or have a general sense of the level of reflection most used by these participants, even before coding the interview or before tallying the coded segments. But, for other participants, it was difficult to predict their level of reflection after our conversation and analysis, and before tallying their coded segments. We noticed that for these participants the coded segments' trends were not that clear or dominant. In our tally and analysis, at least half (or close) of the coded segments were one level of reflection and half were between the other two (we bolded these participants in Table 3). For instance, Paula, a first-year teacher, had 45% of her segments as UR and 55% between CCR and CIR. Although she had a largest percentage of coded segments as UR, more than half of her interview reflection was in a more conscious level of reflection. Or Betty, with 49% of segments coded as CCR, but 51% in the other two levels (40% as CIR and 11% as UR) (we added an arrow to show where the trend of the second half of the coded segments were). It was interesting to observe that second-year teachers identified as CIR, the biggest group of participants, two of the participants tended toward UR and two toward CCR. Again, reflection is a complex construct. It was clear that experience might help to deepen the level of reflection, but there were other actors that might have an effect in teachers' reflective practices.

Table 4. Participants' Levels of Reflection and Teaching Experience. Participants were categorized based on the highest number of coded segments in that level of reflection (% of coded segments).

Years of teaching experience	Unconscious reflection (% UR)	Conscious informed reflection (% CIR)	Conscious critical reflection (% CCR)
0	**Paula (45)** →		
1	←	**Steve (54)/Gina (48)/** Frank (77)/ **Kate (57) Pam (57)** →	Lucy (75)/Elsa (79)
2	**Henry (52)** →		
3	David (80)		Emma (67)
4	**Mary (58)** →	←	**Betty (49)**/Jean (72)/ Matt (60)

**Bolded names show a not clear classification after analyzing coded segments. The arrows show the trend of the other coded segments.*

Analyzing the context and the participants' answers, we concluded that other factors such as teaching out-of-field or teaching for the first time a science content, independently of the number of years of teaching experience, could have an impact in teachers' level of reflection. For instance, Betty, a 5th-year biology teacher, had coded segments as CCR, such as: "*Well, obviously, I want them to learn science concepts, that's important for scientific literacy. But, I also want them to be able to like think and do critical thinking and be able to analyze things and I want them to be able to organize data and be able to come up with conclusions and arguments and back up what they're saying with evidence.* (CCR-3, 12/01/2016; line 72)". However, she used UR in segments where she described her chemistry course, a new course she was teaching, out of her original biology endorsement. Betty described her chemistry course as "getting things done for now" (UR-2): "*I mean, I really, for chemistry, I'm just taking it day-by-day because I have no idea what I'm doing and I'm just going.* (UR-2, 12/01/2016; line 128). Even though Betty was an experienced teacher using CCR in most of her interview, she applied UR when talked about the courses she was teaching out-of-field (a course different from her original endorsement area). Consequently, these also happened to Paula, the first-year participant. All the other participants classified as CIR were teaching in-field (in their original endorsement area) courses.

Also, collaboration seemed to be a factor that influence participants' level of reflection. Teachers' used CCR when they were involved in whole-school professional development (e.g., "*We had staff meeting yesterday, my principal and I did a… an activity with the rest of the staff of… for this Danielson [model of instruction] and… he hands it out different scenarios and they had to identify which part of the model, the teaching model where they came from, and so… and what we're going to go forward with that is okay would this person be ranked as basic, or proficient, or distinguished, or unsatisfactory or how would we do it. And so, things like that, I think the whole school is kind of on a transition to being much more reflective and… in that way"* [Henry's interview, 09/21/2016; line 90]) and reflected with other teachers (e.g., "*One of the new teachers at the school, me and her actually graduated on the same year of high school, so… We talked quite a bit about things like that. I guess that's probably more like extracurricular talk too, and [we] talk about like well this, we did this yesterday and this didn't work. Then, I'll kind of give her ideas too about like lots of like classic, like last year this is what I ran into and stuff like that so... [Kate's interview,11/10/2016; line 5]*), also confirming the social component of reflection. On the other hand, teachers isolated or being the only teacher of a course in the school (e.g., Mary, the only teacher in her private school teaching science and biology) used a lower level of reflection.

Finally, our findings suggest that teachers tend to use more CIR when they have the habit of documenting their lessons to plan or assess their teaching (e.g., "*And I have for that particular lesson like 5 or 6 okay let's make these macro changes on this particular lesson cause that would help next year's class. And I go say having iterative class and that I take the feedback at each year of what didn't and did work and then updated and change it for next year's class cause if you keep doing that eventually it'll be semi-decent, right?* (Frank's interview, 11/29/2016; line 87), and reflect after assessment practices (e.g., "*I look at the quiz x, usually the kids that struggle, you know, they come and retake it the next Monday, and I do a short re-teaching session* [Emma's interview, 11/02/2016; line 29]).

Table 5. Participants' Levels of Reflection and Inquiry-Based Instruction (EQUIP mode).

Years of teaching experience	Unconscious reflection (Mode)	Conscious informed reflection (Mode)	Conscious critical reflection (Mode)
0	Paula (2)		
1		Steve (1)/ Frank (3)/ Kate (2) Pam (2)	Lucy (3)
2	Henry (2)		
3			Emma (3)
4	Mary (2)		Betty (3)/Matt (2)

Similarly, and according to the participants, the themes that emerged as the mediating factors that teachers perceived as assisting their use of reflective practices were collaboration among teachers (from science or other disciplines) (76% of the participants mentioned this theme), setting goals at the beginning of the school year and follow up meetings with science supervisors, mentors, or first-year teachers' institutes (60% of participants), and whole-school professional development and administrators' involvement (27% of participants). Also, teachers with an open attitude toward change and improvement appeared to use these opportunities more often to think about their teaching (20%). As limitations, 33% mentioned that setting goals at the beginning of the school year without a supervisor's follow up becomes busy-work and does not promote reflective thinking; new teachers (or teaching out-of-field) found difficulties reflecting upon their teaching when they were busy preparing new materials or working on several different activities at the same time that required their attention (47% of participants).

After analyzing the EQUIP coded classroom observations (from the larger study) to identify a level of inquiry instruction and related them to the participants' level of reflection (Table 5), we found that the most common level of inquiry based on EQUIP was "developing" inquiry teaching (i.e., 2). Therefore, we found "developing inquiry" in all levels of reflection. However, CCR participants tended to have a higher level of inquiry instruction (i.e., 3, "proficient inquiry") compared with UR (i.e., 2, "developing inquiry").

DISCUSSION AND CONCLUSIONS

Reflection has been considered for teacher preparation programs and schools as a necessary practice for new teachers and a tool for learning how to teach science (McGregor, 2011). For this study, we had three questions about teachers' reflective practices: (1) What are beginning science teachers' reflective practices after finishing their teacher preparation program? (2) What factors may affect beginning science teachers' reflective practices? And, (3) what is the relationship (if any) between reflective practices and inquiry-based instruction? Based on our findings we will try to answer them.

Beginning science teachers' reflective practices (research question 1)

Analyzing the level of the participants' reflection based on Cartwright (2011), we found that we coded segments using the three levels of reflection for almost all participants. Larrivee (2008b), who developed similar levels of reflection to Cartwright (2011), explained that a reflective practitioner incorporates all levels of reflection. Therefore, it is common to find all levels when a teacher reflects about a teaching event.

Although there were all levels of reflection in participants with the same amount of years of teaching experience, in general, we found that beginning teachers require experience to deepen their level of reflection. Participants teaching in-field and with more than one year of teaching experience tended to use CIR and CCR. This is, teachers use their past experiences to inform their teaching and make instructional decisions. For example, Betty, a fifth-year biology teacher teaching for the first time a chemistry course, tended to use CCR in the interview. However, she used UR when she referred to her chemistry classroom. In the case of Paula, the first-year teacher, her reflection during the interview was dominated by UR segments. Cartwright (2011) explained that teachers learn from their own and others' experiences. Reflection on past experiences and learning strategies can develop teachers' self-efficacy and understanding of themselves as learners (Mycroft & Gurton, 2011). Therefore, experiences can help teachers develop deeper reflection about their strategies. Conversely, a lack of experience might promote superficial reflections that do not lead to improvement.

Factors affecting reflective practices (question 2)

Teachers' reflective practices are complex and not static. Teaching experience can support teachers' deeper reflection but there are other factors, such as the context where the reflections are made, the collaboration with others, and an opened attitude toward change, that might have an influence as well. Malthouse, Roffey-Barentsen, & Watts (2014) defined context as the physical surroundings, social setting, and individual dispositions contributing to the quality of reflection. Therefore, all the later elements might have affected the participants' level of reflection. For instance, busy teachers might tend toward more superficial reflections than those who have more time to stop and think about the past. Also, isolated teachers tend to more unconscious reflection compared to those teachers who have peers or mentors to think about their goals, challenges, and expertise development.

York-Barr, Sommers, Ghere and Montie (2006) viewed reflective teaching as related to collaboration and practice. They came up with the idea that reflection can be performed in four interconnected levels of a spiral that includes individual reflection, reflection with partners (e.g., another teacher, a mentor), reflection in a small group or team, and finally, school-level reflection practice that can result in a "cumulative effect on school wide practices and learning" (p. 21). Our findings support that the outer levels of this spiral (i.e., school and group reflection) will support deeper levels of reflection. The later might be because these outer levels of the spiral create a supportive environment for teachers to grow and adopt a specific practice.

Moreover, other researchers have also supported the importance of the context in which reflection takes place. Edwards and Thomas (2010) insisted that educators should be concerned with developing supportive contexts to enhance reflection as part of social conduct. They argued that the context in which teachers solve problems will have a significant impact in their decisions. Collin et al. (2013) agreed that context might influence teachers' ability to reflect. Supportive school environments can provide opportunities to reflect that will enhance teachers' reflective abilities and metacognition. Larrivee (2008a) explained that "even novice teachers can deepen their level of reflection with powerful facilitation and mediation within an emotionally supportive learning climate" (p. 346). Therefore, a supportive environment in schools where teachers, administrators and the community are involved in teaching science as inquiry will be more effective supporting teachers' deeper levels of reflection.

Relationship between reflective practices and inquiry-based instruction (question 3)

There is a general agreement that reflective practices can improve teaching and learning in the classroom (e.g., Belvis, Pineda, Armengol, & Moreno, 2013). We agree that any level of reflection can help teachers improve their practice (Cartwright, 2011) and that no difference exists between "good" or "bad" reflection (Collin et al., 2013). The effectiveness of reflection depends on multiple factors, such as the purpose, teachers' goals, etc. However, McGregor (2011) found that deepening the level of reflection can make it more meaningful and support teaching improvement and creativity more effectively than lower levels of reflection. The later aligns to our preliminary findings, after analyzing the EQUIP coded lessons. In general, participants in CCR tended to have better inquiry rates than teachers mostly using unconscious reflection.

Conclusions

Some of the lessons learned after this study rely on the idea that beginning teachers' reflective practices are complex and not static. Teaching experience can support teachers' deeper reflection (CCR) but there are other factors (e.g., teaching out-of-field, collaboration, whole-school professional development) that might have an influence as well. Therefore, we conclude that TEPs, schools and learning communities need to promote collaborative reflective environments to prepare teachers to become deeper critical thinkers about their professional careers and their proficiency applying inquiry-based strategies.

Moreover, we acknowledge that the participants' level of reflection during our conversations did not represent the way they reflected all the time and that our bias could have affected our coding of their statements. Instead, our purpose was to understand some of the differences in their reflective practices, as part of their conceptual change as beginning science teachers. We found Cartwright's (2011) levels of reflection adequate to analyze reflective practices and their descriptors as a good tool to promote deeper reflection in TPP or schools. Additionally, understanding some factors that might have an influence teachers' reflection could support the understanding of this skill and its social dimension. Therefore, Cartwright's (2011) levels of reflection could be used as a tool to promote/support/analyze more conscious critical reflection and apply a higher level of inquiry instruction for science teachers during their induction phase.

Finally, applying the descriptors used by Cartwright (2011) and additionally to our findings, we noticed a lack of explicit concern about equity issues in the tool and the participants' comments during these interviews. This was despite the fact that during their student teaching experiences they were largely placed in highly diverse school settings during their teaching preparation program and many of them were teaching at high-needs schools. Our suggestion would be to include descriptors connected to teaching for all students as part of a critical reflection.

ACKNOWLEDGEMENT

We would like to thank to the research group involved in the larger longitudinal study: Lyrica Lucas, Amy Tankersley and Aaron Musson.

ANALYSIS OF LEARNING WITH DYNAMIC MODELS AND EXPERIMENTS IN OPTICS

Albert Teichrew and Roger Erb
Goethe University, Frankfurt am Main, Germany

Modelling is an essential step in acquiring scientific knowledge, serving as the basis for experimenting and interpreting collected data. The teaching and research project presented in this paper used an online learning environment to prepare students for experiments in optics, implementing dynamic models created with GeoGebra to encourage virtual exploration. The results support the idea that the learning environment enables model-based hypothesis formation. In this mixed-methods study, screen recordings, videos and questionnaires were used to explore how learning with dynamic models and experiments works.

Keywords: Dynamic Visualisation Tools, Video Analysis, Inquiry-based teaching

INTRODUCTION

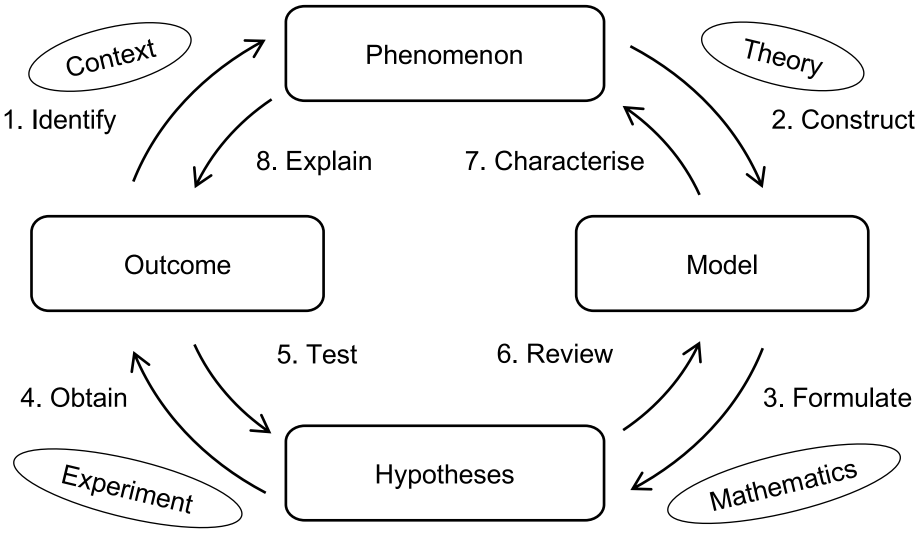
Experimentation is considered the central process of scientific knowledge acquisition in classrooms. However, it is not possible to obtain knowledge from an experiment if subject-specific knowledge and theoretical assumptions are not well presented. One possible way to improve results, explored here, is for students to engage with dynamic models of the phenomenon under instruction.

Scientific knowledge acquisition with dynamic models

Working with models is considered a key capability for research and learning processes (Bailer-Jones, 2009; Thiele et al., 2005). Structural models for scientific thinking or experimental competence aim to depict knowledge acquisition as a problem-solving process with several steps (Mayer, 2007). In general, these are steps to plan, carry out and analyse experiments (Nawrath et al., 2011; Theyßen et al., 2016). However, a model that combines modelling and experimentation in a united problem-solving process would be more appropriate. As a design aid for learning environments, we constructed the cycle of knowledge acquisition shown in Figure 1 (Teichrew & Erb, 2018). The components include four topics (rounded rectangles), which are developed in several steps (arrows) with suitable tools (ovals).

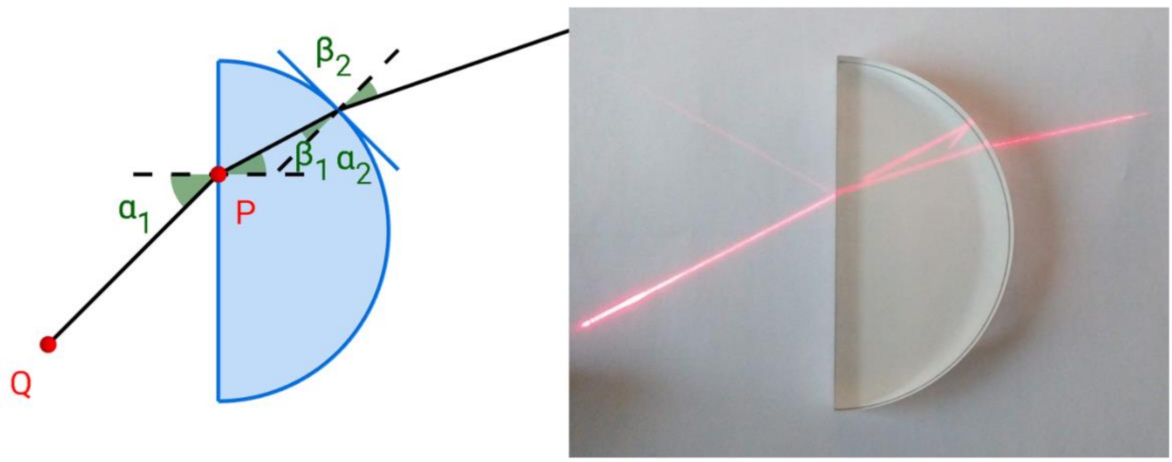
In the first steps, students learn that in order to understand something unknown, they must construct a model for the phenomenon, learn how their model behaves and build their hypotheses from it. The hypotheses are then used to get an experimental outcome. In each of the first four steps, they need input from the learning environment, such as context of the investigation, a scientific theory, mathematics and experimental material. The later steps encourage reflection on the process. Students are directed to test their hypotheses, review their model and identify the limits of it. Finally, they should be able to characterise the phenomenon based on the model and explain new observations with their knowledge of different phenomena.

Figure 1. Cycle of knowledge acquisition with modelling and experimentation.



With dynamic geometry software like GeoGebra, learners can create or work with interactive models, while directly observing the result (Erb, 2016). In this way, they use dynamic representations to construct their own understanding (also referred to as mental models, see Schnotz & Bannert, 2003). At the same time, this exploratory learning activity should produce hypotheses that can be tested experimentally. In this study a dynamic model of refraction of light through a semi-circular disc was used (Fig. 2, left). It contains several variables, principally the entry angle and entry point can be varied in order to analyse different light paths. The instructional materials for the corresponding "real" experiment direct students to produce different paths of light through the disc and the task is to compare observations with the results of the model (Fig. 2, right). At first glance, it is apparent that reality is more complicated and differs from the model. Some reflections distract from the subject under investigation, the refraction of light through the disc.

Figure 2. Example of a dynamic model (left) and the corresponding experiment (right).



Teaching and research project

In order to answer the general research question of the influence on learning outcomes through the interaction with dynamic models and experiments, it is necessary to clarify how to characterise students' approaches. Therefore, we pursued in a mixed-methods study three exploratory research questions:

Q1: How do students interact with dynamic models and experiments in an open learning environment?

Q2: How does hypothesis formation based on a dynamic model work?

Q3: Do cognitive or affective factors have an influence on this learning process and if so which?

Overall, 41 students participated in all parts of the study and answered several questionnaires. Using an online learning environment at home throughout the semester students took part in several lessons on light propagation, reflection and refraction. The core of each lesson was a dynamic model that encourages free exploration and formulation of hypotheses followed by practical work on optical experiments during contact hours at the university. However, research focus was on learning activities related to refraction. First, the participants interaction with the model in Figure 2 on a tablet screen was recorded. After writing down their hypotheses and answering questions about their impressions of the modelling process, the experimentation process with the refraction lab equipment was also recorded.

METHODS

In order to answer the research questions, an integration of qualitative and quantitative data shown in Table 1 was produced. On the one hand, videos were used to measure time on task during modelling and experimentation, adding up the time to read the instructions and modify the model (or work with the equipment). On the other hand, a deductive content-coding, based on the usage possibilities in the model or experiment was carried out. In this case, 12 goals can be achieved in the model and the experiment, whereby following interactions have been counted: Whether a variable was varied (moving one part of the model or the experiment), whether extreme cases were explored (wide variation of a variable), whether relevant settings were found (setting several variables to a certain value).

To answer the second question, hypotheses formulated by the students after their work with the model were inductively coded and divided into three levels with five categories each (111 or 2.8 statements per student in total). Declarative statements about refraction that are probably known from the previous lecture are assigned to Level 1 (55 statements). More complicated hypotheses that included relevant settings for the experiment based on the model are at Level 3 (32 statements). A level in between contains other ideas and observations (24 statements).

In addition, questionnaires were integrated into the learning environment to measure various types of perceived self-efficacy (PSE) such as mathematics, computer use or experimentation (according to Bescherer, 2004; Spannagel & Bescherer, 2009; Körner & Ihringer, 2016). Besides that, various dimensions of intrinsic motivation were measured immediately after interacting with the model (according to Wilde et al., 2009). In this way, influence of different factors can be analysed, such as enjoyment, perceived competence, perceived choice or external pressure. The internal consistency of most factors is satisfying. Furthermore, the students have previously passed a subject knowledge test containing 18 Rasch-calibrated items on the topic of refraction from an item pool from previous studies (Weber et al., 2017). The results were used to estimate prior knowledge using the maximum likelihood method based on item response theory.

Table 1. Mean values and standard deviations of the analysed data.

Constructs and measurements	*n*	*M*	*SD*	*No. of items*	*α*	*Scale*
Modelling time (modtim)	37	358	160	1	-	in s

Intrinsic motivation						Likert from 1 to 5
→ Enjoyment (enj)	39	3.68	0.54	3	.82	
→ Perceived competence (com)	41	3.07	0.74	3	.84	
→ Perceived choice (cho)	39	3.62	0.50	3	.69	
→ External pressure (pre)	41	2.96	0.93	3	.83	reversed

Annotations: N = 41. Adjusted sample sizes result from the omission of outliers.

RESULTS

The interaction with the dynamic model and the corresponding experiment was very heterogeneous in terms of time and goals achieved. That is the consequence of an open learning environment in which no precise learning steps are specified. On average, students spent significantly more time on the model than on experimental verification of it (asymptotic Wilcoxon test: $z = -3.62$, $p < .001$, $n = 35$, $r = .61$), but achieved about the same amount of goals ($z = -.90$, $p = .369$, $n = 41$). The correlation matrix in Table 2 shows that goals correlate stronger with time than with other factors. This result replicates the known connection between time on task and learning outcomes.

Nevertheless, the interaction with the model allowed all learners to formulate their observations as hypotheses. However, the majority were simple statements that had no relation to the special geometry of the refraction medium (Level 1 and 2), but there is a correlation between successful work with the model and the number of Level 3 hypotheses. Overall, the number of formulated hypotheses had no measurable influence on the experimentation process (time and goals).

Furthermore, the correlation matrix shows that PSE in mathematics qualifies as a predictor for successful work with the model, in contrast to PSE in computer use and experimentation. In addition to PSE in computer use, it also appears to be helpful for a variety of Level 3 hypotheses. Besides that, motivational factors such as a high level of perceived competence and the absence of external pressure in the modelling process had a positive effect. The correlation matrix also shows that more experimentation goals were achieved by students reported enjoying the modelling phase.

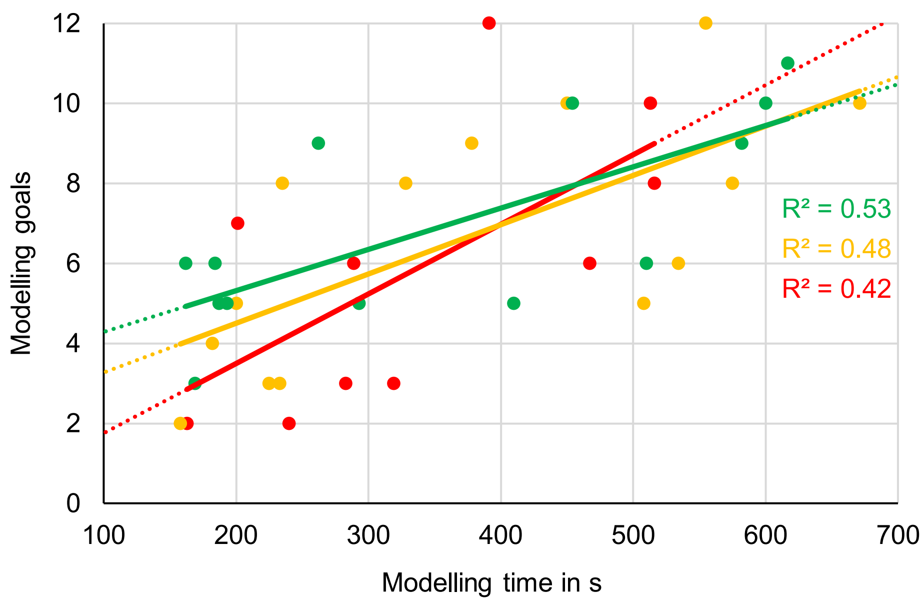
Annotations: Values between -.300 and .300 are hidden. The correlation is significant at the level of *0.05 or **0.01 (2-sided).

Figure 3. Scatter plot of modelling time and goals divided into tertiles based on prior knowledge.



Annotations: Low prior knowledge group in red (n = 10), medium in orange (n = 14) and high in green (n = 13).

Finally, prior knowledge only has a negative correlation with the number of Level 1 hypotheses and therefore a positive correlation with Level 3. On the one hand, this confirms the validity of the content analysis. On the other hand, it seems that the developed learning environment enables a successful interaction with dynamic models and experiments in optics, regardless of the amount of prior knowledge. This impression is confirmed by the graphic analysis of the scatter plot in Figure 3. The low knowledge group achieves less on average in a short time than the high knowledge group, but the students who invest more time can also achieve many of the modelling goals.

DISCUSSION AND CONCLUSIONS

The exploratory research questions were aimed at generating data-based hypotheses about learning with dynamic models and experiments. The study shows that not all students reach their modelling goals in an open learning environment. However, none of the dimensions of intrinsic motivation were measurably responsible for this. The number of modelling or experimentation goals strongly depends on the time invested. At the same time, it was found that the better the prior knowledge, the faster goals can be achieved. As for the formulated hypotheses, more subject knowledge results in a higher quality, but more modelling goals also occur with more Level 3 hypotheses. Based on the results, we expect that using a good learning environment, advanced hypotheses can be formulated based on a dynamic model without much prior knowledge, given enough time. Furthermore, an improved instructional design could help more students to find all the relevant settings for the model and to formulate functional hypotheses. We suggest that this would lead to a purposeful experimentation process and a better understanding of the physics, which will be examined in subsequent studies.

COMPARISON OF COMPUTER-AIDED AND HANDS-ON TEACHING APPROACHES ON STUDENTS' ANXIETY TOWARDS SCIENCE

Aslı SAYLAN KIRMIZIGÜL[1] *and Hasan KAYA*[1]
[1]Erciyes University, Kayseri, TURKEY

The present study was conducted to explore the effect of the use of computer-aided and hands-on teaching approaches on 7th grade students' anxiety towards science. The research was carried out in the spring semester of 2016-2017 academic year with the participation of 70 students from two classes of a middle school in Kayseri, Turkey. The pre-test and post-test quasi-experimental design without a control group was used. Within the scope of the study, "Reflection in the Mirrors and Absorption of the Light" unit was taught through computer-aided instruction in experimental-1 group, and hands-on science in experimental-2 group by developing suitable activities for each approach. In the study, data were collected through Science Anxiety Scale. The data were analyzed through paired sample and independent samples t-tests. According to the results, although both two approaches had positive effects on science anxiety levels, it was seen that computer-aided instruction was more effective. In terms of five sub-dimensions of the scale, there is a significant difference between two groups of students' post-test scores in favour of experimental-2 group.

Keywords: Science education, computer-aided instruction, hands-on science

INTRODUCTION

The middle school years are a critical time for learning science. In addition to cognitive characteristics, affective features such as attitude, anxiety and motivation also affect the learning process. There is a close relationship between anxiety and learning (Cüceloğlu, 2015). Anxiety is defined as the feeling that occurs when situations threaten the ability to meet basic human needs such as competence, control, self-esteem (Fiske, Morling, & Stevens, 1996). Although a certain amount of anxiety is usually beneficial for learning, an advanced level of anxiety prevents learning (Cüceloğlu, 2015).

The science anxiety is defined as the total of experiences such as fail to solve a science problem or understand a scientific concept, or failing a science exam (Mallow, 1986). A high level of science anxiety leads to a decrease in students' success and attitude towards science, and discourage them from entering science-related professions (Udo, Ramsey, & Mallow, 2004). The teaching methods used by teachers have important effects on students' science anxiety (Jegede, 2007).

In the literature, it was emphasized that physical phenomena such as light and mirrors are not sufficiently related to daily life and remain abstract, therefore they cannot be understood clearly and cause science anxiety (Colin & Viennot, 2001; Galili & Hazan, 2000). It is thought that active student participation in the science course will enhance students' self-confidence and lower their science anxiety levels (Kaya & Yıldırım, 2014), and enable concretization of the scientific concepts and link them with daily life (Zacharia, 2003). At this point, computer-aided instruction (CAI) and hands-on science (HOS), which play an important role in the concretization of abstract concepts by addressing many sense organs, come to the fore. Computers play an important role in doing dangerous experiments, obtaining and processing data quickly, and providing immediate feedback. It was revealed in several studies that the computer reduces anxiety when it is used for educational purposes (Newhouse, 2002; Rutten, van Joolingen, & van der Veen, 2012). HOS is defined as laboratory activities that allow the students to handle, observe and manipulate a scientific process (Lumpe & Oliver, 1991). In HOS, students work as scientists to learn the scientific concepts permanently- i.e. they conduct experiments, make observations, and collect data. “Reflection in the Mirrors and Absorption of the Light” unit in science curriculum is well suited for teaching through both CAI and HOS approaches, and there is no accessible study comparing the effects of these two approaches on students’ anxiety levels. Therefore, the research question of the current study was determined as “Is there a statistically significant difference between science anxiety levels of the 7th grade students who taught “Reflection in the Mirrors and Absorption of the Light” unit through CAI and HOS?” Within the scope of this research question, the following sub-problems were searched:

1. Is there a statistically significant difference between pre-test and post-test scores of the students in the experimental groups?

2. Is there a statistically significant difference between the post-test scores of experimental groups in terms of entire scale, and in terms of sub-dimensions of the scale?

3. Is there a statistically significant difference between pre-test and post-test scores of the students with respect to the gender?

METHOD

Research Design

In the study, the pre-test and post-test quasi-experimental design without a control group was used. In order to assess the efficacy of each activity the same scale was administered two times, before and after the five-weeks implementation.

Sample

The sample, which was selected through convenience sampling method, consisted of 70 (34 girls, 36 boys) 7th grade students from two classes of a middle school in Kayseri, Turkey in the spring semester of 2016-2017 academic year. While one class including 34 students (17 girls, 17 boys) was assigned to be the experimental group-1 (E1), one class including 36 students (17 girls, 19 boys) was assigned to be the experimental group-2 (E2).

Instrument

Science Anxiety Scale developed by Uluçınar Sağır (2014) was used to determine the students’ anxiety levels towards science in the study. This 5-point Likert scale has 25 items and five sub-dimensions namely; (1) focusing on class, (2) lack of self-confidence, (3) studying and anxiety for the exams, (4) disturbance, (5) interest. These five factors include seven, six, six, four and two items, respectively. While higher total scores obtained from the scale indicate high science anxiety level, lower total scores indicate low science anxiety level.

In addition to the anxiety scale; after a comprehensive review of the scientific literature was conducted, the teacher and student evaluation rubrics were developed by the researchers to be used for classroom observations.

Implementation

"Reflection in the Mirrors and Absorption of the Light" unit in Turkish science curriculum has six main subjects: (1) Mirrors and their usage, (2) image formation in mirrors, (3) interaction of light with matter, (4) white light contains all colors, (5) reflection and absorption of light, (6) the importance of solar energy.

During five weeks (four hours a week), the unit was taught to E1 through CAI, and E2 through HOS. In E1 group, subjects were taught using smartboard, computers through digital images, videos, animations, simulations (i.e. Algodoo), interactive tests, while in E2 group, activities were done with simple, inexpensive materials. In order to ensure validity and reliability, all the courses of each group were systematically observed by two observers, a researcher and a science teacher, using teacher and student evaluation rubrics which were developed by the researchers.

Data Analysis

In order to examine the first, second and third sub-problems, paired-sample t-test and independent samples t-test were conducted using SPSS (Statistical Package for the Social Sciences) version 24.0.

RESULTS

Firstly, according to the independent samples t-test results, no significant difference was found between E1 (M=58.00, SD=10.354) and E2 group (M=57.08, SD=17.130) students' pre-test scores [$t(68)$=0.273, p>.05]. Similarly, no significant difference was found between two groups' pre-test scores in terms of sub-dimensions (p>.05).

Secondly, according to the paired-sample t-test results, for E1 group, there was a significant difference between pre-test (M=58.00, SD=10.354) and post-test mean scores (M=42.68, SD=9.524) in favour of pre-test scores ($t(68)$ =6.006, p<.05). Eta-squared was found as 0.35, suggesting a large effect size (Cohen, 1988). Similarly, for E2 group, there was a significant difference between pre-test (M=57.08, SD=8.145) and post-test mean scores (M=48.36, SD=16.162) in favour of pre-test scores [$t(68)$ =3.989, p<.05]. Eta-squared was found as 0.19, suggesting a large effect size (Cohen, 1988). In other words, CAI activities in E1 group and HOS activities in E2 group significantly reduced the anxiety levels of the students.

According to independent samples t-test results, there is a significant difference between E1 (M=42.68, SD=9.524) and E2 group (M=48.36, SD=16.162) students' post-test scores in favour of E2 group [$t(68)$= -3.392, p<.05]. Eta-squared was found as 0.15, suggesting a large effect size (Cohen, 1988). The results also indicated that there is a significant difference between E1 and E2 groups for all the five sub-dimensions in favour of E2 (p<.05) (Table 1). For focusing on class, lack of self-confidence, studying and anxiety for the exams, disturbance and interest sub-dimensions, eta-squared values were found 0.08, 0.13, 0.06, 0.08 and 0.05, respectively. While 0.05 indicates a small effect, other values indicate moderate effects (Cohen, 1988).

Table 1. Independent samples t-test results according to the average total scores for Science Anxiety Scale sub-dimensions

Sub-dimensions	Group	N	Min.	Max.	M	SD	t-test		
							t	SD	p
Focusing on class	D1	34	7	19	10.18	3.371	-2.487	3.37	0.016
	D2	36	7	27	11.72	5.069		5.07	
Lack of self-confidence	D1	34	6	19	10.94	3.550	-3.153	3.55	0.003
	D2	36	6	29	12.56	5.828		5.83	
Studying and anxiety for the exams	D1	34	6	18	10.00	3.153	-2.127	3.15	0.037
	D2	36	4	12	11.05	4.804		4.80	
Disturbance	D1	34	4	12	7.88	2.332	-2.371	2.33	0.021
	D2	36	4	17	8.67	3.825		3.83	
İnterest	D1	34	2	7	3.68	1.273	-1.896	1.27	0.062
	D2	36	2	7	4.36	1.726		1.73	

In Figure 1, a line chart regarding the pre and post-test mean scores of the E1 for the five sub-dimensions was given. According to the chart, students' mean scores in all sub-dimensions were increased in post-test dramatically.

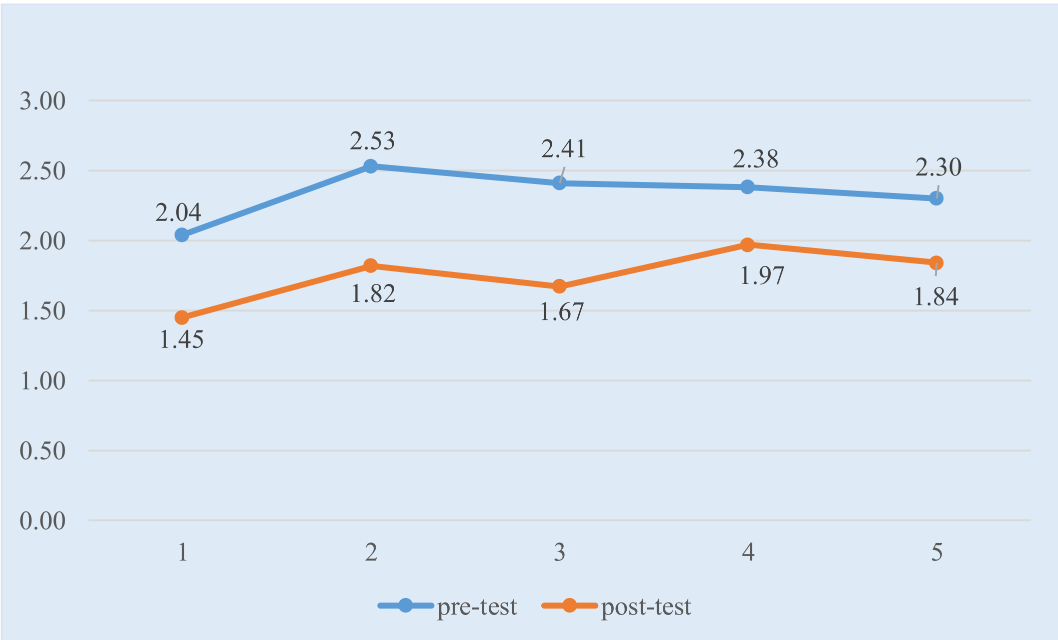

Figure 1. Line chart for the comparison of E1's pre and post-test mean scores regarding the five sub dimensions.

In Figure 2, a line chart regarding the pre and post-test mean scores of the E2 for the five sub-dimensions was given. According to the chart, students' mean scores in all sub-dimensions were increased, but not as much as the students' scores in E1.

Figure 2. Line chart for the comparison of E2's pre and post-test mean scores regarding the five sub dimensions.

Lastly, in order to examine whether there is a statistically significant difference between pre-test and post-test scores of the students with respect to the gender or not, independent samples t-test was conducted. The analysis results indicated that no significant difference was found between both the pre-test mean scores of girls (M=58.40, SD=14.369) and boys (M=57.06, SD=13.219), [$t(68)=-0.435$, $p>.05$], and the post-test mean scores of girls (M=45.02 SD=11.739) and boys (M=46.02, SD=11.756), [$t(68)=-0.375$, $p>.05$].

DISCUSSION OF FINDINGS AND IMPLICATIONS

The research findings revealed that while both teaching approaches decreased students' anxiety towards science, CAI is much more effective than HOS. Unlike HOS, which usually involves collaborative activities, since students usually work individually and feedback is given directly to the student in CAI, the student does not worry about being criticized by his/her teacher or friends when s/he make a mistake. This situation encourages students to participate in the course (Sevim, 2015). It is thought that the use of computer, which the students frequently use in daily life, in the learning process actively makes the students feel more comfortable and decreases their anxiety levels (Newhouse, 2002; Rutten, van Joolingen, & van der Veen, 2012).

The current study is limited to the selected sample and teaching approaches. Thus, it is recommended that future studies be conducted to validate the findings of the current study by incorporating- a larger sample size, different grade groups, a longer period of time, and different teaching approaches.

DIAGNOSIS OF DIFFICULTY-GENERATING CHARACTERISTICS IN PHYSICAL PROBLEMS

Mareike Freese[1] and Jan Winkelmann[1]
[1]Goethe University, Frankfurt, Germany

In general, physics is seen as one of the less favourite school subjects, which has been widely examined in the past. The lessons are perceived as difficult by many pupils, resulting in a deficient number of them choosing physics as an advanced course, or A Levels exam subject. Explaining the difficulty of physics lessons, essential features of physics are often suspected, such as experimental work, thinking in models, mathematization, dealing with different forms of representation, or just the scientific language. Although these individual features have been empirically referenced, their impact on pupils' perception of the difficulty has not been examined sufficiently. Based on four main categories established by Merzyn (2008), this project examined pupils' problems while solving physical tasks, each with an increased share of scientific language, mathematization, modelling or a lack of reference to everyday life. While solving the tasks, the method of thinking aloud was used to answer the following questions: What characteristics make physical problems difficult for pupils while solving a task? How do pupils perceive the problem's level of difficulty? Can pupils articulate a particular difficulty-generating characteristic to ask for targeted support? In an ensuing interview, the pupils were asked to rank the problems according to their level of difficulty and to reflect on the difficulties and individual hurdles during the solving process.

Keywords: Physics, Problem-solving, Task difficulty

THEORETICAL BACKGROUND

As so many pupils see physics as their least-liked school subject (Williams et al., 2003; Bennett & Hogarth, 2006; Fruböse, 2010; Caglar-Öztürk, 2015), it is interesting to explore the main reasons for this unpopularity. Especially its widely perceived difficulty has been stated many times (Ford, 1989; Angell et al., 2004; Ornek et al., 2008). This is also reflected in the alarming results of the PISA survey (OECD, 2016) which are worthy of improvement and brought problem-solving to public attention, as experts feared after those results, that pupils would not learn to deal with real problems in everyday life (Kühn, 2011). Daily and physical problems, as well as the problem-solving competence, will be explained hereafter.

In a previous work (Fareed & Winkelmann, 2019), several factors that are believed to make physics difficult have been examined. Most frequently mentioned, by both male and female pupils, are the following difficulty-generating characteristics: lack of relevance in the daily life, need of personal effort, use of technical terms, modelling and idealisation of physical problems. These factors coincide with the main categories by Merzyn (2008) and will be further explained in the following.

(Physical) Problems and Problem-solving

Although the two terms "problem" and "task" are mostly used synonymously, it is helpful to define them, as well as the process of problem-solving in cognitive psychology. While a task predominantly describes one single (part) of an exercise or question, a problem serves more as a collective term, from which related terms like problem-solving derive (cf. Brandenburger, 2016). Dörner (1976) defines a situation as a problem if a person strives to turn an unpleasant initial state into an opposite final state. A barrier in between prevents the person from doing so, which might be a lack of methods or the final state not being defined properly. Following Smith (1991), every item that needs analyses and conclusions (concluding knowledge of the relevant domain) is defined as a problem. In order to reach the desired final state, a person must make use of problem-solving strategies. Problem-solving is an essential condition to act in simple daily situations, in scientific questions, or in complex socially relevant political and economic problems (cf. Reif, 2008; Brandenburger, 2016). In school, problems need to be solved daily. The ability to do so is called problem-solving competence, which is defined as "an individual's capacity to engage in cognitive processing to understand and resolve problem situations where a method of solution is not immediately obvious […] in order to achieve one's potential as a constructive and reflective citizen" (OECD, 2014). In school, it is also a key competence necessary in all subjects and fields (cf. Brandenburger, 2016) and required in national educational standards and curricula. Therefore, the focus of our research is on the problem-solving competence, which enables students to deal with the presented physical problems successfully. Those problems result from reality; in order to process them appropriately for pupils, they are represented by means of idealization and simplification. Physical models depict those phenomena of everyday life professionally in the form of representations, which are to be solved with mathematical tools. Thus, multiple characteristics are faced, which can generate difficulties during the problem-solving process.

Difficulty-generating Characteristics in Physical Problems

As mentioned at the beginning, Merzyn (2008) collected pupils' impressions of difficulty and sorted them into four prominent categories. These are a) the technical jargon, b) the use of mathematics and quantitative calculations, c) physical statements that are inconsistent with expectations from everyday life, and d) a high degree of abstractness and modelling. These four main categories are difficult to separate in school, as they overlap a lot. They served as a basis for this study, which was conducted to examine the impact of the characteristics on task difficulty.

In school, it is useful to include everyday life phenomena as a context for solving physical problems. Those contexts also help in training scientific literacy (cf. Dorschu, 2013). By applying knowledge to other contexts, it is linked and transferred more strongly, as learning never happens in an isolated way. In this way, physics gets closer to the pupils' lives and more problem-oriented, so authentic problems are needed in class. Furthermore, the higher motivation which comes with it helps create a better attitude of the pupils towards physics lessons (cf. Merzyn, 2008). The ideas of everyday life phenomena are retrievable like previous knowledge (cf. Lehner, 2012), whereas incorrect ideas and preconceptions need to be corrected.

Physics has a high level of abstract words which are used in a technical way (cf. Fruböse, 2010). This results in a contrast between physical language and everyday language (cf. Merzyn, 2008), and is especially difficult when terms are used in both domains with different meanings.

Mathematics plays an essential role in physics. On the one hand, it acts as a helpful tool for capturing physical correlations quantitatively. On the other hand, it helps with formulating precise statements about physics, making it a medium for communication (cf. Pospiech et al., 2015). Furthermore, numerous fundamental physical concepts consist of mathematical operators, making mathematics and physics closely linked and hard to separate. Moreover, mathematics is used for modelling, in order to predict and simplify phenomena (cf. Trump & Borowski, 2012). But transferring mathematical knowledge to physics is often problematic for pupils (cf. Taşar, 2010), as they cannot apply the right knowledge flexibly to physical problems and therefore use mathematical strategies which are inconsistent with the problem (cf. Uhden, 2012).

Scientific models are distinguished through two essential features. The illustrating feature means that a model is the projection of an object, while the reducing feature means that a model includes only a subset of all attributes of an object (cf. Kircher, 2010). Therefore, there are elements of an object which are not part of the model, resulting from the method of idealizing. Idealization means neglecting aspects of reality in a theoretical model which would complicate it (cf. Lehner, 2012). Furthermore, models are always linked to an issue and a purpose, thus they include the opinion of a person or a certain intention for formulating and analysing hypotheses about experiences (cf. Krüger et al., 2018). Another argument in favour of including models in physics class is the fact that they are a way of treating physical subjects like in real scientific research, which can be motivating for pupils (cf. Leisen, 1999).

STUDY DESIGN

Research Questions

In this project, based on the presented background, the following research questions are addressed:

1. Do pupils articulate the difficulty-generating characteristics suspected in the referred literature while trying to solve physical problems?

2. Can pupils use the detected characteristics to overcome difficulties in the solving process by purposefully asking for support?

Preliminary Study

In the preliminary study, experts (n = 25) on creating lesson material (active and retired teachers, scientific assistants, and university professors) were to evaluate, based on the problems we have created, what constitutes the difficulty-generating characteristic which is deliberately built into the task by us. Here, the experts were not required to solve the tasks, but only to find out what is the hurdle that makes the task difficult. The difficulty-generating characteristics that were incorporated are those mentioned before in the theoretical background and have been worked out by Fareed & Winkelmann (2019). This preliminary study was conducted as a validity check of whether experts can recognize the difficulty-generating characteristics in the problem.

Main Study

In the main study, a two-stage qualitative case study, two types of testing were performed. First, our group of pupils (n = 9), was presented with physical problems on four different worksheets. The group consisted of high school (Gymnasium) pupils in the German E-Phase (pre-A levels, year 10, or 11). All the problems dealt with the issue of freefall, which is part of the curriculum of that year. The pupils were asked to articulate their method of solving the freefall situations on each worksheet. Every single problem was designed consisting of a certain built-in characteristic that made the task difficult (cf. preliminary study, above). The pupils' statements were recorded, and they were supervised by one of the study leaders while solving the problems within a time span of 45 minutes, each pupil on his or her own. In their attempt to solve the tasks, they were motivated to use the method of thinking aloud (cf. measuring instruments, below) to explain their solving techniques.

At the end of the thinking aloud phase (second stage), the pupils were to reflect on what was difficult in the individual tasks, and the resulting interviews were then used to check whether the statements match our assumptions. A guideline-based interview supported the pupils' reflection on identifying individual hurdles in the different given problems. First, they had to rate the four worksheets with regard to the level of difficulty. Secondly, every worksheet was discussed regarding each intended characteristic, and the pupils were asked what exactly made the solving process difficult or impossible. In the end, the pupils' half-term marks in physics and their satisfaction with the subject were recorded.

The objectivity of the study was ensured by working with an observation sheet that provided a pre-structured guide to the analysis of the recordings, including keywords which point to the individual characteristics. The recordings were transcribed in order to analyse them qualitatively, according to Mayring (2015).

Measuring Instruments

1. Physical Problems and Rating Sheet

In the preliminary study, the experts received four different worksheets, each of which contained a physical problem with one individual difficulty-generating characteristic. By the experts, this characteristic only needed to be recognized and named without having to solve the problem. For this purpose, the experts received an additional rating sheet to help them to identify the corresponding difficulty-generating feature. Using a five-point rating system, they had to evaluate which feature occurs to what extent in the task. Additionally, we checked the inter-rater reliability.

In addition to the worksheet covering the technical jargon, an alternative one was prepared for the pupils to compare them in the reflection phase. On the alternative version, all technical terms were wiped out, and physical phenomena were explained in simple words.

2. Recordings of the Thinking Aloud Phase

In the main study, the pupils were given the worksheets with the built-in difficulty-generating characteristics, and they were then encouraged to solve them. Successful solving was not required, which the pupils were told beforehand. While solving the problems, the pupils were asked to formulate their thoughts out loud, which was recorded via voice recorder. The voice recordings of the thinking aloud phase were transcribed and served for further analyses.

Qualitative research formed the approach of the study since the openness and flexibility of the qualitative method make it possible to freely and exploratively analyse the pupils' way of solving the tasks and generating hypotheses. Furthermore, the method of thinking aloud is used to capture insights into the mental part of the problem-solving process, which is very complex and sometimes unobservable. Thinking aloud always happens parallelly to the primary task (cf. Völzke, 2012).

3. Guideline-based Interview

The observations from the problem-solving phase were used to ask what the personal difficulty was specifically for each pupil. Also, all difficulty-generating characteristics were addressed, so that the pupils could connect each general difficulty with a concrete problem situation and sort these according to the perceived difficulty.

RESULTS

In the preliminary study, the validity of the material was checked. Unfortunately, only two of the expert questionnaires were sent back to the institute in time to analyse them for this study, so there cannot be drawn adequate conclusions. Moreover, there could be seen a big inter-rater discrepancy between those two questionnaires, so that the preliminary results were not used for the final evaluation.

The main study enabled in-depth structural analyses of problem situations. The pupils' statements during the thinking aloud phase and in the reflective interview suggest that they have issues formulating concrete difficulties and are not able to ask for targeted support concerning the difficulty.

Furthermore, the study should give a brief insight into the pupils' ability to solve physical problems in the sense of identifying the difficulty of the individual problem. Different difficulties can dominate different problems. The identification of those individual hurdles could help the pupils to solve the problem.

Regarding the four examined difficulty-generating characteristics, especially the modelling and idealising, get into the focus. The pupils agreed that exercises with models are rarely used in class. While solving the modelling worksheet, the pupils found it rather motivating that they did not have to calculate at first. They tended to idealize the wrong details, though, in order to approach their model. For example, some pupils thought about the constitution of the landing ground while modelling a suitable parachute situation.

Before pupils have to use advanced mathematics in a problem like the presented one (here: using the reduced quadratic equation), the sense of the problem has to be understood by modelling it. Most of the pupils already failed in this situation, which confirms earlier studies (cf. Angell et al., 2004).

Technical jargon in physical problems was perceived as both an advantage and a disadvantage. On the one hand, new physical terms first sounded difficult and confusing, but on a closer look, they helped in founding the right formula. In the reflection interview, the pupils had to compare it to the alternative version without the technical terms. They perceived that version as childish and not helpful in solving the problem. Last, the pupils expressed the wish for a higher level of everyday life references in all the worksheets.

SUMMARY & OUTLOOK

The results of the study show that it seems worthwhile to focus more on modelling in physics class. On the one hand, pupils express more interest in this kind of exercises, and on the other hand, they show big difficulties in solving the problems.

Almost all pupils complained that they were not able to solve the problems due to the lack of important formulas. The reason for this might be the long period between learning the subject in class and the study, as the issue of free fall had been discovered in the first half term of that year and thus had been a few weeks earlier. The required formulas could have been repeated in preparation for the study, but it would have distorted the results.

Contrary to the literature, the characteristic of the technical jargon was often not perceived as hindering, but as helpful for deriving the necessary formulas. Nonetheless, in future studies, the material should be designed more clearly and unambiguously with the required formulas given, in order to focus more strongly on the actual difficulty-generating characteristics.

Regarding the second research question, if pupils can use the detected characteristics to ask for targeted support, we can see that they were not able to do so. In conclusion, pupils should be sensitized more in class for difficulty-generating characteristics, to facilitate the search for support. One possibility might be the reflection about individual hurdles while trying to solve physical problems.

ACKNOWLEDGEMENT

We thank the Equal Opportunities Council of the physics department at Goethe University in Frankfurt, which supported the presentation of this project at the ESERA 2019 conference financially.

ENHANCING SECONDARY SCHOOL STUDENTS' LEARNING AND INTEREST FOR ENERGY: RESULTS FROM THE IMPLEMENTATION OF AN INTERVENTION

Georgia Toli and Maria Kallery

Aristotle University of Thessaloniki, Greece

In the present paper we briefly describe an intervention aiming at enhancing secondary students' interest and academic achievement for the topic of energy and present the results of its implementation. The intervention was implemented in the introductory physics course in the second year of the Greek High school. The total number of the participants was N=110 for the experimental group and N= 96 for the control group. The learning activities were delivered in real classroom settings. The intervention included experimental hands on activities, outdoor activities, problem solving situations and use of a software specifically designed for the purpose of our study. The control group was taught about the same topics of energy in a traditional way of teaching. We investigated whether there is a relationship between level of engagement, interest and learning outcomes. The results showed that there are significant positive correlations between, interest, academic achievement and level of engagement. This highlights that enhancing interest could lead to better learning outcomes.

Keywords: energy, interest, engagement

INTRODUCTION

The unifying role of energy in all fields of science which makes it a concept that enables the explanation of many phenomena, confirms its multidimensional importance for education. It is recognized as a major learning objective of school science as it is significant for the students' understanding of other concepts and phenomena in school physics. The teaching of energy has been the subject of many studies in the field of education (e.g. Papadouris and Constantinou, 2016) as it is a concept that students find difficult to understand and for which they hold many alternative conceptions. The above diminish the students' interest for the subject making energy an unattractive topic for the students. Given all the above, we consider important to find appropriate teaching approaches to attract and enhance the interest of students and improve their learning outcomes.

Researchers (e.g. Hidi & Renninger 2006, Harackiewicz, J. M., Smith, J. L., & Priniski, S. J. 2016) have highlighted the role of interest as it creates motivation and guarantees the engagement of a person in content-specific activities. It is a powerful motivational factor that energizes and increases learning, and is essential to academic success (Pressley et al., 1992). Interest is both a psychological state characterized by increased attention, effort, and affect, experienced in a particular moment (situational interest), as well as an enduring predisposition to reengage with a particular object or topic over time (individual interest) (Hidi & Renninger, 2006). Situational interest appears to be especially important in catching students' attention, whereas personal interest may be more important in holding it (Hidi and Baird, 1986, Mitchell, 1993). According to Renninger and Hidi (2016) interest is always motivating and engaging and the presence of interest ensures active and meaningful engagement in science classes which is a key contributing to academic success and better learning outcomes (Wang & Degol, 2014b).

Regarding engagement-strongly related to student performance (e.g. Darling-Hammond, et al. (2008)-according to Wang & Degol (2014b), incorporates four dimensions: behavioral, emotional, cognitive, and social engagement. These four components of student engagement are dynamically embedded within the individual and operate at multiple levels. Behavioral engagement is defined in terms of involvement in academic and class-based activities, presence of positive conduct, and absence of disruptive behavior (Fredricks et al., 2004). Emotional engagement is conceptualized as the presence of positive emotional reactions to teachers, peers, and classroom activities, as well as valuing learning and having interest in the learning content (Voelkl, 1997). Cognitive engagement is defined in terms of self-regulated learning, using deep learning strategies, and exerting the necessary cognitive strategies for the comprehension of complex ideas (Zimmerman,1990). Social engagement includes the quality of social interactions with peers and adults, as well as the willingness to invest in the formation and maintenance of relationships while learning (Fredricks et al., 2016). Since there is an alarming decline on students' interest from elementary to high school (Frenzel, Pekrun, Dicke, & Goetz, 2012) educators should take into account the beneficial synergy between interest and engagement in order to design and create appropriate learning environments that enhance these two important components.

In a metanalytic review (Lazowski & Hulleman,2016) there are 74 interventions that highlight the important role of interest in all subjects. In their metanalytic review Rosenzweigh and Wigfield, (2016), found that there are 53 interventions aiming at creating motivation in math and science in general. We found no intervention that targets in enhancing students' situational interest and engagement, concerning the specific topic of energy and the concepts related (mechanical work, kinetic and potential energy), in the secondary education. Based on the above, we designed and implemented in the secondary education an intervention aiming at enhancing students' situational interest, engagement and learning in the topic of energy. In the present paper we briefly describe the intervention and present the results of students' academic achievements and development of their situational interest and their engagement.

METHODOLOGY

The intervention: design and implementation

In order to design an appropriate intervention, we considered Hidi and Renninger's (2006) interest model. According to four-phase model of interest development it is assumed that in the first phase (triggered situational interest), it is necessary that the materials attract a student's attention and lead to momentary enjoyment. In the second phase (maintained situational interest) external factors sustain a learner's attention, such as value (usefulness and importance) of the content. The last two phases include emerging individual interest (Phase 3) and well-developed individual interest (Phase 4). Since our target is to increase situational interest, we are dealing only with the two first phases.

Before designing the intervention, students were asked about themes from every-day life that trigger their interest. Their answers were grouped into categories related to the topics of the energy units (e.g sports, nutrition, space). Furthermore, to investigate students' prior knowledge, a questionnaire composed of questions related to the topic of energy was administered to the students ahead of the implementation of the intervention. A sample of the questions is presented in Appendix A.

Our intervention included experimental hands on activities, outdoor activities, problem solving situations and use of a software specifically designed by the authors for the purpose of our study. The structure of the intervention is presented in Figure 1.

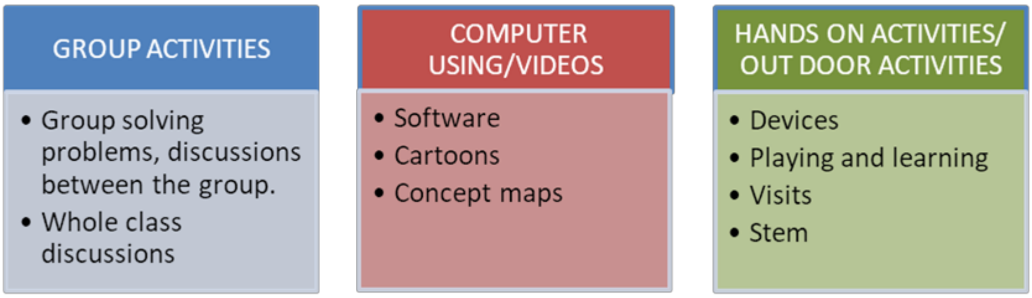

Figure 1. The teaching and learning activities of the intervention

The software was in Java script and included 3D animated experiments. These animations helped students understand easily all the related to energy concepts such as mechanical work, potential and kinetic energy. For example, in order to calculate the work done by constant forces, students had the chance to carry out the same experiment as many times as needed, for various displacements and realize that the work done by a constant force increases with the displacement. Also, they could change the mass of a moving with constant speed object and understand that kinetic energy increases with mass and they could also change the speed of a moving object and understand that it is proportional to the speed's square. Students could furthermore examine how potential energy depends on the distance of an object from the ground (height), its mass and the acceleration of gravity. They also could understand that potential energy is independent of the path a moving body takes. All students, work in small groups and had the chance to use the software. The software was accompanied by worksheets distributed to all students participating in each group. This helped them stay focused during the lesson.

To maintain students' interest their involvement and engagement were considered crucial. Thus, they participated in pleasant activities they could easily deal with which assisted them to comprehend the lesson. To this contributed the fact that all the students were given active roles during the course designing and performing simple experiments on their own and had the opportunity to make constructions as well. They also watched short funny cartoon videos and came into conclusions about energy transformations after whole class discussions. Furthermore, in order to understand energy transformations, they participated in STEM activities, where they constructed a windmill, a solar car etc. Apart from this they had the chance to make connections between the concept of energy and their everyday life and develop a sense of the new content's value at the same time. A large number of the students of the experimental group worked voluntarily and found information concerning various topics like atomic bomb, nuclear energy and also accidents that happened in nuclear factories etc.

The study (which was carried out in a public school in Greece) involved an experimental and a control group. Both groups were taught the units concerning the topic of energy were according to the National Curriculum: mechanical work, kinetic and potential energy, mechanical energy and its conservation. In the experimental group our intervention was implemented while in the control group we used the traditional teacher-centered teaching approach. This involved lectures and students' individual work. The intervention took place during the scheduled Physics course, twice a week, for two separate hours. in the second year of high school (students aged 14). There were two implementations of the intervention during two consequent school years (2016-17, 2017-18), from January until May, where the total number of the participants for both years was N=110 for the experimental group and N= 96 for the control group.

Data collection

Data for students' interest, academic achievement and level of engagement were collected from both experimental and control groups. The data were used to investigate:

a) whether there is a positive correlation between situational interest, level of engagement and learning outcomes for both groups

b) whether there are higher levels of the above factors in the experimental group.

Students' situational interest during the physics class was assessed by a self-report questionnaire with thirteen items, seven items for triggered and six items for maintained interest. The questionnaire was based on Mitchell's (1993) scale and on Linnenbrink-Garcia et al., (2010) scale after appropriate statements' adaptation to the concept of energy. The items for measuring triggered interest and those used for measuring maintained interest are presented in Table 1.:

Table 1. Questionnaire items used to measure interest

Triggered interest	**Maintained interest**
1) The lesson for energy fascinates me and thus it is very easy for me to pay attention during the class.	1) I believe that the field of energy is very interesting in general.
2) I find the lesson about energy interesting.	2) Studying about energy fascinates me.
3) The lessons for energy is so boring that it seems to me that drags on forever.	

To assess the level of students' engagement we adapted for the concept of energy "The Math and Science Engagement Scale" (Fredricks & Wang, 2016) consisting of 14 items. Five for assessing cognitive engagement, 3 for assessing behavioral engagement and 2 for assessing social engagement. A sample of these items are presented in Table 2.

Table 2. Sample of items for assessing students' engagement

Cognitive engagement:
1. I was trying to understand my mistakes concerning the topic of energy
2. When I was confronting a difficult problem, I tried to work hard, and never give up easily
3. I was always trying to connect my new knowledge with my prior knowledge.
Behavioral engagement:
1. I was trying really hard and I was seeking for help when it was necessary during classes concerning the topic of energy
2. I stayed focused during classes concerning the topic of energy
3. I participated during the learning activities.
Social engagement:
1. I liked cooperating with my fellow students
2. I was sharing my ideas during classes.
Emotional engagement:
1. I was feeling joy during classes
2. The lesson was not at all boring because I was actively engaged.

In both questionnaires students rated the extent to which they agree with each item on a four-point Likert -type scale ranging from 1 (totally disagree) to 4 (totally agree).

To assess academic achievement according to the learning goals, a test was administered to both experimental and control groups. The test consisted of 27 items with open-ended questions and with different levels of difficulty. We examined whether our students could apply the new knowledge they were taught in solving various problems concerning the topic of energy and the concepts related to it, according to our learning goals. For example, we examined whether students:

- Could calculate the work done by a constant force when the force and the displacement have the same or the opposite direction and in all other cases.
- Did not confuse the definition of work with everyday notion of work and understand the scientific conception of work.
- Understood that weight is a special case of force and that work can be calculated with another way apart from the conventional
- Understood that kinetic energy is a form of energy and is the energy possessed by an object due to its motion.
- Could calculate the kinetic energy of a moving object and solve more complex problems.
- Understood that kinetic energy has only magnitude and no direction.
- Understood that kinetic energy of an object increases with its speed.

- Can make calculations and solve complex problems using conservation of mechanical energy and be aware of the fact that in case energy is transformed, the total energy remains unchanged.

A sample of items that were used to asses learning outcomes are presented in Appendix B.

Data analysis and results

Initially we calculated the percentages of all the answers that students gave in both questionnaires, using SPSS. In Figure 3 we present an example of the percentages concerning situational interest and specifically from the item: *I find the lesson about energy interesting*. In Figure 4 we present an example of the percentages concerning engagement and specifically from the item: *I was trying hard and I was seeking for help when it was necessary during classes concerning the topic of energy*. As we can see there is a significant difference between the two groups. We had similar findings for all items in both questionnaires which is very encouraging.

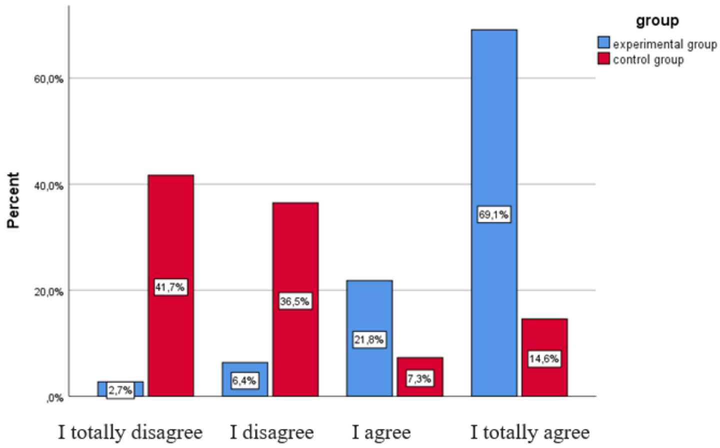

Figure 3. Percentages of students' answers concerning situational interest.

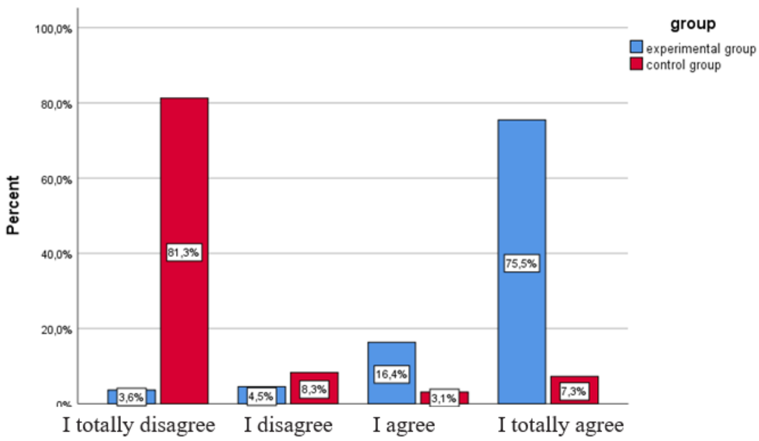

Figure 4. Percentages of students' answers concerning engagement.

Then we calculated the average of the students' answers to the questionnaires for each of the variables interest, academic achievement and level of engagement, using conventional methods. Value 1 was assigned to the lowest levels of each of the three variables and 4 to the highest. We found that the values of the three variables are significantly higher in the experimental group (see Figure 3). Questionnaire data were coded, categorized and statistically analyzed using SPSS. Cronbach's was calculated 0,879 for the interest and 0,866 for the level of engagement. To indicate correlations between the variables Pearson r was calculated. For the experimental group: between interest and level of engagement was 0,867, between interest and academic achievement was 0,757 and between level of engagement and academic achievements was 0,809. For the control group the corresponding values were 0,862, 0,876, 0,905.

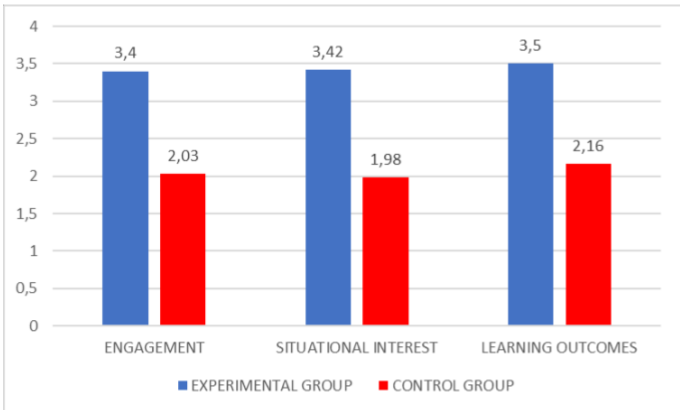

Figure 5. Levels of interest, engagement and learning outcomes for the experimental and control groups.

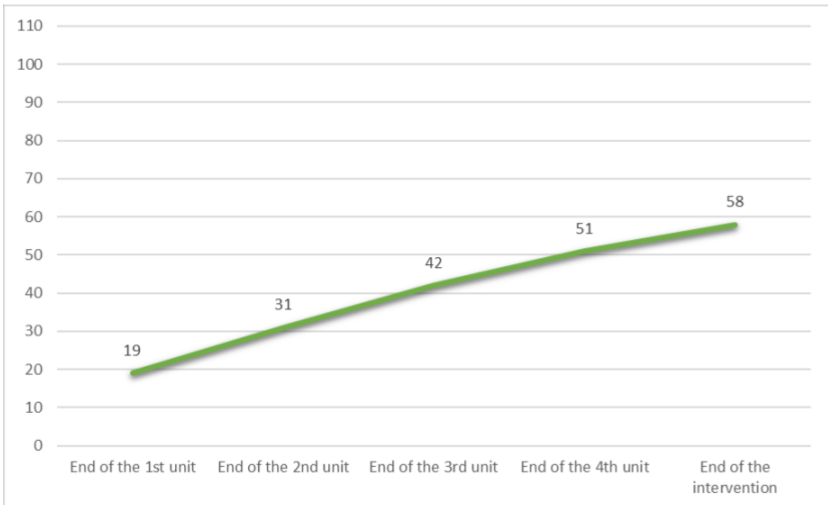

Figure 6. Number of students of the experimental group that work voluntarily during the intervention.

As we mentioned earlier, many students of the experimental group worked voluntarily during the intervention, something that proves that they reengaged with the new content they learned, and situational interest was maintained.

CONCLUSIONS

The results of the statistical analysis coupled with the findings reported in Figure 4, indicate that there is a strong positive correlation between high levels of interest, levels of engagement and academic achievement (experimental group). They also indicate that low levels of interest and engagement is positively correlated with low academic achievement (control group). The results are very encouraging indicating that students' interest is of great importance since it can lead to better learning outcomes and academic achievement. Our intervention seems to be fruitful in enhancing and maintaining the interest of the students of the class in which it was implemented. This can be due on the one hand to the materials used among which the software specifically designed to be simple in use which assisted students' understanding of difficult ideas introduced in the specific intervention, and on the other, to the approach used and most importantly in relating the topic of energy to the students' interests coming from every-day life, the hands on activities, the outdoor activities and the problem solving situations. Also, we consider that having students design and perform simple experiments on their own as well as giving them the opportunity to make constructions engaged them fruitfully in their own learning.

Pretest questions

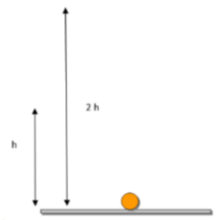
Why do you think the sheep feels tired even if he stays still?

Why do you think the big stone sitting on the rock becomes dangerous if it falls off the rock?

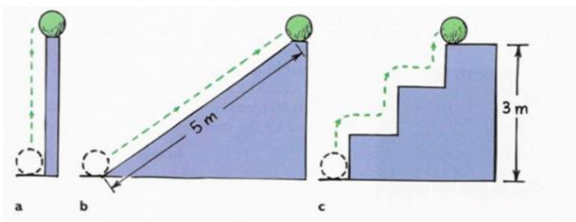
Appendix B

Questions used to asses learning outcomes

1. We lift an object of a mass m, at two different heights h and 2h from the ground. Can you calculate the analogy between its potential energy in these two different heights?



2. The same ball follows three different paths, as presented below. According to your opinion in which path the ball possesses higher potential energy and why?



3. We throw a ball from the ground with a speed equal to uo=40m/sec. What is the maximum height from the ground that the ball reaches? In what height from the ground the potential energy is equal to kinetic energy? (g=10m/sec2). Consider that there are no frictions or other forces from the air.

USING CLASSROOM MANAGEMENT TO SUPPORT INCLUSIVE CHEMISTRY LEARNING

Felix Pawlak[1], Katharina Gross[2]
[1]University of Cologne, Cologne, Germany
[2]University of Vienna, Vienna, Austria

In light of the increasing heterogeneity and diversity of today's secondary school students, it is important to consider innovative developments in science education research. Teachers face challenges on a daily basis as they try to address students' needs adequately in order to provide good-quality education for every student. Particularly chemistry teachers face challenges when teaching in very heterogeneous classroom settings as chemistry is not only taught theoretically but also calls for practical experiments. To cope with these challenges, it is reasonable to use strategies for inclusive chemistry education which have been identified as successful to promote students' learning. Classroom management is a proven approach to promote learning for all students. As the concept of classroom management offers a range of different strategies, it is necessary to identify those strategies most effective and relevant for inclusive science education and chemistry education in particular.

Therefore, this research project aims at identifying effective strategies of classroom management which support students' chemistry learning in heterogeneous and diverse learning groups focussing on the requirements of practical experiments. A qualitative research design was developed to explore major challenges of experimenting in the inclusive classroom and elicit respective strategies of classroom management. Interviews and questionnaires done with chemistry teachers were used as research methods. The successful completion of student experiments in a safe and supportive environment appears to be one of the major concerns in the inclusive classroom. On the basis of this prerequisite the preliminary study found out that learning of all students is best supported in an environment where there are clear procedures and routines, rules and consequences as well as clarity and structure of content. The results of the preliminary study are the starting point for investigating some strategies of classroom management in more detail, especially with respect to experimenting in the inclusive chemistry classroom.

Keywords: Inclusion, Science Education, Teaching Practices

THEORETICAL FRAMEWORK

> *„In addition, chemistry and science teachers are challenged by growing heterogeneity and diversity. This development challenges both the practice of science teaching and science education research development." (Markic, Eilks, Di Fuccia & Ralle, 2012, p.1)*

Following the ratification of the Convention on the Rights of Persons with Disabilities (CRPD) in 2006 and due to the increasing heterogeneity of secondary school students, it is necessary to think about new developments in science education research. Especially in Germany, the

CRPD raised many questions and posed challenges to teachers. Such an in-depth systemic change implies that chemistry teaching is faced with increasing student diversity and, consequently, chemistry teachers have to acquire appropriate strategies to deal with students' needs adequately and to provide high-quality education for all students in mainstream settings (Soriano, Watkins & Ebersold, 2017, p. 6). However, to cope with these challenges, it is useful to return to validated concepts and strategies which have been identified to be successful in promoting students' learning and providing high-quality education for all students. Nevertheless, these concepts must be considered in the subject-specific context of inclusive learning settings. Literature provides several framework concepts (e.g. UDL: Schlüter & Melle, 2017) and pedagogical-methodical approaches (diagnosis, differentiation and individual learning: e.g. Abels, 2015; Menthe & Hoffmann, 2015) to the design of chemistry-specific learning in diverse and heterogeneous learning groups. All of them focus on individual access and pay less attention to the general conditions of learning, like the atmosphere or learning environment. Classroom management is one promising concept.

Why does Classroom Management appear to be a promising approach?

Classroom management is a concept that provides strategies effective for creating a positive teaching and learning environment. This includes general strategies like rules, consequences, instructions, routines, procedures, managing student work and monitoring student behaviour (Bear, 2015; Emmer & Evertson, 2013). Several meta analyses showed the relevance of these strategies for learning in heterogeneous learning groups (Korpershoek, Harms, de Boer, van Kuijk & Doolaard, 2016; Helmke, 2014; Hattie, 2012). Classroom management may seem to be contradictory to concepts of dealing with heterogeneity and diversity initially, as it has a strong focus on routines, procedures and rules, but Seiz et al. (2016) were able to show various positive effects for heterogeneous classes. In general, it is very important for heterogeneous and diverse learning groups to have clear guidelines when learning (Claßen, 2013; Lotan, 2006; Soodak & McCarthy, 2006; Polirstok, 2015). Furthermore, they pointed out that underachieving students benefited greatly from classroom management. Ferreira González et al. (2019) also observed positive effects on learning and working behaviour in inclusive biology lessons. The strategies of classroom management address the general conditions of learning and facilitate students' learning. The concept of classroom management is one possible way to support students' learning successfully (Emmer & Sabornie, 2015; Fricke, 2016; Borich, 2014; Hattie, 2009; Kounin, 1970). One central aim of classroom management is to establish and sustain a structured academic environment which allows all students to participate in learning (Evertson & Weinstein, 2013, p.4).

The theoretical framework is based on three main aspects (see fig.1). Firstly, the concept of classroom management is outlined and the challenges of heterogeneity and diverse learning groups are discussed. The aspect of the project focuses on a distinctly subject-specific issue, the student experiment.

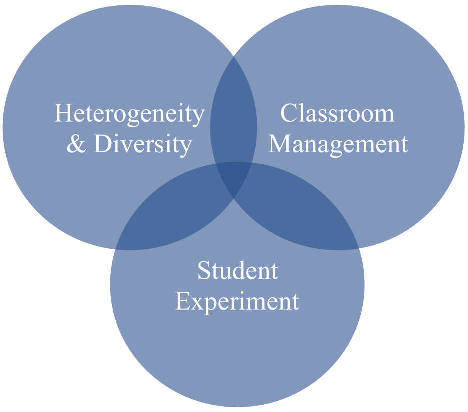


Figure 1. Theoretical Aspects of the Research Project.

The student experiment is a central component of chemistry education. However, experimenting in inclusive learning groups can be very challenging (Reiners & Adesokan, 2017; Menthe & Hoffmann, 2015), as there are several factors that have to be considered: supportive conditions have to be created for students' subject-related learning while ensuring safety, which is both important and demanding in a highly heterogeneous setting. Successful classroom management includes organizational and instructional strategies to ensure a safe and supportive environment so that all students can experiment and learn together in chemistry classes.

A variety of general classroom management strategies are available. But as classroom management is a comprehensive approach to promote learning for all students, it is necessary to identify strategies relevant for chemistry education in general and the student experiment in particular. Therefore, this research project aims at finding out which subject-specific classroom management strategies support students experimenting in inclusive chemistry classes.

METHODOLOGY

In order to be able to identify chemistry-specific classroom management strategies for student experiments in diverse and heterogenous learning groups, this project was divided into five stages (see Fig. 2).

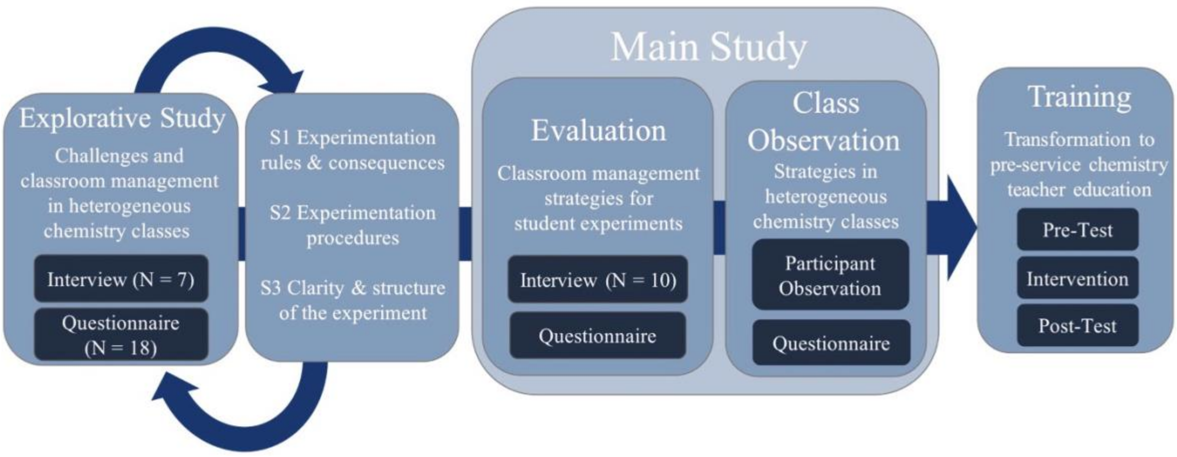

Figure 2. Overview of the project.

The first step of the explorative preliminary study aimed at analysing the particular challenges of inclusive chemistry classes and examining subject-specific classroom management strategies. In order to explore chemistry teachers' experiences and attitudes towards the use of strategies of classroom management in inclusive chemistry classes, a qualitative research approach was chosen. Therefore, semi-structured interviews (*N*=7) and semi-structured questionnaires with other chemistry teachers (*N*=18) were conducted. The questions in the thematic framework for the interview and the surveys dealt with the practice of inclusive chemistry teaching and are based on the theory of classroom management as it has been elaborated in literature (Emmer & Evertson, 2013; Evertson & Weinstein, 2013; Kounin, 1970). The data was analysed by means of qualitative content analysis by Mayring (2014) in which the specific qualitative techniques of summary and inductive category formation were applied. Six main categories were formed in order to identify and structure conditions that promote learning (see Pawlak & Groß, 2019). The data analysis was an iterative process, combining the results of the preliminary study with findings from additional literature research.

This article discusses these findings of the explorative study in order to identify and develop strategies of the classroom management. The three identified strategies and various sub-strategies were analysed and evaluated in the main study by means of interviews with heads of the Centres for Teacher Training at Schools. These are experts on the second phase of teacher training in Germany, they have considerable experience in teaching chemistry as well as teacher training and they also have practical teaching experience with heterogeneous chemistry classes. The qualitative research design was used to evaluate the strategies, the school practical background and make possible suggestions for improvement. As a second step, the lessons and consequently the teaching methods of the interviewed chemistry teachers were observed. Finally, the results were transferred to chemistry teacher education in order to enable pre-service chemistry teachers to face the identified challenges adequately by using strategies of classroom management.

RESULTS AND DISCUSSION

Within the preliminary study, the major challenges of conducting experiments in inclusive chemistry lessons have been identified. It can be said that safety is a central concern for chemistry teachers when carrying out student experiments: "[…] as a chemistry teacher, you have to ensure students' safety, because you have to take the blame for it yourself" (I1). Classroom management offers various strategies for establishing and ensuring safety during student experiments, such as the acquisition of a "laboratory license", where students must demonstrate safe behaviour. Observing these rules of laboratory safety must be practiced by the students continually. The results of the study show that establishing rules and defining consequences for unsuitable behaviour are among the most important strategies of classroom management in the context of safety (*N*=10): "[…], student behaviour is of course influenced by the need to define clear rules for experimenting in chemistry lessons from the very beginning" (I3).

Establishing routines and sticking to procedures can also be regarded as key strategies (*N*=12): "Strategies which limit disruption and conflict are crucial factors for successful chemistry lessons. As the kids carry out experiments by themselves, I hand over control […] therefore they need rules and routines, which are clear. Only if [they] are familiar with certain procedures, experimental chemistry teaching works out” (I5). An example for the practice of experimental procedures is the gas burner driving license, where the students practice the handling of the gas burners.

Experimenting itself does not necessarily promote students’ learning. The understanding for the content of the experiment must also be given. Emphasizing clarity of content and structure of the experiment can help here: "I always think that works quite well, and what is important, is the presence of instructions… and classroom management. What do I have planned for today? I want to make the aim of the lessons and the way how to reach it clear. Be it with symbols or simply explained: ‘We'll do that today, then we'll do the experiment and then we are doing that.’ This is often important for the children, because these long phases with the difficulty of listening are something they have all learned to bear and then they take little of the lecture that the teacher still likes to give. It also happens to me that I talk too much” (I4).

The interviews explicitly emphasised that classroom management was important for successful learning: “Well, I need good classroom management strategies in order to be able to teach in an inclusive chemistry classroom safely. And it is also beneficial for the students. If the class is loud […] it is more difficult for an inclusive student […] he/she already has a handicap. And if the class cannot work silently, it is twice as hard for an inclusive student. A normal student can even work if the classroom management is just average, but for an inclusive student this is probably not enough, I would say” (I3).

The results so far indicate the importance of classroom management, but also highlight the challenges teachers face with? when conducting student experiments in inclusive chemistry classes. In the next step the results of the preliminary study were transferred to three specific strategies relevant when experimenting with students.

Identification and development of chemistry-specific strategies

The identification and development steps were conducted as an iterative process. Therefore, the results of the explorative study and an additional literature analysis were combined. This led to the identification of three chemistry-specific strategies of classroom management and various sub-strategies (S1, S2 & S3, see Tab. 1). The literature analysis triangulated literature on practical chemistry teaching, literature on chemistry didactics and pedagogy as well as research on classroom management strategies for teaching and learning. On the basis of this systematic connection, three chemistry-specific strategies were developed:

Table 1. Specific strategies of classroom management.

S1 EXPERIMENTAL RULES & CONSEQUENCES
Behavioural standards that organize experimentation and form the framework for student behaviour in the classroom. Behaviour must be built up in a targeted manner and, especially in the context of student experiments, inadequate behaviour must be penalized whereas favourable, safe behaviour needs to be fostered. This can be done setting positive and negative consequences.
S1.1 General rules of experimentation
General standards of behaviour which are intended to regulate student behaviour when conducting experiments and ensure safety during preparing, conducting and cleaning up the experiment.

S1.2 Specific experimental rules
Specific behavioural standards that ensure the particular requirements of each experiment and can modified according to the situation.
S1.2.1 Substance specific
Symbols, pictograms, etc are used when handling chemicals considering hazards, safety measures, disposal, special procedures.
S1.2.2 Device-specific
Procedures and safety measures which are characteristic for each device. The device-specific rules are linked to the device routines (see S2.3).
S1.3 Strict realisation
Development of behaviour by supporting desirable behaviour and sanctioning non-compliant behaviour. Consequences are possible intervening measures to react to the obedience and/or disobedience of the experimental rules. Appropriate handling of disturbance and rule violation plays an important role.
S1.3.1 Positive consequences
Set of measures applied when observing experimental rules (e.g. praise)
S1.3.2 Negative consequences
Set of measures applied in case of disregard of experimental rules (e.g. warning)
S2 EXPERIMENT ROUTINES AND PROCEDURES
Specific behaviour and patterns of action for recurring situations during experimentation. Routines and procedures must be introduced and practiced in order to reduce the time and effort required for student experiments and to increase safety during experiments. In contrast to routines, rules are much more explicit and must be recorded in writing.
S2.1 General experimental routines
General behaviour and patterns of action for recurring situations during experimentation.
S2.2 Organisation and mobility routines
Organisation and mobility routines organise experimentation and support the processes during experimentation (e.g. experimental roles, distribution of tasks, movement in the specialist room).
S2.3 Device routines
The device routines include the practice of fixed action scripts (routines) in handling chemical-specific devices such as the Bunsen burner.
S3 CLARITY OF CONTENT & STRUCTURE OF THE EXPERIMENT
The clarity of content and structure aims at a thematically plausible, comprehensible and clear structure of planning, preparation, execution and evaluation of an experiment for the students. The aim is to ensure comprehensibility and linguistic clarity, which can be achieved by means of simplicity, brevity as well as structure, and can be supported by visualisation.

Based on the qualitative study design and the literature analysis, the three key strategies above could be identified. These strategies and their sub-strategies offer a promising approach for establishing safe and supportive learning conditions when conducting student experiments in inclusive learning environments.

CONCLUSION

In summary, the results of the explorative study show that ensuring safety for all students in inclusive chemistry classes pose real challenges for teachers when conducting student experiments. Based on these findings, it can be claimed that establishing rules and routines with respective consequences is an appropriate strategy to ensure safety in an inclusive experimental classroom. As safety is a major concern, strategies that ensure safety offer all students the opportunity to take part actively in practical inclusive chemistry lessons and conduct in experiments themselves. In addition to safety as a basic requirement, the understanding of the experiment must also be supported. For this purpose, further sub-strategies for clarity of content and structure of experiments are needed to be investigated in the following steps.

In the main study, the identified strategies will be qualitatively evaluated and analysed by means of expert interviews and class observation. This should provide further insights into the use of the strategies in inclusive chemistry classes. The interviews will be conducted to investigate the research questions: In what way can the specific strategies of classroom management contribute the safety of student experiments? In what way can the specific classroom management strategies support learning through experiments? Interviews and questionnaires are only one way to examine the views of chemistry teachers and trainers. Therefore, it is also necessary to analyse chemistry teaching practices. For this reason, the chemistry lessons of the interviewed teachers will be observed. The aim is to focus on the use of the strategies in practice. Finally, the findings of the main study will be implemented in university teacher training.

EXPLORING PRACTICING AND PRE-SERVICE TEACHERS' PROCEDURAL METACOGNITIVE KNOWLEDGE: INITIAL FINDINGS AND POTENTIAL IMPLICATIONS

Gregory P. Thomas
The University of Alberta, Edmonton, Canada

Metacognition is a key factor influencing science learning endeavours. While research has been undertaken into science students' metacognition and means to develop and enhance their metacognition, little research has explored practicing or prospective science teachers' metacognition, which includes what they know about how they themselves learn science, i.e., their procedural metacognitive knowledge. This exploratory study aims to help fill this gap. Sixteen science teachers and twelve pre-service science teachers where interviewed within two distinct hermeneutic dialectic circles regarding, (a) their science learning strategies, (b) the extent to which they considered it important to teach explicitly such strategy knowledge to students, and why, and, (c) the extent to which they had been asked to consider such matters previously. Both practicing and pre-service teachers reported a range of responses regarding (a) – (c). Some were able to describe in detail their science learning strategies. Others were less able to do so. Substantial variation was evident regarding the extent to which both populations considered it important to teach explicitly about such strategic knowledge to students and regarding if, how, and why they might do so. Participants reported that they had not been asked to consider such matters before. This study, shortcomings of which are identified, provides a platform for future research that might inform teacher education and professional development.

Keywords: Metacognition, Teacher Thinking, Learning to Learn.

INTRODUCTION: THEORETICAL FRAMEWORK AND STUDY PURPOSE

Over the past 30 years there have been many suggestions for how to improve science education, particularly as such improvement could relate potentially to improving students' conceptual understanding. Prominent and persistent amongst suggestions is the view that developing and enhancing students' metacognition is necessary to effect improved science learning (White, 1988; Georghiades, 2004; Thomas, 2012a; Zohar and Barzilai, 2013). Metacognition is an important factor influencing self-regulation and learning success (e.g., Ertmer & Newby, 1996), and the view in the science education literature is that enhancing students' metacognition does lead to improvements in their science learning (Avargil, Lavi, & Dori, 2018; Georghiades, 2004; Thomas, 2013). Metacognition is defined as an individual's knowledge, control, and awareness of their thinking and learning strategies (e.g., Flavell; 1979, Gunstone, 1994; Thomas, 2012a). Metacognitive knowledge can be categorized as, (1) declarative – related to beliefs and propositions about thinking and learning, (2) procedural – related to the strategies used to think and learn, & (3) conditional – related to when and why to apply procedural metacognitive knowledge to achieve specific, contextually relevant learning goals.

Teachers' knowledge of metacognition, including their own metacognitive knowledge, is an important factor influencing the teaching of the strategic, higher order thinking that is central to science education, e.g., conceptual development, argumentation, and scientific inquiry (Avargil et al., 2018; 2017; Thomas & Anderson, 2014). Research by Thomas (2013, 2017) and Thomas and Anderson (2014) clearly supports the contention that when teachers (a) become more knowledgeable of their often tacit knowledge of science learning processes, including their own, and (b) they are able to articulate explicitly these processes to students, that However, as far back as 1999, Zohar reported that science teachers' metacognitive knowledge as "unsatisfactory for the purpose of teaching higher order thinking skills in science classrooms" (p. 413), and Zohar and Barzilai (2013) and Thomas (2012b) proposed that science teacher metacognition should be given increased attention in science education research. This is because, while substantial research has been conducted into science students' metacognition, research into teachers' metacognition is not prominent in the science education literature, or in the education literature in general (Duffy, Miller, Parsons and Meloth, 2009 Thomas, 2012a,b). Despite these calls, little if any research in any field has been reported that investigated the metacognition of practicing teachers, and to this author's knowledge no research at all has been reported that explores the metacognition of pre-service science teachers.

This study aims to help fill this gap in science education research and stimulate further consideration of this understudied area . Accordingly, this study investigated practicing and pre-service science teachers' self-reports of, (a) their personal procedural metacognitive knowledge related to their science learning strategies, (b) the extent to which they considered it important to teach explicitly about such knowledge to students, and their reasons for their views and, (c) the extent to which they had been asked to consider such matters previously.

METHODOLOGY

An interpretive methodology underpinned by a social constructivist epistemology was chosen for this study. Interpretive research takes into account social action and thought that is "locally distinct and situationally contingent" (Erickson, 1998, p. 1155). Such a stance acknowledges that variation between participants is expected because each of them has constructed individually their metacognitive procedural knowledge on the basis of their personal experiences within their specific social contexts. Therefore any generalizations from this study to other contexts should be made prudently. The participants were a convenience sample of, (a) sixteen teachers from two high schools located on the outskirts of a large metropolitan Canadian city who were all teaching science in grades ten through twelve, and (b) twelve pre-service science teachers who were in the third year (of four) of their teacher preparation programme at a large comprehensive university in the same city. In that teacher preparation programme all students took the same science education courses and their specialist science area, or major, was not a consideration guiding their recruitment for this study. The practicing teachers varied in teaching experience from two to thirty-five years and were teaching across all science subject areas. All participants gave informed consent and all names in this paper are pseudonyms. The data collection involved semi-structured interviews, with each interview taking between twenty and thirty minutes. Practicing teachers were interviewed prior to those of the pre-service teachers. The interviews with each group of participants (practicing or pre-service teachers) took the form of separate hermeneutic dialectic circles (Guba & Lincoln, 1989) in which the tentative assertions generated from initial interviews were used as the basis for seeking data to confirm or disconfirm those assertions for each group in subsequent interviews. A key function of the hermeneutic dialectic circle is to seek consensus; consensus being achieved when no new information arises as the sequence of interviews proceeds. The data from the two sets of interviews were analyzed using a three-stage process of descriptive coding, interpretive coding, and deriving overarching themes, as suggested by King and Horrocks (2010), and consistent with the processes suggested by Braun and Clarke (2006) and Langridge (2004). Results are presented as three assertions. These assertions reflect the overarching themes common to both sets of participants that were derived from the analysis, and that attend to the aforementioned research purposes. Data from the interviews supporting those assertions, and variations between and within practicing teachers (PT) and pre-service teachers (PST), are presented to support the claims made.

RESULTS

Assertion 1: *All participants reported behavioral elements and procedural metacognitive knowledge elements, both being intertwined in relation to their personal science learning strategies.* Participants provided coherent information, varying in detail between them, regarding how they considered they learned science. Reading, memorization and connecting information elements were key elements of the metacognitive procedural knowledge reported by both groups of participants. For example, Steve (PT) reported, “I take an academic article, read it, glean the pieces that I feel are relevant, and meld that into (my) current knowledge, past experience, and beliefs and put that together. I look at it as a puzzle and [ask], “How do I put the pieces together?” I can see how patterns go together and, if I have a problem in front of me, I am going to try to see which of these puzzle pieces that I have stored is going to help me solve that problem.” Brian (PT) claimed, “I’ve got to read it, I’ve got to see it, and I’ve got to do it. You’ve got to read it at the very fundamental level. Information is transferred mainly by the written word. I think I’m a good memorizer, but I need to do some problems and examples to really learn and understand it. I can get a shallow understanding just by reading over it. Inside my head, I think new, uncomfortable connections in the brain become comfortable after repetition. The first time you do something is always the hardest because you’re out of your comfort zone and making new connections, whatever the topic. The more repetition, the easier it gets. The ‘pathways’ (sic) become second nature.” “Alex (PT) suggested, “I really rely on the textbook a lot for reading and reading and re-reading and studying. I try, through just simple repetition to remember the vocabulary and the facts. I was conscious of the etymology of the words a lot to help me remember and I would try to visualize to help me remember a little bit as well.” Erica (PST) suggested, “There’s a lot of memorization. It starts with how engaged I am in class; am I paying attention? But, in the end it comes down to repetition. There’s different ways to do repetition like reading out aloud, writing cue cards, drawing diagrams, or going over the manual…but it all comes back to repetition.” Mitch (PST) explained his procedural metacognitive knowledge in relation to memorization, stating, “Memorization is important. Biology is mostly memorization. Associating a strange memory with whatever you’re learning, just like you have a number system of your flashcards or whatever you have printed out, and then you associate those numbers with your flashcards and the specific word or phrase or whatever you're supposed to memorize, and then associate it with something that rhymes with it or something weird that stands out, and you always remember it. That's how I usually memorize. Rhymes usually help a lot. Also, there's just looking over and over [the material] again." Frank (PST), however, held a different view about the role of memorization for his learning of stating "I suck (sic) at memorizing and I'm pretty good at it [learning]. I love graphic organizers, like making mind maps of everything…If I can make a connection, I say I know it… if you understand it, you make that connection."

Assertion 2: *Participants considered it important to teach explicitly such strategies to students but varied regarding how and the extent to which this might happen and the reasons for their views*. The practicing teachers were all generally supportive of the idea of teaching students about how to employ the strategies that they had reported. However they also identified barriers to this occurring in class. Some of the barriers were to do with personal matters, while others arose from their views about the nature of the students they taught. For example, Dan (PT) proposed, "Yes, it would be useful, but I don't know if students necessarily want to be taught that. I find that high school students' approaches are focused on getting good marks. It might help student achievement if they did [know this], but they might not see the value of it." Marg (PT) suggested, "I don't think I know enough of a language of thinking or learning to be able to teach students about what it means to think and learn." Alex (PT) was of the view that, "There's definite value to be had there [with this idea]. Putting more responsibility on students for their own learning, if they have the tools to do so is a great idea. But I'm not sure if there's time [for me to do this]. They need to find something that works for them. Also, when you're fifteen [years old] it's tough to find that motivation, that commitment, or even that time." The pre-service teachers, without the hindsight of full-time experience as practicing teachers were more enthusiastic about the possibilities of sharing their metacognitive procedural knowledge with their future students. Justine (PST) asserted, "I think is important for you to explain to students how you work through problems in your mind so that you would model that type of thinking." Lincoln (PST) articulated how he might explicitly teach the strategies he used, stating, "I think it's 100% important. If I'm trying to help students, I might do a 'think aloud.' I'll go through the dialogue that's going on in my head...you can show them your thinking process, which can be very useful." Mike (PST), like other pre-service science teachers, identified a lack of attention to such matters in his teacher preparation programme, adding, "I think it's a good idea to teach our students how to memorize; how to learn effectively. I've never thought of that before. Why don't our classes tell us to [think about that].

Assertion 3: *Participants reported that they had never previously been asked to consider the matters that they were asked about in the interviews*. For example, Corrine (PT) stated, "It's never crossed my mind. I've never thought about it. You're so focused on the information, the [science] material. I never thought about what's going on in my head when I'm learning and thinking." Paul (PT) added, "I don't think about what I do; I just do it," while Dan (PT) noted, "I've never thought of this before." Garry (PST) exemplified pre-service teacher replies, stating, "I've never been asked these types of questions before; you can probably tell." Max (PST) added to this them when suggesting that what was valued in his schooling might have influenced his experience; "I've never been asked before. Nobody cares about how you get the results, as long as you get them. As long as you get that eighty or ninety percent, you're good."

DISCUSSION AND IMPLICATIONS

In this preliminary, exploratory study variations were evident in practicing and pre-service science teachers' reports of their metacognitive procedural knowledge, the extent to which they considered it important to teach explicitly such strategies to students and why, and whether they had been asked to think previously about such matters. Because the data were drawn from two convenience samples, generalizations across populations should be undertaken with caution. Also, the affordances and constraints of using self-reports for exploring metacognition have long been discussed with varying levels of support as to their validity and reliability (e.g., Veenman et al, 2006). These factors notwithstanding, the variation identified within and between the groups of participants warrants considered attention and raises matters that might be addressed in future research.

It was clear from the data analysis that reading was a key activity identified by almost all participants as being an essential element of their science learning processes. Some gave substantial detail on how they attended cognitively to the information they accessed when and through reading; for example, looking for relevance (Steve) and being aware of the etymology of vocabulary (Alex). The importance of memorization was a common theme and participants were also able to provide insights into how they performed this mental operation. Notably, the notion of connecting and inter-relating ideas and concepts and the importance of one's existing, prior knowledge was common amongst participants of both groups. This metacognitive procedural knowledge is consistent with and reflects foundational tenets of constructivist learning theory, even if none of the participants verbalized their thoughts in such a specific language. As such, if the participants were able to articulate such views to their students, it might be that students would be provided with a view of science learning that is well supported in the science education literature. This is certainly a pedagogical possibility and, as reported by Thomas (2013, 2017) and Thomas and Anderson (2014), when teachers communicate views of what it means to learn science that reflect the nature of the subject they are teaching it is possible to develop and enhance students' metacognition.

It is generally acknowledged that reflection on the processes of learning is a key component influencing the development of metacognition. Therefore, given the aforementioned importance of teachers' knowledge of metacognition, including their own metacognitive knowledge, opportunities should be provided for facilitating such reflection by practicing and pre-service teachers so that they might consider using their metacognitive knowledge as a basis for teaching students about the strategies and cognition that are important for science learning. In this study the interview processes stimulated such reflection and constituted a metacognitive experience (Flavell, 1979; Thomas 2012a) for all participants. Metacognitive experiences are those in which individuals focus their attention on their cognition and the products of that cognition, and evaluate both. As Flavell notes "metacognitive experiences can affect your metacognitive knowledge base by adding to it, deleting from it, or revising it" (p. 908). Teacher professional development activities that explicitly aim to stimulate metacognitive experiences might prove valuable in assisting teachers to become more conscious of their metacognitive procedural of their science learning processes, and the possibility of framing that knowledge as information that can be taught to students. In undergraduate science teacher education, when students can see potential advantages of teaching students about how to learn science effectively, there is the opportunity stimulate metacognitive experiences so that students can begin to articulate those processes to themselves and others, with a long-term view of being able to teach their future students about them. Doing so in undergraduate teacher education might also be an appropriate time to do so, before these future teachers encounter the often harsh contextual realities of teachers' lives in schools.

Future research might build on this study and use multiple methods and purposive sampling to develop assertions across science teacher populations taking into account factors such as the specific science subjects that teachers teach and teachers' years of teaching experience. Such research could lead to valuable suggestions for science teacher education, teachers' pedagogy, and professional development.

HOW CAN EARTHQUAKES GET INTO A 5TH GRADE CLASSROOM?

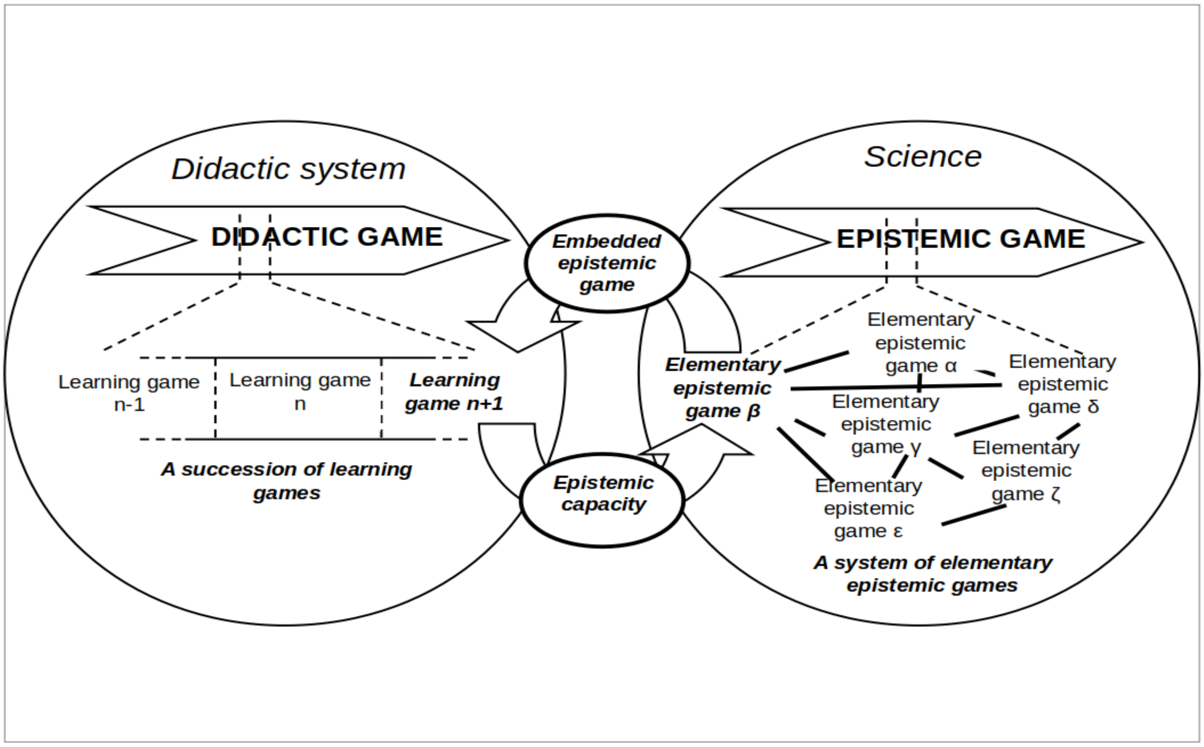
*This paper addresses the issue of the teaching and learning of phenomena that are impossible to get into classrooms, such as that of earthquakes. Over a period of 3 years, we studied the teaching sequences of a 5th grade teacher on the subject of earthquakes. During the 2*nd *and 3*rd *year of this period, a member of the research team cooperated with the teacher in a cooperative engineering teaching sequence. In this case study, we have analyzed the changes in the sequence between the 1st and 3rd year. We situate our work within the Joint Action Theory in Didactics (JATD). The JATD posits that 1) the teaching-learning process is a joint action between teachers and students about the knowledge at stake and 2) that knowledge is inherent in cultural practices. Our methodology relies on a clinical approach using video. Our case study has produced scientific results for science education research and has also become a resource for science teaching. From a science teaching viewpoint, the simulation we devised is a new resource for teaching. From a science education research viewpoint, this new simulation has a kind of "epistemic kinship" with the basic simulations that were used in the seminal works in seismology. We have concluded that this new simulation contributes to students being confronted with a genuine aspect of seismology and that this was made possible thanks to the cooperative engineering approach.*

Keywords: science education, simulations, video analysis

1. GENERAL DESCRIPTION

This paper addresses the issue of the teaching and learning of phenomena which are impossible to get into classrooms, such as that of earthquakes. The subject of earthquakes is part of the French mandatory curriculum for primary schools. Over a period of 3 years, we studied the teaching sequences of the same 5th grade teacher on earthquakes. In this case study, we analyzed the changes in this sequence between the 1st and 3rd year. Our analysis showed that the investigated teacher used two different simulations of earthquakes in his classroom sessions. We compared the two simulations with regard to their potentialities to teach and learn about earthquakes. We think of models and simulations as reducing general theories to particular events (Cartwright, 1999; Sensevy, Tiberghien, Santini, Laubé, & Griggs, 2008). In such an approach the second simulation is better than the first. This second simulation was elaborated in a didactic cooperative engineering (Joffredo-Le Brun, Morellato, Sensevy, & Quilio, 2018; Sensevy, Forest, Quilio, & Morales, 2013) with the first author in the role of a teacher-researcher (Roth, 2007).

We situate our work within the Joint Action Theory in Didactics (JATD; Sensevy, 2011, 2012). The JATD posits that 1) the teaching-learning process is a joint action between teachers and students about the knowledge at stake and 2) that knowledge is inherent in cultural practices. This theoretical position was actualized in a modeling of practices as games (Santini, Bloor, & Sensevy, 2018). Cultural practices are modeled as epistemic games, i.e. games with knowledge at stake and where the dominating focus is not teaching it. Educational practices are thus



modeled as learning games, i.e. games with knowledge at stake and where the dominating focus is on having it learned. The knowledge at stake is modeled as epistemic capacities following an agentive conception of knowledge (Sensevy & Tiberghien, 2015a). In this modeling we apprehend the work of didactic cooperative engineering as embedding epistemic games within learning games.

Figure 1. Knowledge games model in the Joint Action Theory in Didactics (Santini, Bloor, & Sensevy, 2018)

We describe learning games as an interplay between a didactic contract (Brousseau, Sarrazy, & Novotná, 2014) and a didactic milieu (Sensevy & Tiberghien, 2015b). Didactic contracts describe the actual strategic system to play learning games, i.e. what is already known. Didactic milieus describe the potential strategic system to be deciphered so as to play learning games, i.e. what is to be known. From this modeling, comparisons between learning games and epistemic games are undertaken to characterize the value of what is learned in science education with regard to science. That is to say, in the terms of the knowledge games model, (cf. fig. 1), to what extent the epistemic capacities "won" in the learning games enable learners to play epistemic games.

2. METHOD

Our methodology relies on a clinical approach (Bulterman-Bos, 2008, 2017; Foucault, 1963; Leutenegger, 2009) using video studies (Tiberghien & Sensevy, 2012). We videotaped and transcribed all the teaching sequences about earthquakes and volcanoes during the first and the third year of the case study. The sessions of cooperative engineering took place during the second and the third years. We audiotaped and transcribed them. We analyzed the whole data in a progressive refinement of hypotheses (Engle, Conant, & Greeno, 2007).

3. RESULTS

This case study was conducted over a period of 3 years. The investigated teacher was confronted with a problem: how could students work on phenomena which are impossible to get into a classroom? The first option was to represent it with an isoseismal map (cf. fig. 2). The teacher asked the students to explain the concentric pattern on the map. The students agreed that earthquakes "weaken while moving". The teacher used a simulation with playing cards (cf. fig. 3) to test this explanation as seen in the following excerpt. We focused on this learning game in the following analyzes.

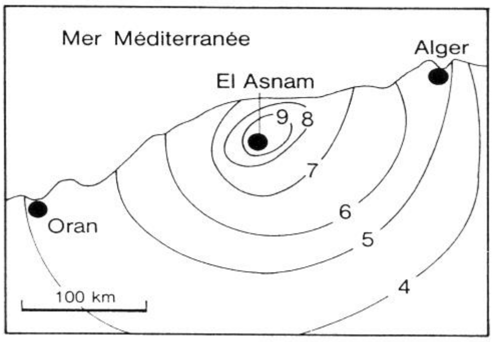


Figure 2. Isoseismal map

Figure 3. The playing cards simulation

The teacher hits the table a little bit harder. The first two pairs of cards remain upright, the ones just after fall and the last one remains upright.		
826	Student	Yeah but it's cards
The teacher hits the table stronger. Only the last pair of cards remain upright.		
827	Teacher	Ah and the last one
828	Student	One more time
829	Teacher	Ah and the last one hush
830	Student	Twelfth degree
831	Guillaume	Harder
832	Student	Twelfth degree
833	Teacher	But the last one as you see
834	Student	It's still standing
835	Teacher	So
836	Mélanie	But there was a problem because some fell down and the first two they stayed steady

837	Teacher	Yes that was what you were saying before it depends on the quality of the buildings because depending on how I put up my cards

The results of the simulation couldn't account for the concentric pattern of the isoseismal map. The teacher and the students tried together to "save" the situation by referring to the "quality of buildings". During the 1st year the didactic milieu did not provide enough feedback to confront the students with the regularities represented with the isoseismal map. The teacher was not satisfied with the playing cards simulation because it did not meet his expectation of regular results. The teacher and one of the teacher-researchers in our study worked together on a new simulation (cf. fig 4) in a cooperative engineering.

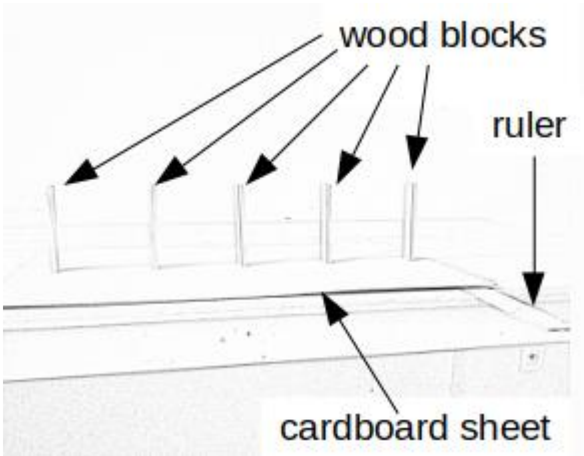

Figure 4. The new simulation designed in cooperative engineering.

The new simulation illustrated above, was then used in the same learning game by both teachers. The transcription below is an extract from a lesson where the simulation was introduced.

5	Teacher	We are going to check. So, if I push lightly [on the ruler; cf. fig. 3] and look closely at what happens - when I push lightly what happens?
256	Student	Nothing
257	Teacher	Ah yes something happened
258	Valentin	It shakes
259	Teacher	Which one? Come and show me ah how about this one?
260	Marine	The closest to the ruler
261	Teacher	It is closer to the center er when I say the center it is the place where it happens. Now I do it - I do it one more time so you can see it's shaking a little did you see it?
262	Student	No
263	Student	Ah yes
264	Teacher	So I do it lightly now we are going to do it a little bit more
265	Student	Harder
266	Teacher	What happened? hush what happened?
267	Guillaume	There were three that fell down and this one on the right that shook
268	Teacher	Yes but it's not enough for me
269	Student	The closer ones to the (inaudible)

270	Teacher	There were three that fell down but they were the closest to the – What did we call that
271	Student	The shaking
272	Teacher	The shaking or the [looks at the hypotheses produced by workgroups and written on the blackboard] center so is this the shaking that has moved?

During the 3rd year, the simulation produced the expected results in the unfolding of the learning game. The didactic milieu provided enough feedback to confront the students with the regularities represented with the isoseismal map. The learning game consisted of *running a simulation of earthquake damage with pieces of wood placed upright on cardboard with a ruler underneath to simulate earthquakes by lifting up the cardboard*. The unfolding of this learning game enacted an epistemic capacity of *assessing hypotheses about the seismic mechanism by managing a concrete model*. The analysis showed that the students are more likely to "win" this epistemic capacity with the 3rd year version of the learning game.

In the history of seismology, Reid (1910) used the results of a concrete simulation (cf. fig 5) to test his theoretical hypothesis of earthquakes as elastic rebounds.

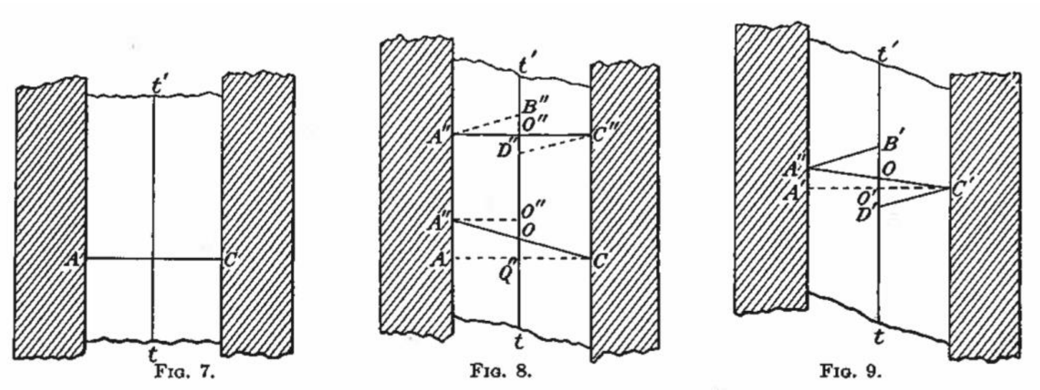

Figure 5. The stiff jelly and wood simulation used by Reid (1910, p. 20).

We modeled this piece of Reid's work as an elementary epistemic game consisting of *designing a concrete model accounting for the mechanical properties of the crust to test the elastic-rebound theory of earthquakes*. In the classroom session, the students and the teacher also tested their hypotheses on earthquakes by means of a simulation. Under such a description there is a kind of "epistemic kinship" between the learning game and the epistemic game. In both games, seismologists, students and teachers rely on basic simulations to test their hypotheses. To have the students confronted with the feedback of simulations is then favorable to give them an effective taste of seismology.

4. DISCUSSION AND CONCLUSIONS

Our case study produced both scientific results for science education research and resources for science teaching. From a science teaching viewpoint, the new simulation (cf. fig. 4) is a new resource for teaching. Its functioning nurtured the didactic milieu with regular results. It supported effectively a didactic contract of inquiry whereas the playing cards simulation didn't. From a science education research viewpoint, this new simulation had a kind of "epistemic kinship" with the basic simulation used by Reid (cf. fig. 5) in his seminal work in seismology. This new version of the learning game was then more coherent with the epistemic game of seismology. We concluded that this new simulation contributed to more effective teaching on earthquakes, and that this was made possible with the cooperative engineering approach. We reached this conclusion following an analysis of teaching effectiveness in a two-step process using our knowledge games model (cf. fig. 1). This consists of asking the following two questions: 1) Can the epistemic capacity be "won" in the unfolding of the learning game? 2) Does this epistemic capacity enable the learner to "win" the epistemic game? It follows from this description that these two conditions are necessary for students to actually experience something of science.

DESIGNING A TEACHING-LEARNING SEQUENCE ABOUT ELECTROMAGNETIC RADIATION FOR GRADE EIGHT

Sarah Zloklikovits[1], Martin Hopf[1]
[1]University of Vienna, Vienna, Austria

Electromagnetic radiation is not part of compulsory education in Austria. As the topic is important in our everyday life, we are working on a teaching-learning sequence to introduce the topic in eighth grade. With the goal to make the subject matter easier to understand for young students, we developed a novel approach to teach electromagnetic radiation, building on existing research on geometrical optics. In this paper we present results of the second and third cycles of the iterative process of design, implementation and evaluation. In both cycles we worked with single students, applying the method of probing acceptance. The results help us to understand which parts of the design work well, which learning obstacles typically arise and which aspects of student learning must be investigated further.

Keywords: Evidence Based Approaches, Secondary School, Teaching Learning Sequences

INTRODUCTION

How can you teach the complex topic of electromagnetic radiation at the middle school level? This is a question we strive to answer with our research. As electromagnetic radiation plays a huge role in our everyday life, we argue that everybody should have some basic understanding of it. However, the topic is not part of the compulsory curriculum in Austria. We see a chance to introduce the topic in eighth grade, as it is the last year in the Austrian school system where all students have compulsory physics lessons. Our aim is to develop a teaching-learning sequence and to evaluate and refine it in continuous cycles. The first challenge we faced was to come up with a way to explain electromagnetic radiation to students in their first years of physics education, especially since the wave model, that is typically used to teach the topic, is not part of the middle school curriculum. We developed a novel approach to introduce electromagnetic radiation, building on results from existing research on geometrical optics (Haagen-Schützenhöfer, 2016). As a first design step, we are developing central explanations, so called "key ideas", which build the foundation of the teaching-learning sequence. A first cycle of evaluation and refinement has already been conducted and presented elsewhere (Zloklikovits & Hopf, submitted). In this paper we present the following two cycles of investigation.

THEORETICAL BACKGROUND

Design Research

The motivation behind design research is to develop evidence-based approaches to teach a certain topic. The most prominent feature is that the development of the material is an iterative process, as the material is designed based on theoretical knowledge, implemented, evaluated and refined (Prediger, Gravemeijer, & Confrey, 2015). It is typical to start to evaluate the design with single students before implementing it in classrooms (Nieveen & Folmer, 2013). Extensive data is collected during such projects, giving many opportunities to not only generate a design that fosters learning in physics classrooms, but to also develop educational theories. There are many examples of what kind of theories can be developed or enhanced through such projects. The presented work aims to enhance domain specific educational knowledge, as the educational research on electromagnetic research is quite scarce (Prediger et al., 2015). The term "teaching-learning sequence" is especially common in the European landscape of science education, describing "medium-scale curriculum product[s] covering a scientific topic" that are developed under a design research paradigm (Psillos & Kariotoglou, 2016).

Findings from physics education

In comparison to other topics, the body on educational literature about electromagnetic radiation is quite small. First efforts to document students' conceptions have been made, showing that students do not have a sound understanding of the topic (Plotz, 2017). For example, students are not able to distinguish between ionizing and non-ionizing radiation (Rego & Peralta, 2006). They often think that every device emits harmful radiation (Neumann & Hopf, 2012), but radiation used in medicine is harmless (Henriksen & Jorde, 2001). Based on his work on investigating learning processes, Plotz (2017) formulated four basic concepts students should know about electromagnetic radiation. These encompass the propagation of radiation, its omnipresence, the classification in the spectrum as well as the interaction with matter and its transmission of energy. These concepts work as guiding principles for our teaching-learning sequence.

Our approach to teaching electromagnetic radiation

In contrast to what you might find in a textbook, the teaching-learning sequence we are developing introduces electromagnetic radiation without waves or particles. As described in (Zloklikovits & Hopf, submitted), our approach follows, what we call, an "optics approach". We came to this approach by building on the outcomes of design research on geometrical optics by Haagen-Schützenhöfer (2016), transferring the educational elements used to teach light to the rest of the spectrum. This results in characterising electromagnetic radiations via its properties and making the distinction between radiation and matter clear. We also adapted the so-called sender-receiver model (meaning that you always follow the propagation of the radiation from the source to the detector), and the depiction of radiation as cone-shaped arrows. Instead of classifying the different types of radiation in the spectrum by wavelength or frequency, we decided to use energy as the distinguishing quantity. We hoped that the different effects that radiation can have on the human body might be explained plausibly to students, as the idea that the absorption of energy causes various effects could align with even naïve ideas of energy.

We designed five key ideas that build the foundation of the teaching learning-sequence. They cover the introduction of the term "electromagnetic radiation", the interaction with matter, the transport of energy, the electromagnetic spectrum and the factors influencing the health risk opposed by radiation. In our previous research, we evaluated the first three key ideas (Zloklikovits & Hopf, submitted). The results were promising, demonstrating that it is worthwhile to investigate this approach further. Our results showed that students tend to think that all types of radiation have a warming effect on our skin. We also found that students sometimes think that radio waves can be heard, or that the reception is better inside a house than outdoors. As these perceptions do not align with the intended concept, we concluded that another context might be more fitting.

Method of probing acceptance

The aim of our research is to develop a teaching-learning sequence that provides a physical framework that students find plausible and intelligible and that they can apply to new problems, as these are necessary conditions for a conceptual change as stated by Posner, Strike, Hewson, and Gertzog (1982). A method that was developed in physics education research for this purpose is the method of probing acceptance (Jung, 1992; Wiesner & Wodzinski, 1996). This form of teaching experiments proofed to be quite useful in recent design-research projects (Haagen-Schützenhöfer, 2016; Wiener, Schmeling, & Hopf, 2015). The idea of the method is to present an explanation to a student and to investigate how the student receives this explanation. After the explanation is discussed and demonstrated on an example, the student is asked to assess it. Here one might be able to observe first resistances towards the explanation. The student is then asked to rephrase the explanation. Omissions and transformations indicate which parts of the explanations might not be well received or understood by the student. Next, the student has to solve a task. At this step, the researcher can see if the student applies the given explanations to the task, as well as which problems arise when working with the explanation.

The instructions that are developed and refined in an iterative process for this method are a prototypical version of a teaching-learning sequence (Wiesner & Wodzinski, 1996). Therefore, in the design research framework, we consider the materials developed for the teaching experiments a first, prototypical design.

Study design

As explained in the theoretical background, the aim in this stage of our research it is to develop a first prototypical design. Therefore, we aspire to answer the following research questions:

- Do students find the key ideas intelligible and plausible?
- Are students able to apply the key ideas to new problems?
- Which learning obstacles and which helpful elements can be identified for the specific learning content?

To answer those research questions, two cycles of implementation and evaluation have been conducted and are presented in this paper. In the following, we refer to them as Study 1 and Study 2. In both cycles, we conducted one-hour long one-on-one teaching experiments, applying the method of probing acceptance. Eighth-grade and ninth-grade students from two different schools in Vienna participated in those studies. We anticipated that there would hardly be a difference between the performance of eighth-grade and ninth-grade students, as the ninth grade curriculum does not cover topics that overlap with our instructions, and our findings confirmed this. Every interview was recorded and transcribed. The data was analysed and the outcomes discussed with experts. The results led us to replace the context of radio waves with mobile phone radiation. We also saw that students tended to confuse radiation, energy and heat – therefore we made sure to avoid the terms “warm” and “heat”, talking strictly about a rise in temperature when discussing the effect of infrared radiation on the human body instead. Another issue was that students were confused by a task that had them explain how the energy emitted by the sun comes to earth. Students tried to argue that the atmosphere absorbed the radiation, so we decided to change the task – instead of the sun and a solar panel, we use a lamp and a solar operated calculator instead, avoiding the distracting aspect of the atmosphere’s role. We evaluated the revised teaching experiment with six students (Study 1), analysed the transcripts and revised the material again, conducting interviews with eight students (Study 2).

Analysis of the data

The recordings were analysed with the method of evaluative qualitative text analysis (Kuckartz, 2014). A coding manual was prepared, defining for every step of the teaching experiments if the performance of the student was good ✓, satisfactory ~, or insufficient ✗. This method of analysing teaching experiments was suggested by Haagen-Schützenhöfer (2016). A “good” assessment means that a student fully approved of the key idea, whereas “satisfactory” means that they agreed with the idea but raised some doubts, insufficient that they didn’t find the explanation intelligible. In case of paraphrasing, a paraphrase was rated as "good" when a student included all the important aspects of the explanation, as "satisfactory" if a part of the explanation was left out or inaccurate, and "insufficient" otherwise. The task solving was coded as "good" when the student applied the presented explanation and was able to solve the task accordingly, needing a small assistance at most. If more assistance was needed, this step of the teaching experiments was rated as "satisfactory". When a student was not able to solve the task accordingly, it was coded as "insufficient". Missing data was not coded. A colleague coded a randomly selected transcript of each study, resulting in a cohens kappa of 0.81 (almost perfect agreement) for Study 1 and 0.71 (substantial agreement) for Study 2 (Landis & Koch, 1977). The passages of the transcripts that were rated as "satisfactory" or "insufficient" were presented and discussed with the colleagues from our research teams.

An overview of the explanations, illustrating examples and tasks the students were given in Study 1 and Study 2 can be found in Table 1. The results of the two presented investigations are displayed in Table 2, which is displayed at the end of the paper. The student names given in the table are pseudonyms. In the following, the results of the two studies are presented and discussed in more detail and give insight into the students' reasoning.

Table 1: Overview of the steps of the teaching experiments

	Study 1	Study 2
Key Idea I	Radiation is different than matter! It can't be touched, it has no mass, and it propagates with the speed of light.	Radiation is different than matter! Task	Which types of radiation might be seen as dangerous?	Which types of radiation might be seen as dangerous?

Key Idea V	Electromagnetic radiation can be dangerous. The level of risk depends on the type of radiation as well as the intensity and duration of the irradiation.
Demonstration	Demonstrating intensity with visible light; light as harmless radiation; danger or X-radiation and how the risk is minimised at X-radiation examinations.
Task	Is mobile phone radiation dangerous?

STUDY 1

Results

Key Ideas I is not discussed in detail this paper, as the results our previous study showed that the idea was well received, and the studies presented in this paper strengthened this finding. However, it has to be noted that some students used the word “heat” or “warmth” instead of radiation.

The results displayed in Table 2 show that the second key idea was well assessed by the students. Some students had problems paraphrasing the key idea. Gülcan talked about radiation being conducted. Hoda and Nina said that radiation is either absorbed or reflected, neglecting that in most cases parts of the radiation are absorbed, reflected and transmitted at the same time. All students were able to solve the first task. For the second task, explaining why there is bad reception in an elevator, Hoda did not apply the given explanations, trying to argue with a change of air pressure instead.

Key Idea III covers the connections between energy and electromagnetic radiation. This idea was well received by the students as well, although some problems arose when they had to rephrase the explanation and apply it to new tasks. Gülcan talked about heat instead of radiation. Kathi stated that energy is “something like radiation, but not radiation”. While solving the task, she did not use the word “energy” at all. Julia left out that energy is transferred when radiation is absorbed.

The electromagnetic spectrum was introduced through Key Idea IV. Some students did not use the word “energy” when rephrasing the explanations, instead saying that electromagnetic radiation is classified by “the extend of impact”, “the energy the radiation emits”, or the “strength” of the radiation. Even upon request the students did not involve the word energy in their elaborations, talking about the intensity and the harmfulness of the type of radiation instead. This problem also occurred when students had to solve the task: Gülcan argued that the danger of radiation depends on the intensity. Nina said that gamma radiation is dangerous: “It is logical as it is the strongest [type of radiation]”, referring to its position in the spectrum. When asked about X-radiation, she said that she did not think that it is dangerous because it is used in medicine. A very interesting observation is that, although she did not change assessment of, Nina raised some doubts about it being harmless as it is so high up in the spectrum. Monika also deemed gamma radiation as harmful but not X-radiation. Surprisingly, she said that visible light is dangerous, as she heard that some types of light bulbs could by harmful to the eye. Looking at Table 2, one can see that all the other students had no problem with this task.

Discussion

Our findings showed that students still confused radiation and heat. Therefore, we decided to leave out infrared radiation all together for future teaching experiments, replacing it with UV radiation. In Study 2, we used UV lamps for the experiments and UV detecting beads as detectors.

We saw that replacing the context of radio waves with mobile phone radiation worked well for the students. Our findings also suggest that using a solar calculator and a lamp instead of a solar panel and the sun is better suited for the task about energy.

Throughout the investigation, we saw that students avoided the use of the word "energy". This could indicate that the idea that radiation "carries energy" might not be plausible to the students. In addition, this idea could let students conclude that energy and radiation are two different entities. In an attempt to make the connection between energy and radiation more clear, we decided to build on the forms approach of energy, as this is the common approach how energy is taught in school (Nordine, Fortus, Lehavi, Neumann, & Krajcik, 2018). Therefore, we changed the third key idea to "Electromagnetic radiation is a form of energy. If electromagnetic radiation is absorbed, energy is absorbed", elaborating that the radiation is transformed into other types of energy.

STUDY 2

In addition to the changes described in the section before, we added a new key idea to the teaching experiments, covering the potential risk posed by electromagnetic radiation. In order to keep the duration of the interviews to one hour, we only asked the students to solve one task per key idea.

Results

In Study 2, we also saw students saying that radiation is either absorbed, reflected or transmitted. The use of UV radiation instead of infrared radiation led to some problems, as students tried to detect the radiation with their eyes instead of using the UV detecting beads.

While trying to paraphrase the third key idea, Petra struggled to verbalise the connection of energy and radiation. She did not use the word energy at first, and then said that when the calculator absorbs radiation, the calculator "has energy". Only after pressed by the interviewer she said that radiation is energy. Rosa said that radiation could be transformed into energy instead of radiation being a form of energy. When solving the task, Quentin was not able to verbalise the connection between energy and radiation.

When discussing the key idea about the electromagnetic spectrum, Timo did not use the word energy and talked about the "strength" instead. He elaborated that infrared "only sees the body" and X-radiation "is able to see the bones". He was not able to verbalise what the spectrum is. Almost every student struggled with the task. Olga, Petra and Timo only argued with their pre-instructional knowledge. Petra was not able to establish a link to the spectrum. Quentin did not use the word energy in his argumentation. After request, he said that the role of energy in the spectrum is clear to him. He also said that radio waves are dangerous because *Radio*-acitvity is dangerous. Rosa talked about the "size" of the radiation and only used the word energy upon request.

Key Idea V deals with the potential risk posed by electromagnetic radiation. While Olga and Rosa included the intensity and the duration in their discussion on the potential risk, they did not take the type of radiation into account. This happened again when Rosa tried to solve the task. When asked to explain further, she said that the heat of a mobile phone could be dangerous, "like in the sun, where one gets cancer when it is 40 degrees". Quentin argued that mobile phone radiation is the radiation a mobile phone emits via the display. Steven gave a similar answer.

Discussion

One of the most prominent problems in Study 1 was that students avoided to use the word "energy" in their argumentations. We tried to make the connection between energy and radiation more clear in the second study, building on the forms approach of energy, but we could not see a difference in the results. As the ideas of the spectrum and the potential risk build on the concept of energy, this is a problem we have to take a closer look at in future investigation. Interestingly, while the spectrum helped most of the students to argue about the danger of radiation in Study 1, in Study 2 they struggled with the task. This could be a clue that explaining radiation as a carrier of energy might be a more helpful idea.

Not including infrared radiation helped to avoid the problem of students mixing up heat, energy and radiation. However, it has to be noted that it was not easy to construct the material without using infrared as an example, as it enables to easily experiment with a type of radiation that is not visible, whereas UV radiation is more abstract as one has to use detectors like UV beads to work with it. We therefore suggest starting with visible light, then moving on to infrared radiation, and then including UV radiation, a type of radiation you can neither see nor feel, as we think this might be a good learning progression.

A surprising finding was that the students seemed to have no idea what mobile phone radiation is, although it is a topic often discussed in Austrian Media. The notion that the radiation the visible radiation emitted display is quite interesting, especially as it was raised by a student who is very interested in physics and is known as a very good student.

Another interesting comment was that the light from the sun causes cancer when it is warm enough. This adds to our previous findings – students seem to think of the radiation from the sun as one type of radiation that is warm, visible and responsible for suntan and skin cancer. This is most likely a result from every day experiences.

We are aware that we worked with a small sample size and that these results are not generalizable. However, to see how students react to certain explanations, contexts and tasks are vital findings, as they help us to make informed design decisions before conducting large-scale investigations.

CONCLUSION & OUTLOOK

In this paper, we presented results from two cycles of an iterative design research process with the aim to develop a teaching learning-sequence suitable for middle school students. The first two key ideas were plausible and intelligible to the students and they were able to apply them to new problems. Problems surfaced as soon as the key ideas included the energy concept. This is the next challenge our research has to face.

THE NARRATIVE INSIDE: TEACHING PHYSICS WITH A NARRATIVE-BASED APPROACH

Michele Canducci[1], Silvia Demartini[2]
[1, 2]Department of Education and Learning, University of Applied Sciences and Arts of Southern Switzerland, Locarno, Switzerland

This article shows how it is possible to structure physics content in terms of narrative structure, in order to promote learning. First, we outline four possible kinds of relationship between science, education and narrative form, in order to set our proposal in the state-of-the-art on the subject. Then we give a concise overview on basic narrative structure and grammar. Moreover, we provide two examples of "conceptual story" (two physics tales), followed by the transposition of some typical elements of narrative into conceptual story frame. Lastly, after having outlined how narrative is a crucial form of human beings' organization of reality, we try to draw some conclusions in terms of appropriation by students.

Keywords: Physics, narrative, appropriation.

NARRATIVE AND SCIENCE, NARRATIVE IN SCIENCE

Despite its prearranged structure, one of the most powerful aspects of narrative is that a story can be told not only in one, but in many ways. Research on the theme has clearly explained that "narrative" is the story (the *fabula*, the sequence of events) and "narration" is the form of the story (the plot). The plot may mirror the story or not: in this case, we have a complex plot, called *non-linear*. This distinction generates a multiplicity of visions typical of the narrative genre, but often precluded to other text types. By contrast, this characteristic is certainly shared with science: as Bruner asserts, narrative «subjunctivizes» reality opening multiple perspectives and this is the same attitude of scientific approach (Bruner, 1996, chapter 6).

Different works and studies[1] let us point out four different kinds of relationship between science and narrative (the last one, d., is the one we are going to examine in this paper):

a. Narrative *by* science (to narrate): use of images from science to represent and narrate human feelings and existential issues in a figurative way. Authors as Italo Calvino, Primo Levi and Jorge Luis Borges are recent examples of this category: many specific studies have shown that concepts and images from math, physics, chemistry, and astronomy pervade their essays, short stories and novels. Borges himself explicitly said he has drawn inspiration and ideas from books of logic and mathematic (Simon, 1971).

b. Science *by* narrative (to communicate): use of narration as a tool for communicating scientific research to a non-expert audience (cf. Dahlstrom, 2014). Narrative formats are widespread for communicating science to public, because narrative enhances comprehension, interest, and engagement. Almost every media platform sometimes proposes "narrative scientific communication" (i. e. in documentaries), because it promotes inductive reasoning and activates efficient and quick pathways of comprehension. Not least, it stimulates memory and gets people fond of the characters: everybody feels

[1] Here we mention only a few of the existing ones.

connected with a wild animal if *one* specific animal is the protagonist of a documentary, observed in its everyday life made of ups, downs and troubles. It becomes a character.

c. Science *by* narrative (to teach): use of narration as a tool for bringing students to discover scientific statements, properties etc. with an inductive and more exiting approach (cf. Demartini & Sbaragli, 2015; Prins, Avraamidou, & Goedhart, 2017). Different narrations (stories, picture books, theatre performances, puppet shows etc.) can draw pupils' attention and activate their comprehension better than a decontextualized conceptual learning. The reason for why it happens is simple: listening to a story is more involving and memorable than passively try to learn data and information. To illustrate this approach, we can mention the Italian language books written by Anna Cerasoli, designed to introduce even very young children to mathematical issues and concepts through engaging, invented plots.

d. Narrative *in* science (to teach): use of narration to make explicit the narrative structure intrinsically present in the development of scientific concepts. The difference between type d. and c. stories is that "type c. stories" are variously and imaginatively composed (i.e., the author can freely add characters and personalise its narration in a playful way), while "type d. stories" are intrinsic to scientific concepts (so we can call these stories "conceptual stories"). This kind of narrative-science relation is poorly studied; we have only found an example in mathematics (Dietiker, 2016). Here we try to point out the matter with the final purpose of encouraging its employing in teaching.

BASIC NARRATIVE STRUCTURE AND CONCEPTUAL STORIES

The structural elements of a narrative text make it reassuring and gripping at the same time. In particular, the narrative text is characterized by a constant structure consisting of an *abstract*, an *orientation*, a *complicating action*, an *evaluation*, a *result* (or resolution), and a *coda* (cf. among several studies Labov & Waletzky, 1967, Labov, 1972, Levorato 1988, Bernardelli, 2019). This widely-accepted narrative sequence − influenced by the classic Propp's story grammar and functions (Propp, 1965) − has been investigated in many studies that emphasize different aspects (i. e. Greimas, 1966; Stein & Glenn, 1976; Peterson & McCabe, 1983); also Minsky (1986), from computer science, worked on stories structure (calling it "story-frame"). We also consider Todorov's narrative theory (1969, 1981), that identifies five main stages in every narrative: *equilibrium*, *disruption*, *realisation of the disruption*, *attempt to fix disruption*, *return to a new equilibrium*. He says that

> an ideal narrative begins with a stable situation that some force will perturb. From which results a state of disequilibrium; by the action of a force directed in a converse direction, the equilibrium is re-established; the second equilibrium is quite similar to the first, but the two are not quite identical. Consequently there are two types of episodes in a narrative: those that describe a state (of equilibrium or disequilibrium) and those that describe the transition from one state to another. (Todorov, 1981, p. 51).

For our goal, the main assumption is that there is a universal and constant set of textual units that we call *equilibrium*, *perturbation*, *disequilibrium*, *outcome*, and *new equilibrium*. This sequence offers a strong and natural support to hook information into a template; as we will see above, these units naturally fit "conceptual stories" development.

TWO "CONCEPTUAL STORIES" FROM PHYSICS

In our vision, a "conceptual story" (type "d") is a story focused on conceptual development, in which the conceptual sequence is the *fabula*. Other traditional key elements of narrative text (i. e. actions, intentions, teleology, sense of time) could be more or less present depending on the phenomena, but the story can be told even without referring to them. It means that we can suppose that the narrative can be found inside the conceptual progression, regardless external agents. This paragraph provides two examples of conceptual stories.

The "Conservation of energy"

The first tale concerns the conceptual shift from the idea of conservation of mechanical energy to the idea of conservation of the total energy of a physical system. The *fabula* can be naturally framed in a narrative structure: starting from a conceptual equilibrium (the conservation of mechanical energy), a new equilibrium is reached, which is not identical to the first one, even if it has physical relations with it (the conservation of total energy, not only the mechanical one).

Equilibrium: conservation of mechanical energy
In a field of conservative forces, the work does not depend on the trajectory of the bodies, but only on their initial and final positions. In a conservative field, the mechanical energy, which is the sum of kinetic and potential energy of a mechanical system, is preserved. This result is a law that can be expressed in mathematical form: $\Delta K+\Delta V= 0$.

Perturbation: friction comes into play
On Earth, these phenomena are usually ideal. On Earth, in addition to conservation forces, other forces, such as friction, must be taken into account. The problem is that when such forces come into play, the law of conservation of mechanical energy is lost. Where is it, now?

Disequilibrium: temperature and heat
In this new state of disequilibrium made up of conservative and non-conservative forces, it could be discovered that when a friction force acts on a body, that body heats up. Here it is possible to meet the concept of heat and the quantity temperature, which expresses an internal property of the bodies. After showing how even a mechanical work can produce a rise of the temperature of a system, the relationship between work and heat is clear: they both are ways of transferring energy. In all this, however, there is still no energy conservation law.

Outcome: the internal energy of a system and the first principle of thermodynamics
Conceptually, internal energy is an energy similar to the kinetic and potential energy of a mechanical system, and it defines the internal energy state of a system. Between an initial and a final state of internal energy, there must be a certain transfer. If energy is transferred (removed) to a system in heat or work mode, the internal energy of that system increases (decreases). Mathematically speaking: ΔU=Q+W: the first principle of thermodynamics. This relationship between internal energy, heat and work, describes how the total energy, no longer just the mechanical energy of a system, changes.

New equilibrium: the conservation of the total energy of a system

Non-conservative forces have not disproved the law of energy conservation, they have only generalized its spectrum of action.

Following the definition of "type d. story", this is a pure "conceptual story", where the explicit agents, the characters, are only physical concepts such as heat, friction, temperature, internal energy etc.

The "Copernican Revolution"

The second story is partially different from the one before because characters are not only physical concepts, but physical models of interpretation of the Universe. The main character of the story is the physical conception of the causes of motion: starting from a mainly philosophical conception (the starting *Equilibrium*), it is possible to reach a more scientific vision, based on the gravitational theory and the Newtonian dynamics (*New equilibrium*).

Equilibrium: the causes of the motion of the planets

In the geocentric system, the Earth is the center of the spheres on whose surfaces stars and planets move. In such a system, the celestial world is eternal and perfect, and respects perfect laws and geometric constructions; the human world is instead imperfect and mutable. In the geocentric system, the causes of the planets' motion around the Earth are mainly philosophical and religious: on the one hand, the hypothesis of a circular movement of the celestial bodies, which are eternal, divine and immutable, corresponds to the idea that the circular trajectory is the most regular one, thus, perfect; on the other hand, the fact that the Earth is immobile and at the center of these spheres corresponds to an anthropocentric conception of nature, in which the human being is placed in the center of the Universe (and of the whole creation).

Perturbation: Heliocentrism vs *Geocentrism*

Observation of planets' motion shows that their movement cannot be exactly circular around the Earth. The geocentric model then, becomes more and more complicated: epicycles, eccentrics and equants have to be added. On the other hand, a heliocentric model, with the Sun at the center of the circular movements of the planets, seems to be more effective in representing the celestial movement. In addition, the phases of Venus, the satellites orbiting around Jupiter, craters, valleys and mountains on the Moon are discovered. These latest discoveries, however, have a consequence: the celestial world loses its character of perfection, coming to assume a nature similar to that of the Earth. In this new framework, reasons that associate planetary motion and Earth immobility to philosophical and religious ideas have been lost: the Earth is no longer the center of the Universe, and it moves in circular motion on itself and around the Sun, despite its changing and imperfect nature. Why?

Disequilibrium: between kinematics and dynamics

In the heliocentric world, some problematic phenomena need to be justified. In fact, if the Earth were really moving around the Sun and on itself, such movement would cause effects that have never been observed. For example, a constant wind from east to west, or the displacement of any object thrown into the air from its initial position. These troubles are solved by the relativity principle in classical mechanics. This principle is part of the kinematics, which aims to describe geometrically the motion of bodies. Thanks to kinematics, it is possible to formulate the first version of inertia principle; it also allows to study uniform and accelerated motions. In addition, in the heliocentric model it is possible to formulate three empirical laws concerning the motion of the planets, based on direct observations and conjectures. In particular, one of these laws states that the orbits of the planets around the Sun are not circular, but elliptical.

Outcome: the three principles of dynamics and the law of universal gravitation

The three principles of dynamics have been formulated. The first one establishes a direct proportionality between the force acting on a body and the acceleration of the body itself. Thanks to these principles, the law of gravitation is also formulated, and it is applicable to all the bodies of the Universe. It identifies a force acting between any two bodies endowed with mass. This force is called gravitational force, and its intensity depends only on the mass of the bodies and on the distance between them. Thanks to the three principles of dynamics and to the gravitational law, it is possible to deduce the three empirical laws governing the planets' motion and to physically justify it.

New equilibrium: the causes of motion

The heliocentric system requires that the planets move along elliptical orbits, with the Sun located in one of the foci. In this system, we find physical causes for the motion of the planets. These causes find a synthesis in the gravitation law and in the three principles of dynamics.

The new equilibrium leads to the new scientific vision, after many twists and turns worthy of the most adventurous narrations.

KUHN'S STRUCTURE OF SCIENTIFIC REVOLUTIONS AND NARRATIVE STRUCTURE: A REMARKABLE SIMILARITY

In *The Copernican Revolution*, Kuhn (1957) writes that «the construction of Newton's corpuscular world machine completes the conceptual revolution that Copernicus had initiated». In fact, «Newton's universe was not merely a framework for Copernicus' planetary earth. It was a new way of looking at nature and man, a new scientific and cosmologic perspective» (Kuhn, 1957, p. 261). Our *Copernican* tale follows the vision of Copernican revolution proposed by Kuhn. Following his interpretation, it is easy to put the different stages of the Copernican revolution within the narrative structure. Why? Let's consider briefly the structure of every scientific revolution proposed by Kuhn. In Kuhn's work (1962), the evolution of science is composed by 5 phases or steps: *Normal science*, *Anomalies*, *Crisis of paradigm*, *Revolution*, *Paradigm Change*; then, back to Normal Science. We think that it is quite obvious, but also amazing, to see analogies between this structure and the structure of narrative proposed in this paper (Table 1).

Kuhn's structure of a scientific revolution	**Narrative structure**
1) Normal science	a) Equilibrium
2) Anomalies	b) Perturbation
3) Crisis of paradigm	c) Disequilibrium
4) Revolution	d) Outcome
5) Paradigm change	e) New equilibrium

Table 1. Kuhn's structure of a scientific revolution and the basic narrative structure: a comparison**.**

The similarity between the two structures strengthen the hypothesis that every scientific revolution could be profitably explained in a narrative framework, without forcing. Is it possible to build a physics tale on more than one scientific revolution?

OTHER ELEMENTS OF NARRATION IN CONCEPTUAL STORIES

Now we will try to analyse and reinterpret some other typical elements of narration in the particular case of conceptual stories.

Excursus

In narratology, an "excursus" is a form of digression: it could consist of an extra-explanation, a background story, a short episode or an anecdote. Also in conceptual stories it is possible to insert a series of "excursus" useful to better understand the main physics issues. For example, in the first phase of the *Conservation of Energy* tale, it is possible to insert a digression on the conservation of mechanical energy and the results that link the concept of work to those of conservative forces and mechanical energy. In the disequilibrium phase, in order to understand the concepts of temperature, heat and their relationship, it is possible to come across the laws of calorimetry, the coefficient of thermal conductivity as responsible for the sensation of heat/cold, and many other relations between the involved quantities. In the final phases, it is possible to point out the difference between process and state variables, as well as dig up the relationships between the first principle of thermodynamics and the law of state of perfect gases, or even interpret situations of evolution in the state of gas on the basis of the new found principle.

Fabula and plot

As we said, in narratology *fabula* is the chronological cause-and-effect chain of events, while *plot* denotes the sequence of events as they are presented to the reader or listener. Both the *Conservation of Energy* tale and the *Copernican Revolution* tale have been written following the *fabula*, but this is not the only way. In the *Copernican Revolution* tale, we could start from Galileo's findings in physics and motion, then coming back to the problem of the motions of the planets, and finally moving to the new physics proposed by Newton. In the *Conservation of Energy* tale, we could start from the definition of temperature, then wondering how temperature can be increased or decreased; at this point, after introducing friction, we could question the problem of the conservation of mechanical energy, and then introduce the internal energy of a system to reach the first principle of thermodynamics.

Perspectives

The possibility of telling several versions of a story maintaining the same narrative frame also involve *focalization*. In *Conservation of Energy* tale, for example, you can follow the development of events from at least two different points of view. A first point of view is given by the macroscopic and phenomenological treatment: this is the story we proposed. The same narrative structure can be used to tell sort of another story, exploiting the microscopic approach to thermodynamics: by interpreting all the thermodynamic variables in a microscopic key (following the statistical thermodynamic theory), thermal phenomena can be studied, up to the microscopic formulation of the first principle of thermodynamics in the case of perfect gases.

INTERSECTIONS: NARRATION AND *APPROPRIATION*

Telling (and listening to) stories makes us human

As shown by many studies from different approaches (i. e. Bettelheim, 1976, Bruner, 1991, 1996, Levorato, 2000, Gottschall, 2014), narrative is a basic human instinct and a strategy for coming to terms with fundamental elements of experience. This is because narrative boasts an advantageous property: it generates meaningful contexts. This means that if an *informative text* often conveys pieces of information (sometimes weakly related and context-free), a narrative text puts knowledge in a coherent structure, naturally internalized by human beings. That is exactly why stories can be intrinsically persuasive, even more than arguments (as shown by the extreme theory of the "narrative paradigm", Fisher 1994; 1995). In this sense, stories can give instructions and information as well as pleasure and entertainment. This is also confirmed by the fact that narration is one of the earliest emerging discourse form in children (D'Amico & Devescovi, 2013). In extreme synthesis, this means that human beings are "storytelling animals" (Gotschall, 2014), naturally inclined to understand and organize the world in a narrative form. Recent and persuasive arguments are also given by cognitive science and neurosciences (i. e. Bernini & Caracciolo, 2013; Young & Saver, 2001): emotional experiences stimulated by narrative positively activate and shape our brain making our learning more durable. It is not without reason that Bartes and Duisit (1966: 237) wrote that narrative «is present at all times, in all places, in all societies; [...] there has never been anywhere, any people without narrative».

The idea of *Appropriation*

This deep connection between narration and human mind lets us link narration and Appropriation. The idea of Appropriation is a vygotskijan notion, deepened in linguistic by Bakhtin (1981), developed in the socio-cognitive field by Rogoff (1995), Sfard (2007), and adapted in order to consider the scientific discourse (Delgatto, 2011). Moving from this literature, Fantini (2014) and Levrini *et. al.* (2014, 2018) have listed some observable features that allow to recognize students' appropriation of scientific discourse when this discourse is:

A. developed around a set of words or expressions repeated several times and linked together so as to express a *personal, idiosyncratic "signature" idea* with respect to physics (thermodynamics, in this case);
B. *disciplinarily-grounded* i.e. the signature idea was used by the student as a tool for focusing on pieces of disciplinary knowledge;
C. *thick* i.e. the signature idea involved a metacognitive dimension (What does learning physics mean for the student?) and an epistemological one (What sense of the discipline does the student have?);
D. *non-incidental*, i.e. the signature idea was expressed in several activities throughout the students' classroom experience, not just in one interaction;
E. *carrier of social relationships*, i.e. the signature idea allowed the student to play a specific role in class discussions, and this role was acknowledged by others in the classroom community. (Levrini *et al*., 2018, p. 305)

From these markers an operative definition of Appropriation has been drawn up:

Appropriation is a complex, reflexive process (Marker C) of transforming scientific discourse (e.g., scientific words and utterances) so as to embody it in one's own personal story (Marker D). This process:

- results in a discourse populated with one's own intentions, idiosyncratic tastes, purposes (Marker A);
- respects the rules and constraints of science as a discipline (Marker B); and
- is intrinsically social in nature (Marker E). Namely, it is sensible both for oneself and also within the social context of the classroom. (Levrini *et al.*, 2014, p. 27).

Because Appropriation of a scientific discourse is a complex process for a student, it is necessary to activate different sub-processes, which can be enhanced by significant physics teaching/learning's tools. Of course, there are different set of activities and methodologies that can stimulate this "making one's own" of a scientific discourse.

Apart from concrete or cognitive activities, it is also important to rethink the teaching of physics from the point of view of conceptual reorganization: how is it possible to organize scientific knowledge, at the level of content and logical connections, to make students appropriate it?

A first answer is quite logical: it is necessary to create rich and dense conceptual formats, which incorporate practices of constructive and stimulating complexity. These forms of complexity are codified in terms of a multi-perspectiveness (same contents analysed from different perspectives), multidimensionality (contents analyzed from a conceptual, experimental, formal, epistemological etc. point of view) and longitudinality (widening, refining and revising already acquired knowledge) (Levrini *et al.*, 2014).

A second answer specifically concerns the idea that a narrative conceptual restructuring is one of the critical and preliminary aspect which encourage appropriation. As Fantini says:

I think that the base, for the universe of scientific discourse to be transformed by everyone, should be an adequate disciplinary restructuring that restores an image of physics not as a set of truths, but as a construction of thought, as a narration of stories of concepts, so as to be able, as Bakhtin said, to make the words of other their own. (Fantini, 2014, p. 182, translation by the authors)

Now, we think that this last aspect could be a further evidence to support the creation and the use of "type d." stories in the teaching/learning of physics. If listening to stories and storytelling make us human and help us to give meaning to the world, then using a narrative approach in physics teaching could help students to deeply internalize scientific information, improving long-term scientific literacy and stimulating interest. In particular, this approach could spontaneously boost the appropriation process because it encourages students to discover and build sense, constructing their utterances and discourses in a situated, dialogic and participative way.

CONCLUSION

In light of what we have said, we believe that a framework involving narrative can contribute to a fruitful teaching and learning process, because narrative may stimulate and enhance comprehension, curiosity, and involvement, offering a natural stepping-stone to an in-depth knowledge. In *The Culture of Education* (Bruner, 1996), Jerome Bruner deals with a strong postulate: there are essentially two ways to organize and manage knowledge, the logical-scientific thinking, and narrative one. Actually, in many cases the two attitudes can profitably combine.

IMAGINATION; WHERE SCIENCE FORMULATE DIFFERENT HYPOTHESIS AND EXPLANATIONS HELPING THE UNDERSTANDING OF THE LANGUAGE AND SOUL OF CHEMISTRY

Ann Mutvei[1], Ulrika Tobieson[2] and Jan-Eric Mattsson[3]
[1,3] School of natural sciences, technology and environmental studies, Södertörn University, Stockholm, Sweden,
[2]School of teacher education, Södertörn University, Stockholm, Sweden,

New understanding is realized by creative learning where students are involved in meaningful learning, ownership of learning, control of learning processes and innovation. In order to produce learning situations where creative learning is achieved, teachers have to create trustful atmospheres where students are allowed to think and discuss without critical evaluation from the teacher. It is also important to create practical exercises in which theoretical models are processed and connected to observations and subject matter. During several years we have developed courses in science with the goal to promote students to become independent learners and explorers out of their own prerequisites as future professional teachers. We have investigated different methods and designs of teaching; conceptual understanding and conceptual change theory, discourse-based understanding and Dewey's view of learning. In this study we are focusing on exploring the variation of students creative learning through a chemistry course. Permitting the particulate subject matter of chemistry to demonstrate as universal dramaturgical framework for conceptual learning and embodied experience. Chemistry involves considerable amounts of abstract conceptual thinking, molecular understanding and language. The focus of our study is the exploration of how conceptual abstract molecular understanding of phenomena in nature emerges through different teaching approaches, and imagination transformed into universal understanding, which provides the students with a sense of empowerment and a positive outlook on their future profession as teachers.

Keywords: knowledge construction, aesthetic learning process, reflection

INTRODUCTION

"Imagination is the meeting ground where old and new come together - what was, what is, and what could be. The imagination takes us beyond and behind the everyday." (Ellen Levine prof. EGS)

It is important for teachers to establish an environment for knowledge construction and creative learning that allow students to think and discuss without critical evaluation. In changing from teacher-centred to student-centred teaching, as well as ethically observing the boundaries where students are responsible for their own learning is part of achieving an open and trusting learning environment (Pollard et al., 2018). Creative learning emerges when learning is meaningful, self-motivated and innovative (Jeffrey, 2006). Teaching should be inquiry based and connect observations to theoretical models for students to create their own knowledge (Jeffrey, 2006). By asking questions and solving problems during inquiry, students can make connections between theories and praxis (Jeffrey, 2006). Another important aspect of creative learning is when students are engaged, collaborating with others and enjoying further exploration (Gibson, 2010; Pollard et al., 2018).

Our work with aesthetic learning process is based in intermodal art theory and the philosophy of phenomenology (Knill et al., 2004). An aesthetic learning process is where one or more modalities are expressed through their specific language in art (music, art, dance, etc.). As one expression develops and encounters a second expression which then flows into a third modality of felt sense the dramaturgical sequence evolves and moves. In our study we implemented a five-part psychokinetic imagery model created by Daria Halprin. (Halprin, 2002; Knill et al., 2004) .

We have developed courses in science in order to achieve and motivate students to become independent learners focusing on their future as teachers. A variation of methods and designs of teaching have been investigated and the students creative learning has been equally analysed, to further develop an understanding of what signifies a trusting learning environment. In this study we have been exploring and focusing on a chemistry course for future 4 – 6 grade primary school teachers. Chemistry involves considerable amounts of abstract thinking. Furthermore, as many students have had bad experiences of chemistry from school the encounter with new knowledge of chemistry is in many cases perceived as a challenge.

OBJECTIVE

The focus of our study was the exploration if and how a universal understanding of conceptual abstract molecular thinking and language as well as phenomena in nature emerges and manifests itself through different designs of teaching and imagination.

Could the design of the course promote creative thinking and create conceptual understanding of chemistry? How do students experience aesthetic learning processes in connection to their own learning in chemistry?

COURSE DESCRIPTION

17 preservice teacher students were trained by one science teacher and one teacher in aesthetic learning process to foster their independent and creative learning of chemistry. The course consisted of 10 days over a four week-period, which included practical activities mixed with discussions in groups followed by discussions with the teacher in order to connect theory with practical exercises. The students wrote short reflections at the end of each week as well as a short reflection after the two sessions of aesthetic learning process answering the following two questions: “What do you take with you from your own learning process and/or in connection with other’s and/or the working process of the session?”, “What amazed and/or surprised you the most?”. Students were studying and working with questions in a science textbook in English as well as a textbook on chemistry education in Swedish during the campus

free days. A guided visit to the Vasa museum in Stockholm at the end of the course showed the chemistry around a wrecked ship from 17th century saved sixty years ago. At the end of the course the students were assessed through a written examination.

METHODS

The five written reflections where analysed by qualitative methods scoring demonstrations of professional development, process thinking and learning processes. The analysis was focused on six categories: A. changed attitude towards chemistry, B. connection to everyday life, C. importance of practical exercises for learning, D. importance of group discussions for learning, E. chemical descriptions using concepts and F. connection to future profession as teacher. The quality of the five individual written reflections were also analysed using the quality markers 4R's of Doll's, *Relations*, *Recursion, Richnes*s and *Rigor* (Doll, 1993) (Mutvei, A. et al., 2017). Recursion is understanding in depth by the connection of the past with the present in depth. Relations is understanding through interaction with and connection to the other unknown, things and people within the context. Richness is understanding and expressing different levels and dimensions of interpretations and perspectives, to give different interpretations, perspectives and possibilities. Rigor is consistently using knowledge in new ways and in new unexpected situations. The use of the R's was assessed using a scale 0−3 where 0 refers to the absence of the specific concept and 3 to regular and active use of the processes referred to by the concept. The aesthetic learning process sessions were analysed by ethnographic method making observation and taking careful and meticulous written notes (LeCompte & Goetz, 1982). The different steps of the five-part model during the aesthetic learning process (Tobieson, U. & Mutvei, A., 2017) were identified and the outcome was assessed by the students through oral reflections at the end of each session as well as a written individual reflection.

RESULTS

Our results showed that students with a negative conception to chemistry changed their opinion during the 10 days that the course lasted and thereafter enjoyed paying attention to phenomena in everyday life with a multiple of perspectives on chemistry. All students expressed the importance of practical exercises, aesthetic learning process and group discussions for their own learning skills. The reflections contained detailed explanations of chemistry, concepts used properly in describing their particulate learning through a universal language. They also used their experiences when they discussed how to design teaching situations and lesson content. The first week many students expressed their negative experience of chemistry at school and that they were more interested now and found it meaningful (Figure 1, A reflection 1). At the end of the course students described how they will teach as professional teachers (Figure 1, F reflection 3). Also, a few students reflected on chemistry as school subject and learning in more general terms at the end of the course.

A	changed attitude towards chemistry
B	connection to everyday life
C	importance of practical exercises for learning
D	importance of group discussions for learning
E	chemical descriptions using concepts
F	connection to future profession as teacher

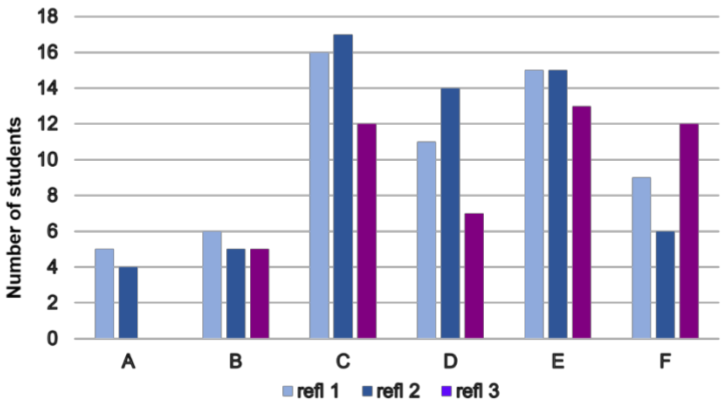

Figure 1. The graph shows the number of students using categories A – F in each reflection (refl. 1 – 3.)

How did the students express their learning in chemistry after one week of the course?

The chemistry reflections after one week of the course were analysed by using the 4R's of Doll's (Doll, 1993) to evaluate the students' learning of chemistry by using literature studies, group discussions, lab exercises and inquire based learning (Table 2). The quality of the students' understanding, by answering two questions about what they have learned and what surprised them, showed that they already after the first week, used concepts to explain different phenomena, and especially, how to use their experience of learning in their professional lives as teachers. All students noticed the importance of interactions with and connection to the other, sometimes unknown parts of the content knowledge and persons within the context for their learning processes (Relation 2 and 3). Many of them could also describe the process (Relation 3) (Table 2). All students expressed their understanding by using factual terms that belong to the current discourse in everyday life and in their own language. The use of own words indicates acquired knowledge (Richness 2 and 3). A few students also could express their knowledge from several perspectives and dimensions (Richness 3). However, only two students described their knowledge related to new situations (Rigor) (Table 2).

Table 2. Qualitative analysis of students' reflection 1 using the 4 R's of Doll's. The lower row of the table shows the percentage of total students that had high quality (2 and 3) in their understanding (n=17).

level of 4 R's of Doll	**Reflection 1** (number of students)			
	Recursion	Relations	Richness	Rigor
3	1	9	4	1
2	3	8	12	1
1	2	0	1	0
0	11	0	0	15
	35%	100%	100%	12%

Example of students' learning from reflections after the first week of the course:

"What surprised me most is probably how much the literature is linked to the practical parts that are carried out during the laboratory work and how to share the knowledge with my peers and connect their knowledge to and with my own."

"To think about, in my future role as a teacher I have to let the students draw their own thoughts and ideas before using illustrations from different textbooks, maybe start from the students' own thoughts, questions and statements instead of – it is like this."

"What surprised me was that because of the experiments we conducted, I more easily understood the connection between the different phases (liquid, solid and gas) as well as sublimation, diffusion and evaporation. This could then be reworked theoretically and related to one's own experiences in everyday life."

How did the students express their learning in chemistry using aesthetic learning processes?

At the end of the course, the students had two sessions lead by an art teacher with the aim of connecting the knowledge in chemistry of the course with aesthetic learning processes, both for developing more and deeper perspectives and to use this in their own teaching. Through aesthetic learning processes, chemistry is repeated in new ways through the making of art, providing more perspectives and creating new knowledge (Knill et al., 2004). The artmaking awakens emotions and creates experiences when using the whole body and all the senses, necessary to deepen the learning processes (Tobieson, U. & Mutvei, A., 2017). At the end of each session an aesthetic analysis of the shared and achieved experiences was done together in the class. The students shared their experiences of the importance to use representations from the theory of chemistry and how they realized the differences between everyone's view. The students showed each other different perspectives on the molecular world which gave them new experiences. They appreciated the group processes and the inclusive way of working, and also the way of repetition of concepts which gave a holistic view of chemistry. The students should also write a reflection on what surprised and amazed them and what they brought from their work process and content during the sessions.

The reflections from the aesthetic learning process were analysed using the 4R's of Doll's assessing the students' quality of description of their learning. The students' reflections showed a considerable increase in using their chemistry knowledge outside the context (Table 3). All students were better in seeing patterns in other areas (Rigor 1) and many could see patterns through unexpected orientations related to unrelated subject areas (Rigor 2). One third of the students were also able to see, pay attention and use other subject areas to show a deeper understanding and to generalize a complex content (Rigor 3). The students also saw the importance for learning out of previous experiences (Recursion 2) and noticed, described and explained moments of change in the learning process that have led to insight and/or understanding (Recursion 3) (Table 3).

Table 3. Qualitative analysis of students' Aesthetic learning process reflection 2 at the end of the course using the 4R's of Doll's. The lower row of the table shows the percentage of the total number of students that showed high quality (2 and 3) in their understanding (n=17).

level of 4 R's of Doll	**Aesthetic learning process reflection 2** (number of students)			
	recursion	relations	richness	rigor
3	6	5	10	6
2	7	12	5	3
1	3	0	2	7
0	1	0	0	1
	94%	100%	100%	94%

Examples from aesthetic learning processes, reflection 2

"The practice of giving each other an aesthetic response, was a great way to interpret and connect different concepts that we have learned so far, together with the different paintings. It sounded a bit fuzzy at first but after two, three paintings I started to see the different concepts take shape and suddenly, I could name many of the concepts of chemistry. It surprised me that I knew more concepts than I thought. It was really a way of going from abstract to concrete."

"We got to paint chemical reactions. To find new ways to create new perspectives on the theory was important. It gives joy but also greater understanding as the aesthetic gives new angles and makes us think differently."

"It was interesting partly that you got to take into account what you had already studied and worked with. Then, to have the opportunity to do something completely different during art-making was a chance to create a deeper understanding of the different parts of chemistry. A lot of the various chemical concepts that had been spinning around in the head were now actually being embodied."

SUMMARY

It is important to design teaching using a variety of learning situations in order to reach a good understanding of chemistry where students use a particle model, show understanding of different chemical relationships, define concepts and make explanations. The students appreciated group discussions and practical exercises for their learning especially when they used their concepts to explain different phenomena in everyday life. Our results show that art making in the aesthetic learning processes deepens the understanding of concepts in chemistry as learning occurs beyond the usual environment. During the aesthetic learning processes students also expressed wonder and imagination for their own learning in their reflections.

CONCLUSION

All students expressed the importance of practical exercises, group discussions and art-making, as well as the wonder of imagination for their own learning. Our results showed that the course design promoted creative thinking and deepened the students understanding of chemistry, which provided them with a sense of empowerment and a positive outlook on their future profession as teachers.

A PLAY-CENTRIC APPROACH TO SCIENCE EDUCATION

Adriana Cardinot[1] and Jessamyn Fairfield[1]
[1]School of Physics, National University of Ireland Galway, Galway, Ireland

Game-based learning has attracted increasing attention as an effective approach to teaching. Researchers have shown that games are highly engaging and motivating, which can benefit science education. However, taking advantage of these qualities to facilitate the teaching and learning of complex science subjects may not be an easy task. To discuss how non-digital games could be designed and used to support a wide range of learning outcomes in science education, a workshop was delivered at ESERA 2019, which was divided into two parts. In the first part the participants were introduced to an educational astronomy board-game developed by the researchers and had a chance to play the game with other participants. In the second part, the participants were divided into groups and presented step-by-step on how to create an educational board/card game. At the end, the participants reflected on and discussed their experience with game development during the workshop and shared their ideas with the other participants in the room. Here we present the structure and content of the workshop and propose a discussion of the advantages and barriers when adopting games for educational contexts.

Keywords: Teaching methods in science, Collaborative learning, Knowledge construction.

INTRODUCTION

Students who are deeply inspired and engaged by the things they learn in science classrooms early on will often carry these attitudes through their lives and are more likely to expand on what is taught (Laursen, Liston, Thiry & Graf, 2007). Science education is recognised worldwide as having a critical role in society. It is important to bring scientific knowledge continuously to broader society in order to promote science literacy and expand students and educators' views of where science can lead (Gil Pérez & Vilches, 2005). It also allows students to make decisions critically and have a better understanding of the scientific and technological processes in the world in which we live. However, new methods are necessary to provide adequate access to science across all parts of society (National Research Council, 2002).

The use of creative learning methods, such as games, in formal education can be a valuable method to immerse and engage learners with science (Cardinot & Fairfield, 2018). The growing popularity of games has led to an increase in the numbers of studies that focus on the use of Game-Based Learning (GBL) as a creative approach the teaching and learning of science subjects (Ramani, Siegler & Hitti, 2012). This methodology has been shown to facilitate learning in a variety of subjects, to motivate learners and to promote the development of social skills. Gee (2008) argued that play-centric approaches can have a positive impact on student's motivation to learn due to the challenges and immersed experience promoted within a game which are fundamental for science understanding. In recent years a number of studies have investigated the effect of learning through play to convey scientific concepts in classrooms (Su, Cheng & Lin, 2014), yet there is very little use of games in the everyday teaching and learning of science.

Learning new and complex material can be intimidating (Tan and Barton, 2010). Particularly, in science learning previous studies have found a cause and effect relationship between competence, engagement and perceived difficulty. The fear of failure in science can prevent students from pursuing a career in STEM (Science, Technology, Engineering and Maths). However, GBL can provide an effective way to offer engaging experience in which students are provided an opportunity to manipulate, to experiment and to explore science (Beier, Miller and Wang, 2012). It presents problem-solving situations through game mechanics at different levels, allowing students to learn as they advance in the game but also when they fail to complete a task, which turns failure into an opportunity to iterate toward success (Spires, Rowe, Mott and Lester, 2011). Thus, one remarkable thing about the benefits of using games in science education is that they could remove much of the intimidation inherent in the learning process of complex subjects (Subrahmanyam and Renukarya, 2015).

Currently, in the literature, there is evidence showing that games can create learning environments that facilitate immersion (Jennett et al., 2008), allowing interactivity and collaboration among peers (Pange, Lekka and Katsigianni, 2017), and increase motivation to learn (Foster, 2008). However, there is currently little guidance on how to design such materials to best support the learning of science. When creating educational games, it is important to take into account the design issues that may arise when merging learning outcomes in games. This paper intends to provide a practical and straightforward framework for science educators and researchers to design educational science games (Michael and Chen, 2005). By presenting a structure for the game design process, we hope to provide instructors, curriculum developers, and researchers with new principles for designing effective educational games for teaching different concepts in science.

WORKSHOP STRUCTURE

The workshop presented a space for discussing how to exploit games in real learning practice and how to create meaningful learning experiences with GBL. Through hands-on exercises, the workshop brought together research and practice for reflecting on the value of games in science education. The design process guided participants to exercise their critical-thinking and problem-solving skills, gaining insight into the implementation of game design to teach science subjects and the integration of non-digital games in their future practices. The workshop is divided into two main sections:

1. Get started: captivate learners with non-digital games in the classroom

The first section of this workshop introduced the attendees to an educational game designed for teaching a novel astronomy board game developed to facilitate the learning and teaching of astronomy topics (see Figure 1). The learning mechanism in the board game was focused on integrating the curriculum to pedagogical elements into the design process, which made gameplay more enjoyable. Participants had the opportunity to play the game and, then, critically reflect on the learning opportunities that a non-digital game has to offer. After the gameplay, the attendees were presented with an evaluation form to assess different aspects of the game that could promote scientific learning (see Figure 2).

Figure 1. Board-game designed for teaching physics and astronomy, which participants played during the workshop (Cardinot & Fairfield, 2019).

Evaluation Form

		Poor	Fair	Good	Very Good	Excellent
1	The game has clear learning objectives that are merged with gameplay.					
2	The game is a valid formative assessment, actionable for teachers.					
3	The game includes instruction to guide students toward greater understanding					
4	The game promotes strategic thinking.					
5	The game shows multiple representations of the content.					
6	The game deeply engages students.					
7	The game motivates students to challenge themselves.					

Additional notes on the game?

What do you think is the best way to use this game for your students?

Figure 2. Evaluation form used to evaluate the game. The resource was given to the attendees to assess the strengths and weaknesses of games for teaching science.

2. Dive into non-digital game design: discover tools and techniques

The second part aimed to get participants started in educational game development in small groups. The exercise had seven steps (see Figure 3) along with discussions, in which participants were asked to complete a workbook with their answers. At the end, each group presented their ideas to the other groups followed by a discussion with participants on the value of using games in science education, and get top tips for incorporating games into teaching practice. Below is a short description of what included in each step.

Learning outcomes	Verbs	Content	Output (mechanics)	Constraints and Challenges	Components	Rules

Theme: ____________________

Figure 3. Workbook used to support the development of an educational game.

Part 1 - Setting learning outcomes and action verbs. Similar to any other teaching intervention, the learning outcomes should be specific, well defined and taken into account from the beginning of the development. However, designing a learning outcome is not a simple task and requires careful consideration and reflection before implementation. Since this was a group exercise, participants were asked to find a general aim, i.e. a general overview of why they were creating a game. When designing a game, the learning outcomes of a game are essentially the details of what students should have learnt by the time they have finished the game. In addition, learning outcomes can also be used to assess their learning.

Part 2 – Mechanics. This refer to the players' actions in the game. Participants were given a list of popular games (e.g. Monopoly, Jenga, Uno, etc.). Each participant picked one of the game on the list and asked to explain how you play that game to the rest of the group. Then, they were asked to brainstorm how they could change that game mechanics to fit their learning outcome, using the matrix to write their ideas.

Part 3 – Constraints and challenges. This means what actions players need to perform to advance in the game, i.e. obstacles placed in the players' way to make reaching the goal a fun and interesting journey.

Part 4 – Components. In this part, they should consider what their game should have included to meet their mechanics, for example a board game, dice, cards, pawns, timer, etc. They should also take into consideration their audience, number of players and gameplay time length.

Part 5 – Rules. These may be defined as statements and directions that players must follow within the game in order for it to be played correctly. For example, one should consider the win and lose conditions for the game to end.

Part 6 – Theme. The scenario of the game to immerse the players. It should provide a context to help players remember the rules of the game and make better and more informed decisions in the game, and can also be related to the educational content of the game.

Part 7 – Prototyping. Participants used the materials provided to create a quick physical prototype, including a board, cards or any other bits as needed. The most important thing about this initial prototype is to run through their ideas quickly and gather feedback about the game from others before moving to the design.

CONCLUSION

Knowledge construction that takes place while playing games is fundamentally different from the learning experiences associated with traditional teaching tools. The GBL methodology entails setting learning goals in which learners maintain the enjoyment of play while ensuring that students will absorb and embrace the knowledge. Hence, students feel ownership over their learning and are motivated to establish relationships with other players. However, this is not an easy task, as educators and researchers alike encounter barriers in adopting games for teaching science such as the lack of professional development/training on how to use games. The workshop we have outlined explores learning principles in games and shows to the participants how to apply them into their practices to enhance student engagement and performance. Furthermore, our hands-on approach provides a valuable opportunity for both in-depth technical discussion and networking.

PART 4: STRAND 4

Digital Resources for Science Teaching and Learning

Co-editors: *Jesper Haglund & Jesper Bruun*

CONTENTS

STRAND 4: INTRODUCTION

DIGITAL RESOURCES FOR SCIENCE TEACHING AND LEARNING

Strand four focuses on science learning in digitally enriched environments. Within this focus, a wide range of perspectives and topics were presented as part of the strand at ESERA 2019, and this is reflected in the 22 papers in this section of the electronic proceedings. The breadth of the strand can also be seen from the countries of the authors of the contributions, in Europe: Austria, Cyprus, Finland, France, Germany, Greece, Italy, and Slovenia, as well as outside Europe: Argentina, Brazil, Japan, and the USA.

One prominent theme among the papers in the study of the use of mobile digital devices in science education, including mobile apps and sensors for data collection. Related areas include the use of computer programs that support students' learning of science content. In this regard, gamification is a clear trend, in which game-based teaching approaches are developed and tested in order to support students' learning and attitudes towards science. Other digital tools focus on the use of different modalities, such as simulations and the use of signing language for deaf students.

Other studies focus on teacher education, with studies of teachers' knowledge and beliefs in relation to teaching with digital tools, and studies of the use of digital tools in the teaching of pre-service and in-service teachers. The conditions for teaching is also central in studies of online learning platforms and online forums, and how they can be combined with physical teaching, as reflected in concepts like blended learning and flipped classroom teaching, and comparisons between virtual and physical lab environments. Such questions have risen to the top of the agenda of many teachers and educational researchers at the time of editing the electronic proceedings, although tragically to a large degree due to the Covid-19 pandemic.

Furthermore, a few of the studies explore how digital resources may be recruited in the development of novel methods in science education research, including the use of automatic network analysis to study teachers' and students' dialogue in physics classrooms, and eye tracking in the study of determination of butterfly species.

We hope that strand four will continue to provide a forum for those who are interested in science teaching and learning in digitally enriched environments to share findings and exchange ideas to improve the future science education.

Jesper Haglund & Jesper Bruun

CHARACTERISING THE EDUCATIONAL POTENTIALS OF MOBILE APPLICATIONS RELATED TO ECOLOGY

María Zoe Maldonado Velez[1], Romina C. Torres[2] and Leticia Garcia Romano[1,2]

[1]Science and Technology Teaching Department, National University of Córdoba, Córdoba, Argentina

[2]National Scientific and Technical Research Council, Córdoba, Argentina

Ten free-download mobile applications (apps) to be used for Ecology teaching and learning have been characterised. The analysis has included not only their technological characteristics but also their ecology content as well as the didactic aspects proposed by such apps. The technological resources studied have shown a high degree of usability, but two-dimensional images with low or null degree of realism have prevailed. Most of the apps have shown a wide variety of contents in their proposal. Few apps included activities for users, and when they did include them, the activities were limited to closed-ended questions or games. In most cases, no assessment activities that would enable meta-reflection were presented. The scientific thinking skills that were mostly promoted were: categorising observations, recognising patterns and thinking about causes and effects. As a result of the systematic analysis of the apps, they can be classified into three large groups: 'simulations', 'gaming apps' and 'encyclopaedia apps' in which different levels of interactivity, multimedia content, breadth, skills involved and cognitive demand prevail.

Keywords: ICT Enhanced Teaching and Learning, Secondary School, Multimedia and Hypermedia Learning

INTRODUCTION

Ecology is the epistemological support for understanding environmental problems, and it feeds school knowledge with a complex, open, multidimensional vision of science. In this context, ecology offers a systemic, non-mechanistic perspective: working with complex entities, the global vision of the world and the integration of analysis with synthesis, with a strong tendency towards multi- and inter-discipline (Hill, Wilson & Watson, 2004). However, at school, ecology concepts are usually presented as a set of dogmas; students deal with topics such as the ecosystem or ecological relationships as closed, static concepts, with one single possible formulation (Gonzalez del Solar & Marone, 2001). Without doubt, this way of teaching makes it difficult for students to acquire ecology school knowledge in line with scientific knowledge, and limits their capacity to establish relationships and combine contents.

For more than 15 years, the use of ICT as Ecology learning mediators has been proposed, with the development of specific computer programmes that enable the simulation of population and community dynamics, among other things. Nowadays, educational systems face the challenge of incorporating mobile phones in the classroom. In this scenario, mobile phones have long ceased to be mere communicative mediators to become centres of information, communication, audio and video recording and editing, and resource and content repositories.

Therefore, taking advantage of this device in the teaching and learning processes has many more advantages than one can imagine. This study is then based on two important premises: the availability of this educational tool and the ability of students to use it (Cantillo Valero, Roura Redondo & Sánchez Palacín, 2012). However, despite their ubiquity and the types of learning they can reinforce, these technologies are often not allowed or ignored in formal education systems. This represents a missed opportunity, as the potential of mobile phones can be significant and will continue to grow (Villalonga & Marta-Lazo, 2015).

In view of the prevailing need to incorporate mobile technologies in classrooms and considering the advantages of mobile apps that have been studied for the teaching of other biological contents, it is of interest to investigate the potentials of ecology-related mobile apps.

METHOD

The keywords 'Ecology', 'Ecology Teaching', 'Learning Ecology', 'Ecology Education' (both in English and in Spanish) were used in the search. Ten free-download apps developed for Ecology teaching and learning for the Android operating system (the main one used in Argentina) were selected for the analysis. The chosen apps, which were available in the Google Play Store digital platform, were the following: The Rain Forest Game, TaddyPole, Ksolve-Ecology, Ecology and Evolution Test - ECO, Ecology and Biosphere, Cours d' Ecologie, Ecosystem, Ecology Nuggets, Perspectives in Ecology, and Trilha Ecológica.

A methodology based on content analysis (Bardin, 1986) was followed, and those apps that included biodiversity and ecosystem structuring contents were selected. A qualitative analysis tool was developed, and categories contained in three dimensions were defined for such tool.

The 'ICT' dimension included the technical characteristics of each app taking up the categories proposed by Fernández-Pampillón Cesteros, Domínguez Romero & de Armas Ranero (2013); Martínez, Mir & Garcia Romano (2017) and Oliveira & Galembeck (2016). The 'Content' dimension analysed the depth with which the central Ecology topics were presented; to such end, the ideas presented by Adey (1997) and Bermudez & De Longhi (2006) were taken into account. As regards the 'Didactic' dimension, the pedagogical-didactic potentials of the apps were analysed according to the categories suggested by Vázquez-Alonso & Manassero-Mas (2018). Aspects emerging from the analysis were included in the tool, which was validated by means of a revision process carried out by experts in the field of Ecology.

RESULTS

Eight of the ten apps that were analysed were in English, one in French and one in Portuguese. With respect to the 'ICT' dimension, in general, the apps did not require Internet connection for their use. Usability was high, as the contents that were searched could be found quickly and the interface was intuitive. The multimedia content mostly included content with decorative or ornamental audio, 2D images with illustrative purposes and strong predominance of text. The degree of realism was low or null in most of the cases (Figure 1).

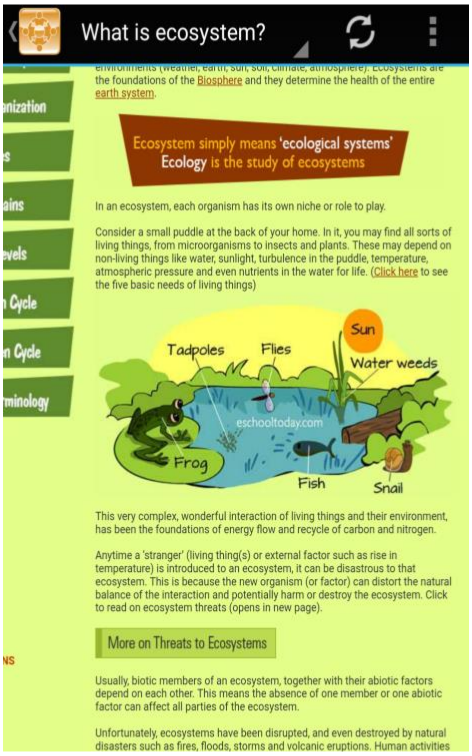

Figure 1. Example of an app that featured ornamental audios, illustrative images and predominance of text (Image taken from the Ecosystem app).

Interactivity was predominantly low, given the fact that the user's actions are limited to selecting steps to move forward in only one direction within the framework of the app proposal. Only one of the apps enabled to modify the values of different variables, and to observe different results according to the selection (Figure 2 a and b).

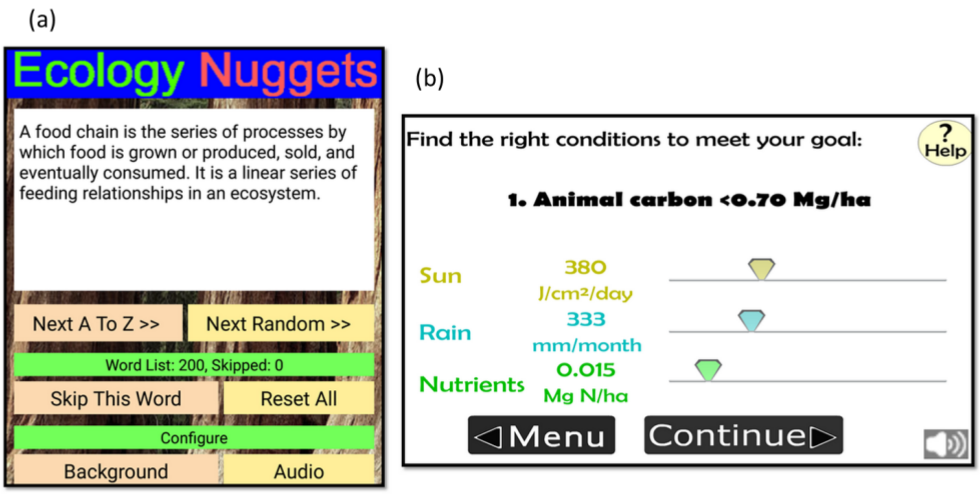

Figure 2. Example of an app with low interactivity (a) and an app with high interactivity (b) (Images taken from the Ecology Nuggets and The Rain Forest Game apps, respectively).

In relation to the ‘Content’ dimension, the Ecology branches that were most frequently found in the apps were General Ecology and Community and Ecosystem Ecology. Most of the apps included a wide variety of contents in their proposal, and only a couple of them focused on specific concepts (Figure 3 a and b).

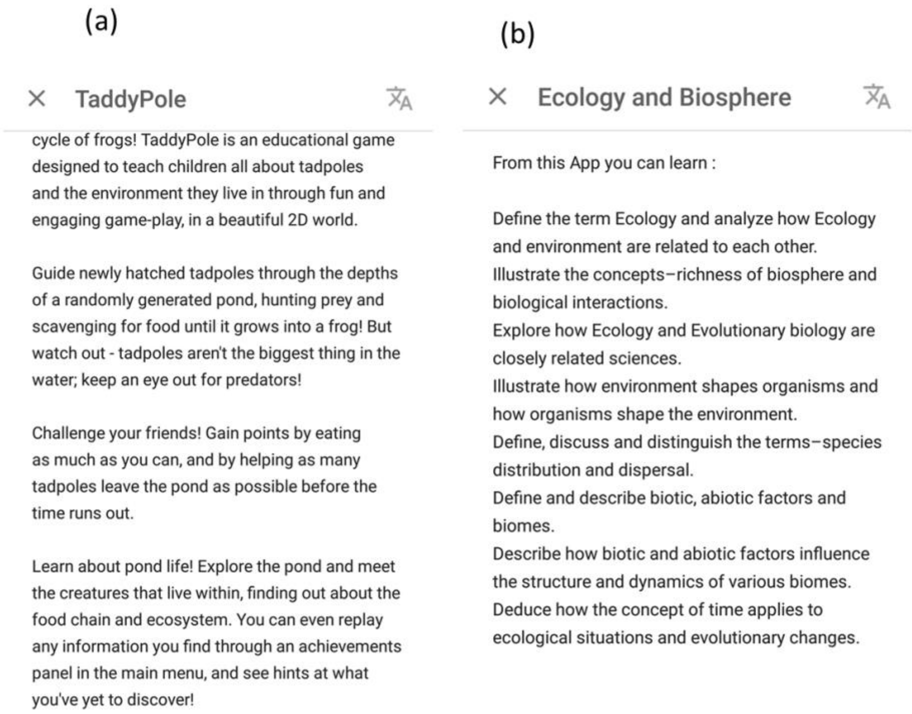

Figure 3. Example of an app with low breadth centered on the topic wetland ecosystem (a) and an app with high breadth that includes numerous topics (b) (Images taken from the TaddyPole and Ecology and Biosphere apps, respectively).

The biodiversity and ecosystem structuring contents were dealt with at different levels of complexity in the apps analysed, finding cases in which the description of elements and relationships present in the ecosystem were presented from an additive point of view that may reinforce students’ prior ideas, and biodiversity was explained from a perspective that does not recognise its different levels of expression. However, some apps address a higher level of complexity and describe the variety of life, including species, ecosystem and genetic diversity (Figure 4 a and b).

Regarding the ‘Didactic’ dimension, it was found out that, in general, activities are not included in the proposals offered by the apps. In those cases in which activities were actually included, none of them was collaborative, and they focused on the development of close-ended questions or game-type instructions (Figure 5). In most instances, no assessment activities that would enable meta-reflection were presented. Finally, it can be stated that the scientific thinking skills that are mostly promoted by the apps are: categorising observations, recognising patterns and thinking about causes and effects. Moreover, the apps mainly require defining concepts and classifying.

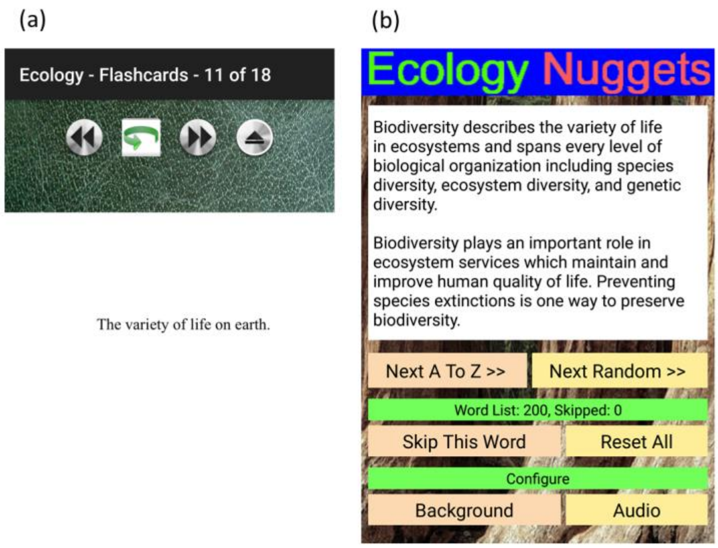

Figure 4. Example of an app that addresses biodiversity structuring content at a low level and in an additive way (a) and an app that presents a higher level of complexity (b) (Images taken from the KSolve-Ecology and Ecology Nuggets apps, respectively).

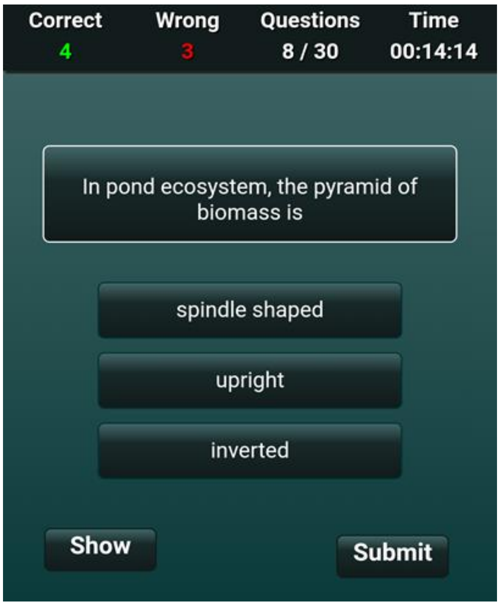

Figure 5. Example of an app that presents activities focused on closed questions (Image taken from the Ecology and Evolution Test - ECO app).

As a result of the systematic analysis of the apps, they can be classified into three large groups: 'simulations', 'gaming apps' and 'encyclopaedia apps', as shown in Table 1. Interactivity decreased considerably from an app that enables to simulate phenomena to another one with an encyclopaedia-type approach. In simulation and gaming apps the multimedia content was used to explain the topics whereas in encyclopaedia apps the multimedia content had an ornamental purpose. Simulations and gaming apps centred on specific topics, while encyclopaedia apps presented a wide content breadth. Expected skills and cognitive demand showed significant parallelism, with higher values in simulation apps.

Table 1. Characteristics that are fostered in each type of app. (+++): High level. (++): Intermediate level. (+): Low level.

Category	Simulation	Gaming	Encyclopaedia
Interactivity	(+++)	(++)	(+)
Multimedia content	(+++)	(++)	(+)
Breadth	(+)	(+)	(+++)
Skills involved	(+++)	(+)	(+)
Cognitive demand	(+++)	(+)	(+)

DISCUSSION AND CONCLUSIONS

The results found in this study regarding the 'ICT' dimension were similar to those reported by Martínez, Mir & Garcia Romano (2017) and Oliveira & Galembeck (2016). On the other hand, taking into account the ideas proposed by Vázquez-Alonso & Manassero-Mas (2018) and Hill, Wilson & Watson (2004), just a few apps are aimed at developing more complex skills and at transmitting a vision of ecology closer to the scientific one.

Considering the availability of mobile devices, we suggest the design and selection of apps that enable students to take an active role in their learning. In this sense, this research provides valuable information to interdisciplinary teams working on the development of user-centered mobile apps that want to contribute to the education of people, so that they not only have "ecological awareness" but also "ecological knowledge" (Bermudez & De Longhi, 2008) Furthermore, given that teaching requires a constant planning process and that mobile apps alone do not guarantee learning, the categories of analysis presented in this work can be useful for teachers who want to design teaching sequences and activities with these technological resources.

As for further work in this research line, it would be of interest to incorporate other structuring contents of Ecology such as the notions of environment and sustainability, or general Biology apps, which may contain sections devoted to Ecology.

ACKNOWLEDGEMENT

Thanks to the National Interuniversity Board (CIN) in Argentina for the funding granted to conduct this research.

DEVELOPMENT OF AN INCLUSIVE, DIGITAL MEDIA-SUPPORTED LEARNING ENVIRONMENT FOR INQUIRY-BASED LEARNING

Sandra Puddu[1], Brigitte Koliander[2] Philipp Spitzer[3]
[1]University College of Teacher Education Vienna; University of Vienna, Austria
[2]University College of Teacher Education, Lower Austria, Austria
[3]University of Vienna, Austria

Inquiry-based learning (IBL) is one possible teaching approach used to develop competences in three aspects: doing science, understanding scientific knowledge acquisition, and learning scientific content. Various studies show that IBL is successful under certain conditions, like proper scaffolding and teachers' reasonable understanding of scientific knowledge acquisition. Our project aims to support the implementation of IBL by supporting teachers and students alike. It offers additional digital scaffolding via a mobile website for students while they are participating in real-life experiments in the classroom. To develop digital support, in a first step teaching materials on inquiry-level 1 and 2 on the topic "chemical reactions" are implemented in two different urban schools in the eighth and ninth grade. Analysis of the gathered data (audio-recordings and the laboratory journals) helps in detecting areas for scaffolding. A digital environment providing scaffolding for the analysed areas is developed and assessed in an eighth grade of an urban secondary school. This paper shows the development from the first analogue inquiry box to the revised second inquiry box.

Keywords: scaffolding, multimedia and hypermedia learning, inquiry-based teaching

INTRODUCTION AND THEORETICAL BACKGROUND

Inquiry-based learning (IBL) is considered an important part of laboratory practice and it can contribute to gaining manifold competences in the field of doing inquiry, knowledge about inquiry and its connection to acquiring scientific content (Abrams, Southerland, & Evans, 2008). Nevertheless, it is not widespread, which is certainly because it is not easy to implement (Blanchard et al., 2010). Many national Science Education Standards and the curricula demand an implementation of inquiry-based science education. However, for example in Austria, only one in four teachers applies inquiry-based learning in regular lessons (Hofer, Lembens, & Abels, 2016). Therefore, the main aim of this project is to increase the use of inquiry-based learning by supporting teachers. Amongst the common reasons teachers give for a poor implementation of IBL are the high requirements for both teachers and students. In addition, there are several other potential areas of difficulty when implementing IBL. Two of the most-frequently mentioned pitfalls are a lack of scaffolding (cp. Blanchard et al., 2010; Kirschner, Sweller, & Clark, 2006; Mostafa, 2018) and the lack of meta-skills in doing inquiry (Blanchard et al., 2010; Lustick, 2009).

Our project (www.inquirysteps.com) aims to tackle both of the aforementioned pitfalls by introducing a digital media-supported learning environment to support teachers and students alike in inquiry-based lessons. In IBL, individual support for students – especially considering the high diversity in the classroom – is a particular challenge. Here, our project offers the possibility of increased individual and problem-specific support with the help of a website. In addition to the task-specific information, information about scientific inquiry and about scientific knowledge acquisition are provided. In other words, hypermedia provides multifaceted access to information (Arnold, Kilian, Thillosen, & Zimmer, 2018). However, the blended learning environment is what makes this project special, as it combines real-life hands-on experiments with digital scaffolding, supplemented with real-life scaffolding by the teacher.

Scaffolding should be provided in a way so that every student can learn within the “zone of proximal development” (Vygotsky, 1978). In diverse classrooms, the learning of all students has to be supported so the high as well as the low achievers should be actively addressed (Sliwka, 2010). Scaffolding is multidimensional and it may be divided into macro-scaffolding (planned in advance) and micro-scaffolding (ad-hoc scaffolding) (Hammond & Gibbons, 2005). The project focusses on macro-scaffolding which encompasses the tasks and all information and aids prepared to support the activities of the students. This will be applied to hands-on teaching material for inquiry-based learning at level 1 and 2 (Blanchard et al., 2010). Table 1 shows the responsibilities of the teachers and the students for each level.

Table 1: Levels of Inquiry (Blanchard et al., 2010)

	Source of the question	Data collection methods	Interpretation of the results
Level 0: Verification	Given by teacher	Given by teacher	Given by teacher
Level 1: Structured	Given by teacher	Given by teacher	**Open to student**
Level 2: Guided	Given by teacher	**Open to student**	**Open to student**
Level 3: Open	**Open to student**	**Open to student**	**Open to student**

On level 1, the teacher provides the question as well as the method to gather data. Only the interpretation of the results is left to the students, whereas on level 2, the teacher only provides the question to be answered. The method and the interpretation are open to the students.

Other aspects of the scaffolding that needs to be provided include language, easy access, structure and navigation of the supporting website.

METHOD

In a previous project, a unit concerning the topic “chemical reaction” without digital support was designed and tested with middle-school students. The tasks and instructions of the unit can be assigned to Level 1. As a first step in the project, the tasks were formulated and expanded to enable IBL at level 2. In addition, it was important to adequately formulate the tasks for a diverse group of students.

This enhanced learning unit was tested by students of the 8th and 9th grade to detect learning difficulties and to research possible supporting mechanisms to overcome the pitfalls mentioned in the introduction. The unit was still analogue. The analysis was guided by the following research questions: Which scaffolding measures do they already use? What obstacles do the students encounter? What do the students need additionally? These questions were formulated against the background that the hurdles and needs are identified before digital implementation.

The timeline of our project is shown in Table 2.

Table 2. Timetable of the research project

Date	Data sources	Collected Data, expected outcome

December 2018	Data collection 9th grade chemistry class, urban business school	Audio-recordings
February 2019	Data collection 8th grade, urban secondary school	Audio-recordings, laboratory journals
March – May 2019	Data analysis – extraction necessary scaffolding measures	Deductive analysis of the audio-recordings and the lab journal using the scaffolding categories (Puddu, 2017) supplemented by inductive categories (Temper, 2019)
May – June 2019	Realising of the digitalised scaffolding measures	
End of June 2019	Implementing of the new digitalised scaffolding Data collection 8th grade, urban secondary school	Audio-recordings, digital lab journal entries Analysis with deductive and inductive coding for further improvement of the digital scaffolding

The first inquiry box on the topic chemical reactions is shown in Figure 1 on the left side. It contained petri dishes, a flask, a spatula, a balloon, snap-on lid glasses containing the chemicals, etc.

Figure 1: Content of the first (on the left side) and the second inquiry box (on the right side).

The data was analysed by using qualitative content analysis (Kuckartz, 2014) using deductive scaffolding categories (Puddu, 2017) which were supplemented by inductive categories (Temper, 2019).

Using the results, the tasks were digitalised and the inquiry box updated. The second inquiry box is shown in Figure 1 on the right side. The required support was implemented digitally following the premises: Which parts of the required scaffolding can be digitally adopted? What additional scaffolding has to be implemented to make the setting as inclusive as possible? How can digital help be made available to students in the best possible way and at the right time? The website was tested with eight graders concerning usability, acceptance and comprehension.

RESULTS

The first inquiry box (see Figure 1 left) contained the following tasks: The first task addressed the wording of the German word "Stoff" which means substance or matter. In German, the same word is used for cloth or fabric, so the scientific use of the word is introduced. The second task is about the mixing of substances, especially about the mixing of watercolours. Subsequently, the leaners fulfil the third task in which different substances react. The fourth tasks contrasts mixing and a chemical reaction between substances to highlight the differences. Afterwards the development of gas is introduced as an additional example for a chemical reaction. Up to this step, the learners only work on level one tasks. The next one, "What has bubbled?" is a level 2 task where the students have to plan the research. Finally, the students have to answer questions if the mentioned processes are chemical reactions or not.

The students' answers were collected and analysed to detect possible improvements of the box.

Table **3** lists the processes and the answers the groups have given on the question "Is this a chemical reaction?".

Table 3: results of the first box

Process: (12 groups)	Yes, this is a chemical reaction:
Tearing paper	0/12
Gas formation in the effervescent tablet	7/12
Mixing of two substances	**7/12**
Inflating a balloon	1/12
Burning paper	0/12
Reaction of two substances	8/12
Breaking a glass ball	0/12
Mixing colors	**7/12**

The results show that the answers to two questions were problematic. The students stated that the mixing substances and mixing colours are chemical reactions. To gain an in-depth perspective and explain this outcome, we analysed the audio-recordings and the laboratory journals in this order.

Problem 1: Too long to wait

The title of the inquiry box is "chemical reactions", but the students have mastered two tasks before they experience the first chemical reaction. The expectations the box raised might have compromised the observations and the interpretations. Based on the results obtained from the analysis of the data, the digital version was different. The aim to contrast mixing and reaction was skipped in favour of concentrating on chemical reactions.

Problem 2: Too many devices

One problem might be the overwhelming number of things in the first inquiry box. The students had difficulties with finding the necessary things in due time. Therefore, an additional game was introduced in the digitised version, in which the students had to assign pictures and names of the laboratory equipment, as shown in Figure 2. Those difficulties might have distracted the students from the learning goal.

Figure 2: Game: „laboratory equipment“

Problem 3: Too much to read

The analysis of the audio-recordings showed that the students did not read the manual and skipped the explanations. Some groups even mentioned that in the discussion. Sentences like “We should have read everything first.” were found repeatedly in the data. As a consequence, for the digital version, videos were made instead of written explanations. In the videos, the students can hear and see what to prepare for the next experiment. At important positions, as after preparing the required materials, the video would stop and the students have to press a button to continue with the video.

The revised inquiry box

The revised inquiry box (see Figure 1) contained less equipment and the tasks differed a bit. The first task was the game “laboratory equipment” followed by the task about the wording substance/matter. After that, two chemical reactions were made by the students, identified by colour changing. The next task offered the development of gas as an example of a chemical reaction. The level 2 task “What has bubbled?” remained the same. The last task again comprised the questions about chemical reactions.

The design of the website for this revised box complies with current guidelines (cp. Arnold et al., 2018; Golser, 2019; Mair, 2005). We wanted the website to be easy to use, so a clear navigation and colouring was needed. It has to be easy to read with adjustable font size, left justified. We used short sentences und few technical terms. Many instructions were adapted and supported by videos and pictures.

The following table (Table 4) shows the results of the last task of the inquiry box where the students read about different processes and they have to answer the question “Is this a chemical reaction?”.

Table 4: Results of the second box in comparison to the first box

Process: (10 groups)	Yes, this is a chemical reaction:	Yes: original box
Tearing paper	0/10	0/12
Gas formation in the effervescent tablet	8/10	7/12
Inflating a balloon with the mouth	1/10	1/12
Burning paper	4/10	0/12
Reaction of two substances to a new substance	10/10	8/12
Breaking a glass ball	0/10	0/12

Mixing of watercolours	0/10	7/12

The answers collected in the last task of the revised box suggest that the new structure was more effective (see Table 4). Most of the answers were correct, except the burning paper. Only four out of ten groups recognized this process as a chemical reaction. The reason is unclear and subject of further investigation.

OUTLOOK

The first step was to create a website, which is working for the students for their first steps in inquiry-based learning and is also be easy to use for teachers so they implement the inquiry box into their teaching. To be able to provide more inquiry boxes a new, professional website was programmed which included more scaffolding and support possibilities. With this new website, systematic research is needed to find out whether learning with inquiry boxes is effective. For this purpose, qualitative as well as quantitative methods are used.

A BLENDED LEARNING APPROACH FOR IN-SERVICE TEACHERS TRAINING BASED ON ONLINE MOODLE PLATFORM

Chiara Schettini[1], Rossana Galassi[1], Daniela Amendola[2]

[1]School of Science and Technology, Chemistry Division, University of Camerino, Camerino, Italy

[2]School of Biosciences and Veterinary Medicine, University of Camerino, Camerino, Italy

As part of the Italian ministerial project "National Scientific Project" (PLS, Piano Lauree Scientifiche), on chemistry's learning empowering, the University of Camerino has been holding residential training courses addressed to in-service high school science teachers. Meeting the demands for the implementation of digital media in education, a course in blended mode has been run since 2016, offering teachers both face-to-face classes and online activities, hosted on a dedicated e-learning Moodle platform.

"The online chemical experiments: instructions for use" course was planned with a bottom-up approach, which included discussions with a group of teachers in order to reach a common agreement on which key chemistry concepts should be addressed. The first aspect involved refreshing some disciplinary issues as Science teachers are often not graduated in chemistry but in other subjects. The second task was the adoption of the extended Johnstone's model (Mahaffy,2014) for the presentation of chemistry topics, considering that the three levels are normally showed in the curriculum, but its tetrahedral extension to real life cases is often neglected. Then the implementation of multimedia tools followed, thus providing original materials in Italian and in English to respond to the demand for CLIL (Content and Language Integrated Learning) methodology. The analysis of the final questionnaire administered at the end of the course showed the teachers' positive ratings on the blended training method and on the quality and usefulness of digital materials.

Keywords: Technology in Education and Training, In-service Teacher Training, Computer Supported Learning Environments.

1. INTRODUCTION

Since 2007, the Italian Ministry of Education (MIUR) has promoted and funded many initiatives with the main objective of changing learning environments and promoting digital innovation in schools. Despite the investments, in the S.Y. 2014/15, regarding the students' skills, Italy was 25th in Europe for the number of Internet users (59%) and 23rd for basic digital skills (47%).

This gap was also visible in the case of specialist ICT skills (Italy 17th) and the number of graduates in STEM disciplines, for which Italy was 22nd, with 13 citizens per 1,000 (Mangione, Mosa & Pettenati, 2016).The data from the OECD TALIS 2013 survey saw Italy in first place for the ICT training needs of its teachers: at least 36% said they were not sufficiently prepared for digital teaching, compared to an average of 17% (OCDE, O., 2014). The 2015 Eurydice Report also underlined how digital skills were certainly among the training needs most felt by Italian teachers, both in terms of teaching enhanced by technologies, both as regards the use of technologies for their profession (European Commission/EACEA/Eurydice, 2015). In 2015

MIUR launched the new National Digital School Plan (Schietroma, 2016) with numerous actions aimed at strengthening technological infrastructures and a massive investment on in-service teacher training, On the other side, in Italy the development of e-learning system in Universities has taken place in the absence of significant regulatory action but through independent initiatives for elevating the quality of traditional didactics with the support and integration of online communication (Capogna, 2012).

In addition to the promotion of digital innovation, since 2004 MIUR has been funding "Piano Lauree Scientifiche" (Marasini, 2010), a project designed to increase the number of chemistry careers and the enrolment to the academic course of chemistry, industrial chemistry and materials science. The strongest point of the project is the collaboration between schools and universities for the development of STEM skills in high school students and for the training of teachers on the design of digitally supported teaching and learning contents.

2. THE "ONLINE CHEMICAL EXPERIMENTS: INSTRUCTIONS FOR USE" COURSE- I EDITION

Since 2006, the Chemistry Department of the University of Camerino has been taking part to "Piano Nazionale Lauree Scientifiche", with activities for students and residential training courses for in-service teachers of Natural Sciences. In 2016, a chemistry training course was set up in blended mode to comply with the requests of institutions and teachers, with multiple aims regarding the teaching and the learning of chemistry.

2.1 Design of the course

Over the last ten years, blended learning has been growing in demand and popularity in higher education and has become a large-scale teaching phenomenon. It becomes increasingly evident that blended learning can overcome various limitations related to online learning and face-to-face instruction. A meta-analysis of more than 1100 empirical studies published between 1996 and 2008 concluded that blended learning proves to be more effective than either online learning or face-to-face instruction (Means,Toyama,, Murphy, Bakia,& Jones, 2009). Among the different blended learning approaches described in the literature, the high-impact method was chosen, building our course from scratch (Alammary,Sheard & Carbone,2014).

The benefits of building a course from scratch are widely discussed (Littlejohn & Pegler, 2007; Wozney,Venkatesh,& Abrami,2006), including the possibility of rethinking and redesigning the course considering the learners' needs and the learning outcomes to achieve. Designing an effective blended learning course requires indeed to identify all parts of the course that could be better presented in an online format, and then an examination of available educational technologies is needed to select those that best meet the users' needs.

Regarding the modality of e-learning, the course designers chose to adopt the model of assisted training (Banzato &Midoro, 2015), that provides both individual study based on materials prepared specifically for self-learning and interaction with online tutors, experts and colleagues.

Once established the model of the course, a bottom-up strategy was adopted to fulfil the training needs of the teachers, most of them haven't a Chemistry degree, but graduated in Biology, Geology or Natural Sciences. A working group was then set up to respond to the demands of a group of natural science teachers who previously followed the residential training courses.

Teachers' main requests were:

(i) mastering technological tools both for the immediate use in the blended course and for their introduction in teaching practice,

(ii) refreshing topics to be treated with an experimental approach,

(iii) acquiring new teaching methods that integrate new technologies, such as the Flipped Classroom method (Tucker, 2012).

2.2 Design of the chemistry units

The extended Johnstone's model, also called the tetrahedral model, proposed by Mahaffy (2014), was adopted for the organization of the chemistry units. The three thinking levels in learning chemistry are widely used into the design of secondary and post-secondary curriculum. The rehybridization of the triangle metaphor into a tetrahedron (Sjöström,2013) introduces the human contexts in chemistry as fourth vertex, thus providing a clear framework for grounding the three dimensions of chemistry curriculum in "real world" problems and solutions, including industrial processes and environmental applications. Highlighting the human element provides strong rationale for emphasizing case studies, active learning, and investigative projects for linking "school chemistry" to everyday life.

This model's issues were therefore adopted in the design of the course units, with the precise aim to make chemistry topics nearer to students' interests.

2.3 Structure of the course

In November 2016 the first edition of the "Online Chemistry Experiments: Instructions for Use" course was hosted on the UNICAM Moodle platform, followed by 28 science teachers belonging to 12 high schools of Marche Region. The total duration of the course was 25 hours, including 5 hours of face-to-face training, organized in 2 residential seminars, and 10 hours of online activities, assisted by two tutors. The first residential meeting illustrated the chemistry issues of the course, while in the second meeting teachers tested themselves the digital tools for building innovative paths.

On the Moodle platform, the course was structured in 12 units, addressing different general chemistry concepts model (Table 1) and designed according to the Mahaffy's tetrahedral model.

Table 1. The topics of the 12 units of Inorganic Chemistry hosted on the Moodle Platform.

Unit	*Topic*
1	Reaction of calcium and water to form gaseous Hydrogen
2	Double exchange reactions and an approach to qualitative chemical analysis
3	Effect of temperature on NO_2 dimerization
4	Test of CO and CO_2 during the aspiration process of a lit cigarette
5	Ammonia reaction with cupric sulfate
6	Effect of concentration and temperature on chemical equilibria in solution
7	Reactivity of alkaline metals
8	Reactivity of earth alkaline metals
9	Visualization of water polarity
10	Electrolytic properties of solutions highlighted by a toy car
11	Thermal conversion of an allotropic form to another one

12	Photo-assisted reduction of thionine

Teachers were also supported with a webinar, held by the online tutors, addressing new approaches in chemistry education, such as IBSE methodology, problem solving in the chemistry laboratory, the implementation of authentic tasks and the assessment of laboratory activities. Moreover, the “Scientix” project was presented, a European project that collects and promotes best practices in science teaching and learning in Europe and organizes trainings and workshops for STEM teachers. A technical and a disciplinary forum were also hosted on the learning platform, allowing discussion and exchange of ideas among the participants and with the tutors. At the end of the course a final monitoring questionnaire was administered online. All the materials were in Italian and in English to respond to the demands for the introduction of CLIL methodology in the Italian school curricula (Leone, 2015).

Furthermore, during the course, two teachers undertook an action research project on the teaching of some chemical concepts, involving two 11th grade classes of pupils (16-17 years old) and using the pedagogical model of the Flipped Classroom and the IBSE approach, with emphasis on the 5E Learning Cycle (Schettini et al., 2017).

2.4 Structure of the units

The core of each unit is a video showing a laboratory activity related to the topic (Figure 1). The adoption of video tutorials leads to optimized teaching and learning processes in the fundamental chemistry education in universities (He,Swenson & Lents, 2012). The main advantage of videos is the connection of both visual and auditory elements. Mayer’s Cognitive Theory of Multimedia Learning additionally states that the simultaneous presentation of verbal and visual material, as realized in videos, is the most effective solution for beginners and visual-style learners (Mayer, 2009).

According to the fourth vertex of the tetrahedral model, in-depth materials in digital form were provided in every unit, as examples of real-life connections and cross-sectorial applications of the chemical concepts (Figure 2). A technical sheet of the experiment, theoretical references with description of the symbolic and sub-microscopic level of the phenomenon, problem solving exercises and a self-assessment test were associated to each video.

Figure 1. Screenshots of the video of Unit 1 (Reaction of calcium and water to form gaseous hydrogen).

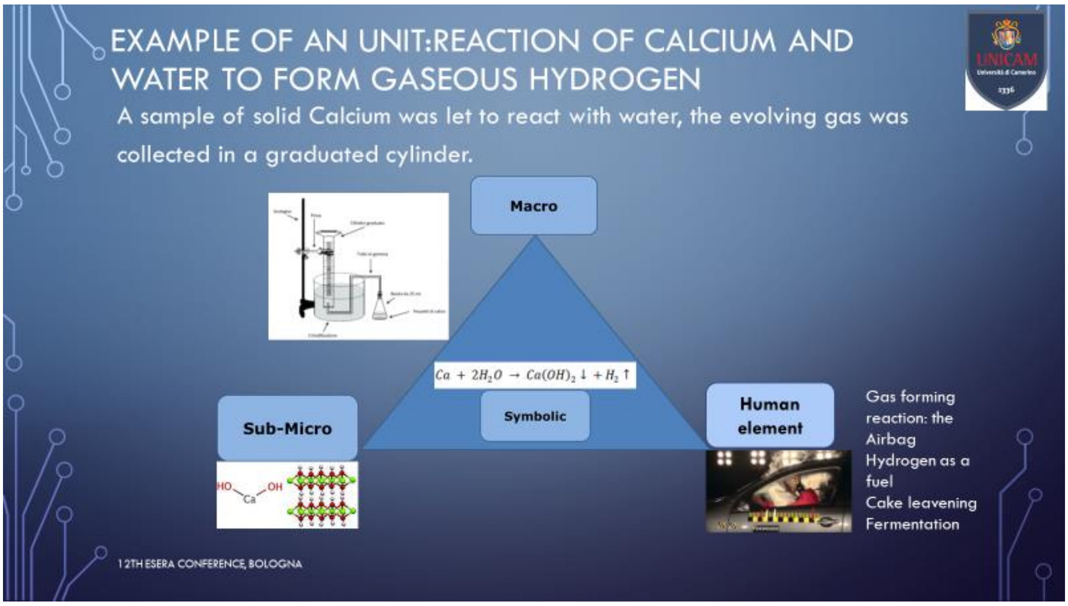

Figure 2. Structure of Unit 1, according to Mahaffy's model.

2.5 Teachers' survey

At the end of the course, a final questionnaire of 61 questions was administered to assess the degree of teachers' satisfaction about the training. The questionnaire was divided into four sections (general aspects of the course, usefulness of the videos and related materials for the training, use of the videos and related materials with students, webinar on new approaches in chemistry education) and directly administered online on the Moodle platform. All the 28 teachers, attending the course, completed the questionnaire. The responses were automatically elaborated by the Moodle software and provided in the form of percentage of the different answers (for closed questions where more than one answer was possible) or delivering the statements answered to open questions. Regarding teachers' general opinion on the course, 25% judged it "excellent", 42,86% "very good" and 32,14% "good" and 75% of the teachers would recommend its frequency, even charged. When teachers were asked to rate (with a score from 0 to 10) the skills acquired by the different activities, the best results were achieved by "using and studying the videos of the experiments", followed by "refreshing basic chemistry knowledge" and "studying examples from real life situations" (Figure 3).

Furthermore, when asked on which aspects of their professional development the course provided the best upgrade, teachers chose the "introduction of examples in lessons" (23,08%) and "contextualization in real-life situations" (15,38%), highlighting science teachers needs for connecting chemistry topics to everyday life to increase students' motivation, according to Mahaffy's model. 19.23% of the teachers chose the" knowledge of online training opportunities" option, as the course focuses also on web resources for teachers' training (Figure 4).

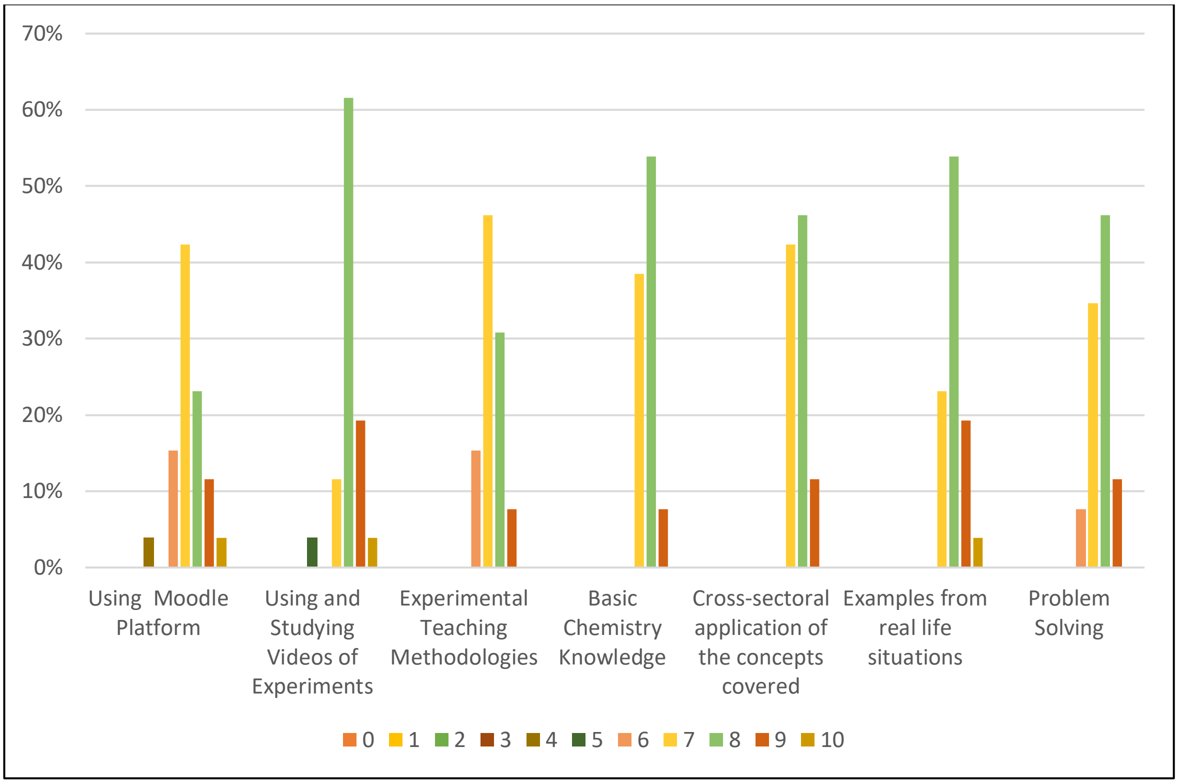

Figure 3. Ratings of the different activities' impact on teachers' skills.

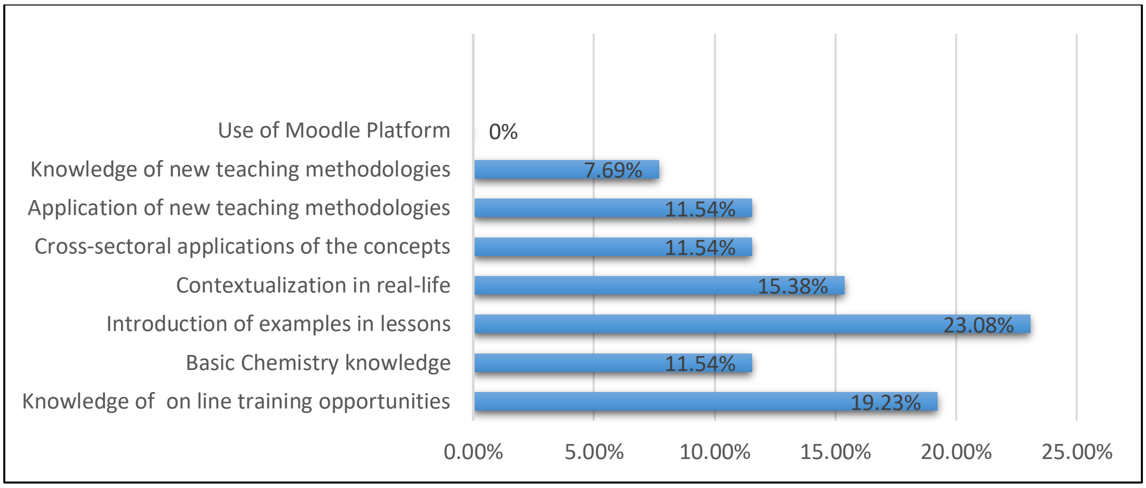

Figure 4. Percentage of answers to the question about skills upgrade.

On the overall, teachers considered more useful for their training the educational material accompanying the videos, followed by simply watching the videos and then by the webinar's attendance, probably for its short duration (Table 2).

Table 2. Percentage of answers to the questions about different activities' usefulness.

How useful was for your	YES	MORE YES THAN NO	MORE NO THAN YES	NO

professional development?				
Watching the videos	73.08 %	19.23 %	3.85 %	3.85 %
The education material accompanying the videos	96.15 %	3.85 %	0.00 %	0.00 %
The webinar	61.54 %	30.77 %	0.00 %	7.69 %

Regarding the use of videos in the classroom, 15.38% of teachers employed them a lot and 42.31 % only a little. Most of them considered the videos *"well described in the different steps, taking a short time and with a visual impact able to arouse students' curiosity and attention"*. Some teachers used the videos in the absence of laboratory and others, after the practice, for reviewing and reflecting on the different steps. Some teachers reported that they didn't use the videos extensively, because the topics were not included in their current course of study and asked for more experiments to record, even about organic chemistry. Some teachers showed videos in their classroom as a starting point before introducing an analytical law or as validation, after studying an analytical law, even in flipped classroom modality. Furthermore, 42.31% teachers included video-related questions in their tests.
Regarding the other resources 'use with students, teachers reported, above all, the use of examples related to real-life, followed by the cross-sectorial application to concepts. The lack of use of video in English was motivated in some cases by the limited time available or by students' insufficient language skills (Figure 5).

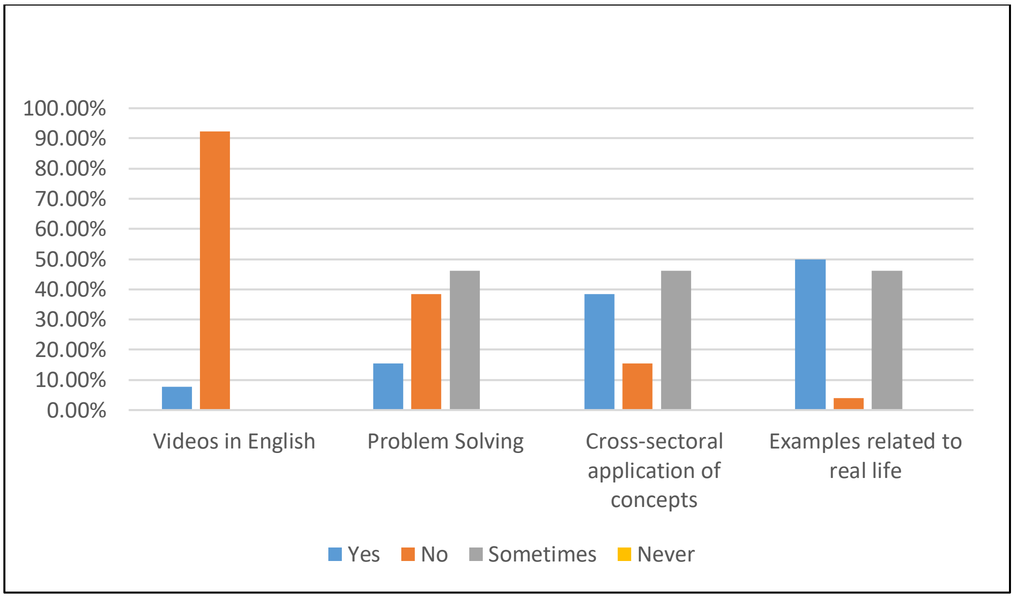

Figure 5. Percentage of answers to the question about use of resources with students.

Regarding the interest of the topics afforded in the webinar, teachers preferred the assessment of students' skills by the means of authentic tasks and the suggestions for the evaluation of laboratory activities (more than one answer available), as showed in Figure 6.

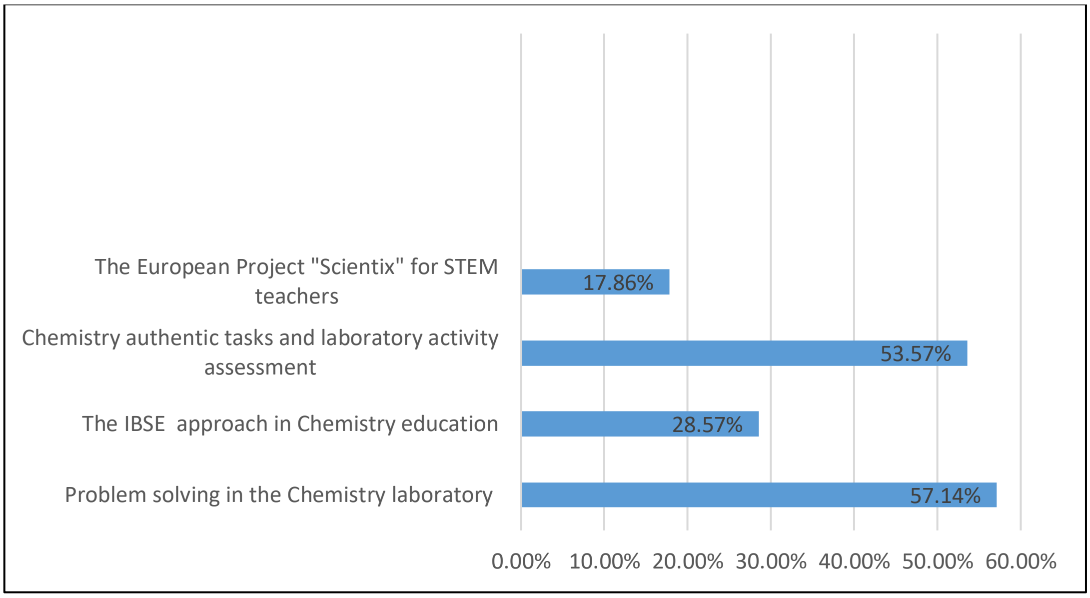

Figure 6. Percentage of answers to the question about webinar's topics interest.

3. THE "ONLINE CHEMICAL EXPERIMENTS: INSTRUCTIONS FOR USE" COURSE- I EDITION

In 2017, a second edition of the course was delivered with 13 teachers and it was implemented, following teachers' opinion and suggestions derived from the reported survey. Two webinars were included, instead of one, and the teachers received training in the Flipped Classroom methodology, as required.

Furthermore, all teachers were asked to design a learning unit, including the digital materials of the platform, especially videos, and adopting one of the innovative teaching methods experimented during the course.

Then, they were asked to approach the fourth vertex of the tetrahedron model in their units, connecting the chemical concepts to students' experience and real-life contexts. The learning units were evaluated with a rubric, considering the following aspects: (i) adequacy to the students' characteristics and to school context, (ii) structure of the educational path, (iii) use of the Moodle platform materials and originality of the proposal , (iv) propriety of the real-life connections and (v) quality of evaluation tests.

4. CONCLUSIONS AND FURTHER IMPLEMENTATION

The course has been useful as a stimulus for the teachers' active reflection on the benefits derived from adopting an experimental approach to the teaching of chemistry, for the acquisition of experimental procedures and for the possibility of replacing a "real" chemistry lab, in the absence of reagents or suitable equipment. Conversely, lack of familiarity with the Moodle platform, inadequate Internet connection and, in some cases, the impossibility of repeating the experiment in a laboratory were perceived as critical issues.

According teachers' request, a greater number of videos will be designed and provided, introducing also organic chemistry topics and they will be made accessible to pupils as well. For the next editions it is expected to increase the number of webinars, introducing more examples of new approaches to chemistry teaching and learning. Furthermore, collaborative activities among group of teachers to be developed in the Moodle learning context will be promoted.

ACKNOWLEDGEMENT

We are grateful to Piano Lauree Scientifiche and to the School of Advanced Studies of University of Camerino for their support. The University of Camerino's e-learning coordinator and its personnel are profusely acknowledged for the competent and helpful technical support.

COLLABORATING PRIMARY STUDENT TEACHERS IN DESIGNING EXPERIMENTS WITH THE USE OF ICT

Argyris Nipyrakis, Dimitris Stavrou

University of Crete, Rethymno, Greece

Technology enactment in science education is a continuous, yet unaccomplished goal. Contributing factors, as the student-oriented use of Information and Communication Technology (ICT) tools, collaboration and reflection between peers should be taken into account. This research aims to study how student teachers collaborate in a Learning Community (LC) framework in order to design and develop science experiments with the use of ICT tools, such as dataloggers. Data analysis provide empirical data supporting that collaboration played an important role a) in the discussion at the LC meetings, as teachers showed an increasing tendency to use participatory dialog for knowledge construction and to engage in peers' conversations about their experiments, b) in the design process, as there was an increasing influence from peers in the development of experiments.

Keywords: Peer Interaction, Classroom Discourse, Data Logging

INTRODUCTION

Using Information and Communication Technology (ICT) tools such as microcomputers/dataloggers i.e. electronic sensors & probes, data collection devices and the appropriate data analysis software in the school laboratory has the potential to enhance science learning. In specific, using data logging can contribute to increased conceptual learning (Nikolaou et al. 2007, Sokoloff et al. 2007), graph construction & interpretation skills (Nikolaou et al. 2007) and interdiscipline connections with the relative mathematical modelling of the phenomena (Lavonen et al. 2003). Additional attitudinal benefits can be obtained, since data logging motivates students as well as procedural advantages concerning the reduction of time needed to collect data and to repeat the experiment (Barton 2005).

However, there are several crucial factors to consider in order to take advantage of the additional value that ICT offer in the classroom. Factors like the pedagogy used, e.g. whether technology is used in a student-oriented and inquiry-based approach, as also the general "classroom ecology" effects dramatically on the efficiency of using ICT for science teaching (Prestridge 2017, Bell et al. 2013, Odom et al. 2011, Waight & Abd-El-Khalick 2007). In particular, using ICT for administration purposes, to complete worksheets and reading reflects "passive"/mechanical use and is not correlated with increased student achievement; on the contrary, using ICT in the classroom as part of the inquiry process with the active engagement of the students, e.g. for observation and prediction of phenomena reflects "active" use and contributes to better student achievement (Waight & Abd-El-Khalick 2018, Prestridge 2017, Odom et al. 2011). Moreover, using ICT in an authentic context for science learning (Bell et al. 2013) which relates to students' everyday life (Iliaki et al. 2019) also effects on successful integration of technology, because teachers learn how to use ICT for the accomplishment of specific teaching goals. The idea of learning *with* technology rather than *about* technology is crucial when implementing ICT for science teaching (Waight & Abd-El-Khalick 2007).

As implied from the above, successful integration of ICT in science education highly depends on the teacher, regarding cognitive factors i.e. knowledge on how to use technology for science teaching, and affective factors i.e. his beliefs and attitudes towards technology (Prestridge 2017, Ertmer & Ottenbreit-Leftwich 2013), whilst the general context and the characteristics of ICT tools also have an impact (Waight & Abd-El-Khalick 2018). In order to define the needed knowledge to implement ICT, a framework for teacher professional knowledge for efficiently teaching science with the use of technology was presented by Mishra & Koehler (2006). Technological, Pedagogical & Content Knowledge (TPACK), knowledge derived from the intersection of Technological Knowledge, Pedagogical Knowledge and Content Knowledge, is required by teachers in order to develop and efficiently integrate experiments with the use of ICT in their teaching.

Collaboration can play an important role in supporting teachers on implementing an educational innovation, such as the meaningful integrating of ICT discussed above (Juuti et al. 2016, Kafyulilo et al. 2015, Bell et al. 2013). As any educational innovation, implementing ICT is an open-ended task that cannot be used in just one way in the classroom, whilst collaboration between teachers, researchers and experts through several iterations is needed (Waight & Abd-El-Khalick 2018, Juuti et al. 2016). During this process, discussion and reflection between peers can promote the inquiry stance needed from the teachers (Kervinen et al. 2016, Waight & Abd-El-Khalick 2007) and assist them to change their beliefs and their teaching practices concerning ICT (Prestridge 2017, Elster 2010). Under this prism, the establishment of Learning Communities (LCs), small groups that may consist of students, teachers and experts, has the potential to provide the student-centered learning environment and the collaborative and dialogic environment needed. Therefore, through reflection and mutual engagement, LCs can assist the design of experiments with ICT and effect on changes in teaching practices with the use of ICT.

However, further parameters regarding the operation of the LC, such as reflection with peers, guidance from experts, members' active engagement and inquiry stance have to be promoted for an efficient LC (Couso 2016), since in many cases LCs are overtaken from administrative issues, pressure from test scores and limited availability of time (Jones et al. 2013) . In specific, discourse with emphasis on meaning making, where conflicts and different views take place, supported by a group leader who promotes task engagement, is suggested for an efficient LC (Bennett et al. 2010). Consequently, training teachers through participatory meaning-making dialog and interacting with peers is needed in order to facilitate technology enactment in schools.

Hence, the present study implemented a collaborative LC framework to support primary student teachers on meaningful integration of ICT, particularly data logging, to the design and development of science experiments in an authentic science education laboratory context in order to teach school students. The discussion that took place during the LC meetings and the influence that discussions had in the design of the experiments were analysed in order to study the potentialities and obstacles that student teachers address as well as the effect that collaboration had in the design process.

Research questions

Therefore, the research questions of the study are:

- What is the content and the nature of primary student teachers' conversation during the LC meetings concerning the design of science experiments with the use of ICT?
- How far the discussions in the LC influence the development of science experiments with the use of ICT?

METHOD

Implementation of the study

The study was carried out during an undergraduate science laboratory lesson and lasted 13 weeks. Participants were 12 fourth graded primary student teachers, divided in 6 groups of two student teachers, whilst teacher groups were separated in two sets of groups (3 groups in each set). The task assigned to the student teachers comprised the design and development of experiments with the use of dataloggers in three branches of science, i.e. either Mechanics/Waves/Optics for the first set of teacher groups (Figure 1a) or Electromagnetism/ Thermodynamics/Chemistry for the second set (Figure 1b).

Figure 1a: Science branches for set A

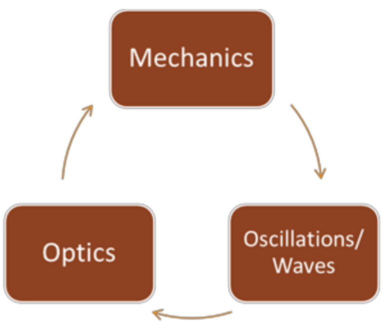

Figure 1b: Science branches for set B

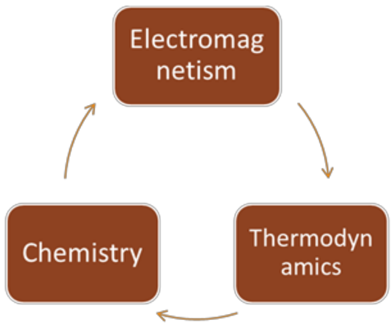
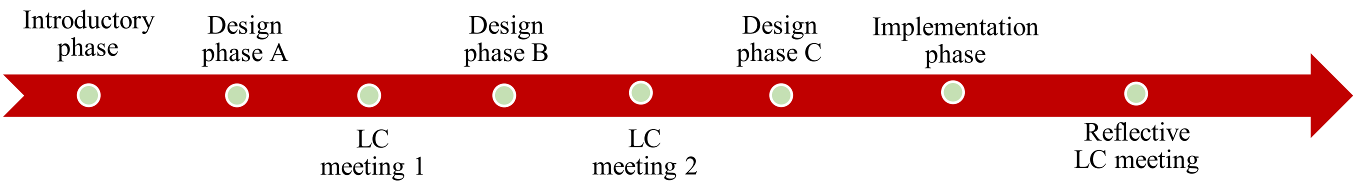


The study, as shown in Figure 2, comprised: a) an introductory phase, where student teachers got familiar with the datalogging devices, b) three design phases. The first two design phases consisted of two weekly lab sessions and a LC meeting, in terms of reflection from the design and development of experiments at the previous lab sessions. At the end of each of the two phases, there was a cyclical switch of the science branches between the groups, which ended with a third design phase consisted of two weekly lab sessions c) an implementation phase, where student teachers were called upon to apply the developed material in teaching school students during organized visits to the science education lab of the university and d) a reflective LC meeting on the whole procedure.

Figure 2: Implementation of the study



Theoretical framework

Theoretical framework of the study is the Model of Educational Reconstruction for Teacher Education (ERTE) (Van Dijk & Kattmann 2007). According to this model and as it was adapted to the present study, there is a continuous and dynamic interaction between: a) the educational reconstruction made from the student teachers in order to design science learning environments with the use of data logging with: b) empirical studies on teacher training, TPACK, integration of technology and c) the overall design of teacher education contexts.

Data analysis

The data source of our study was: a) the transcripts from the discussions during the LC meetings, b) the experiments developed from the student teachers, c) the weekly lab reports and d) field notes during the lab sessions. Data analysis was carried out following two directions: analysis *of the conversation* and analysis *of peer interactions* in the LC meetings.

In order to analyse the conversation in the LC meetings, categories from Kittleson & Southerland's (2004) research were used and further modified for the needs of the present study. Thus, discussion was analyzed (y axis) as for its content to: a) Conceptual: referring to underlying science concepts, b) Laboratory: concerning the experimental procedure and the inquiry method used, c) Technology: conversation about implementing ICT and the use of ICT tools, d) Administrative: organizational talk e) Off-Task: conversation that doesn't address the task at hand, e.g. extracurricular talk. Discussion was also analyzed (x axis), as for its rhetorical nature to: a) Explanation: when a LC member or teacher group was transferring information in a rather traditional teacher-centered way e.g. lecturing the others, b) Negotiation: when multiple people participate in the conversation, both in consonant and dissonant ways. Discussion held in the LC meetings was semi-scaffolded from the administrator/expert and was based in two elements: the teaching goals that the experiments address and the use of ICT in the experiments. The analysis unit used is the *thematic quotation (TQ)*. TQ was defined as an excerpt of the conversation, which includes adequately codable information, considering the above categories. Data from the LC meetings trancripts were analysed statistically with the use of non-parametric tests, since TQs were coded in categories and exported in binary mode. Furthermore, the transcripts from the LC meetings were also analysed with the use of qualitative content analysis (Mayring 2014) in order to triangulate data from the statistical analysis and to provide more deep insights about the teachers' views and obstacles about the design of experiments with the use of ICT.

In order to analyze the peer interactions about the design of their experiments, network analysis was used (Borgatti et al. 2018). The analysis unit used is the *Design Influence (DI)*. DI was defined as any idea or comment expressed from a LC member, regarding the design of an experiment, which was implemented by a peer teacher group in subsequent design phases. In our study, each DI was represented with an arrow starting from the sender –the one who expressed the idea/comment and ending to the receiver –the teacher group which implemented the idea in the design process of experiments. Several network metrics were used for the analysis, such as: a) degree i.e. the sum of DIs, b) density –the sum of DIs divided to the theoretical maximum DIs, c) centralization which is related to whether the network is dominated by one person or not and d) homophily, the extent to which the nodes interact more between a specific sub-group (the set of groups that share the same science branches in our study) in relation to the total interactions. Respective sociograms in each phase were created to represent the network activity.

RESULTS

Conversation in the LC

Considering the nature of the conversation, it seems that student teachers' discussion was based on negotiation much more than explanation of concepts. This tendency became even more evident in the second LC meeting (p<0,001), as shown in Figures 4&5 and in Table 1. As for the content of the discussion, we can see in Figure 3 that student teachers dedicated adequate time in all three domains, even though Lab domain discussion prevails (p<0.001). Interesting is also the fact that the discussion about ICT showed a reduction from LC1 to LC 2 (p=0,001), which, according to the qualitative analysis of the transcripts, is related to the initial difficulties concerning the use of ICT that student teachers addressed at the first phase, where they seem to have discussed more about ICT comparing to the second phase.

Figure 3: Discussion in LC1,2 – Summary

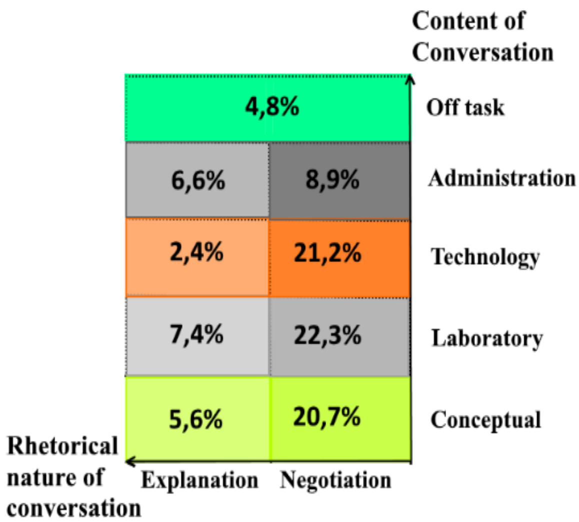


Table 1: TQs in LC1 & LC2

Content of conversation	LC2	LC2	Sig.

Conceptual	1702	1482	p=0,644
Laboratory	1867	1715	p=0,160
Technology	1594	1263	p=0,001
Administration	967	908	p=0,149
Off Task	284	295	p=0,045
Rhetorical Nature of conversation	**LC1**	**LC2**	
Explanation	1551	1114	p<0,001
Negotiation	4581	4254	p<0,001

Figure 4: Discussion in LC1

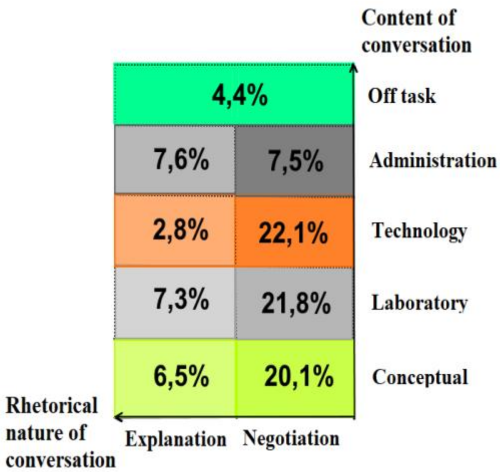

Figure 5: Discussion in LC2

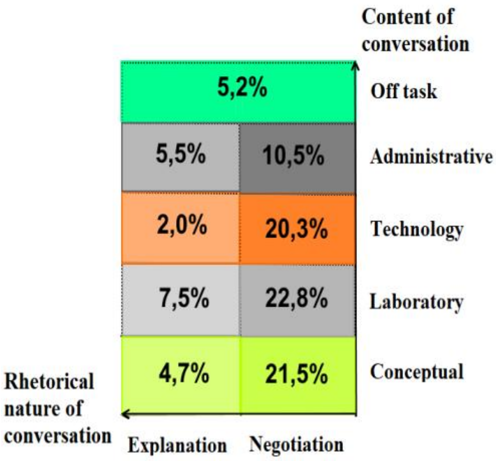

Investigating the participation of student teachers in discussions about the experiments of their peers in relation to discussions about their own experiments, encouraging is the fact that 5 student teachers showed significant increase ($p<0,01$) from LC1 to LC2, whilst only 2 showed significant decrease ($p<0,01$), as shown in Table 2. That means that student teachers showed a tendency to engage more in discussions concerning peers, which is deemed to be an indicator of collaboration between them.

Table 2: Participation of teachers in discussions about the experiment of their peers

Teacher	**LC1** %TQs to peer groups	**LC2** %TQs to peer groups	Sig.
1a	21,1%	33,9%	p=0,008

1b	24,2%	45,6%	p<0,001
2a	48,3%	44,5%	p=0,368
2b	27,7%	50,0%	p<0.001
3a	56,6%	27,0%	p<0,001
3b	18,2%	23,6%	p=0.096
4a	63,6%	74,5%	p<0.001
4b	35,7%	47,9%	p=0.004
5a	29,0%	22,1%	p=0,109
5b	60,4%	46,4%	p<0.001
6a	23,4%	24,8%	p=0,778
6b	50,5%	51,8%	p=0,773

Peer Interactions

As far as the influence of the discussions in the development of experiments is concerned, it seems that student teachers evaluated peer discussion as quite an auxiliary factor in the design procedure, as they adopted ideas and drew information from the conversations with peers to a significant extent (n=28 DIs in respective total 60 experiments in phases B & C, as shown in Figure 6). Furthermore, a respective tendency to increase this influence from their peers from design phase B to design phase C was also noted (n=11 DIs implemented in phase B to respective n=17 DIs in phase C). On the other hand, the network of DIs could be characterised moderately dense and highly centralized, which means that student teachers made significant use of the guidance of the expert. Moreover, need for support from the expert was needed more in latter phases, since centralization increased in LC2, which can be related to the increased difficulty that student teachers address in designing new experiments in latter phases, according to the qualitative analysis of the discussions.

Figure 6: Total DIs in both LC meetings & whole network metrics

	LC1,2	LC1	LC2
Degree (DIs)	28	11	17
Density	0,359	0,141	0,218
Average Degree	4,308	1,692	2,615
Centralization(out)	0,472	0,403	0,542
Centralization(in)	0,201	0,132	0,181

Regarding the DIs between peers (expert excluded), we can calculate the homophily for the two set of teacher groups. As seen in Figure 7, teacher groups in each set interacted more with peers that shared the same science branches. This result can be interpreted in relation to the increased TPACK that these peers potentially developed in these specific science content areas and by using the specific data logging tools, so that they could influence peers in the same set of teacher groups, respectively.

Figure 7: Homophily between the two set of teacher groups

	Set of teacher groups A	Set of teacher groups B
Set of teacher groups A	8	4
Set of teacher groups B	8	14
Homophily:	-0,294	

DISCUSSION

Considering the analysis of the discussion and the analysis of the peer interactions, we can conclude that student teachers interacted collaboratively in a continuously growing manner: a) in the discussion at the LC meetings, by participating in negotiation of concepts and cognitive conflicts, b) in engaging in conversations concerning their peers and c) in the design process of experiments, by been influenced from their peers. Furthermore, the need for assistance from the expert was also found critical in the design process, as well as in managing the on-task discussion through a semi-scaffolded way. Moreover, interactions between peers were enhanced in cases where teacher groups shared same goals e.g. same science content and same data logging tools. Empirical data of this study seem to advocate that collaboration and on-task participatory discussions seem to be helpful for student teachers in order to integrate technology in science education laboratories.

PROFESSIONALISATION OF PROSPECTIVE TEACHERS FOR DIGITISATION IN CHEMISTRY EDUCATION – DEVELOPMENT AND EVALUATION OF A UNIVERSITY SEMINAR

Franziska Zimmermann[1], Insa Melle[1]
[1]TU Dortmund University, Chemical Education, Dortmund, Germany

With the publication of "The Digital Competence Framework for Citizens" and "The European Framework for the Digital Competence of Educators", the development of digital competences and thus learning with and about digital media at school has greatly increased in significance in the past few years (Redecker, 2017; Vuorikari et al., 2016). While education policy makers have recognised the great potential of innovative information and communication technologies regarding teaching and learning, schools are facing the challenge of implementing the frame of reference and adapting to the increasingly digitalised society (Drossel & Eickelmann, 2017). Since the majority of teachers does not feel well enough prepared to meet the requirements, it is of great importance to professionalise both teaching staff and prospective teachers for the use of digital media in the classroom (Cetin-Dindar et al., 2018; Drossel & Eickelmann, 2017). Consequently, this project aims to develop and evaluate a university seminar that prepares prospective chemistry teachers for implementing digital tools in teaching and learning effectively as well as appropriately.

The study is an intervention study that tests the interventions' effects by using a quasi-experimental design with repeated measures. Based on the adapted evaluation steps by Kirkpatrick, this seminar is evaluated on the four levels attractiveness, cognitive changes, practical implementation, *and* effects on the learners *(Kirkpatrick, 1979). The first results of the pilot study show that the seminar participants assess the seminar as very attractive. Moreover, the seminar participation leads to a significant positive change regarding the prospective teachers' attitudes towards the implementation of digital tools in chemistry lessons, their TPACK self-efficacy beliefs and TPACK competence regarding lesson planning. Additionally, the learners at school assess the digitally supported lessons executed by the participants as positive.*

Keywords: Technology in Education and Training, Teacher Professional Development, ICT Enhanced Teaching and Learning

THEORETICAL BACKGROUND AND MOTIVATION

Since the publication of the strategic concept "The Digital Competence Framework for Citizens" and its identification of key components of digital competence, schools are urged to adapt to the digitalised society and prepare their students for the challenges in a digital world (Gerick et al., 2017; Vuorikari et al., 2016). Accordingly, teaching professions are facing the great challenge of transforming their teaching and learning methods in order to introduce digital learning as a habitual teaching practice on a pan-European basis (Drossel & Eickelmann, 2017). In order to support educators in developing digital competences on professional level, "The

European Framework for the Digital Competence of Educators – DigCompEdu" serves as a reference frame. However, most teachers lack the necessary skills to effectively use digital tools to improve student performance and therefore also assess their own digital competencies as very limited (Chai et al., 2013; Drossel & Eickelmann, 2017). Yet, the successful implementation of digital tools highly depends on the teachers' self-efficacy in using digital tools and their attitude towards the general implementation of technology in the classroom (Eickelmann & Vennemann, 2017; Mishra & Koehler, 2006; Sánchez-Prieto et al., 2016). Consequently, it becomes evident that there is an urgent need for action regarding the professionalisation of teaching staff and prospective teachers (Chai et al., 2013; Drossel & Eickelmann, 2017; Gudmundsdottir & Hatlevik, 2018). In this context, it is not only important to strengthen teachers' digital skills, but also to promote digital self-efficacy perception and to positively influence teachers' attitudes towards technologies in continuing education and training programs (Bastian & Riplinger, 2016; Cetin-Dindar et al., 2018; Instefjord & Munthe, 2017).

In response to these challenges, we developed a university seminar to professionalise prospective chemistry teachers in the effective and appropriate use of digital tools in teaching and learning. The central theoretical framework in this research to investigate the seminar participants' development is the technological pedagogical content knowledge (TPACK), which is a model to describe the knowledge required by teachers to integrate technology in teaching and learning (Mishra & Koehler, 2006; Schmidt et al., 2009). The TPACK model originates from the pedagogical content knowledge (PCK) according to Shulman (1986), which describes the central domains of professional knowledge of teachers. It consists of pedagogical knowledge (PK), content knowledge (CK) and their intersection, pedagogical content knowledge (PCK). The TPACK model is an extension of this original model, which added the domain of technology knowledge. At the same time, further knowledge domains emerge. These are the technological pedagogical knowledge (TPK), the technological content knowledge (TCK) and ultimately, the technological pedagogical content knowledge (TPACK), which represents the intersection of all knowledge domains. Moreover, these specific knowledge domains are additionally bound to their respective contexts or situational conditions such as the technical equipment, the interior design or the school concept (Mishra & Koehler, 2006). In this project, the focus is on the technology-related areas of knowledge.

THE SEMINAR

Basis of this project is the seminar entitled "Teaching Methods and Multimedia for Chemistry Education". We developed the seminar with the aim of professionalising students of chemistry education for the competent use of digital tools in chemistry lessons. Within the seminar sessions, the students therefore deal with different aspects of implementing digital tools in chemistry lessons at both theoretical and especially practical level. In the following, the revised seminar concept of the main study are described.

The selected contents of the seminar sessions derived from various examples of best practice and research results on the use of digital tools from a detailed literature review. This included the identification of the necessary professional knowledge of teachers for the use of technologies as well as research on the concrete practical implementation of digital learning in both general and chemistry-specific school teaching. Proceeding from this literature research, we designed our seminar sessions for a pilot study. During the first and last seminar sessions, we collect the required data for our study. Another seminar session serves as a buffer. Since we only slightly optimised and modified this piloted seminar concept, Table 5 depicts the adapted contents and their associated thematic blocks of the main study (cf. Zimmermann & Melle, 2019). However, the evaluation of the seminar of the main study is still pending.

In these seminars sessions, the students first receive new content and information via PowerPoint presentations, followed by a practice-oriented working phase. The seminar's strong focus on the practical implementation of the covered topics aims at establishing a close link between the topics dealt with and actual teaching practices (Eickelmann & Vennemann, 2017). Hence, the students try out new programs and apps, or independently develop a wide variety of teaching examples. Each individual student has access to an iPad for this purpose. The students work very independently in order to be able to test all digital tools as effectively as possible.

13.	Pool of Ideas and Lesson Planning	
14.	Post Tests	

Session 2: Legal and Educational Framework

The seminar starts with defining and classifying the broad term ‘media’ as well as emphasising the general importance of media as mediators in the classroom. In this context, the presentation also points to the particularity of media in teaching chemistry which intends to show that the reflected selection of teaching media depends on the learning objective (Bernholt et al., 2018). Subsequently, we discuss the topic of media socialisation and digitalisation of society with regard to the technical equipment in German families and the possession of devices by young people, leading to the conclusion that it can be assumed that learners at school are fundamentally familiar with digital media (MPFS, 2018). The second part of the presentation focuses on what it means for students at school to be digitally competent (KMK, 2017; Medienberatung NRW, 2018; Vuorikari et al., 2016), followed by the necessary skills of educators for promoting digital competences (Mishra & Koehler, 2006; Redecker, 2017). This seminar session concludes with a description of the current educational, infrastructural, and personnel conditions for digital learning as well as the formulation of prerequisites for the successful implementation of digital technologies in teaching and learning.

Session 3: Organisation of Teaching in the Digital Classroom

The beginning of this session focuses the potential of different hardware available in schools. After presenting different possibilities of classroom management in the digital classroom, we list various learning scenarios and their terminology. These include the following: E-learning, mobile learning, massive open online course, game-based learning, blended learning, station rotation model and flipped classroom. Directly after this information input a station rotation follows with three different stations and tasks. At the first station, the students try out various functions of an interactive whiteboard app by connecting the iPad to the Apple TV. Thus, they get to know a way in which tablets can serve as a substitute for interactive whiteboards. Station two deals with digitising analogue teaching materials and editing it with the Apple Pencil. At the third station, the students create a mind map.

Session 4: Potentials of Digital Tools in Dealing with Diversity

Since innovative information and communication technologies (ICT) promise great potential in terms of education and participation, especially in the age of inclusion, we point out the potential of the advancing digitisation for teaching in heterogeneous learning groups in this seminar session. The potential of ICT especially lies in their adaption to users' needs since the information ICT provide can be adapted flexibly to the individual users' processing requirement (Meyer et al., 2014). Additionally, we refer to the educational concept Universal Design for Learning (UDL) (CAST, 2018), which provides a framework and specific guidelines for planning lessons with universal accessibility and thus enables joint teaching in heterogeneous learning groups. Furthermore, technologies are seen to be indispensable for the implementation of the UDL guidelines because they contribute meaningfully to increasing individual adaptability (Edyburn, 2010; Rose et al., 2007). This is followed by demonstrating different possibilities to differentiate with the aid of digital tools. In the subsequent working phase, the seminar participants discuss and analyse various digitally supported possibilities for individually supported teaching and learning in reference to specific teaching unit examples.

Session 5 to 7: Multimedia Teaching Materials

The topic "Design of multimedia teaching materials" covers three seminar sessions and is designed in the form of a workshop. In the first of these three sessions, the students receive a short introductory lecture on multimedia learning, especially focusing the "Cognitive Theory of Multimedia Learning" (Mayer, 2014). The aim of this lecture is to show that digital media have the potential of increasing the accessibility of the learning content and support the storage of information in our long-term memory by the combined use of different cognitive structures, for example through the dynamic combination of different visual forms of presentation and auditory information. Since the human information processing system is limited, especially when learning with multimedia teaching materials, we also discuss the "Cognitive Load Theory" (Sweller, 2005) and its implications for the design of multimedia teaching and learning material to avoid overloading the working memory of the learners (Clark & Mayer, 2011; Hartley, 2014; Mayer, 2014). Afterwards, the workshop starts in which the students work independently and at their own pace at seven different stations. Thematic focuses are the creation of Books, stop-motion videos, augmented reality, digital representations of chemical compounds, animations with PowerPoint, staged learning aids and differentiated teaching materials with QR codes.

Session 8: Learning with YouTube and Explanatory Videos

Since explanatory videos are among the most popular digital learning tools for both young people and adults and are considered effective and motivating, we devote an entire seminar session to this topic (Kulgemeyer, 2018). The information input mainly focuses the categorisation and the application of explanatory videos in informal and formal e-learning scenarios, meaning that explanatory videos are not only used to present information within the classroom but are also frequently used by students without pedagogical supervision (Buzzetto-More, 2014; Szeto & Cheng, 2014). This leads to the issue that likes or views are the most decisive selection criterion for students when choosing a specific video, however, the popularity of a video is not necessarily a predictor of correct content (Peters & Kulgemeyer, 2016). Finally, we present various possibilities of integrating explanatory videos in the classroom (e.g. flipped classroom). During the following working phase, the students create a storyboard and then their own explanatory video on a topic of their choice. For this purpose, the students receive an additional information text as well as a selection of possible apps or programs with which they can create different types of explanatory videos.

Session 9 and 10: Chemical Experiments with Digital Tools

In the first seminar session on "Chemical Experiments with Digital Tools", the students learn about different possibilities to support the introduction and instruction of experiments using technologies. For this, the students create a trailer, a short and interesting video for arousing interest in the learning content. In addition to further possibilities and teaching examples, we discuss and try out the introduction of a new topic via a self-developed comic strip. At the end of the first of these two seminar sessions, we present potential benefits of digital tools for the instruction of experiments. In the second session, the focus lies on the digitally supported conduction and documentation of experiments. Possibilities for conducting experiments are for example virtual screen experiments or virtual reality experiments. Subsequently, we demonstrate the potential of digital measurements via sensors and the digital display and analysis of the measured values. Afterwards, different possibilities of video documentation and their integration into the classroom are considered. In this context, we address the documentation of experiments in slow motion and in a time-lapse. Among other benefits, these are either suitable for decelerating chemical processes and thus for capturing phenomena that pass too quickly for the human eye or for accelerating chemical processes that are usually only observed in the initial and final state of a reaction in the classroom (Vollmer & Möllmann, 2018). In the subsequent work phase, the students work on three different stations: At station 1, the students carry out a virtual screen experiment, at station 2, they record a slow-motion experiment and at station 3, the students work on a multimedia experiment protocol with the aid of which they carry out an experiment and document it in a time-lapse.

Session 11: Gamification and Game-based Learning

This seminar session is methodically designed according to the flipped classroom model. Hence, the seminar participants receive a preparatory learning video which deals with various theories and approaches to gamification and game-based learning. According to the methodology of the flipped classroom, the seminar participants deepen the contents of the preparatory video during the seminar. For this purpose, they discuss the potential of game mechanics used in given examples. Moreover, they create playful interactive exercises themselves on different learning platforms.

Session 12: Assessment, Diagnostics and Feedback

This seminar session focuses various theories on assessment, diagnostics as well as feedback and concludes that diagnostics and feedback should be interlinked processes. Additionally, the strong influence of feedback on learning performance is highlighted (Hattie & Timperley, 2007), while also emphasising that the timing of feedback is crucial as its immediacy has a particularly strong impact on the effects of feedback (Hattie, 2008). Thus, based on the advantages of automated correction, the great potential of digitally supported feedback in the classroom lies in the direct individual feedback of audience response systems (ARS). The lecture concludes with the presentation of possibilities of integrating ARS in the classroom. In the further course of the seminar session, the students create ARS themselves and try them out in the seminar group, while displaying the individual results in real time via the projector.

Session 13: Pool of Ideas and Lesson Planning

The aim of this final seminar session is to provide the seminar participants the opportunity to connect and structure the contents learned in the seminar. In this context, the idea is not to design a whole lesson, but to generate specific ideas for the design of individual teaching phases within a lesson. Hence, we ask the students to assign the range of programs, apps and methods they learned in the seminar to their respective teaching phases and to add a short note on their functionality. Finally, we discuss the opportunities and limitations of digital tools in teaching and learning at German schools.

REASEARCH DESIGN AND METHODS

The developed seminar "Teaching Methods and Media for Digitisation in Chemistry Education" is an obligatory course for all chemistry teacher students in the master's programme. Since the seminar participants attend this seminar directly before their school internship semester, we can also evaluate the practical implementation of the contents learned. To measure the intervention's success, we use various test and evaluation instruments (cf. Zimmermann & Melle, 2019). With regard to the evaluation steps by Kirkpatrick (1979), we evaluate the seminar on the four levels (1) attractiveness, (2 & 3) cognitive changes, (4) practical implementation and (5) effects on the learners, focusing on the following main research questions:

(1) Do the future teachers assess the seminar as attractive?

(2) Does the seminar have an impact on the prospective teachers' …

a: … attitudes towards the implementation of digital tools in chemistry lessons

b: … TPACK self-efficacy perceptions?

(3) Do the future teachers improve their skills in integrating digital tools in their lesson plans?

(4) Are the future teachers able to implement the seminar contents during their internship semester adequately?

(5) Which effects do the seminar participants' lessons have on the students at school?

The study is an intervention study with which we measure the seminar participants' development by means of a repeated measures design. In the first seminar session, we assess the seminar participants' attitude towards teaching with digital tools (5-point Likert scale, 34 items, α = .968, according to the technology acceptance model by Davis et al., 1989) and their TPACK self-efficacy (5-point Likert scale, 31 items, α = .968; focused TPACK domains: TK, TCK, TPK, TPACK; cf. Schmidt et al., 2009). Moreover, we determine their skills in designing lesson plans for digital learning. For this purpose, the students have the task of planning a lesson in which they should implement digital tools in the best possible way. Afterwards, we conduct an interview with the students in which they have to present, explain and justify their lesson plans in detail. To evaluate these results, we developed a coding manual to analyse the TPACK competences, focusing on the changes in the domains of TK, TCK and TPK (5-point Likert scale, $ICC_{unjust.} = .961$*).*

After these pre-tests, the intervention follows. During the intervention, we examine the quality of the seminar after each of four different thematic blocks (5-point Likert scale, 24 items, α = .850). In the last seminar session, we again measure the attitude and TPACK self-efficacy as well as the ability to design lesson plans for digital learning in order to compare the pre- and post-results. Additionally, the students assess the overall seminar quality by means of an attractiveness test with open questions. Within the following internship semester, the practical implementation of the seminar contents is examined (κ between .665 and 1.000). Besides videotaping the implemented lessons, we determine the effects of the seminar participants' lessons on the learners at school with a questionnaire (5-point Likert scale, 10 items, α = .878; open task format). At the end of the internship semester, we measure the seminar participants' attitude and TPACK self-efficacy in dealing with digital tools a third time to assess the long-term effect of the seminar.

PRELIMINARY RESULTS

With regard to the evaluation step *attractiveness,* the first results of the pilot study show that the seminar participants assess the seminar as attractive ($M = 4.37$, $SD = 0.45$, $n = 7$, from 1 = negative to 5 = positive). Moreover, the students are also very positive about the lecturer ($M = 4.80$, $SD = 0.07$, from 1 = negative to 5 = positive) as well as the working phases and the methodological design of the seminar ($M = 4.54$, $SD = 0.20$, from 1 = negative to 5 = positive). Focusing the level of *cognitive changes,* the future teachers' attitudes ($M_{Pre} = 3.91$, $M_{Post} = 4.32$, from 1 = negative to 5 = positive, $p < .001$, $d = 2.60$, $n = 7$) and their TPACK self-efficacy beliefs ($M_{Pre} = 3.05$, $M_{Post} = 4.26$, from 1 = negative to 5 = positive, $p = .001$, $d = 2.09$, $n = 7$) increase significantly with a large effect size. Moreover, the participation in the seminar significantly improves the students' TK ($M_{Pre} = 2.63$, $M_{Post} = 4.33$, $p < .001$,

$d = 4.16$, $n = 7$), TPK ($M_{Pre} = 2.53$, $M_{Post} = 4.35$, $p =< .001$, $d = 3.68$, $n = 7$) and TCK ($M_{Pre} = 2.77$, $M_{Post} = 4.41$, $p < .001$, $d = 3.58$, $n = 7$) with regard to lesson planning on a scale from 1 = negative to 5 = positive.

Regarding the assessment of the *practical implementation* at school, first impressions of the sample of the pilot study show that the knowledge domains TK and TCK of the seminar participants are already relatively advanced, while the knowledge domain TPK indicates further need for improvement. Lastly, the analysis of the evaluation step *effects on learners* shows that the learners were attentive ($M_{Attentiveness} = 4.19$, $SD = 0.70$, from 1 = negative to 5 = positive, $n = 88$) and experienced the digital learning materials used by the students as motivating ($M_{Motivation} = 4.37$, $SD = 7.69$, from 1 = negative to 5 = positive, $n = 88$).

DISCUSSION AND OUTLOOK

Overall, these first results presented are only preliminary as they only include data collected from the pilot study and thus, only comprise a small sample of seven students. Nevertheless, the first results of the pilot study suggest that the seminar is effective in improving pre-service chemistry teachers' TPACK self-efficacy perception as well as their TPACK skills regarding lesson planning and practical implementation. Moreover, we were also able to improve the seminar participants' attitude towards the implementation of digital tools in chemistry lessons and to detect positive outcomes concerning the effects on the learners at school.

In the course of the further investigation, we are currently examining the yet unevaluated data such as the prior experience and the long-term effect of the seminar on the participants TPACK self-efficacy perception and attitude.

After we had revised the seminar sessions and test instruments, we began our main study in November 2018 in which we are testing the seminar with a targeted sample of $N \approx 30$. Depending on the number of seminar participants, we will run the seminar as shown in Table 1 further times. Moreover, we will compare the results to a control group at another university in order to exclude effects caused by test repetition or the natural development of the students.

ACKNOWLEDGMENT

We would like to thank the participating future chemistry teachers and the cooperating schools of the seminar participants' internship semesters.

AUTOMATIC NETWORK ANALYSIS OF PHYSICS TEACHER TALK

Daniela Caballero [1], Toni Pikkarainen[2], Jouni Viiri[2], Roberto Araya[1] and Catalina Espinoza[1]

[1]Centre for Advanced Research in Education (CIAE) - University of Chile, Santiago, Chile
[2]Department of Teacher Education – University of Jyväskylä, Jyväskyla, Finland

Literature shows that the characteristics of the instructional content have a direct influence on students' learning. Those characteristics could be number of connections between the content structure elements, the number of important topic-related concepts and the occurrence of key concepts. This type of analysis takes enormous quantity of time, if it is done manually. Thus, our aim in this study is to make the lesson analysis automatic and to find what network measures correlate with students learning gain. We automatically studied lessons from 25 teachers and 328 students and compared the teachers' networks with students' learning gain (LG) through the analysis of teachers' concept networks. The network measures are the Number of nodes, Number of edges, Density, Diameter, Average clustering, Average degree and Average degree centrality. The results show that the measures Density, Diameter and Degree Centrality resulted to be significant for the LG. Density is related with LG in negative way: as more dense the graph is, less LG for the students. The results are coherent with previous results and open a new branch for automatic analysis of lessons.

Keywords: Classroom Discourse, Measurement, Diagnostic Tools.

INTRODUCTION

Since decades it is known that the characteristics of the instructional content have a direct influence on students' learning (Shavelson, 1972; Geeslin & Shavelson, 1975; Fischer, Labudde, Neumann, & Viiri, 2014). It has been found that the number of connections between the content structure elements is positively related to students' learning gains, the number of important topic-related concepts is significantly correlated with students' learning gains (Müller & Duit, 2004; Klieme, Pauli, & Reusser, 2009; Drollinger-Vetter, & Lipowsky, 2006).

In the QuIP project Helaakoski and Viiri (2014) coded the lesson videos manually, produced concept networks and calculated network measures. They found that the number of different physics concepts and connected concept pairs had correlations with students' learning gains.

Since manual coding is time consuming, our aim in this study is to make the lesson analysis automatic. Our research question (RQ) is:

RQ: What network measures correlate with students learning gain?

METHOD

Data Collection

Our data consists of 25 videotaped lessons from the QuIP project. The topic of the lessons was the introduction to the relation between electrical energy and power in ninth grade.

Participants. Each of the 25 videotaped lessons matches with one teacher and his/her students. In total, a sample of 328 students from 25 teachers from different schools of Finland are considered for the analysis. The average student age was 15.6 years.

Instruments. To measure the change of students' content knowledge in terms of quality, an instrument was developed by the researchers of QuIP project. The main topic of the test was the concepts of electrical energy and power. The test consisted of multiple-choice tasks, open-ended questions and calculations with a six-level complexity model. The process of the development of the instrument involved several steps: (1) selection, adaption and authoring of items, (2) expert review of items, (3) revision of items and (4) compilation of test booklets utilizing the final set of test items (see Geller, Neumann, Boone, and Fischer, 2014). The booklets for the Pre-test had 18 items and the booklets for the Post-test had 36 items. Each of the items was evaluated as correct (1 point) or incorrect (0 points). As general overview, the Pre-test had a mean of 7.9 points, whereas the Post-test has a mean of 15.67 points.

Procedure. Every teacher of the project performed a lesson with the same topic: introduction to the relation between electrical energy and power. There was no guidelines or materials given by the researchers to the teachers: they were supposed to teach the topic with their normal practice. On the other hand, the lesson was performed in between the Pre- and Post- test.

Data Analysis

Data analysis involved a process of different steps with several intermediate outputs. During this process a concept network was generated from each lesson recorded. Then, measures describing the concept networks were used to explain the students' learning gains. The main focus was to automatize as much as possible and reduce the manual work as shown in Caballero, Araya, Kronholm, Viiri, Mansikkaniemi, Lehesvuori, … & Kurimo (2017). Figure 1 gives a simple pipeline of the process.

For all the videotaped classes, an Automatic Speech Recognition (ASR) algorithm was used to automatically convert the teacher speech into text (class transcriptions). The ASR process was performed with the system developed by the Aalto University (Kronholm, Caballero, Araya, & Viiri, 2016).

Once the class transcriptions were done, a pre-process of stemming was performed in order to extract the root of the words. With the stemming we obtain the group of words that have the same root and therefore are related to the same concept. Text Data Mining (TDM) process was run to find keywords and their connections in a 10 seconds window time. In order to do so, a keyword list of 450 physics concepts was used as input. The keyword list was done manually by a physics teacher. If the teacher mentioned two concepts in a 10 seconds window time, then the two concepts were related each other. The edge has the direction of time, which means the first concept mentioned "goes" to the second one.

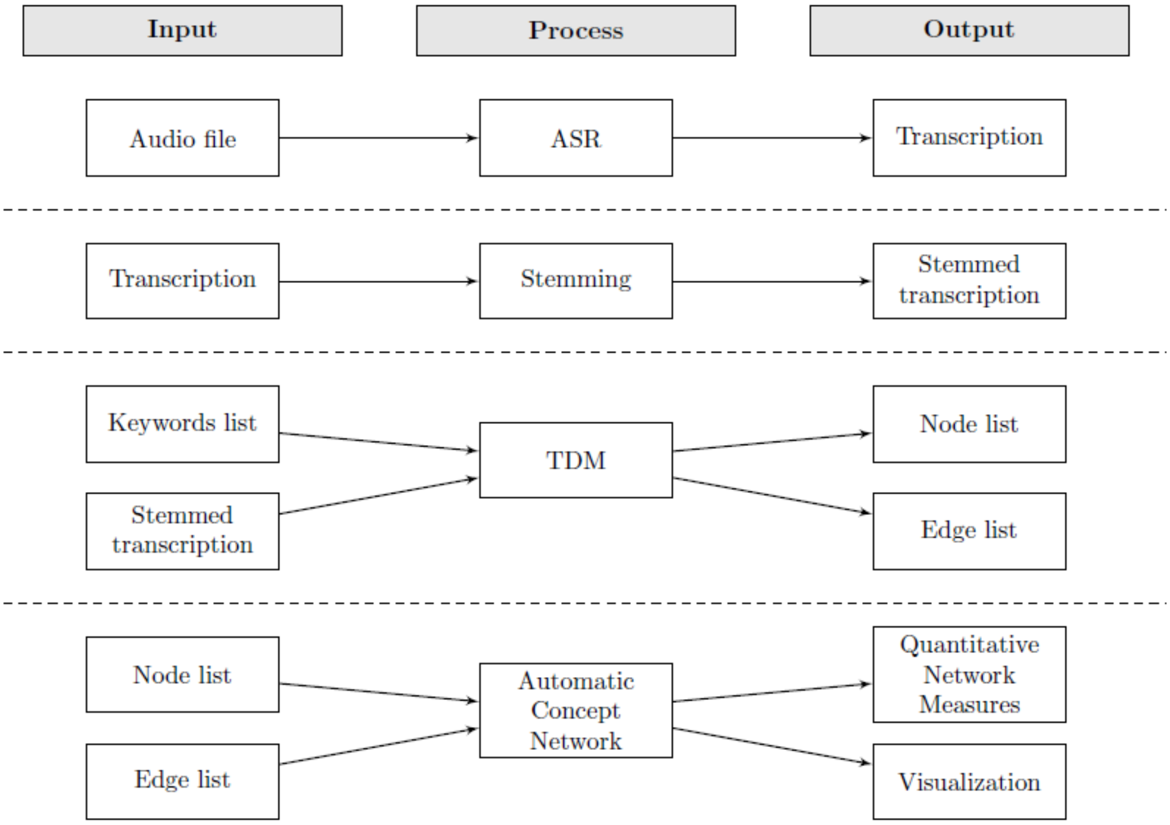

Figure 1. Pipeline for data analysis

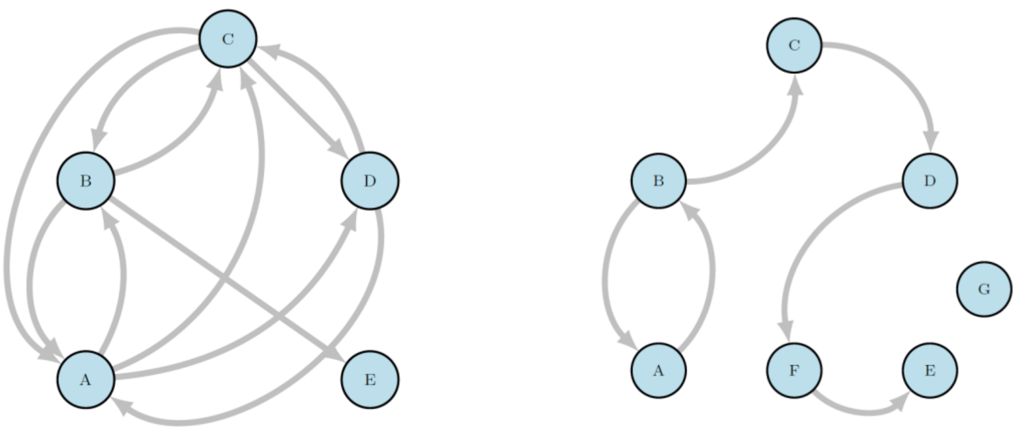
With the keywords and keywords connections, an automatic concept network was generated (see Figure 2 for two examples of the Visualization output shown in Figure 1). In the concept network, nodes are concepts and the edges between two concepts mean that the concepts were said in the same 10 seconds window time.



(a) Network A (b) Network B

Figure 2. Example of two concept networks with different network measures

Afterwards, network measures were calculated. These are measures of Social Network Analysis applied to the concept network to see whether there is a relationship between the measures and students' learning gains. The measures are taken from Vargas et al. (2018). Table 1 shows the meaning we give to the network measures (Quantitative Network Measures output in Figure 1) and the results of them in the example networks shown in Figure 2.

Table 1. Network measure description and values for examples given in Figure 2

Network Measure	Meaning	Network A	Network B
Number of Nodes	How many different concepts the teacher said and related with other concepts. In Network A, the teacher said 5 different concepts: A, B, C, D, and E but teacher in Network B mentioned two more: F and G	5	7
Number of Edges	How many concepts were said in the same time window. Teacher of Network A had more connections between the 5 concepts than teacher of Network B. The arrows indicate which concept was mentioned first (e.g. in Network A, concept B was said before concept E)	11	6
Density	Proportion between number of edges and number of all possible edges. Network A is more dense than Network B. A network with no edges has a Density of 0 and a complete network has a Density of 1	0.55	0.14
Diameter	The greatest distance between any pair of concepts of the network. For Network A, the greatest distance is 3 (from concept D to concept E), whereas the greatest distance in Network B is 5 (from concept A to concept E)	3	5
Average Clustering	The average tendency of the concepts' neighbors to cluster together. In Network A, neighbors of concepts tend to cluster together more than in Network B.	0.5	0
Average degree	The average of how many linked concepts has each concept of the network. Teacher of Network A connected, in average, each concept to other 4.4 concepts, meanwhile Teacher of Network B connected, in average, each concept to 1.7 concepts.	4.4	1.7
Average Degree Centrality	The average of the proportion of how many neighbors does a concept has, normalized by dividing by the maximum possible degree in a simple graph n-1 where n is the number of nodes in the network.	1.1	0.28

The students learning gain (LG) was calculated as

$$\mathrm{LG} = \frac{\mathrm{Post} - \mathrm{Pre}}{\mathrm{Total}_{\mathrm{post}} - \mathrm{Pre}}$$

Where Post is the score of Post-test, Pre is the score of Pre-test and $\mathrm{Total}_{\mathrm{post}}$ is the maximum possible score for Post-test.

To answer the research question, a robust regression (Li, 2006) was run. In the model, the independent variables are the networks' measures and the dependent variable is the LG.

RESULTS

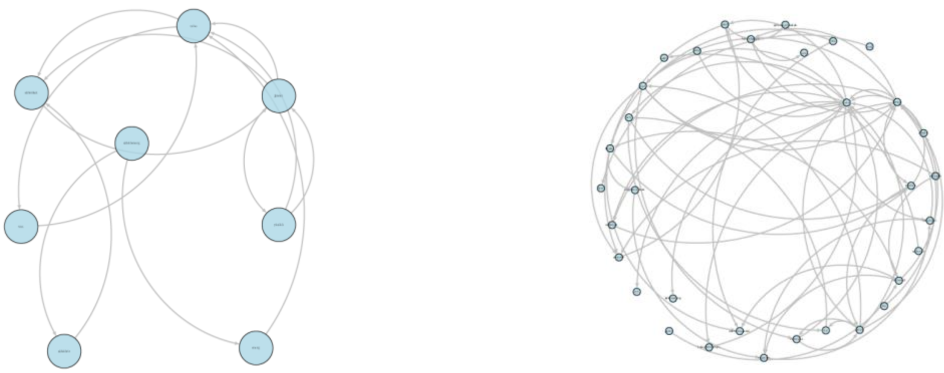
From the results shown in Table 2, we conclude that the variables Density, Diameter and Average Degree Centrality resulted to be significant for the LG. Density is related with LG in negative way: as more dense the network is, less LG for the students.

Table 2. The results of the robust regression, with the p-value of each of the measures

	Value	Std. Error	t – value	p - value
(Intercept)	-9.547	7.220	-1.322	0.188
NODES	0.510	0.300	1.701	0.091
EDGES	-0.146	0.138	-1.058	0.291
DENSITY	-4.193	1.864	-2.249	0.027
DIAMETER	0.939	0.389	2.653	0.016
CLUSTERING	2.269	7.770	0.292	0.770
AVG_DEGREE	1.461	1.723	0.848	0.398
AVG_DEGREE_CENTRALITY	25.277	9.865	2.563	0.010

Residual standard error: 5.286 on 307 degrees of freedom.

To analyse a concrete example, the lessons from two teachers are compared. Figure 3 shows their respective network visualization and Table 3 shows the network measures that turned to be significant.



(a) Lesson Teacher A (b) Lesson Teacher B

Figure 3. Two networks of two real lessons, with different network measures

Students in Teacher B lesson had higher LG (mean = 0.44) compared with students in Teacher A lesson (mean = 0.29). Moreover, students in Teacher B lesson had higher minimum and maximum values of LG. As Table 3 shows, the lesson of Teacher B has less density and less Average Degree Centrality, but higher Diameter.

Table 3. Network measures for the lessons shown in Figure 3

Network Measure	Lesson Teacher A	Lesson Teacher B
Density	0.20	0.05
Diameter	3	6
Average Degree Centrality	0.4	0.11

DISCUSSION AND CONCLUSION

Previous studies have shown that the characteristics of the instructional content have a relationship with students' learning. Particularly, the connections between content structure and the number of topic-related topics. The analysis of teachers' discourse is time consuming. In this proposal we take the advantage of Automatic Speech Recognition algorithms performance to automatically analyse the teachers' lesson through network analysis.

Social network analysis metrics are used to analyse the network created from teachers' talk. Those measures give the structure of the concept network of a teacher. Using the data of QuIP project, we studied 25 teachers and 328 students from Finland. The results show that the Density, Diameter and the average Degree Centrality of the concept network have a significant relationship with students' LG. This means that the greater the Diameter and the Degree Centrality, higher LG and the sparser the network is, greater LG. The results are coherent with previous results since we demonstrated that network measures relate significantly with students' learning as in Helaakoski and Viiri (2014).

On the other hand, automatic analysis was less time consuming than manual analysis. Automatic network analysis - starting from automatic speech recognition to automatic network generation and analysis - could help researchers in classroom talk analysis and could be used in teacher education as formative feedback tool. We will leave as future work which is the best way to give this kind of feedback in real-time.

In the future, we would like to find new ways of analysis, using other network measures like different centrality measures or cluster analysis to obtain a way of measuring the "importance" given to each concept during the class or how likely is the teacher to relate two specific concepts. Also, we expect in the future to gather more data from more teachers and students to test whether the results shown in this paper are robust and hold in other contents, subject matters beside physics, grade level, etc. Moreover, it could be interesting including in the analysis time series analysis so we could be able to identify which concept was being taught at any moment, and thus observe how the network changes from the start to the end of the lesson. This could lead to discover interesting time-related patterns that teachers might present when developing a lesson. Finally, we think it is imperative to consider students' talk to understand the class discourse as a whole, not only how the content is presented by the teacher.

ACKNOWLEDGEMENT

Funding from PIA-CONICYT Basal Funds for Centers of Excellence Project FB0003 is gratefully acknowledged and to the AKA-EDU-01 grant from CONICYT. The authors are also thankful for the funding provided to project No. 294218 by the Academy of Finland.

UNPACKING THE PROMISES OF THE MAKER MOVEMENT IN STEM EDUCATION: THE DEVELOPMENT OF SCIENTIFIC AND ENGINEERING PRACTICES THROUGH TINKERING

Cristina Simarro[1] *and Digna Couso*[2]
[1] Universitat Autònoma de Barcelona, Cerdanyola del Vallès, Spain
[2] Universitat Autònoma de Barcelona, Cerdanyola del Vallès, Spain

Tinkering, a subset of Making, is newly delineated as a specifically process-focused approach to learning through physical/digital creation and characterized by a creative and improvised way of solving problems. Advocates argue that it holds great promise as a means of STEM learning, though few empirical studies yet exist. In this research, we analyse the impact of Tinkering activities with regard to children's participation in scientific and engineering practices. Our results confirm preliminary expectations of learning through Tinkering, however, they suggest that while specific engineering practices can be easily seen through learner participation, scientific practices do not emerge spontaneously despite the existence of potential situations to promote them.

Keywords: STEM education, informal learning, primary school

INTRODUCTION

Making (or Maker movement), a grassroots movement related to digital and physical fabrication, has increasingly been embraced by formal and informal education (Bevan, 2017; Marshall & Harron, 2018; Martin, 2015). Characterized by the creative design, the construction and customization of objects, artefacts and other constructions with a fun or useful purposes, the playful nature and multiple entry points that characterize a Maker activity is seen by advocates as a powerful approach for helping students to gain confidence in their own ability to undertake new scientific and technological challenges (DiGiacomo & Gutiérrez, 2015). In the current era were design is seen as a new literacy (Blikstein, 2013), Making environments are seen as rich contexts for acquainting young people with STEM practices that will empower them to change their world (Project Zero, 2015). Moreover, the multidisciplinary nature of the Maker movement is championed as a potential context in which to tackle new STEM standards which place science and engineering practices at the forefront of STEM education (Duschl & Grandy, 2008; Grandy & Duschl, 2007; National Research Council, 2012; Osborne, 2014).

In this context, Tinkering, as newly-defined approach to learning framed in Making, has grown in popularity, educational interest, and specificity in the last few years (Bevan, Gutwill, Petrich, & Wilkinson, 2015; Vossoughi & Bevan, 2014). In a Tinkering activity, participants are invited to explore several material and phenomena to build their own creations (Petrich, Wilkinson, & Bevan, 2013) which can be easily tested in order to get an immediate feedback about their results (Resnick & Rosenbaum, 2013). While research on Tinkering has surfaced 'learning dimensions' as well as theoretical learning potentials (Bevan et al., 2015; Wardrip & Brahms, 2015), scant evidence exists regarding the real impact of Tinkering on scientific and engineering learning of both concepts and practices. In this context, our study seeks to interrogate the impact of Tinkering in STEM education. Specifically, it seeks answers to the following question:

- Which scientific and engineering practices are promoted through a Tinkering activity in an informal learning context?

METHOD

Our research is based on Creactivity, a Tinkering space located in the CosmoCaixa Museum in Barcelona, Spain. It is addressed to families with children between 7 and 12 years old and to school groups from 2nd to 6th grade. Inspired by Exploratorium's Tinkering Studio in San Francisco, it includes four areas (some with more than one space): Mechanics (with gears' corner and marble and pinball machines), Wind, Electricity and Light (with shadows and stop motion) (Figure 1).

Figure 1. The four Creactivity areas, which their corresponding spaces

Each session at Creactivity was attended by two facilitators, who received participants and made a brief introduction of the space, offer their support during the activity (giving materials, proposing challenges, etc.) and take care of making the closure of the session. No direct instructions were given to students, although implicit objectives (examples, drawings…) were present in all four areas. The study was carried out during a school year, focusing on the sessions with schools and including the activities carried out in the four areas of Creactivity.

Data gathering and analysis

The study was designed as a qualitative research with video and audio-recording as main data sources together with researcher's field notes. A total of 13 Tinkering sessions (26 hours) were observed. In each observation, two cameras and three audio recorders were placed in a Creactivity area, chosen randomly. Data analysis was based on the selection of 12 cases which were considered rich in content according to the information gathered in the field notes. Video and audio were edited for each case, in order to guarantee good sound quality and the best camera angle images. Edited videos were analysed using the qualitative data analysis software Atlas.Ti. Following a qualitative approach based on multimodal discourse analysis (Gee, 2011; Jones, 2013), relevant clips were identified. Each clip was first coded following an inductive categorization, describing the tasks carried out during a Tinkering activity (see Table 1) In a second round, these tasks were deductively coded - based on an adaptation of the NRC (2012) list of engineering and scientific practices- seeking to classify the identified tasks with the corresponding practices.

Table 1. Emerged categories regarding participants' tasks.

Student tasks- Emerging categories
To propose several assemblies/creations and choose one to carry it out
To do partial tests of parts of the assembly
To assemble/build their creations
To test creations
To analyze the result of the tests done (works / does not work)
To justify their creation
To explain a phenomenon
To investigate a phenomenon

RESULTS

Results confirm the development of some engineering practices and, to a lesser extent, of scientific practices. Specifically, our results confirm that engineering practices (blue/green scale) related to the *Materializing the solution* (33%), *Planning and carrying out tests* (32%), *Identifying multiple solutions and selecting the optimal one* for its realization (20%) and *Analysing and interpreting of data to identify points of improvement* (13%) were the most relevant during Tinkering activities (Figure 2). However, in most cases practices were usually shallow. For instance, when carrying out tests, students were directly testing, using the mechanisms included in the Tinkering space for having immediate feedback regarding the creations, without a thorough planification of the investigation, (e.g.: button for turning on the wind tube). Only in some cases, this testing evidences planification, focusing on testing some of the variables at play. As for the materialization of the solution, there is a certain difference between the participants: while some boys and girls make a deliberate choice of materials in order to make their creation real, others follow a more exploratory choice just picking one of the available materials and trying to use it.

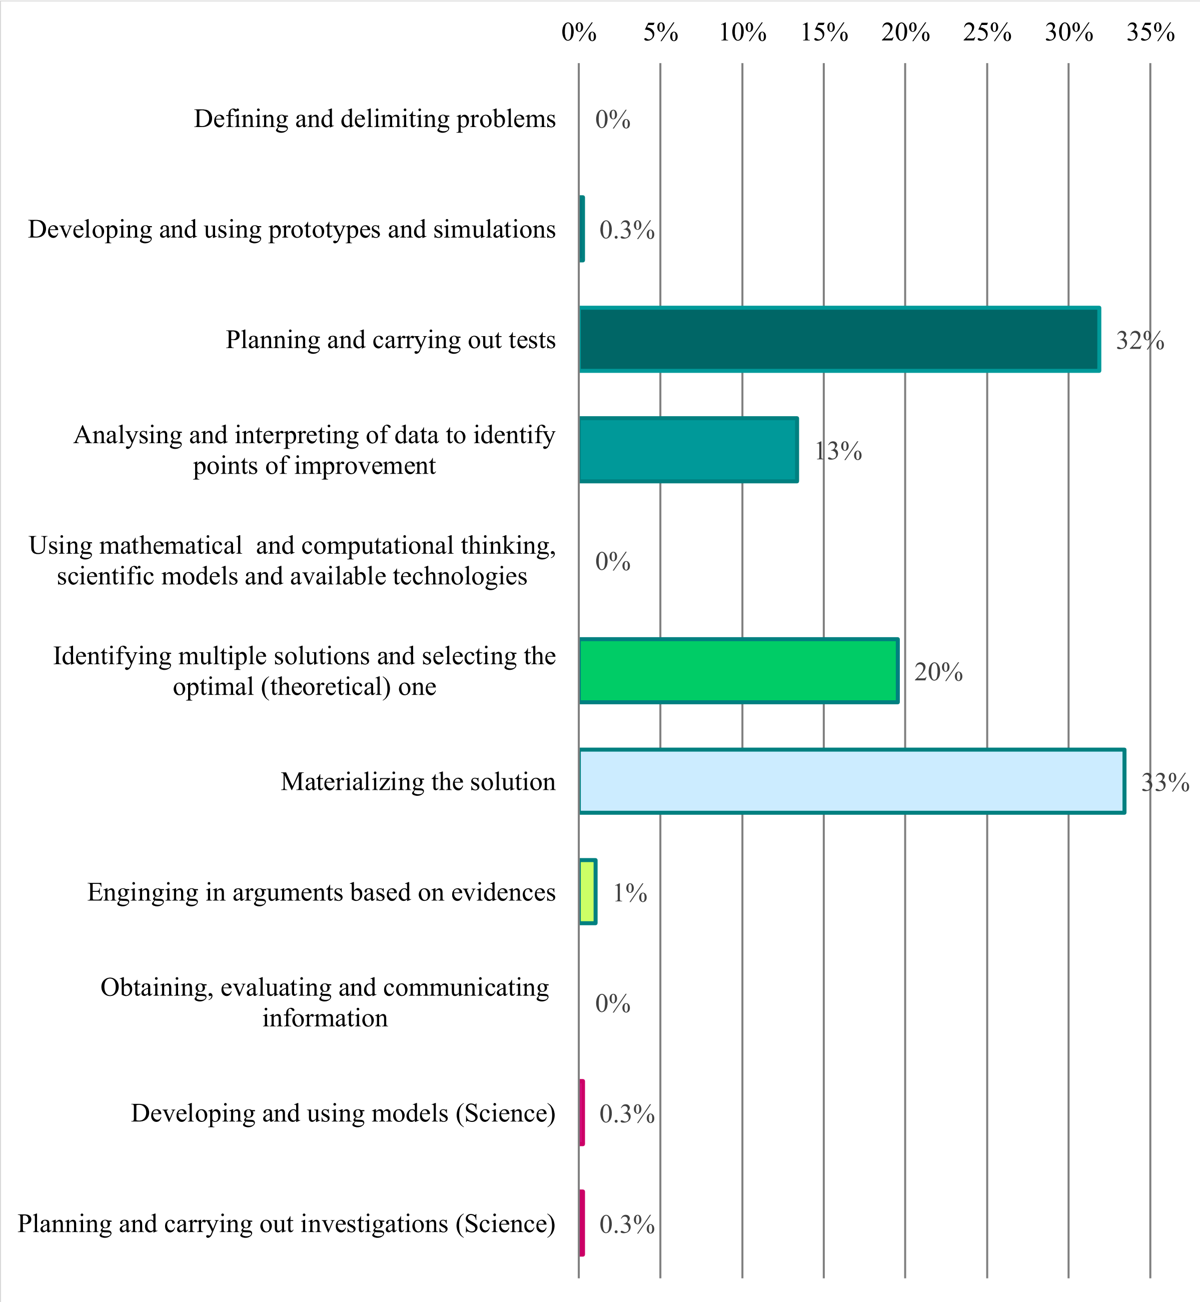

Figure 2. Engineering and scientific practices evidenced in Study 1 cases. Percentage of total observed practices.

Finally, beyond this construction and testing of creations, the other practice that seems to be encouraged in is the selection of an optimal solution. This practice involves identifying several possible solutions before selecting a specific one. In this sense, it is common to see students engaging in a kind of brainstorming in order to evaluate the different options that emerge or to look at the solutions made by others to get ideas among possible solutions.

Regarding scientific practices (pink scale), they seem to have a residual presence and are basically reduced to *Developing and using models* and *Planning and carrying out investigations.* Again, these practices are shallow, and students tend to devote little time to them moving easily to the engineering ones.

DISCUSSION AND CONCLUSIONS

Our study shows that students in a Tinkering activity are engaged in practices relevant to engineering and, to a lesser extent, to science. In both cases, most practices are usually shallow: there is testing but no test is planned, there is analysis of test results but it is not based on data,... The nature of the space (e.g.: the type of material with no measurement tools) and the methodological proposal that accompanies it (e.g.: a type of test for each space, few restrictions given to students, ...) could explain this lack of depth while also promote the greater or lesser presence of the various practices.

Regarding engineering practices, our study suggests that Tinkering activities promote certain practices that often play a residual role in engineering education or technology (i.e.: identification multiple solutions). As Mader and Dertien (2016) point out, the idea of making decisions about design is usually relegated to a pre-established decision, focusing most of the activities on framing the problem and building the solution. Hence, giving to students the opportunity to participate in Tinkering activities helps them to develop creative practices which are central for engineering.

On the other hand, the results show that throughout a tinkering activity there are situations in which scientific practices can be promoted but which do not seem to be maintained. The nature of the context and the methodology used by facilitators, much focused to engineering, would explain this result. These findings confirm what King and English (2016) argue: a STEM approach based on engineering design does not need to promote the development and learning of scientific practices and concepts. Unless the work around scientific practices is explicitly stated, they will not be given in a context where the practice of engineering is primarily promoted, however multidisciplinary the space may be.

EYE MOVEMENTS DURING DETERMINATION OF BUTTERFLIES WITH IDENTIFICATION KEY

Tanja Gnidovec[1] *and Gregor Torkar*[1]
[1]University of Ljubljana Faculty of Education, Ljubljana, Slovenia

The purpose of the present research was to observe pre-service teacher's eye movements during the determination of butterfly species with a simplified dichotomous key containing illustrations, photographs, and written descriptions. Our aim was to explore if they prefer to use illustrations or photographs in the determination of butterfly species? The eye-tracking measures showed that students (n=58) used more illustrations than photographs of butterflies. Students reporting having more experiences with keys and butterflies had a significantly higher percentage of total fixation duration on illustrations in comparison to less experienced students. Achievements in tasks were not significantly correlated with visual attention towards different elements in identification steps. Implications for teaching biology are discussed in the conclusion.

Keywords: biological key, eye tracker, butterfly, observational skills

INTRODUCTION

Dallwitz, Paine, and Zurcher (2002) wrote that the identification of organisms is a process in determining which taxon species belong to and represents a basic skill for understanding nature. In biology, an identification key is a tool that aids the identification of biological entities (e.g., plants, animals, animal tracks). Thus, one of the most fundamental objectives in biology teaching is to strive for developing students' skills and abilities to use biological identification keys (Randler and Zehender, 2006). Each identification step in simplified identification keys requires from learner to choose between two options (dichotomous keys) or multiple ones; consisting of text, graphics or both. Simplified keys mostly contain organisms from the student's local environment and which gives them the opportunity to get to know these organisms more closely through identification (Bajd, 2016). There is an increasing number of studies (e.g., Anđić, Cvijetićanin, Maričić, and Stešević, 2018; Laganis, Prosen, and Torkar, 2017; Stagg, Donkin, and Smith, 2013; Randler, 2008; Bromham and Oprandi, 2006; Randler and Bogner, 2006) investigating the effectiveness of identification keys. Most of these studies were done with primary and secondary school students. In the present study, we focus our attention on pre-service teachers, who are going to teach students to use simplified identification keys in primary and lower secondary school. The results indicate that using identification keys in biology teaching is an effective educational tool to explain scientific principles (Randler and Bogner, 2006). Through the process of determination with identification key students improve their observational skills (Laganis, Prosen, and Torkar, 2017) and can work independently, without the teacher's help (Bromham and Oprandi, 2006). Students are more motivated for learning about plants when working with identification keys, although botanical content is not attractive for students (Silva et al., 2011).

Nowadays, loads of identification keys are available, usually using words, illustrations and/or photographs that guide a learner through the identification of the organism. For a review on the use of images in field guides and identification, keys see Leggett and Kirchoff (2011). Authors exposed best practices in image use in guides and keys, based on their review e.g., multiple images should be included to illustrate the taxon descriptions (characters indicated with arrows to direct the user's attention); an observed organism in the photograph should be pointed out from the backgrounds, where possible, the background should be of a standard color; the use of drawings is reasonable than photographs when representing a typical example of an organism; when used, illustrations should be prepared by professional botanical illustrators, and clearly labeled. However, little is known what type of visual representations (illustrations or photographs) users prefer to use.

Eye-tracking is a technique for studying various visualizations because it makes it possible to monitor cognitive processes due to the links between eye movements and cognition. Eye movements indicate where attention is being directed and total fixation time (i.e. cumulative duration of fixations within a region) is considered as a sign of the amount of total cognitive processing engaged with the fixated information. Data gathered with eye tracing provides information about the cognitive process of the student, such as reading, scene perception, visual search and other information on processing the problem (Rayner, 1998, 2009). The eye-tracking technique has been used in many studies, analyzing the learning process and problem-solving (e.g. Lai et al., 2013). For detecting information about students' procession of various visualizations, the eye-tracking is also efficiently used (e.g., Ferk Savec, Hrast, Devetak, and Torkar, 2016). With regard to this fact, collecting eye movements can provide important information in investigating students' identification of organisms with simplified keys.

Research goal and questions

The goal of the present research was to observe pre-service teacher's eye movements during the determination of butterfly species with a simplified dichotomous key containing illustrations, photographs and written descriptions that guide a learner through the identification step.

The main questions underlying this research were therefore threefold:

(1) Do pre-service teachers prefer illustrations or photographs through identification steps?

(2) Are there any differences between students with more or less prior experiences with identification keys and butterflies?

(3) What are the differences between students who identified organisms correctly and those who were not able to answer correctly?

RESEARCH METHOD AND DESIGN

Slovenian pre-service teachers (n = 58) participated in the study. They will teach science or biology subjects in primary or lower secondary school. Education staff at school level have to hold relevant educational qualification (ISCED 7 for primary school and lower secondary school teachers) and they have to pass the state professional examination for education staff

(Eurydice, 2019). Even though the curriculum varies among universities, pre-service teachers typically take content knowledge courses, pedagogical content knowledge courses, and general education courses. Pre-service teachers learn how to create and use simplified identification keys in general biology or science courses. Participating pre-service teachers were in the second, third or fourth year of studies at the University of Ljubljana's Faculty of Education. They all learned how to use simplified dichotomous identification keys before the study in the field of systematic botany and zoology.

Eight tasks were presented on a computer screen in the form of text and images. Each task was presented with one identification step: two different written descriptions (A and B), an illustration and a photograph of an organism (for example see Figure 1). Students had to identify which description (A or B) correctly describes the organism on the images. On four out of eight tasks illustrations were placed on the left side and photographs on the right side of the slide. The remaining four slides had the opposite pattern.

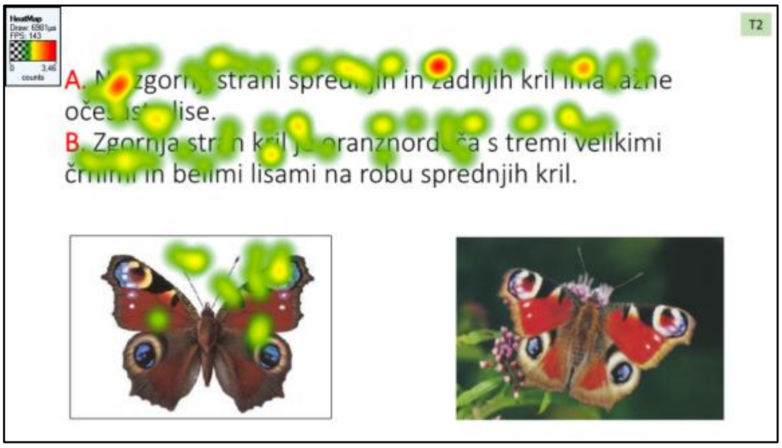

Figure 1. An example of a student focusing on illustration, placed on the left side when identifying the butterfly species (represented with heat map).

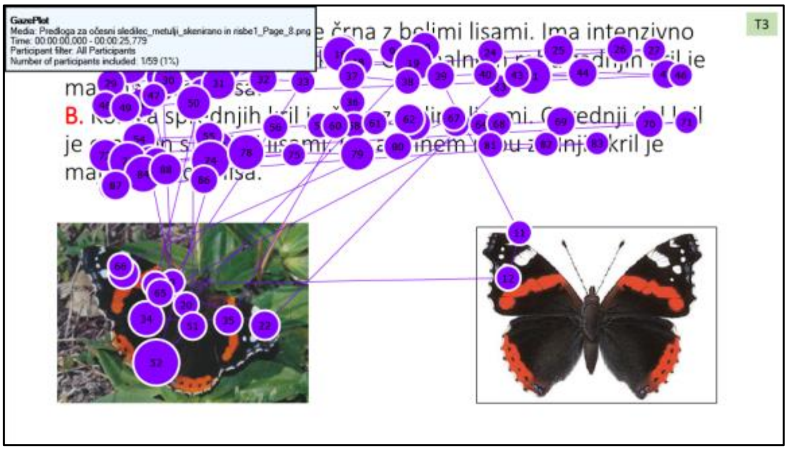

Figure 2. An example of a student focusing on the photograph of the organism, placed on the left side, when identifying the butterfly species (represented with gaze plot). Through the representation with the gaze plot, the many integrations between images and text could be observed.

To determine students' visual attention towards different elements of the slides while solving the tasks, we focused on the total amount of time (total fixation duration) spent in particular areas of interest (AOI). The tasks displayed on the computer screen were divided into several AOIs with regard to the placement of the images/texts investigated. Fixations refer to maintaining the visual gaze on a certain location (Figure 1), and fast eye movements from one location to another are called saccades (Figure 2). The identification of saccades or fixations is based on the motion of gaze during each sample collected. When both the velocity and acceleration thresholds (in our case: 30 degrees per second and 8,000 degrees per second squared) are exceeded, a saccade begins; otherwise, the sample is labeled as a fixation.

Data entry and analysis were conducted using the Statistical Package for the Social Sciences (SPSS). Basic descriptive statistics for numerical variables (mean, standard deviation, and frequency) were employed. The inferential statistical methods used were the Pearson product-moment correlation and the Student's t-test. In addition, effect sizes (Cohen's d) were calculated.

FINDINGS

Findings show that 41.40% of pre-service teachers solved correctly all eight tasks, 27.60% seven, 22.40% six, 6.90% five and 1.70% four tasks. Table 1 shows students' success in solving specific tasks. On average they solved 7.00 (SD = 1.04) tasks correctly. They spent on average 18.19 seconds (SD = 6.95) on each slide (tasks 1-8). While solving the tasks they devoted on average 26.17% of the time on images and the rest of the time on written descriptions of butterflies. Those that spent on average more total time on the slide, focused more attention on images. Percent of integration of images and texts was calculated which represents the number of times a student looked on images while reading written descriptions, excluding the number of saccades between text A and B. Average percent was 68.94% (SD = 8.01). In problem solving students used more illustrations (13.86%, SD = 4.33) than photographs (12.31%, SD = 4.18) of butterflies (t = 1.966, df = 114, p = 0.05, Cohen's d = .364). Students showing higher percent integration of images and texts used significant more illustrations of butterflies.

Table 6. Correctly and incorrectly solved tasks.

	Task solved correctly		Task solved incorrectly		Total	
	f	*f%*	*f*	*f%*	*f*	*f%*
Task 1	49	84.5	9	15.5	58	100.0
Task 2	52	89.7	6	10.3	58	100.0
Task 3	41	70.7	17	29.3	58	100.0
Task 4	56	96.6	2	3.4	58	100.0
Task 5	52	89.7	6	10.3	58	100.0
Task 6	51	87.9	7	12.1	58	100.0
Task 7	58	100.0	0	0.0	58	100.0
Task 8	47	81.0	11	19.0	58	100.0

Students were asked about their experiences with butterflies and identification keys (Table 2). A great amount of them (79.3%) exposed they like observing butterflies in nature, but only 6.9% of students have sampled and determined butterflies so far. Most of the students (84.5%) mistakenly thought widespread butterfly species in Slovenia *Lycaena virgaureae,* has yellow-colored wings. Also, only 5.2% of students would recognize butterfly species clouded yellow *Colias croceus*. Students also reported about their knowledge on the biodiversity of butterflies. None of them answered knowing the biodiversity *excellent*; one of them responded his knowledge is *very good*. Most of the students (58.6%) exposed their knowing the biodiversity of butterflies is *fair*, and 25.9% tell their biodiversity knowledge is *poor*.

Table 7. Self-reported experiences with keys and butterflies.

Self-reported experiences with keys and butterflies	Experienced	Not experienced
	f%	*f%*
I like observing butterflies in the meadow.	79.3	20.7
I could recognize a butterfly species yellow clouded *Colias croceus*.	5.2	94.8
I have sampled and determined butterflies more than three times.	6.9	93.1
Butterfly species *Lycaena virgaureae* has yellow wings.	15.5	84.5

Results in Table 3 show that students spending more time on images also integrated more images and texts. Students reporting having more experiences with keys and butterflies had significantly higher percent fixation duration on images in comparison to less experienced students. To solve the tasks, students with more experiences focused more on illustrations. The eye-tracking measures in students that solved tasks correctly and in those that were not able to solve the tasks correctly did not differ.

Table 8. Correlations.

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Correctly solved tasks (1)	1	-.236	-.144	-.056	-.204	.015	-.205

Statistically significant * $p < .05$, ** $p < .001$.

DISCUSSION

The use of identification keys in biology teaching is a great opportunity to develop the scientific skills of students (Randler and Bogner, 2006) and familiarize them with biodiversity (Bajd, 2016). Identification keys can be simplified at many points to make it more fitting for educational purposes. Wisniewski (2002) suggests that the taxon descriptions should be supported with multiple images to help students visualize the presentative features of an organism. The findings of the present research suggest that Slovene pre-service teachers, who are going to teach science and biology subjects in primary and lower secondary school, spent on average one-quarter of a total fixation duration on images (illustration and/or photograph of a butterfly) while solving the problem through the step of butterfly identification.

Students preferred more illustrations than photographs for the determination of butterfly species. Also, students reporting having more experiences with using identification keys used substantially more illustrations in the identification process. A possible explanation is that students dislike photographic backgrounds because they distract them from the subject (Leggett and Kirchoff, 2011). Leggett and Kirchoff (2011) recommend that backgrounds should be of standard color. A finding of the present research suggests that students rely more on illustration prepared by professional biological illustrators in comparison to a photograph even though later depicts butterfly more realistically. Those students that reported having more experiences with keys and butterflies were not more successful in problem-solving in comparison to less experienced students, which can be explained through the simplicity of examples presented in the tasks. Drawings that are prepared by a trained botanical illustrator show specimens typical of the species and focus on and emphasize their specific features (Meicenheimer, 2007, 2009).

CONCLUSION

The present research provides four main conclusions about the use of identification keys when teaching and learning about the biodiversity of butterflies. First, students report having very little prior experiences with identifying key for, and determining of, butterflies. Second, students have successfully determined butterflies with provided identification keys. Due to relatively small numbers of incorrectly solved tasks, it is difficult to make solid conclusions on the effect of visual attention towards different elements of identification keys. Therefore, further research is needed to find out if selective visual attention is in any interplay with students' achievements. Next, the number of accurately determined butterflies and the students' total fixation duration on images were positively correlated. Last but not least, students with more prior experiences relied more on illustrations when using the keys. These findings have important implications for the development of educational materials and instructions for observing and studying the biodiversity of butterflies. It is an important goal to teach pre-service teachers to prepare and use identification keys in order to enable school students can learn about biodiversity more actively and independently of teacher help.

DIGITISATION IN CHEMISTRY LESSONS

DEVELOPMENT AND EVALUATION OF AN EXPERIMENTAL DIGITAL LEARNING ENVIRONMENT WITH UNIVERSAL ACCESSIBILITY

Mats Kieserling[1], Insa Melle[1]
[1]TU Dortmund University, Dortmund, Germany,

Today, learning with and about digital media is absolutely essential and explicitly demanded in the German strategy paper "Bildung in der digitalen Welt" (Education in the Digital World; KMK, 2016). At the same time, the digitisation offers great potential for teaching highly heterogeneous learning groups individually and comprehensively (Edyburn, 2010; Meyer, Rose, & Gordon, 2014). However, the use of digital media at German schools is still in its infancy (MPFS, 2018). In order to create a basis for the successful implementation of digital media in teaching, we intend to generate profound knowledge about the effectiveness of digital learning environments on the one hand and considering heterogeneous learning groups on the other hand.

Against this background, the aim of our project is to develop and evaluate a digital learning environment for lower grades in secondary education (age 13 to 14). Regarding the design of the teaching unit, we follow the concept of Universal Design for Learning (UDL; CAST, 2011), a model for joint learning of students with and without special needs. After a short introductory video, the teaching unit mainly consists of an experimental phase and a theoretical phase.

The aim of the study is to investigate the effects of the use of tablet computers in these different teaching phases on the students' learning outcome. To do so, we determine the content knowledge previous to the teaching unit and after every single teaching phase. Moreover, the students' attitudes towards the given teaching material as well as their cognitive load are retrieved after each teaching phase. With the help of a screen-capture-software, it is possible to retrace the steps of the students during their work with the devices. Additionally, the lessons are filmed to analyse the work behaviour of the learners using the tablet computers while experimenting.

Keywords: Computer Supported Learning Environments, Multimedia and Hypermedia Learning, Digital and post-truth era

INTRODUCTION

In addition to an abundance of various digital tools, tablets, in particular, are increasingly being used in teaching. They are seen as a valuable addition to the use of digital media, especially in secondary schools. The wide range of different applications (apps) available for tablets make them versatile learning companions, whose simple and intuitive operation is particularly suitable for children and young people (Rikala, Vesisenaho, & Mylläri, 2013). In addition, the devices enable the creation of digital learning environments in which students can learn at their own pace and via various sensory modalities (Huwer, Bock, & Seibert, 2018). Tablets thus also have the great potential of providing individualised and comprehensive support for students in heterogeneous or inclusive learning groups (Meyer et al., 2014). However, with regard to the effectiveness of digital learning environments, firstly in chemistry lessons and secondly in the context of a heterogeneous student body, there is still a need for research (Hughes, Ko, & Boklage, 2017).

THEORETICAL BACKGROUND

Digital learning

Compared to traditional analogue media, digital media offer a number of new potentials for teaching and learning at school. On the one hand, they facilitate storing, processing, distributing and organizing information. On the other hand, they expand existing media by various factors. Through their *interactivity*, digital media enable, for example, the development of collaborative and synchronously editable projects, which are accessible to all learners and can be constantly supplemented with comments, notes, images, etc. Due to their *adaptivity*, it is relatively easy to adapt information to the individual needs of learners using digital devices. Based on their *multimediality,* digital learning offers the possibility to mediate content through different forms of representation and sensory modalities. Since auditory and visual information are processed in different cognitive structures, the simultaneous activation of several channels allows a better use of the learner's brain receptivity (Mayer, 2014; Petko, 2014).

At the same time, however, there are also limitations of digital learning: For example, the use of digital media may pose the risk of overloading the working memory of students as digital learning content often has a higher information density and complexity. Multimedia learning material should therefore be designed in such a way that learners can use their cognitive resources as efficiently and effectively as possible (Sweller, Ayres, & Kalyuga, 2011). Moreover, through their dynamic transitions and linked contents, digital media might mislead learners to just skim through the content without gaining a deep understanding of the learning content (Girwidz & Hoyer, 2018). Finally, it should be pointed out that digital media should not only be used to replace their analogue predecessors, because in such cases their diverse applications would remain unused. In school practice, however, this can still be observed to a great extent. Summarising, it can be stated that digital media have great potential, but do not lead automatically to better learning (Puentedura, 2006).

Digital-supported experimentation

Experiments are an elementary part of teaching chemistry. Digital media offer possibilities to support experimentation at school in different ways. Starting with the introduction to the experiment, digital media can have a motivating and introductory function. Possible options are playing a trailer or video or using online articles or comics (Huwer, Seibert, & Brünken, 2018; Kuhn & Müller, 2014; Sieve & Schanze, 2015). Video instructions or animations can also be used to plan and guide experiments. At the same time, it is possible to compile overviews of the required materials and equipment as well as to present the construction of more complex experimental apparatuses both statically and dynamically (Ardac & Akaygun, 2004; Huwer, Bock et al., 2018; Sieve & Schanze, 2015). Moreover, there are different possibilities of using digital media regarding the experimental procedure. Nowadays, there are various providers offering so-called virtual labs in which experiments can be simulated. Digital devices such as computers, smartphones or tablets make it much easier to carry out a wide variety of measurements to collect and evaluate data extensively and have it graphically displayed. Experiments that cannot be carried out at school can be integrated by showing video demonstrations of these experiments. However, digital media can also have a supporting and differentiating character during the experiment, for example by offering learning aids and additional information (Bresges et al., 2014; Huwer, Bock et al., 2018; Irwansyah, Lubab, Farida, & Ramdhani, 2017; Kuhn & Vogt, 2013; Sieve & Schanze, 2015). Finally, there are useful application possibilities for the documentation of experiments. Smartphones or tablets can extend experimental protocols with the help of their photo function. The audio recording function provides auditive storage of experimental documentations. At the same time, phenomena that happen too fast for the human eye can be recorded and slowed down with the slow-motion function, just as particularly slow chemical processes can be recorded and shortened with the time lapse function (Vollmer & Möllmann, 2018).

Universal Design for Learning (UDL)

Even today, school lessons are usually planned for an imaginary average learner, which is why most of the times only one common access to learning is provided for all students. However, for some learners this may create barriers that cannot be overcome without additional support. In contrast, a learning environment with universal accessibility offers different ways of overcoming these barriers or creates alternatives so that each learner can individually choose their path to successful learning. In this context, the approach of Universal Design for Learning

Principles		Provide multiple means of Engagement	Provide multiple means of Representation	Provide multiple means of Action & Expression
Guidelines	Access	1. Recruiting Interest	4. Perception	7. Physical Action
	Build	2. Sustaining Effort & Persistence	5. Language & Symbols	8. Expression & Communication
	Internalize	3. Self Regulation	6. Comprehension	9. Executive Functions
Goals		Purposeful & Motivated	Resourceful & Knowledgeable	Strategic & Goal Directed

Figure 3: The Universal Design for Learning (cf.

(UDL; CAST, 2011) from the USA, which is a concept for the design of inclusive teaching, offers great potential. The UDL is particularly distinguished by the production of flexible and varied teaching materials. Its main aim is to minimise barriers that learners might encounter in the classroom. The UDL is divided into three principles, each of which is subdivided into three subordinate guidelines (see Figure 1). Thus, the UDL table can be used as a kind of checklist when designing inclusive lessons, whereby not all guidelines necessarily have to be observed. Furthermore, digital media are very helpful to implement the UDL guidelines, as they offer a higher degree of flexibility compared to analogue media. Thus, they have the potential ofincreasing the individually adaptable support in school education (Edyburn, 2010; Rose, Hasselbring, Stahl, & Zabala, 2007).

RESEARCH QUESTIONS

In the context of this project, we focus on the following research questions:

Expertise Knowledge

Q1: Do the students increase their expertise knowledge?

Q1.1: Is the use of digital teaching materials differently effective in particular teaching phases?

Q1.2: Are there differences regarding the increase of the expertise knowledge when learning with exclusively digital or analogue teaching materials?

Attractiveness

Q2: How do learners rate the digital teaching materials compared to the analogue ones?

Cognitive Load

Q3: What influence do digital teaching materials have on the cognitive load of learners compared to analogue teaching materials?

RESEARCH DESIGN & TEST INSTRUMENTS

The following research design was developed in order to investigate the research questions. As depicted in Figure 2, the intervention is carried out in form of a project day at schools. The students of a class are divided into two comparable groups according to their expertise knowledge and cognitive skills, which are determined in the pre-test. At first, both groups receive a motivating introductory video. Afterwards, G1 continues to work digitally in the following two teaching phases, while G2 works analogously. In this way, a comparison between digital learning and learning with analogue learning materials in different teaching phases can be realised.

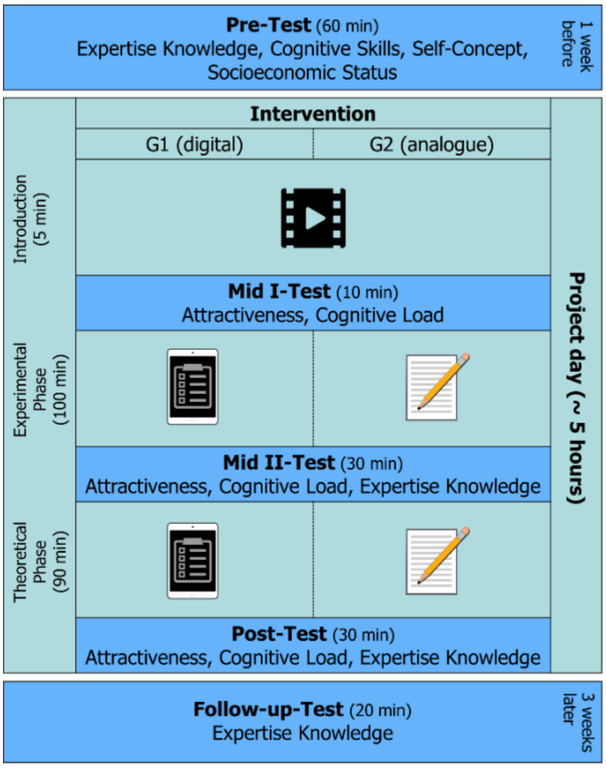

Figure 4: Research design.

The research questions are examined using various test instruments. One week before the intervention, an expertise knowledge test (24 items, α = .795) is carried out as part of the pre-testing in form of a multiple-choice test to assess the learners' prior knowledge. In addition to an intelligence test to determine the cognitive abilities (CFT 20-R; Weiß, 2006), a questionnaire to assess the school self-concept (Rost, Sparfeldt, & Schilling, 2007) and a questionnaire on the socioeconomic status (Torsheim et al., 2016) are carried out. Within the intervention, an attractiveness test (10 items, 6-point Likert scale, α = .871) as well as a cognitive load test (6-point Likert scale, 10 items, α = .834) in form of assessment sheets are used after the individual teaching phases. Moreover, the expertise knowledge test is conducted again after the experimental and theoretical phases in order to determine the effects of the individual phases on the learning growth of the students. Three weeks after the intervention, the follow-up test takes place in order to measure the long-term effects. Furthermore, the individual actions of the students working with the iPads are documented via screen recordings. Selected students working with the teaching materials are videotaped.

THE LEARNING ENVIRONMENT

Our study is conducted with students of the 8th grade of General schools (age group 13 to 14) on the subject of separating mixtures. The learning environment mainly consists of three phases: An introductory video, an experimental phase and a theoretical phase. Starting with the video, this is intended to provide a motivating leading-in to the topic, although no subject-related content is focused. After that, the experimental phase takes place, in which the learners carry out the different separation processes. The students work individually here. Each student receives an own experimental box and the corresponding teaching materials. After the experimental phase, the contents are taken up in more detail within the theoretical phase. Here the students are firstly provided with general information about the particular separation process. After this, the students can solve different tasks and finally have to summarise their newly acquired knowledge. In the theoretical and experimental phase, the students work with either an interactive iBook or with analogue paper pencil materials. These were designed in form of a workbook, which have identic content as the iBook.

FIRST RESULTS

In the course of this project, two pilot studies have been carried out so far, which is why in the following, we will contrast the results of both of them. Essential changes from pilot study I (PS I) to pilot study II (PS II) is the revision of the test instruments for evaluating the expertise knowledge, attractiveness and cognitive load. These have further improved with regard to their Cronbach's alpha values. In addition, within the framework of PS II, index cards were made available at the end of the theoretical phase for students who had finished this phase at an early stage. These index cards summarised the theoretical content.

Q1: Do the students increase their expertise knowledge?

Starting with the results for research question Q1 first regarding PS I, Figure 3 shows, that the expertise knowledge of both the digital and the analogue group has improved significantly in the pre-post-comparison (digital: $p < .001$, $\varphi = .75$, analogue: $p = .002$, $\delta = .62$). With regard to the increase within the individual phases, it can be observed that in the experimental phase, meaning from PRE to MID II, both groups learn significantly (digital: $p = .009$, $\varphi = .39$, analogue: $p < .001$, $\delta = .76$). In the theoretical phase, from MID II to POST, however, only the digital group learns significantly, while the analogue group stagnates (digital: $p < .001$, $\delta = .69$, analogue: $p = .618$, $\delta = .09$). In PS II, these findings cannot be observed. Here, both groups significantly improve their expertise knowledge in the experimental phase (digital: $p < .001$, $\delta = .81$; analogue: $p < .001$, $\delta = .70$) as well as in the theoretical phase (digital: $p < .001$, $\delta = .77$, analogue: $p < .001$, $\varphi = .57$).

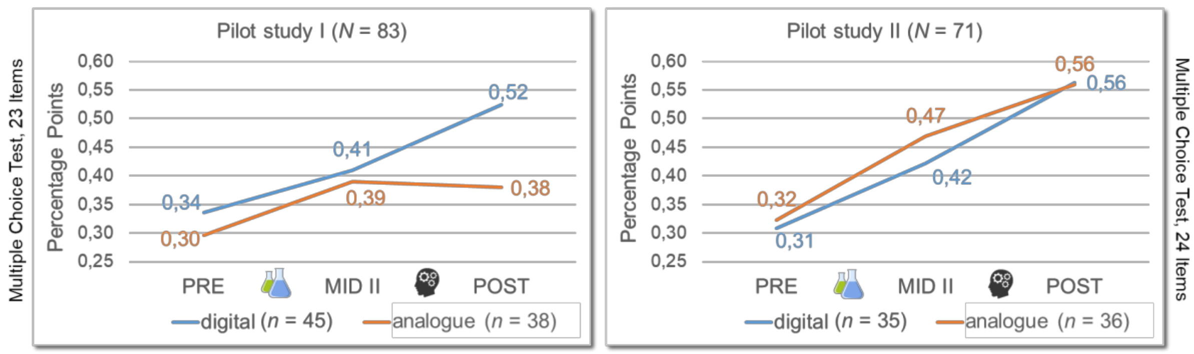

Figure 5: Results of pilot study I + II regarding expertise knowledge.

Comparing the digital and analogue groups, there is a significant difference between the two groups in the POST test of PS I ($p < .001$, $\delta = .76$). This difference, however, cannot be found in PS II ($p = .831$, $\varphi = .03$). It can be assumed that this is related to the use of index cards at the end of the theoretical phase of PS II, in which the analogue group could have learned a lot more from them compared to the digital group. As we took a closer look at these cards again, we noticed that the contents of the cards were very similar to the tasks of the expertise knowledge test, which could have led into "teaching to test". This might have concealed possible effects, which is why it can no longer be determined whether the increase in expertise knowledge is due to the learning environment or the final index cards. Furthermore, we suspect that the index cards were especially effective in the analogue group since they were an additionally provided medium to the workbooks. While the analogue group paid special attention to the new medium, the students working in the digital learning environment were only provided with additional pages containing digital index cards in the iBook. However, we can only confirm these results with certainty once we have evaluated the video and screen recordings. At MID II, after the experimental phase, there were no significant differences between the two groups in either of the two pilot studies (PS I: $p = .854$, $\varphi = .02$, PS II: $p = .233$, $\delta = .29$).

Q2: How do learners rate the digital teaching materials compared to the analogue ones?
In order to investigate research question Q2, an assessment sheet with a 6-point Likert scale was used to measure the attractiveness of the teaching materials, whereby the value 6 corresponds to the highest and 1 to the lowest attractiveness. As Figure 4 shows, both, PS I and PS II, show similar results: In principle, the students of both groups in both pilot studies rate the learning materials as attractive. Nevertheless, the experimental phase is rated slightly more attractive by all learners. In total, no significant differences between the digital and analogue groups could be identified, neither in PS I (MID I: $p = .853$, $\varphi = .02$, MID II: $p = .293$, $\varphi = .11$; POST: $p = .059$, $\varphi = .20$) nor in PS II (MID I: $p = .235$, $\varphi = .14$, MID II: $p = .085$, $\varphi = .21$; POST: $p = .916$, $\varphi = .01$).

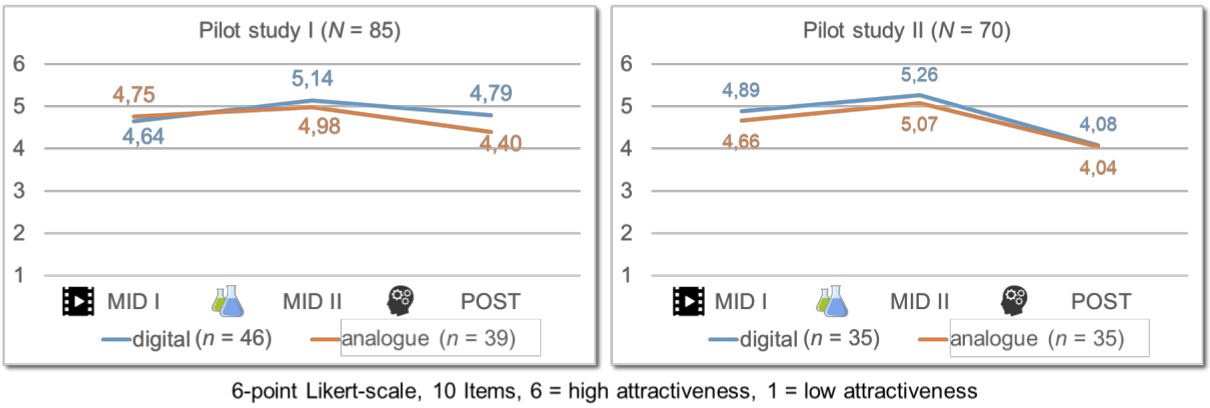

Figure 6: Results of pilot study I + II regarding attractiveness.

Q3: What influence do digital teaching materials have on the cognitive load of learners compared to analogue teaching materials?
Research question Q3 concerning the cognitive load was examined with a further assessment sheet, which was also based on a 6-point Likert scale, in which the value 6 corresponds to a low and 1 to a high cognitive load. Here, as well, the two pilot studies show similar results. Hence, Figure 5 shows that there are no significant differences between the digital and the analogue group in PS I (MID I: $p = .885$, $\delta = .03$, MID II: $p = .996$, $\varphi = .00$; POST: $p = .233$, $\varphi = .13$) as well as in PS II (MID I: $p = .953$, $\delta = .01$, MID II: $p = .165$, $\varphi = .17$; POST: $p = .725$, $\varphi = .04$). Both groups in both studies rate the experimental part as the least stressful part, followed by the theoretical part and the introductory video.

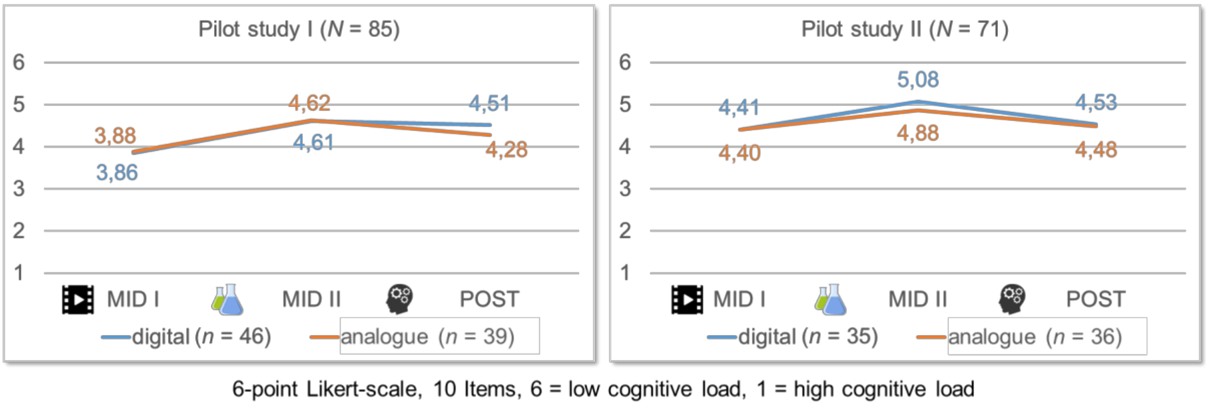

Figure 7: Results of pilot study I + II regarding cognitive load.

CONCLUSION

In summary, it can be stated that in terms of expertise knowledge, a significant increase could first be ascertained through the learning environment within both groups and in both pilot studies. What is striking is the very significantly better result of the digital group in the post test of PS I, which does not occur in PS II. This is probably related to the use of the mentioned index cards. As a consequence, the index cards are not used in the following main study. Furthermore, no significant differences were found between the two groups with regard to both the attractiveness of the teaching materials and the cognitive load when working with the materials.

Overall, these first results suggest that the use of digital media in both pilot studies did not have any negative effects in either case, but tend to have a positive influence on the learning outcome of the students. Regarding the increasing digitisation of German schools, this may dispel initial concerns about a decline in the quality of teaching. On the basis of these first findings, future projects can investigate how the potential of digital media can be fully exploited and how digitally supported chemistry teaching can be further optimised.

After the revision of the developed learning environment of the second pilot study, we have begun the main study of the project with a sample size of about 250 students, which will be concluded in February 2020. Moreover, the development of coding manuals for evaluating the screen and video recordings as well as the final analysis of the collected data after the main study are still pending.

ACKNOWLEDGEMENT

We would like thank to the participating chemistry teachers and the learners.

ARE SIGN LANGUAGE EQUIVALENTS FOR TECHNICAL TERMS REQUIRED FOR DEAF SCIENCE EDUCATION?

Miki Namatame[1], and Toshiyuki Kiriake[1]
[1]Tsukuba University of Technology, Tsukuba-City, Japan

Many technical terms are used in university lectures. However, the terminology of scientific disciplines is not often used in the common vernacular of the hearing-impaired community. We chose 100 technical terms related to information science. Of these, fifty nine percent of these terms were authorized.", but the remaining 41% did not have a sign language equivalent, or sign language expressions were not yet established. Therefore, in this study, by first focusing on the technical terms of information science, we created a Japanese sign language video dictionary for learning the technical terms used in science information. We continued the study with the following steps: 1) Identification of the technical terms used in information science. 2) Investigation of the common sign language signs for technical terms. 3) Filming of these signs. 4) Proposal of appropriate representation for classifier. 5) Building of the web video dictionary site. 6) Evaluation of the video dictionary site by users. 7) Improvement of the video dictionary site. Twenty-three sign language users evaluated the sign language video dictionary. Around 70% of participants answered that the sign language video dictionary for technical information science terms was necessary, and about 80% of respondents said that it was useful. Furthermore, many people (about 90%) answered that they could learn new technical terms in sign language. The sign language video dictionary of technical terms would be highly effective in science education for students who are deaf or hard-of-hearing. Sign language and CL (classifiers) can express invisible logic and the mechanical characteristics of objects. For that reason, sign language and CL can encourage anyone to understand science. A knowledge of technical terms in sign language and CL may lead to a scientific education based on a universal design perspective.

Keywords: Information Science, Sign Language, Video Dictionary, Universal Design

BACKGROUND

Despite the widespread use of sign language, the number of native signers in the world has not been accurately counted. The WHO said that "around 466 million people worldwide have disabling hearing loss, and 34 million of these are children" (WHO, 2019). Additionally, Michael (2006) reported that there are 250,000 to 500,000 American Sign Language users. The Japanese Ministry of Health announced that there are 60,000 Japanese sign language users (2008). We must seriously consider education and communication for people with hearing impairment.

Many technical terms are used in university lectures. Higher education institutions that target the hearing impaired in Japan have lectures conducted in sign language. However, the specific terminology of scientific disciplines is not often used in the common vernacular of the hearing-impaired community. The hearing-impaired students who attend a specialized class may not be able to understand the lecture. Alternatively, various sign language expressions may be made using the same technical term, and this may cause confusion.

Therefore, in this study, by first focusing on the technical terms used in information science, we create a sign language video dictionary for learning information science terminology through self-study before and after the lecture.

Similar projects have focused on American Sign Language (the ASL STEM Forum in 2019) and British Sign Language (the BSL Glossary project in 2019). Several specialized areas were covered, including mathematics; information and communication technology; physical science and physics, and meteorology. However, these kinds of international resources cannot be transferred to Japan, because Japanese sign language is very different. There is not yet a sign language video dictionary to contribute to science education for hearing-impaired students in Japan.

RESEARCH QUESTIONS

1. How many technical terms from scientific disciplines are there in Japanese sign language?
2. Do deaf students need the sign language video dictionary to aid in their science education in Japan?

PRODUCTION OF THE SIGN LANGUAGE VIDEO DICTIONARY

Design procedure

Science education has a very wide range; therefore, we limited this study to information science terms only. We carried out our research as follows:

1. Identification of the technical terms used in information science.
2. Investigation of the common sign language signs for technical terms.
3. Filming of these signs.
4. Proposal of appropriate representation for classifier.
5. Building of the web video dictionary site.
6. Evaluation of the video dictionary site by users.
7. Improvement of the video dictionary site.

1. Identification of the technical terms used in information science.

We selected 92 technical science terms using materials from information science and mathematics lectures. Deaf or hard-of-hearing students from the Department of Information Science at Tsukuba University of Technology were required to fill out the questionnaire. They decided on which technical terms to include in the dictionary and added the missing technical terms. In total, we selected 100 technical terms on information science.

2. Investigation of the common sign language signs for technical terms.

As a result, we found that 37 of these signs were posted in a dictionary, and 22 expressions were published on the Internet. These results indicated that 59% of all the technical terms were approved, while the remaining 41% had no equivalent sign, or no sign language expression had been established (Figure 1).

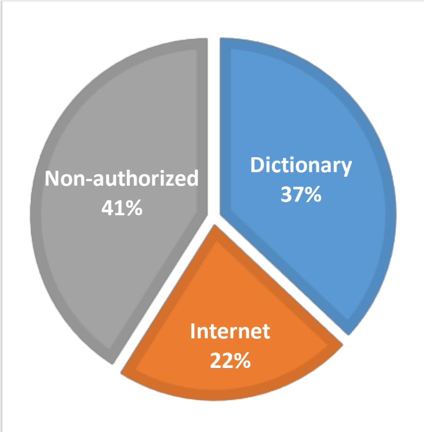

Figure 1. How many technical terms do we have in Japanese sign language?

3. Filming of sign language.

We represented the generic words in sign language dictionaries, but we needed to create the non-generic words by CL (classifier). To make the sign language easy to see, the performer wore a long-sleeved back shirt against a white background. Both M4V and MP4 file formats were prepared. MP4 made one file 8 MB or less. We edited the videos in both normal speed and slow motion. These videos were prepared from a front view and a side view.

4. Proposal of appropriate representation for classifier.

We needed to create the non-generic words by CL. What is CL? CL means classifier. The sign containing "handshapes in particular orientations to stand for certain semantic features of noun arguments" (Frishberg, 1975) came to be called classifier predicates (Lindell, 1977). The commonly recognized handshapes that are typically used to show different classes of things, shapes, and sizes are called "classifiers." Classifiers are basic elements of sign language, and they are widely used in deaf education. Classifiers share some limited similarities with the gestures of hearing non-signers. Those who do not know sign language can often guess the meaning of these constructions.

We assigned the following task to deaf students: express the technical terms "xx" with your fingers and arms. We recorded their ideas, discussed them together, and narrowed them down to one idea.

We give specific examples below (Figure 2). The definition of an electric circuit is "a complete electrical network with a closed-loop giving a return path for current. (Wikipedia)" The student said, "The CL on the left looks like paper. On the other hand, the CL on the right represents the path through which the current from the battery flows."

After narrowing them down to one idea, we conducted a questionnaire on the clarity of the proposed CL. An idea that received a rating of at least 3 points was adopted (Figure 3).

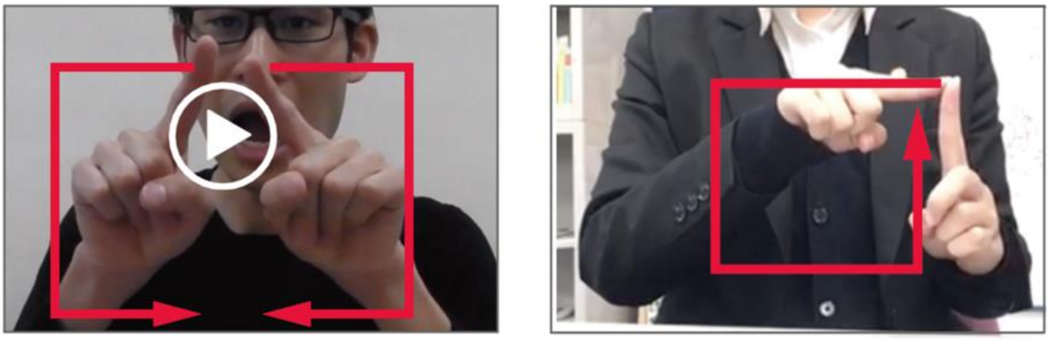

Figure 2. Proposed expression of "electric circuit"

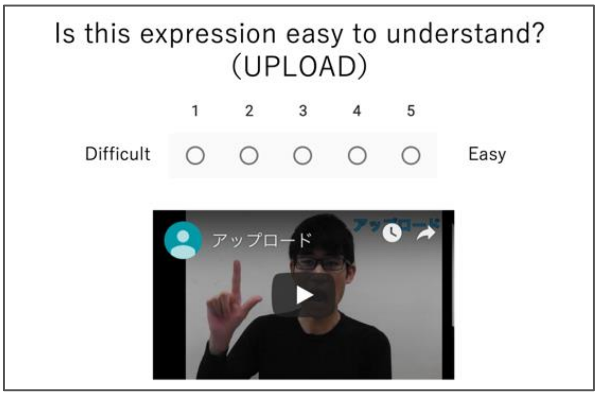

Figure 3. Screenshot of evaluation questionnaire.

5. Building the web video dictionary site.

We designed web pages where students could search the targeted sign language from a list of the Japanese alphabet. We explained how to sign particular words and the origin of the movements used to sign them.

6. Evaluation of the sign language video dictionary.

From November 16th to 30th, 2018, we conducted an online questionnaire using Google Form in order to evaluate the site prototype. In total, 23 students and teachers participated in this evaluation (14 university students, six junior high school students, and three junior high school teachers). All participants were sign language users.

7. Improvement of the video dictionary site.

The following revisions have been made in response to advice from participants. In addition to the Japanese alphabet list, an English alphabet list was created. Icons that were referred from Microsoft Word were also added to allow users to identify at a glance whether the sign language term was quoted from the dictionary or the original-CL (Figure 4, 5).

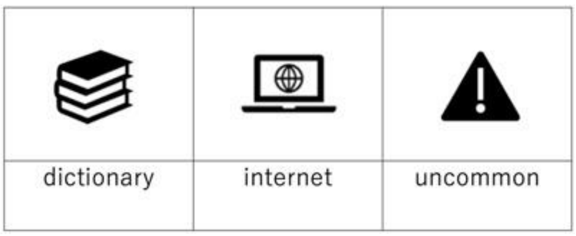

Figure 4. **Icons for citation sources**

Figure 5. Design of the web video dictionary

RESULTS OF THE EVALUATION

The results of user evaluation indicated that 78.3% of participants thought the sign language video dictionary was useful, 69.6% thought it was necessary, and 60.9% said they would like to use it (Figure 6).

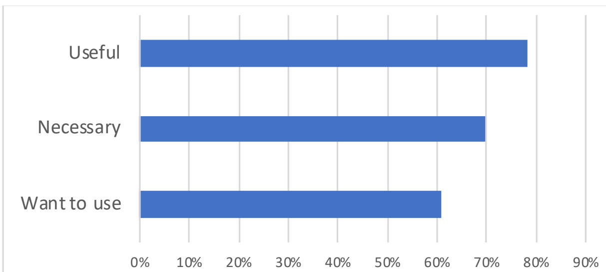

Figure 6. Comprehensive evaluation of the sign language video dictionary.

In evaluating the efficiency of the site, 95.7% of participants responded that its "operation was easy," while 78.3% of participants answered that it was "easy to see on-screen information" and 69.6% of participants answered that "I was able to find the necessary information at once." As for its effectiveness, 91.3% of participants answered: "I was able to learn new technical terms in sign language," and 82.6% of participants answered that "I could acquire new knowledge." Overall, 56.5% of participants were satisfied, and 65.2% of participants answered: "I would like to introduce this site to someone else (Figure 7)."

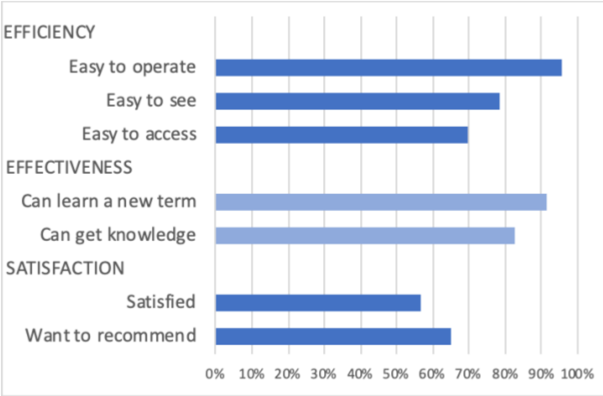

Figure 7. Evaluation of the usability of the sign language video dictionary.

To confirm that the site was easy to understand, the following three questionnaires were set. The results showed that 82.6% of participants answered that "the explanation of technical terms in the sign language video was easy to understand," 82.6% of participants answered that "the explanation of the motion and handshape were easy to understand," and 78.3% of participants answered that "the sentences about how to express sign language were easy to understand (Figure 8; Left)."

In response to the animated expression of the sign language terms, 47.8% of participants answered that "the slow-motion version is necessary" and 47.8% answered that "the voice data is necessary." Furthermore, 73.9% of participants answered that "the side view of the motion is necessary (Figure 8; Right)."

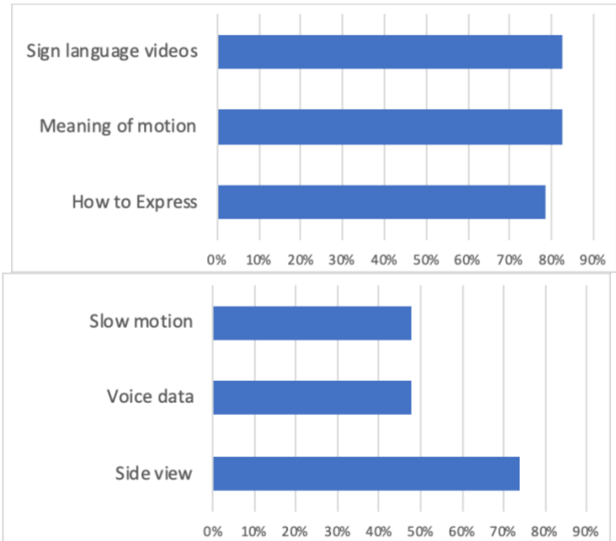

Figure 8. Left: Information on understandability / Right: Information on necessary elements

DISCUSSION

Around 70% of participants answered that the sign language video dictionary for technical information science terms was necessary, and about 80% of respondents said that it was useful. The results show that the sign language video dictionary was both necessary and useful for students who are deaf or hard-of-hearing. Furthermore, many people (about 90%) answered that they could learn new technical terms using sign language. This sign language video dictionary would be highly effective for hearing impaired students.

The sign language video dictionary we created was easy to operate and could provide information relatively efficiently. This dictionary was fine from a usability and information accessibility perspective. The level of understanding of information in sign language, including the original CL, was also high. However, as the satisfaction level was 57%, we think that there is a need for improvement. We understand that the slow-motion videos in sign language were unnecessary. Unfortunately, we do not know what caused the lack of satisfaction. Elucidating points for improvement need to be addressed as a future task. We plan to hold workshops to create a robust language while incorporating research from previous studies (O'Neill, 2016).

CONCLUSION

In Japan, 59% of technical terms for information science in Japanese Sign Language were authorized and 41% were not. Therefore, we designed the Japanese Sign Language video dictionary site using the original CL. Sign language video dictionaries for scientific information have proved necessary and effective for deaf and hard-of-hearing students. We were convinced that the development of a large-scale Japanese sign language science dictionary would be needed.

The sign language video dictionary of technical terms can be highly effective in science education for students who are deaf or hard-of-hearing. Sign language and CL (classifier) can express invisible logic and the mechanical characteristics of objects. For that reason, sign language and CL can encourage anyone to understand science. A knowledge of technical terms in sign language and CL may lead to science education based on a universal design perspective.

HOW STUDENTS COMBINE REPRESENTATIONS FROM DIFFERENT MEDIATIONS TO UNDERSTAND THE ELECTRIC FIELD CONCEPT IN ELECTROSTATICS.

Graciela Paz Meggiolaro[1], Agostinho Serrano de Andrade Neto[2]

[1] Federal University of Fronteira Sul, Cerro Largo, Brazil

[2] Universidade Luterana do Brasil (ULBRA), Canoas, Brazil

The use of simulations in Physics Teaching is effective in aiding the visualization and the correct understanding of the physical models, for example, in electrostatics. Therefore, with the use of a computer simulation (GeoGebra), this work aims to investigate the preferred mediation chosen by five undergraduate Engineering students when solving a problem of the intensity of the electric field. The Cognitive Mediation Networks Theory (CNMT) was used as theoretical referential. We used as methodology a qualitative analysis of the speech and depictive gesture produced by the students. Thus, our results indicated that through computer simulation, all five students appropriated the hypercultural representation of the software, establishing a relation between the distance of the charge and the electric field point. Nonetheless, the psychophysical mediation and social mediation is preferred to describe the concept of charge.

Keywords: Computer Based Learning, Physics, Video Analysis.

INTRODUCTION

It is argued that the study of physical phenomena related to electromagnetism is more prone to be an abstract than a mechanical, “hands-on” problem (Lopez & Silva, 2015). However, students' understanding of the physical phenomena involved still causes discomfort, due to some complex elements of visualization and the difficulty that students have in creating and using representations of the application of physics (Gire, 2014). In this sense, Kneubil & Ricardo (2014) point out that students may fully understand the theory, but there seems to be a great distance between formalism and reality.

According to Guisasola et al. (2008), there are few papers that analyze the phenomena of the electric charge whose focus is on the interpretation of the students in relation to the electric charge processes in a body, or that actually is interested in the understanding of the knowledge and cognitive skills that the students need to have to interpret these phenomena.

The students use common sense, being characterized by the lack of consistency in the analyzes in relation to different situations, and that the explanations have a lack of consistencies and scientific interpretations to describe the phenomena related to electrostatics (Furió, Guisasola and Almudí, 2004). According to Boss et al. (2009), although students have worked on the concept of electric charge in high school, they have confused conceptions and difficulties in explaining the concept when they encounter the discipline of General Physics in higher education.

The didactic use of computer visualization of eletromagnetic phenomena is reported to increase students' understanding and their ability to internally visualize microscopic and macroscopic electromagnetic representations, as is well-known in the science education literature (Pieper, F. C. & Serrano, A., 2016, did a review on the topic). In this article, we aims to investigate the preferred mediations evidenced by five students when solving a problem of electrostatics using the Cognitive Mediation Theory as theoretical referential. Do they have different preferred mediations when learning different concepts within electromagnetism?

THEORETICAL REFERENTIAL

In his Cognitive Networks Mediation Theory, Campello de Souza, Silva, Silva, Roazzi, & Carrilho (2012) indicates that cognitive development involves the interaction of an individual with objects and systems that have the ability to perform computations, being a process that involves the simultaneous emergence of internal and external mechanisms of mediation. The individual not only allocates the same computational resources, but also gains new concepts, where the new internal mechanisms present in the cognitive structure of the individual are named *drivers* (as employed in computation) that make possible the use of external mechanisms. The brain, to guarantee cognitive mediation with an external mechanism, formulates new specific competences that allow communication. For an integration between information processing carried out by the brain and external mechanisms to occur, computational devices that translate inputs and outputs are necessary, as if software were installed, "*device drivers*" that recognize and program external hardware. Cognitive mediation occurs by relating internal and external processes to the cognitive structure through internal mechanisms through individual knowledge and access and use of external mechanisms, enabling the acquisition of knowledge and development of the cognitive structure. In relation to mental images they can be static and can be dynamic, and drivers are associated with dynamic mental images, while static mental images are much more related to representations.

Regarding the levels of mediation, in Campello de Souza, Silva, Silva, Roazzi & Carrilho (2012), also detailed in Serrano et al. (2018), there are essentially four major levels of mediation: Psychophysical Mediation, related to the physiological characteristics of the subject with the composition of the object; Social Mediation, when interaction occurs with different people in the same environment; Cultural Mediation, implying the language and the capacity of society to report events involving categorizations of ideas and concepts; And Hypercultural Mediation, which uses access to technology, to the computer, to simulations, that is, there is use of technological tools. Therefore, when learning a new concept, students may make use of one or more mediations to make sense of it. Our research question is then: How students combine representations from different mediations to understand the electric field concept in electrostatics?

METHODOLOGY

The study was done in the first half of 2017, with five students of the Civil Engineering under graduation course. The methodology consisted of six stages that were explained below.

Pre-test: performed individually with four open problems, involving electric field concepts before computer simulation, aiming to investigate the students' initial knowledge about concepts related to the conceptual field of electrostatics. Essentially we progressively proposed problems that grow in complexity regarding the value of an electric field in a specific point of space (bidimensional), starting with a single charge and adding a second charge so the student had to calculate the resulting field at a given point, changing the charges signal.

Computer Simulation Guide: The activity guide was intended to guide pairs of students, performing the simulation while talking to each other, in the development of the proposed activity in GeoGebra, referring to the electric field. The activity was based on the P.O.E. (Predict-Observe-Explain) methodology, where the students had to first discuss on how to compute the electric field, then, which means to predict-observe-explain (Tao & Gunstone, 1999).

Simulation: The chosen simulation is available at <https://www.geogebra.org/m/eHyU8ZmU> according to figure 1, it refers to the content of Electrostatics, which is the study of charges at rest. In this simulation it is possible to visualize the electric field vector generated by the charges, which indicate the intensity and direction of the field.

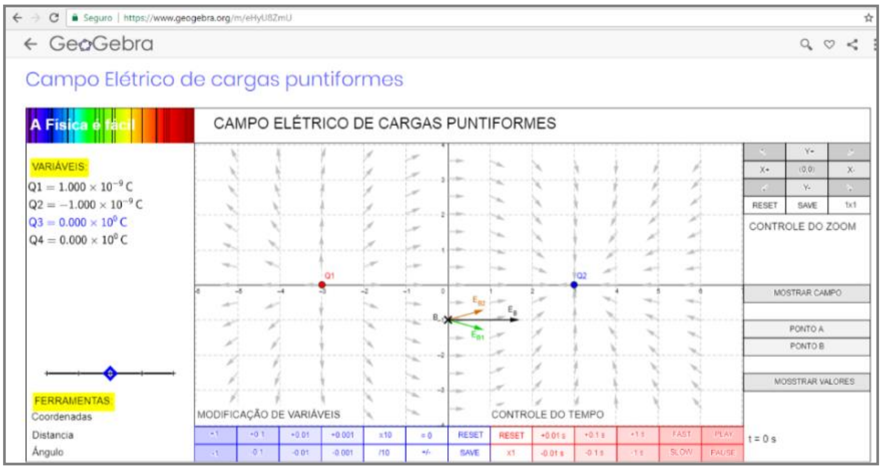

Figure 1. Computer similation used in the didactic activity. The charges can be changed and the student can interact with the position of the test point (X at the middle), while watching the resulting electric field changing. Source: https://www.geogebra.org/m/eHyU8ZmU

Post-test: the problem situations were similar to those of the pre-test, however, our objective was to find evidence in the construction and / or modification of mental images associated with the use of different external mediation mechanisms in the domain of problem situations.

Interview: Were recorded and were individual, we use the Report Aloud technique in which the student reports his thought process while answering questions, associated with the analysis of descriptive gestures. Ramos (2015), Wolff (2015), Trevisan (2016), Veloso (2017) and Meggiolaro (2019) used the Report Aloud technique, that is fully explained in Trevisan, Serrano, Wolff and Ramos (2019). and observed that even with a few days between the activity with the resolution of the questions and the interview, the student remembered the triggers he applied in the activity.

Transcription and gestures: Each student was renamed in order to identify them and preserve their original names. The interviews were transcribed and the images of the gestures were coded.

With the intention of analyzing the verbal language present in the production of data, we use the Discursive Textual Analysis proposed by Moraes & Galiazzi (2007), which involves identifying and isolating statements from the materials submitted to analysis, categorizing these statements and producing texts, integrating them into the description and interpretation, using the constructed category system as the basis for its construction.

Descriptive Gestural Analysis in relation to students' gestures, based on Mornaghan & Clement (1999) and Clement & Stephens (2010), in which they state that when students use hand movements they are suggesting dynamic images of mental simulations during the resolution of relative motion problems.

RESULTS

Our first main result is that the mental image that the electric field varies with distance is established by hypercultural mediation. More specifically, students 5, 6, 7, 8 and 9 internalized the hypercultural mediation derived from computational simulation to understand the relationship between distance and intensity of the electric field vector.

Evidence: The conception that student 5 (Figure 2) describes was incorrect (in the pre-test) in relation to the intensity of the vector, since, when we approach the electric charge, the module of the electric field vector is larger, not smaller: "*when I approached the point of charge (Figure 2), the vector diminished* "; "[...] That I understood, because I would take ... If I had a point here and a positive charge here, the positive charge, it repels. I departed off the (infinitesimal) point (charge). Then I learned that the vector departs off the charge". Making gestures to show the point and the charge at a certain distance.

Figure 2. Student 5 showing a depictive gesture referring to charge and point.

The mediation that the student employed to understand this relation was the hypercultural mediation because the student associates with the computer simulation, pointing out earlier in the interview "*the field line started from the charge. That's what I learned most from GeoGebra.*"

What student 5 indicated is explained by CNMT principles, when this theory concludes that brain capacity is limited and the brain naturally uses external tools that make it more capable to perform tasks. By using GeoGebra the student, to interact with the software, had to understand the graphic representation of the electric field vector while manipulating the position of the test point. By moving the test point (Figure 2) the student could see, in the simulation, the resulting electric field changing as it gets closer to each point charge. The essence of the CNMT is that, by interacting with the hypercultural tool, the student internalizes the operations made by the simulation (albeit partially), as *drivers*, and is able to use those *drivers* even without the presence of the simulation.

Student 6 responds that "it would be larger, the value of the intensity greater" (Figure 3); "... because the closer, the greater the electric field." We can see that the mediation was from the GeoGebra simulation - hypercultural mediation: "*I saw in GeoGebra, according to the charge a little higher, according to the slightly smaller charge.*"

Figure 3. Student 6 showing a depictive gesture referring to a vector.

Our second main result is that the mental image of charge is acquired by psychophysical, cultural and social mediation, depending on the student. Students 6, 8 and 9 internalized a psychophysical mediation taken from day-a-day objects while students 5 and 7 internalized a social mediation and/or cultural mediations from their previous classes.

Student 6 (Figure 4) describes the charge by relation to a truck: “for example, what is the load (charge and load are synonyms in Portuguese) of a truck? It is the weight of the truck! The load that the truck carries, the weight, is a value that it has assigned. A charge, a particle, is the little weight it has"

By means of gestures, the student 6 represented the displacement of the truck on the table. This comparison of the electric charge with a truck points to evidence of psychophysical mediation. Student 6 referred to her routine or common sense to relate the electric charge to the weight (load), that is, the electric charge is a property of the particle and the weight is related to the truck's load carrying capacity. Student 8 in a similar way associates the concept of charge to the representation of a quick animal (rabbit) while student 9 associate charge to the popular electrostatic experiment of using piece of papers being repelled after electrisation.

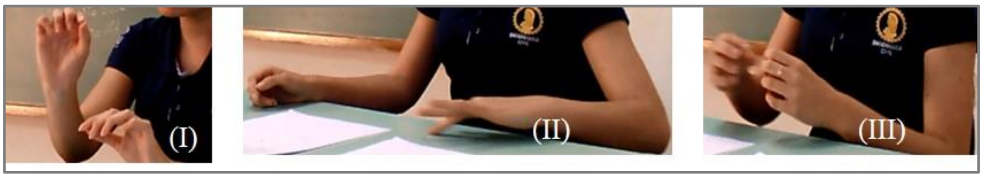

Figure 4. Student 6 showing (I) Gesture representing charge and point; (II) Dynamic gesture representing a truck running; (III) Static gesture representing weight.

Student 5 describes charges using representations that he developed from (high school) chemistry classes, social mediation from a teacher: “Charge, I think, an electron or a charge that has a ... A positive and negative, has sense of ... Charge, for me, it is ... It may be so. Charge, for me, are three types: the positive, the negative and the zero, right? Hence because I know that the positive donates and that the negative receives; the null is when it has the same level, same number of cations and ions.”

When asked whether this concept of charge is positive, negative or null, the student refers: “from the chemistry class, but then, I used knowledge of chemistry to do this”. In this fragment, we realized that the concept of charge was established by the chemistry class, possibly being a social mediation due to this interaction and evidence of hypercultural mediation by studying videos “Ah, I also watch videos, so I’ve already watched a lot of atomic bomb videos”, on YouTube.

Student 7 describes that an electrical charge can have “excess electrons or lack of electrons” and that, “if the two are lacking or excess, they will not interact; otherwise if it was a positive or negative charge. One has, the other does not ”. "Anything has a charge", and "it is like property, it has a material or a particle, [...] of each one". During the interview, when asked where we found electrical charges, he says:

Student 7: Oh, like, a stick like that, let's say there's a lot in the books ...

Researcher: Great. Do you remember any book where you saw that?

Student 7: Yeah, I remember a photo, a little bit over the top, a little thing with a ball, like this, fully charged.

Researcher: Great. Do you remember what book this is? In what book did you see this image?

Student 7: I don't remember the book.

Researcher: Yes, but when did you study this? Now, or when you were doing physics in high school?

Student 7: In high school.

Researcher: High school, the little stick with ..?

Student 7: Yes, with a ball.

Probably, the mental image that student 7 describes, with the stick, and, at the end, a ball with charges around it – is a classic representation commonly printed in Didactic Physics books, referring to the electrification processes by contact or by induction. We observed that the student used mental images acquired from cultural mediation, like a book, to explain the electric charge. And Social mediation, referring to High School Physics teachers.

DISCUSSION AND CONCLUSION

Our objective was to investigate the mediation evidenced by five students of higher education when solving a problem situation related to the intensity of the electric field. From the results aforementioned, answering the research question, we observed that different mediations – psychophysical and hypercultural or social and hypercultural are used combined to conceptualized the electric field produced by a charge. While the concept of charge is acquired by psychophysical and social mediations, the comprehension of the electric field is acquired using the hypercultural mediation. One could argue that the students, by using a concept of charge that is not related to electric field domain is "wrong" or showing an alternative conception, but the student can employ different representation and yet be able to correctly predict the qualitative behaviour of the electric field.

GeoGebra, used in this research, proved to be an excellent computational resource, being adequate to achieve the objective of this work, providing an effective tool in the visualization and in the correct understanding of the concepts involved in the resulting electric field vector, allowing to analyze and conjecture establishing hypotheses contributing for the student in expanding his knowledge.

And the interpretation of the gestures provided information that was not identified only through speech, since we found in the analysis the importance of the gestural and verbal association in the transmission of information, and through gestures it was feasible to analyze the actions expressed by the students in relation to to the concepts of electric charge, electric field lines, electric field vector, resulting electric field vector and electric force.

In the analysis of the electric charge, knowing that the intensity of the electrical interactions of a particle depends on the electric charge, we conclude that the articulated use of the external mechanisms of psychophysical, cultural, social and hypercultural mediation proved to be important, but social mediation stood out. learning the concept of electric charge, pointed out by four students.

INVESTIGATING STUDENTS' ACTIONS AND DISCUSSIONS WHEN EXPERIMENTING WITH PHYSICAL AND VIRTUAL MANIPULATIVES IN SCIENCE

George Olympiou[1], Zacharias C. Zacharia[1] & Tasos Hovardas[1]
[1]University of Cyprus, Nicosia, Cyprus

Many studies investigating the effectiveness of the use of physical and virtual manipulatives (PM, VM) and their combination for experimentation purposes revealed varying learning outcomes, which were attributed to PM and VM differing affordances. We examined how students' actions and discussions differed when they experimented with PM, VM, and a blended combination (PM&VM). An introductory science course on Light and Color was used. The participants were 22 undergraduate students of a university in Cyprus who were randomly separated into three conditions (PM condition, 7 students; VM condition, 7 students; PM&VM condition, 8 students). Data sources included whole group videotaped conversations (discussion between peers and between students and instructors), instructors' reflective/observation journals and screen captured data. A total of 12 meetings were analyzed (two meetings in each group of each condition). Data analysis involved both quantitative and qualitative methods and focused on coding and analyzing students' actions and discussions during experimentation. The qualitative analysis of actions/discussions in all conditions was combined with a Wilcoxon sign rank test, a Kruskal Wallis test and a correspondence analysis for comparing the three conditions. The analysis showed that students' actions and discussions appeared to be influenced by the means of experimentation in specific aspects. Specifically, the PM&VM condition enabled students to confirm and extend their observations because it offered them a wider range of affordances when experimenting, which in turn resulted in more rounds of experimentation. This implies that the means of experimentation were crucial for optimizing the actions that need to take place during experimentation and for establishing productive conversations among peers and between students and the instructors.

Keywords: Physical, Virtual, Experimentation

PHYSICAL AND VIRTUAL EXPERIMENTATION IN SCIENCE: THEORETICAL PERSPECTIVES

The extant research of the domain has documented the value of using Physical Manipulatives (PM) and Virtual Manipulatives (VM). In this line of research we define PM as real-world physical material and apparatus, whereas VM are defined as virtual apparatus and material in computer-based simulations (Brinson, 2015; Chen, Chang, Lai and Tsai, 2014; de Jong, Linn and Zacharia, 2013; Hovardas, Xenofontos and Zacharia, 2017; Hmelo-Silver, Liu, Gray and Jordan, 2015; Hsu and Thomas, 2002; Kapici, Akcay and de Jong, 2019; Zacharia and Anderson, 2003; Zacharia, 2007; Zacharia, Olympiou and Papaevripidou, 2008; Zacharia and Olympiou, 2011; Zacharia and de Jong, 2014). Olympiou and Zacharia (2012) studied prior comparative studies between PM and VM and attributed the differences in outcomes to their differing affordances (assets that offer the opportunity for an interaction with PM or VM in accordance with the ability of a learner to interact).

A series of PM and VM affordances are reported in the literature as unique affordances. For example, in the case of PM, physicality (kinesthetic use and active touch of concrete material) is reported as one unique affordance that the VM could not offer in a virtual learning environment (Zacharia, Loizou and Papaevripidou, 2012). On the other hand, a large number of unique affordances exist in the case of VM compared to PM (for examples see Smetana and Bell, 2012 and Zacharia, 2015). In an effort to resolve issues resulting from the deficiencies of PM experimentation in physical learning environments, a number of VM unique affordances were developed and implemented in VM manipulatives. Parameters and variables from the physical world that couldn't be altered, simplified or augmented through PM, could now become a reality and be manipulated through the use of VM (e.g. studying the consequences of the greenhouse effect under extreme temperatures and gas emissions). Based on a gamut of affordances offered both from PM and VM, many researchers argued in favor of blending the affordances of the two means of experimentation in an effort to take advantage of the maximum number of benefits (for example see Olympiou and Zacharia, 2012).

Despite the fact that research has shown that the presence of PM and VM can be vital for studying complex scientific phenomena/systems (e.g., Brinson, 2015; Zacharia, 2015) and has revealed a positive impact on their content knowledge performance, we know very little about how PM and VM affect students' actions and discussions while experimenting and how these in turn relate to their learning. In other words, researchers have not yet thoroughly examined the experimental procedures/actions that students follow and their discussions during experimentation and how these relate to their science learning. Any effort in understanding science laboratory experimentation's effect on student learning must involve, among others, an understanding of how PM and VM affect students' actions and discussions.

THIS STUDY

The main purpose of this study was to investigate students' actions and discussions, who used either PM alone, VM alone or a combination of PM with VM (PMVM) for conducting the same experiments and compare those, while having in mind the counteractive results emerging from the literature regarding the effectiveness of both PM, VM and their combination. The students' actions while experimenting, were coded and analyzed, based on three main axes, namely: a) the type of activity that is customarily defined by the curriculum material or at some point, defined by the inquiry or procedural issues the students tend to follow, e.g. experimentation, completion of worksheets etc., b) students' interactions, and c) student-teacher interactions.

The study followed the Physics by Inquiry curriculum (McDermott and The Physics Education Group, 1996) in order to compare students' actions and discussions along PM, VM and a blended combination of PM and VM experimentation, in the domain of Light and Color.

The main purpose of this study was to examine: *How do student actions and discussions compare, when experimenting with the PM or VM alone, or with the use of a blended combination of PM and VM?*

METHODS

The sample of the study comprised of undergraduate students of a university in Cyprus, who enrolled in an introductory science course. The sample was drawn randomly. In total, 22 out of 70 participants were randomly selected and separated into three conditions: PM condition (7 students); VM condition (7 students); and PM&VM blended combination condition (8 students). These participants had never taken college physics prior to this study. The students in all conditions worked collaboratively, after they were randomly assigned to subgroups of three or four persons, as suggested by the curriculum of the study (McDermott *et al.*, 1996).

The study's curriculum focused on the colored light section by McDermott et al. (1996). For the purposes of this study, two experiments were analyzed. The first experiment was on mixing colored light and colored paint. The second experiment focused on having colored light passing through color acetates and prisms. The rationale behind the selection of these two experiments was for the students to develop an understanding of the nature of the colored light.

PM involved the use of physical materials and instruments in a regular physics laboratory, whereas VM involved the use of the virtual laboratory *Optilab* (Hatzikraniotis, Bisdikian, Barbas, & Psillos, 2007). The blending of PM and VM followed the Olympiou and Zacharia (2012) framework.

Procedure

All participants were familiarized with the materials and the instruments, either PM or VM, before engaging in any of the experiments. During experimentation, the role of the instructor was supportive in terms of engaging students in dialogues and enacting their experiments (actions). All conditions shared the same instructors. The duration of the whole study was 13 weeks, whereas, the duration of the two experiments at task was 2 weeks. All students, regardless of condition, worked in a science laboratory that included both the PM and VM needed for the study.

Data Collection and Analysis

The study's data sources involved group videotaped conversations, instructors' reflective journals and screen-captured data. The unit of analysis was single utterances, derived from students' and student-teachers' conversations, which were first examined and analyzed separately and, second, each utterance received a single code. A total of 744 minutes of conversations were analyzed, corresponding to 12 meetings overall. Data analysis focused on coding and analyzing qualitatively students' actions and discussions during experimentation. The video data analysis involved the open-coding scheme of Chin (2006). A quantitative analysis was also conducted using the categories that emerged through the qualitative analysis (i.e., Wilcoxon sign rank test; Kruskal Wallis test; correspondence analysis).

RESULTS

Students elicited different actions across conditions (e.g., during experiment observations) and discussions. In particular, the PMVM students were found to have made more direct observations during the first experiment than the other two conditions. Our analysis also revealed that PM&VM students discussed longer than their peers in the other conditions in the first experiment. In the second experiment, no such differences were found. The same pattern emerged during the discussions between instructors and students.

The qualitative analysis revealed differences among the three conditions in students' actions during both experiments. Specifically, our analysis revealed that students using both means of experimentation would compare their direct observations, conducting each mixture of colored light with both manipulatives and then reaching to a result, which was noted down before proceeding to the next test/observation. Using both means in conducting each mixture of colored light was mostly evident during the first experiment, despite the fact that this was observed to a lesser extent during the second experiment also. In particular, when secondary colored light beams were mixed, students of the blended combination condition used both VM and PM, despite the fact that they were called to use only VM for that specific part of the experiment. Additionally, when PM students experimented with setting up the first experiment, in terms of arranging the colored light beams in front of a screen, certain difficulties emerged which called for the instructors' assistance. Students using VM did not confront any of these difficulties. Interestingly, PMVM students, despite the fact that they were using both manipulatives, managed to solve such difficulties emerging from the concrete use of PM on their own, by just watching how the set up was arranged at the virtual environment. Again, this was not called for by the curriculum used. For the purposes of this study, the discussion analysis between the three conditions was quantitative.

The quantitative analysis further revealed a pattern in favour of the PMVM condition, which presented highest counts in several variables (see Table 1). For instance, students in the PMVM condition made more observations (*Kruskal-Wallis Chi-square* = 14.38, $p < 0.001$), formulated more scientifically valid (*Kruskal-Wallis Chi-square* = 12.63, $p < 0.01$) and invalid statements (*Kruskal-Wallis Chi-square* = 13.46, $p < 0.001$), and had more questions on content for their peers (*Kruskal-Wallis Chi-square* = 13.81, $p < 0.001$) and instructors (*Kruskal-Wallis Chi-square* = 14.62, $p < 0.001$). These variations disappeared after the first experimentation. No statistical difference among conditions was computed in the second experimentation, which seemed to come along with a homogenization of student performance and behaviour across conditions (see Table 2). Indeed, Wilcoxon signed ranks tests revealed a number of significant trends, which reflected such a convergence among conditions. For example, there was a decrease in the number of observations (*Wilcoxon Z* = -2.10, $p < 0.05$) questions on content (*Wilcoxon Z* = -2.52, $p < 0.05$) and experimentation for peers (*Wilcoxon Z* = -2.20, $p < 0.05$) in the PMVM condition.

Characteristic Features for PM, VM and their Combination

To examine which variables were singled out as characteristic features for each condition, we performed a correspondence analysis. The biplot of the correspondence analysis is presented in Figure 1. Conditions are shown in black cycles and variables describing student performance and behavior are portrayed with white cycles. A first remark is that both experiments were placed quite close along the plane for each condition. To explain the positioning of conditions relative to variables, we need to take into account the projections of each point on the axes (i.e., coordinates). In this regard, conditions are characterized by the variables, which have the largest projection on the axis along which conditions have been positioned.

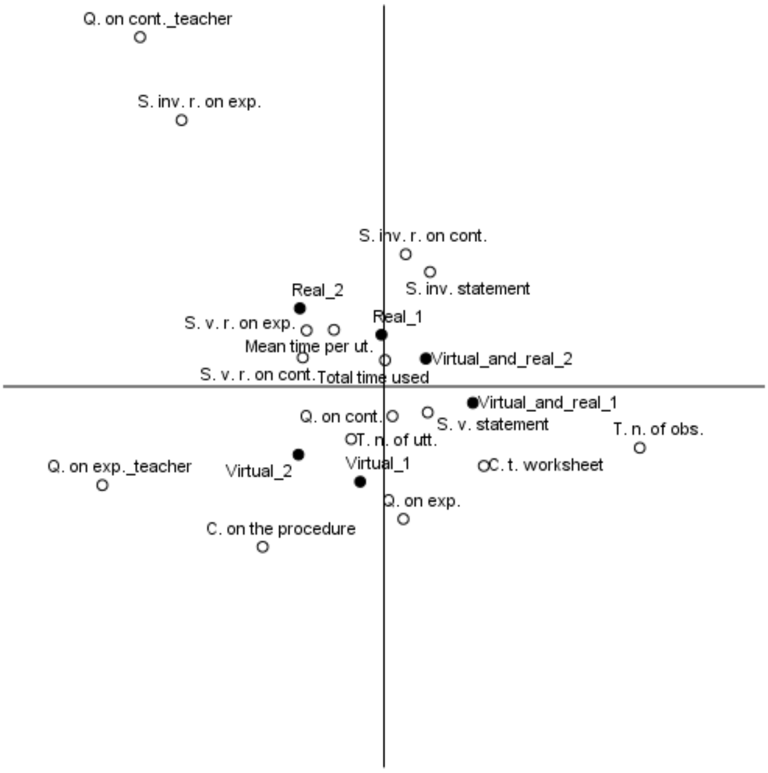

Figure 1. Biplot displayed by the correspondence analysis. The horizontal axis explained 45.3% of variance in data, while the vertical axis explained another 26.3% (cumulative variance explained = 71.6%). Black cycles depict conditions in the first and second experiment (denoted by numbers), while white cycles depict variables examined: T. n. utt. = Total number of utterances; Total time used; Mean time per utt. = Mean time per utterance; T. n. of obs. = Total number of observations; C. t. worksheet = Completing the worksheet; C. on the procedure = Comment on the procedure; S. v. statement = Scientifically valid statement; S. inv. statement = Scientifically invalid statement; Q. on cont. = Question on content; S. v. r. on cont. = Scientifically valid response on content; S. inv. r. on cont. = Scientifically invalid response on content; Q. on exp. = Question on experimentation; S. v. r. on exp. = Scientifically valid response on experimentation; S. inv. r. on exp. = Scientifically invalid response on experimentation; Q. on cont._teacher = Question on content addressed to the teacher; Q. on exp. teacher = Question on experimentation addressed to the teacher.

Despite the homogenization among conditions after the second experiment, which has been underlined in the previous section, there were still a number of dimensions, which were relatively more pronounced in each condition. For instance, the condition that involved both virtual and real experimentation was placed on the positive part of the horizontal axis and it was characterized by an increased number of observations. The conditions including PM or VM only were allocated to the negative part of the horizontal axis and they were marked by questions addressed to the teacher, either on content (upper left quartile) or on experimentation (lower left quartile), respectively. Overall, the horizontal axis may be conceptualized as distinguishing student interaction with the learning environment, which was indicated by number of observations for the condition using both PM and VM, from student interaction with instructors, which was pronounced for students who have used PM or VM only.

Students engaged in real experimentation seemed to have voiced an increased number of invalid statements or invalid responses on experimentation and content (positive part of vertical axis). On the negative part of the vertical axis, students performing virtual experimentation seemed to have focused on procedural aspects (comments on the procedure; questions addressed to peers and the teacher on experimentation). Taken together, the vertical axis distinguished invalid statements of responses, associated with the condition that included PM only, from elaborating on the procedure (linked to the condition that used VM only).

CONCLUSIONS/SIGNIFIGANCE

The most important aspect of this study was that the PMVM condition was found to cause more rounds of experimentation. Given this, we conjecture that this repetition may have increased student confidence in terms of the validity of their results, since the same results emerged using different means of experimentation. Additionally, students in the PMVM condition raised more questions concerning the conceptual aspects of the topic at task and spent more time elaborating on them in peer discussions or discussions with the instructor. The latter when combined with the former appears to portray a pattern, in which more rounds of experimentation result in more actions and more discussions related with the learning objectives at task. One explanation could be that the presence of VM in the PMVM condition may have worked as a catalyst in resolving procedural issues (e.g., set-up issues) and thus allowed students to focus on the conceptual aspects at hand (see also Olympiou and Zacharia, 2012). This kind of findings are in line with research studies advocating in favor of VM, based on their unique affordances and their effect on conceptual understanding (Olympiou, Zacharia and de Jong, 2013). On the other hand, students in the PM condition, were found to spent their time mostly on procedural than conceptual issues. Thus, valuable discussion time was spend on non-important issues.

The homogenization of student performance and behaviour among conditions in the second experiment may imply that the distractions found in the first experiment, were resolved for all three conditions. This means that the actions and, especially, the discussions followed in experiment 2 were about the same. This underlines the necessity to resolve any possible distractions for the students as early as possible during their experimentation journey.

Overall, this study showed that different means of experimentation have a different effect on student actions during experimentation (e.g. making more observations, enacting more inquiry cycles) and for establishing productive conversations among peers and between students and instructors (Olympiou and Zacharia, 2012; 2014), at least when the affordances of the manipulatives do not support the students in resolving and handling distractions that relate to the enactment of their experiments (e.g., the messy nature of PM). Of course, additional research is required to reaffirm these results across several science domains.

INVESTIGATING ONLINE OPEN FORUMS AS EDUCATIONAL SPACES FOR HAZARDS LITERACY LEARNING

Kathryn Rende[1], M. Gail Jones[2], Rebecca Ward[3]

[1]NC State University, Raleigh, United States

[2]NC State University, Raleigh, United States

[3]NC State University, Raleigh, United States

Research has begun to investigate how discourse on social media sites influences risk perceptions and decision-making surrounding natural hazards like hurricanes, but little work has been done to define these spaces as learning environments where natural hazards literacy can be developed. In this study, qualitative interviews and comprehensive content analyses of two hurricanes-centered forums on the social media site Reddit were conducted. With a focus on discourse and communication surrounding hurricane-related imagery, this paper provides insight on Reddit as an informal learning environment and documents common inaccurate information and gaps in public knowledge related to disaster impacts.

Keywords: weather, public science, informal education

The ability to accurately interpret probabilistic information like forecast models and other weather visualizations is one of the factors, along with socioeconomic constraints, demographic patterns, and cultural preferences that influence public decision-making about the risks associated with hurricanes (Morss et al., 2017). However, many of the technical images that depict a storm's potential path, like spaghetti models or the cone of uncertainty model, are easily misunderstood (Broad et al., 2007). Misinformation can be easily misjudged and, in cases where it is re-communicated in social settings, can lead to a cascading spread of distorted interpretations from person to person resulting in under or over inflated perceptions of risk within groups or communities (Morss et al., 2017). An example of this was seen in the public communications about the risks associated with Hurricane Florence in 2018. The hurricane became a national example of the shortcomings of the Saffir-Simpson Hurricane Wind Scale which categorizes hurricanes by wind speed (de la Garza, 2018). This measurement alone supplies little information about the strength of the storm or potential to cause damage, yet is most often conflated with perceived risk (Agdas & Webster, 2012). Though it made landfall as a Category 1 storm, Florence dropped over 35 inches of rain causing nearly $17 billion dollars in damages in North Carolina alone (Stradling & Bennett, 2018). The storm's track was well-forecasted by the National Hurricane Center, but its intensity, and consequently the magnitude of its impacts, proved to be a challenge (Stewart & Berg, 2019). These factors — the storm's long life over the ocean, its potential for landfall in the Carolinas, and the uncertainties with its intensity and impacts sparked a social media frenzy and sent waves of viral misinformation surging ahead of the storm (Bonazzo, 2018). Florence-related posts on social media sites like Facebook and Twitter ranged from doctored images of sharks swimming up flooded highways, to the more alarming re-communication of erroneous risk-related interpretations of the forecasts and models which consequently downplayed the potential for damage to life and property (Bonazzo, 2018).

Rationale

Though researchers have begun to investigate how evolving information and social interactions on social media platforms influence people's risk interpretations and decision-making (Morss et al., 2017), little work has been conducted to explore or define these social media spaces as learning environments where knowledge and literacy surrounding natural hazards and environmental risks can be fostered. By investigating the way hazards like hurricanes are communicated via social media, this research examines how social media platforms, particularly open online forums like Reddit (described further below), act not only as spaces where social communication of information exists, but also as venues of social learning where conversations about particular topics contribute to both individual learning and group practice (Haythornthwaite et al., 2018).

This comparative case study analyzed the ways in which communities of users engaged with visual content in two hurricanes-related subreddits. Through content analysis of user engagement with hurricane-related imagery, this study a) supports and draws additional conclusions about the platform's categorization as a learning environment, b) assesses the accuracy of public interpretations of hurricane related imagery, c) identifies common themes in erroneous information presentation, and d) documents evidence of correction or amplification of misinformation. Qualitative interviews conducted with Reddit participants yielded further insight about user preferences for information seeking and image sharing. The following research questions were asked in order to investigate the roles that online social learning environments like Reddit play in facilitating hurricane and hazard-related image literacy learning:

1. What patterns of discussion, knowledge-seeking, and knowledge dissemination exist in hurricanes-specific subreddits?
    a. Do these patterns differ from patterns of online discourse previously established by the literature?
2. Can specific learning outcomes be documented within these conversations?
3. How do Reddit users determine the validity of visual information on Reddit and what are their preferences and rationales for types of images sought and shared?

CONCEPTUAL FRAMEWORKS

Social learning on Reddit

Online communities constructed within social media platforms like Twitter and Facebook that have greatly influenced not only learning environments, but the roles and behaviors of learners and educators who construct learning experiences (Gruzd et al., 2016). Social media has become a space where users can seek new learning experiences under their own direction and in collaboration with others. User-constructed learning spaces like the online open forum Reddit offer information-seekers an opportunity to come together to solicit and supply resources related to shared interests. Reddit in particular has been established as a platform for examining learning practices because its "user-generated and participatory online culture" (Haythornthwaite et al., 2018, p. 1936), allows individuals to engage in sense-making through connecting resources and actively constructing "learner-generated contexts" (Luckin, 2010 as cited in Haythornthwaite, et al. 2018, p. 1934) that support individual and group knowledge (Gunawardena, Lowe, and Anderson, 1997).

Within subreddits, the questions solicited and the answers supplied form the basis of a participant-led discussion structure that is contributed to, and moderated by, members of the site. Posts are organized categorically by way of user-created discussion boards called subreddits. These subreddits or "subs," can be created for nearly any conceivable topic. Redditors (users of Reddit) subscribe to subreddits of interest and contribute content or commentary. User posts within each subreddit are not sorted and presented based on chronology or by a computational algorithm like Twitter, Facebook or Instagram. Instead, Reddit relies on Redditors to vote posts up or down. This creates a hierarchical presentation of the most popular posts and rewards users who submit high-impact content and adhere to the appropriate social rules and norms of the site, or "reddiquette" (Anderson, 2015). Users not only have the ability, but the expectation, to comment on, correct, and argue about information presented by others and to then further group knowledge and learning by providing citations to sources and further additional resources (Anderson, 2015; Haythornthwaite et al., 2018; Moore and Chuang, 2017).

METHODOLOGY

This cross-case analysis focused on two weather-related subreddits as unique cases in which user-developed hazards literacy learning occurs. The data collection process consisted of two dual-part phases: 1) a two-part comprehensive content analysis to investigate a) social learning processes and b) outcomes, followed by 2) a series of a) structured and b) semi-structured interviews. Together, these procedures provided an in-depth understanding of the ways the Reddit community communicates, interprets, and engages with images associated with hurricane-related risks.

Data Collection

Content analysis. A purposive sample of publicly available comments within two subreddits, HurricaneFlorence and TropicalWeather, was selected. Within each subreddit, new, or parent, posts consist of either an image and corresponding title or text and corresponding title. Because this research investigated communication and outcomes related to visual imagery, only comments nested within parent posts containing an image were selected for comment coding. Qualifying images included ''iconic'' representations, such as maps of impact, and ''indexical'' images, such as photographs of on-the-ground conditions (Messaris, 1997 as cited in Rickard et al., 2017, p. 472). Memes were excluded from this analysis. Because the TropicalWeather subreddit contains posts related to a number of storms, only those that directly referenced Hurricane Florence were included. Additionally, posts were constrained by date from the time that Hurricane Florence became a sustained hurricane (September 9, 2018) to the date it was downgraded from a tropical depression to a post-tropical cyclone (September 18, 2019). Based on the precedent set forth by Haythornthwaite et al. (2018), one percent of the total number of comments for HurricaneFlorence (*n*=99) and TropicalWeather (*n*=582) were coded.

Table 1. Subreddit descriptive statistics

Subreddit Community	Number of Moderators	Number of Subscribers (at the time of data collection)	Number of Total Comments in Purposive Sample	Coded Sample (1%)

HurricaneFlorence	3	2,300	9,894	99
TropicalWeather	10	62,200	58,167	582

Interviews. Due to the open nature of Reddit and its structure as a discussion and resource board, the interview protocol for this study was centered around the forum model of computer-mediated communication (Salmons, 2012). An invitation to participate in this study was posted in each subreddit along with an initial set of structured, exploratory questions centered around the types of images being shared. A semi-structured follow-up procedure was pursued with all participants who responded to the initial query. In total, ten users responded to the questions in the initial post, with nine agreeing to take part in a second stage that included an interview. Methods of response varied between users, with three responding to initial posts via private message (one of these requesting to conduct the interview via email), and the other six answering the initial and follow-up questions within the thread of the original public post.

Analyses

In the first stage of content analysis coding, comments were evaluated for communication and discourse patterns according to the 'learning in the wild' coding schema established by Haythornthwaite et al. (2018). In the second stage, the same comments were coded for the accuracy and validity of scientific claims or explanations. Two researchers (one a university climatologist and the other an education/communication researcher) independently coded the online social discourse for processes and patterns, and 2) accuracy and validity of hazards-related scientific claims or explanations. Interrater reliability testing was conducted for 20% of the comments with Krippendorf's Cu-Alpha coefficients of 0.93 and 0.85 respectively. The thematic analysis of interview data was conducted by organizing excerpts from the interview transcriptions into thematic categories and utilizing a priori and emergent codes related to user's self-assessments of learning outcomes and processes. Participants were asked about their preferences and rationales for sharing iconic versus indexical images and how they determine validity in the information they both seek and find on Reddit.

Content Analysis for Learning Processes and Patterns. The 'learning in the wild' coding schema was developed with the purpose of describing the different types of discourse, exploratory talk, and conversational dialogue occurring in online open forums (Haythornthwaite et al., 2018). To develop the codes, researchers documented variation in conversation and discourse patterns across four 'Ask'-style Reddit domains: 'askscience,' 'Ask_Politics,' 'AskAcademia,' and 'AskHistorians.' These subreddits function as knowledge-focused informal learning environments where users seek and supply scholarly information and are generally comprised of both experts and non-expert subscribers (Moore and Chuang, 2017). Haythornthwaite et al. (2018) determined that comments on Reddit generally fall within three categories of purpose: Explanation, Socializing, or Information Exchange. Explanation and Socializing can be further subdivided around central trends of emotionally positive, negative, or neutral valence, while Information Exchange is described as pertaining to either seeking or providing resources. A final code for Rules and Norms describes communications related to internal Reddit culture or "reddiquette." The full codebook included: Explanation with *Disagreement*, *Agreemen*t, or *Neutral Presentation*; Socializing with *Negative* or *Positive Intent*; *Information Seeking*; *Providing Resources*; and *Subreddit Rules and Norms*.

The TropicalWeather forum examined here functions similarly to an 'Ask'-style subreddit where subscribers engage in ongoing discussions related to the general topic of tropical weather as well as event-specific topics like individual storms or phenomena. Weather events around the globe are featured in this subreddit, and storms are often discussed regardless of whether or not landfall is projected. Additionally, knowledgeable others and experts are encouraged to self-identify with Reddit flair (markers or 'tags' that can be attached to a post) as a way of adding additional validity to scientific claims or explanations. By comparison, the Hurricane Florence forum was created specifically for information-sharing related to the isolated weather event. The subreddit was created when the storm was forecasted to have impacts on the United States and remained active through the duration of the event and for some time after as post-storm impacts were still being observed. Although these subreddits have similar purposes and rules related to civil engagement and expectations of accurate information, differences in posts may exist due to the structure and function of the subreddits, particularly if those differences pertain to the initial development of the subreddit as a space for academically-focused inquiry, the presence of experts within the community (Moore and Chuang, 2017) or expectations for group maintenance and civic engagement (Haythornthwaite et al., 2018).

Content Analysis for Accuracy and Validity of Hazards-Related Information. In order to assess communication specifically related to image literacy, comments in the two subreddits were open coded for accuracy of scientific concepts or principles and common themes related to misconceptions or naive conceptions of scientific processes were identified. Correction or amplification of misinformation was also documented and coded for accuracy and validity.

RESULTS

Conversational Processes and Patterns

The analyses of the HurricaneFlorence and TropicalWeather subreddits revealed unique patterns in the types of discourse and engagement presented in each community (see Table 2). Explanations with Neutral Presentation, Information Seeking requests, and mentions of Subreddit Rules and Norms were similar across both HurricaneFlorence (7%; 11%; 0%) and TropicalWeather (8%; 12%; <1%). TropicalWeather contained a substantially larger percentage of comments with positive valence including Explanations with Agreement (32%), and Socializing with Positive Intent (30%). Patterns within HurricaneFlorence indicate a community that engages in positive (19%) and negative (24%) social discourse with similar frequency, but presents more counter arguments or disagreements to previous comments (21%) compared to subscribers of TropicalWeather.

Table 2. Results from "learning in the wild" content analysis schema application

	Frequency of comments in HurricaneFlorence	Frequency of comments in TropicalWeather
Sample Size	99	582
1. Explanation with Disagreement	21 (21%)	54 (9%)
2. Explanation with Agreement	14 (14%)	185 (32%)
3. Explanation with Neutral Presentation	7 (7%)	47 (8%)
4. Socializing with Negative Intent	24 (24%)	21 (4%)
5. Socializing with Positive Intent	19 (19%)	177 (30%)
6. Information Seeking	11 (11%)	71 (12%)
7. Providing Resources	12 (12%)	36 (6%)
8. Subreddit Rules and Norms	0 (0%)	4 (<1%)

Note: Counts represent the tabulated frequency of comments assigned to each code.

Accuracy and validation

Open coding of comments for accuracy of scientific concepts or principles led to the identification of four common themes: *Oversimplification; Size, Scale, and Measurement; Tropical Cyclone Physics or Dynamics;* and *Skepticism around Informational Resources*.

Oversimplification. Coders identified frequent occurrences of oversimplified explanations of weather forecasts and models with an identifiable trend of overreliance on individual factors or models as the basis of explanation or argumentation. In several cases, users posted images of the outputs from individual 'spaghetti' models (ex. 18Z GFS or 12Z European) and provided interpretations and forecast predictions about Florence's track or intensity based on these singular models. Spaghetti models, or spaghetti plots, are amalgamations of the individual outputs from various computer models around the world that predict the paths of hurricanes. When visualized together and laid over a map of a potentially impacted area, the models of the predicted storm paths resemble strands of spaghetti. When the strands or tracks cluster together, it is a general indication of consensus between the models. Models presented in isolation lack this context and therefore cannot display a high degree of confidence or accuracy. Posts of this nature occurred across both subreddits. However, the comments in both forums were a mixture of discussion about the implications of overreliance on singular models and the pitfalls of making predictions based solely on these visualizations alone. Subscribers also demonstrated an overreliance on or oversimplified understanding of individual physical factors generally reported during hurricane forecasts like wind speed, rain, storm surge, or forward motion. Discourse within posts and comment threads generally focused on one or two of these factors while either not considering or downplaying the importance of other factors and the interactions between them.

Interpretations of size, *scale, and measurement.* Misinformation or miscalculations appeared in discourse related to the influence of storm size; timing and duration; and local geography on predicted and actual impacts, particularly flooding. Within HurricaneFlorence, there were several instances of discourse surrounding images where perceptions of flood water depth were based on point perspective. For example, water in the foreground of photographs appearing shallower or deeper than water in the background. In nearly all cases, misinterpretations or incorrect inferences as to the magnitude of the flooding were later corrected on the basis of topographical variation and the lack of dimensionality in 2D images. Discourse in TropicalWeather centered around question-and-answer comments regarding what the storm surge height is measured against, and how risk from storm surge inundation relates to land elevation and inland distance. Explaining responses included references to other factors that influence risk of flooding from storm surge, such as tide levels, rainfall, and other local geographic factors. In both subreddits, discussions demonstrated evidence of connecting multiple factors acting at a variety temporal and spatial scales and that can amplify or reduce the magnitude of an impact.

Misinformation about tropical cyclone physics or dynamics. Misinterpretations of meteorological phenomena often appeared in comments related to characteristics of a tropical cyclone. These were often, but not always, corrected in subsequent discourse.

> "Is there any science to support my curiosity that once over land and then taking this turn, depending on where you are, like southern South Carolina for example, the storm actually blows the water off the coast out to sea, as opposed to causing a surge into the coast, like what's happening right now as it approaches?" (Redditor– Tropical Weather)

The first comment after this sought to provide an answer.

> "...the difference is the volume of water. Water gets spread around when it's small and will quickly dry up over dry land. When you are dealing with a massive amount of water like the ocean, the energy stays in the water, and overflows leading to the surges" (Redditor – Tropical Weather).

This response provided accurate information. However, this information does not adequately answer the original question, which could lead to misinformation that it is the relative volume of water on land vs. the ocean that is the primary factor in storm surge inundation. A subsequent comment in this thread offered a scientifically correct explanation.

Skepticism around Informational Resources. There were instances of general mistrust of image-based resources including maps, visualizations, and eyewitness photos and videos. This appeared within the HurricaneFlorence and TropicalWeather subreddits as a lack of familiarity with graphics leading to misinterpretations and also as misinterpretations related to out-of-context visual representations. A lack of familiarity with graphics was demonstrated by users who would frequently disagree with or challenge the validity of certain graphics presented in new posts, occasionally even accusing them of being doctored or hand drawn when they were in fact official government forecasts. This suggests that even graphics that are frequently produced by the NHC are not universally accepted or understood. In HurricaneFlorence, there were additional challenges made against indexical, or eyewitness images. Users were more skeptical of images that presented hurricane-related impacts without context, like photographs of floodwaters being taken without any other representation of scale. In both cases and without corrections, assumptions of falsehood on accurate information can spread misinformation information just as significantly as if the information was truly inaccurate.

Interviews

Interview participants were asked questions related to their preferences for seeking and sharing visual information related to hurricanes and how they determine validity and accuracy in the information sought or solicited.

Iconic versus indexical images. Both groups of subscribers indicated that visual information was the most helpful way to communicate hurricane-related risks. In both HurricaneFlorence and TropicalWeather, users who preferred indexical images like photos and videos cited the additional context and real-life depictions of impacts as being most helpful in developing risk perceptions. Those who preferred iconic, or graphical, representations of information did so with the caveat that in isolation these images have the highest risk of misinterpretation and that overreliance on models out of context can negatively impact public perception of the dangers associated with hurricanes.

Establishing accuracy and validity. When asked about the spread of misinformation, subscribers of both subreddits referenced the social rules and expectations of the forums as actively curtailing the intentional or unintentional spread of false or errant information. Moderators and knowledgeable others of both subreddits tended to self-identify as experts and gatekeepers, and expressed a desire to meet the expectations of non-experts by being sources of accurate and objective information.

DISCUSSION

The results of the first stage of content analysis describe the difference between the two subreddits on the basis of emotional valence. In general, HurricaneFlorence presented a greater number of eyewitness photographs and tended to be more personal and subjective in both socialization and explanations. By contrast, TropicalWeather functioned with greater similarity and followed discourse patterns similar to the to more objective and scholarly-focused AskAcademia, AskHistorians, and askscience subreddits described by Haythornthwaite et al. (2018). However, the second stage of content analysis that coded for the accuracy and validity of scientific claims and documented evidence of correction identified that misinformation was corrected in nearly almost every instance regardless of the subreddit. Though TropicalWeather provided opportunities for experts and knowledgeable others to self-identify, this did not necessarily impact the accuracy and validity of the information presented within the forums. In both cases, these subreddits were established as venues for information exchange and were held to equivalent standards. Users of both forums were expected and encouraged to engage in discourse that provided the most timely and relevant information related to Hurricane Florence. The analysis for accuracy in the HurricaneFlorence and TropicalWeather subreddits did however expose issues of oversimplification of scientific concepts; misconceptions related to size, scale and measurement; a limited understanding of tropical cyclone physics and meteorological phenomena amongst users; and also identified that many Redditors may lack a framework for assessing the validity or accuracy of visual imagery.

Not only do these results have implications for those who work to communicate and educate the public about the threats of hurricanes and other natural hazards, but also for formal and informal educators. As others have suggested, K-12 classrooms are a starting point for hazards education (Mitchell, 2009). However, research has shown that hazards education is not standard across curricula, and that instruction surrounding the physical and social impacts of hazards on people, communities, and infrastructure are underrepresented with respect to both standards and classroom texts (Mitchell, 2009).

FUTURE RESEARCH

More research is needed on who uses Reddit and how people make sense of the various types of science-related information that are communicated. Little is known about how people accept or reject Reddit information compared to information from other sources such as television or radio. The ways students and the public locate information about the natural world are changing rapidly and we need to know what and how information is being shared. This is particularly important when individuals must make sense of science related risks or hazards that can be life-threatening.

EFFECTS OF DIGITAL MEDIA IN HETEROGENEOUS CHEMISTRY LESSONS

Lars Greitemann[1] *and Insa Melle*[1]
[1]TU Dortmund University, Chemical Education, Dortmund, Germany

Digital media play an increasingly important role in almost all areas of life. With the growing presence of laptops, smartphones, and tablets, daily life as well as professional needs are changing (Hanekamp, 2014). That means that mobile devices are becoming an important part in schools and classrooms (Frechette & Williams, 2016; Noonan, 2013). In particular, tablets are seen as a useful possibility to implement digital media in school (Rikala et al., 2013). Of particular importance regarding the use of digital media in classrooms are explanatory videos. Furthermore, with the digitisation at school, proven formats, such as tasks, can be realised with tablet support. Against this background, this project is analysing how to optimise the effect of a tablet-based learning environment for lower secondary education. The digital learning environment bases on a learning program for laptops. For this project, the contents of the learning program are modified to be used on iPads. The aim of this project is to investigate the effect of the use of tablets in two teaching phases: For the input phase, a laptop-based learning environment was modified and evaluated for the use on iPads. In the internalisation phase, the work with tablet-based tasks is compared with the creation of student explanatory videos regarding their effectiveness considering knowledge, attractiveness and cognitive load.

Keywords: Computer Based Learning, Multimedia and Hypermedia Learning, Differentiation

MOTIVATION

Over the last years, digital media have played an increasingly important role in almost all areas of life. The proceeding digitisation of everyday life is also evident in the use of media by students. Various studies, such as the Bitkom (Bitkom, 2017) or the JIM study (Medienpädagogischer Forschungsverbund Südwest, 2018), show that the smartphone use in Germany – especially among young people – has increased rapidly in recent years. Furthermore, the JIM study points out that the video portal YouTube is one of the most popular websites (Medienpädagogischer Forschungsverbund Südwest, 2018). This makes it clear that video use is extremely important for students. Due to this development, more and more schools try to get mobile devices. This is also reflected in the education policy guidelines in Germany as the strategy paper "Education in the digital world" by the Conference of Education Ministers explicitly calls for learning with and about digital media (KMK, 2017). In addition, the "*DigitalPakt Schule*" – under the leadership of the Federal Government and the Länder – provides financial support for schools (BMBF, 2019).

THEORETICAL BACKGROUND

With regard to the theoretical background, two aspects become important: Digital Learning and Universal Accessibility. Concerning digital learning, we will focus on possible applications and didactic functions. In regard to universal accessibility, the aim is to make teaching materials accessible, if possible, for all students, which is particularly important in heterogeneous learning groups. In this context, digital media have the advantage of offering a variety of possibilities for developing a learning environment with universal accessibility.

Digital Learning

When implementing digital learning technologies, it is essential to think about the specific way mobile devices are used. For this reason, we focus on the SAMR model by Puentedura (2006) (see Figure 8). This model consists of four levels: While at the substitution level digital media replace other tools, which means, for example, reading a text on the iPad instead of an analogue worksheet, functional enhancements can be achieved through the use of digital media at the level of augmentation (Bastian, 2017). For instance, when a written text is spell-checked. Both of these levels are summarised under the term enhancement, the next two levels indicate a transformation. At the level of modification, digital media allow tasks to be redesigned. An example would be the possibility for students to create video recordings (Bastian, 2017). However, digital media can be used for redifining learning, so that completely new methods, such as a collaborative writing tasks, are imaginable (Bastian, 2017).

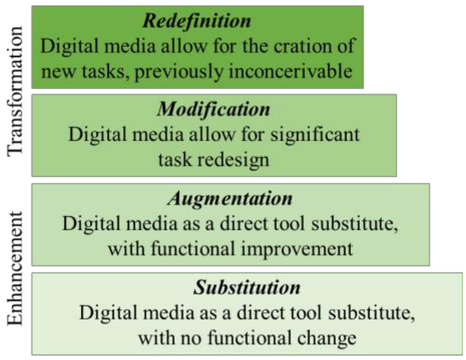

Figure 8. SAMR model (cf. Puentedura, 2006).

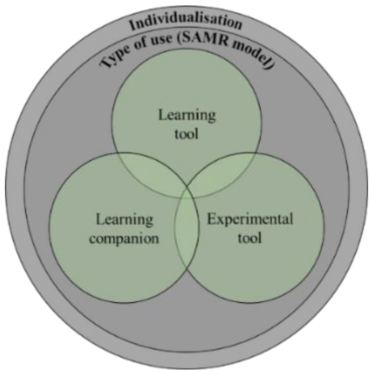

Figure 9. Didactical functions of digital media (cf. Huwer & Brünken, 2018).

If digital media are used in the classroom, the didactic functions in science teaching as a learning tool, experimental tool and learning companion should be considered as shown in Figure 9 (Huwer & Brünken, 2018). As a learning tool, digital media can support the learning process in a concrete learning situation, while, as an experimental tool, digital media can promote the conduction of experiments. If digital media are used as learning companions, they enrich the learning process over a longer period of time. The didactic functions are embedded in the type of use (Huwer & Brünken, 2018) that can be described with the SAMR model. Thus, all four levels of the SAMR model can be implemented for each didactic function. The last dimension is individualisation. With help of digital media, it is possible to achieve different levels of individualisation for a given learning setting (Huwer & Brünken, 2018).

One possibility for using digital media and especially tablets in the classroom is the use of explanatory videos. According to Wolf and Kratzer (2015) explanatory videos are self-produced short films that explain how to do something or how something works respectively in which concepts and relationships are explained. These videos have the advantage of meaningfully linking auditory and visual forms of presentation (Grodach, 2018). The effect and the value of explanatory videos can be differentiated according to which person produces the video and to who receives it (Kulgemeyer, 2018; Wolf, 2018). For instance, students can learn from professionals (producer: teacher, recipient: student), whereby the explanations can be repeated as often as needed. Another option of using explanatory videos in school is that the students create their own explanatory video in order to deal with the topic in more detail (producer: student, recipient: student or teacher) (Kulgemeyer, 2018; Wolf, 2018).

In the context of digital learning, proven teaching formats, such as working on tasks, should be considered for the use on digital devices. The great advantage of processing digitally prepared tasks is that students can receive direct and individual feedback on their given answer (van der Kleij et al., 2015).

Universal Accessibility

Since the ratification of the UN Convention on the Rights of Persons with Disabilities in Germany in 2009, people with disabilities have the right to equal participation in school life (United Nations, 2006). Overall, Germany has switched to an inclusive school system in which people with and without disabilities are taught together. As this goes hand in hand with the fact that the heterogeneity in school classes is increasing more and more, education needs to consider this aspect. Hence, teachers have to adapt their teaching in such a way that each student – regardless of age, gender, origin, level of performance, etc. – is able to participate in the classroom. To reach this goal, the Universal Design for Learning (UDL), developed in the USA, shows possibilities for planning a lesson with universal accessibility (CAST, 2018). The UDL is characterised by a high degree of flexibility. In addition, possible barriers to successful learning are reduced. The UDL is based on three principles, which are shown in Figure 10 as columns. Each principle is subdivided into three guidelines, giving a total of nine guidelines. The guidelines are explained in more detail by checkpoints. For example, the guideline 5 "Language & Symbols" is further described by the checkpoint "Clarify vocabulary and symbols". For reasons of clarity, the checkpoints in Figure 10 are not shown but can be found at the homepage of CAST (2018). The first principle addresses possibilities for supporting learning motivation. Moreover, the second principle of the UDL deals with different possibilities of information presentation. The third principle focuses on the support of learning activity and the presentation of learning outcomes. In general, the UDL can be used as a checklist. However, not all nine guidelines necessarily need to be implemented.

Principles		Provide multiple means of Engagement	Provide multiple means of Representation	Provide multiple means of Action & Expression
Guidelines	Access	1. Recruiting Interest	4. Perception	7. Physical Action
	Build	2. Sustaining Effort & Persistence	5. Language & Symbols	8. Expression & Communication
	Internalize	3. Self Regulation	6. Comprehension	9. Executive Functions
Goals		Purposeful & Motivated	Resourceful & Knowledgeable	Strategic & Goal Directed

Figure 10. The Universal Design for Learning (cf. CAST, 2018).

Various ways are possible to implement the UDL. On the one hand, for instance, many aspects of the UDL can be realised by implementing cooperative learning settings (Hall et al., 2003; Jiménez et al., 2007). On the other hand, the digitisation in schools makes a major contribution to the implementation of the UDL. In this context, digital media offer the possibility of individualisation and differentiation (Tulodziecki & Grafe, 2012). In addition, learning with digital media realises multichannel learning to support the internalisation of information

(Paivio, 1990). Moreover, digital media can provide individual support for the students, for example by helping to read, write and solve tasks (Hall et al., 2015; Rose et al., 2007).

AIM OF THE RESEARCH

Subject of this research is a learning environment for the use on iPads, which we modified based on a laptop-learning environment (Baumann & Melle, 2019). Simultaneously, we complemented the learning environment by two different forms of digitally supported internalisation methods as we compare the creation of explanatory videos and tasks with automated feedback on student performance. To evaluate the developed digital learning environment, we determine the increase in knowledge, the assessment of attractiveness as well as the impact of the learning materials on the cognitive load of the students. In addition, the usage behaviour of the learners when using the learning software is recorded and analysed. Based on this project, we aim to gain deeper insights into the effects of tablet use on knowledge conveyance and internalisation.

METHOD

Design

The following research design (cf. Figure 11) was developed to answer the research questions above. In this case, it is an intervention study, that is carried out as a project day at schools. The sample includes students of the 8th grade (age 13 to 15) in initial chemistry tuition at comprehensive schools in Germany. The advantage of conducting the study on a single day is that learners go through the whole intervention and then fill out the post-test. In this way, sample reduction due to the absence of learners can be avoided.

One week before the intervention, the students write the pre-test. Based on these test results, the class is divided into two parallelised groups. In the input phase, the students of both groups work with the same digital learning environment individually, followed by the internalisation phase in a cooperative pair work. The students in one of the two groups create their own explanatory videos, while the students in the other group work on tasks using the iPad. The project day ends with the post-tests. Three weeks later a follow-up knowledge test is conducted.

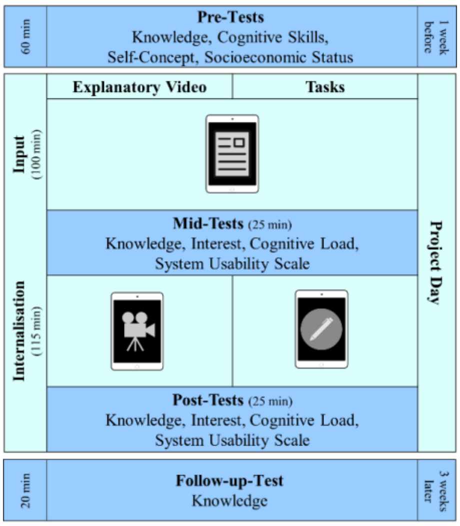

Figure 11. Research Design.

Instruments

The quantitative data are collected by various test instruments. For the pre-tests, we use a knowledge test with 28 items (Cronbach's $\alpha = .769$) to record previous knowledge (Baumann & Melle, 2019; cf. Michna & Melle, 2018), the CFT 20-R to determine cognitive abilities (Weiß, 2006), a questionnaire to determine the school self-concept (Rost et al., 2007), and a questionnaire on the socio-economic status of the students (Torsheim et al., 2016). On the project day itself, we run an assessment test (10 items, Cronbach's α = .865) to determine the attractiveness of the teaching materials (Kieserling & Melle, 2019) and an assessment test (10 items, Cronbach's α = .821) for the cognitive load (Kieserling & Melle, 2019; Leppink et al., 2013) after the input and after the internalisation phase. Furthermore, a test (10 items) is used to record the system usability scale (Brooke, 1996). At the same time, we also apply the knowledge test. In addition to these selective tests, the individual actions of the learners are documented by screen and video recordings.

THE LEARNING SOFTWARE

The learning environment, which was developed within this study, deals with the introduction to the basic concept of the chemical reaction and is a further development of a multimedia learning environment by Baumann and Melle (2019). This learning program by Baumann and Melle (2019) is designed for the use on laptops for the initial tuition of chemistry at comprehensive school. In this laptop-based learning environment, universal accessibility was achieved by implementing various aspects of the UDL. For our project, we modified the multimedia learning environment for the use on iPads. The digital implementation was carried out with iBooks Author (Apple Inc., 2019) and further developed with regard to the implementation of more aspects of the UDL. A detailed description of the transfer of the laptop-based learning environment for the use on iPads is given by Greitemann and Melle (accepted). The structure of the iPad-based learning environment is shown in Figure 12. First, the students work through an introductory chapter in which the functions and the handling of the learning environment are described. This is followed by an information input phase. The students work on the chapters Chemical Reaction, Chemical Equation, Physical Process and Oxide Formation. Afterwards, a practical phase in the form of experiments follows. In the final internalisation phase, the students either create own explanatory videos or work on tasks.

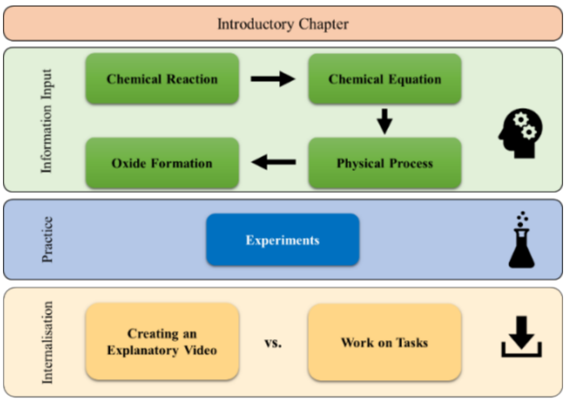

Figure 12. Structure of the iPad-based Learning Environment.

In the input phase, the learning environment serves as a learning tool. The contents of the learning environment are differentiated into three levels. While at the lowest level one reminders of previous knowledge are embedded, additional information is displayed at the highest level three. The students are free to choose the level and can switch between the levels at any time. Moreover, an interactive information presentation is realised so that, for example, short video sequences can be watched as well. Furthermore, the students are given the option to have the texts in the learning environment read aloud. The visual presentation of the contents supports the students iconically. At the end of each chapter, the content is summarised in short sentences, in which the important information is emphasised in bolded letters.

Furthermore, the learning environment serves as experimental tool in the practical phase. In total, the students carry out four experiments. The experimental instructions are offered in form of a text, in form of an image as well as in form of video instructions. Futhermore, the documentation is carried out by using the photo function so that the students' observations can be recorded by a before-and-after comparison. During the evaluation, the students have to answer one closed and one open question. For the closed question, they receive a direct feedback and a sample solution for the open question.

In the subsequent internalisation phase in cooperative pair work, both groups get an additional structuring to support the work process. The students of the explanatory video group start by watching an explanatory video, in which a fictive person serves as motivating strategy: Mario is doing an exchange year and does not understand the topic chemical reaction. Therefore, he asks his friends to send him a video explaining this topic. Afterwards, the students are asked to first work on their own and then with their partner on the content again. The next step is the creation of a storyboard in pair work. With the help of the storyboard, the students plan their video by making drawings of the image sequences and noting down the speaker text. In the final phase, the video is implemented on the iPad using the screencast-based app doceri (SP Controls, 2019). The presentation phase of the videos is done in the chemistry lessons outside of the research. In the task group, the students first watch a video. Subsequently, the students work on tasks for the four theoretical chapters of the learning environment one after the other. Here, the students first work on some tasks individually in order to clarify open questions and work on further tasks in a subsequent pair work phase.

FIRST RESULTS

In the following chapter, the results of the first pilot study are presented. As this is a pilot study with a small sample ($N = 48$), the results should be considered as preliminary.

How do (1) the digital learning environment, (2a) the creation of explanatory videos and (2b) the digitally supported task processing affect the knowledge growth of the students?

The results of the knowledge test are presented in Table 9. The graphic representation is shown in Figure 13. It should be noted that the two groups do not differ with regard to the tasks in the input phase (Pre to Mid). All in all, it becomes clear that both groups learn significantly and with a very high effect size in the input phase. Considering the internalisation phase, there is no significant increase in knowledge in either group. Differences between the two groups cannot be detected at any point in time.

Table 9. Results of the Knowledge Test.

	n	M^*_{pre}	M^*_{mid}	M^*_{post}	Pre - Mid		Mid - Post	
					p	d	p	d
Explanatory Video Group	26	.29	.50	.50	< .001	1.504	.780	.030
Task Group	22	.29	.50	.51	< .001	1.565	.719	.051

*percentage

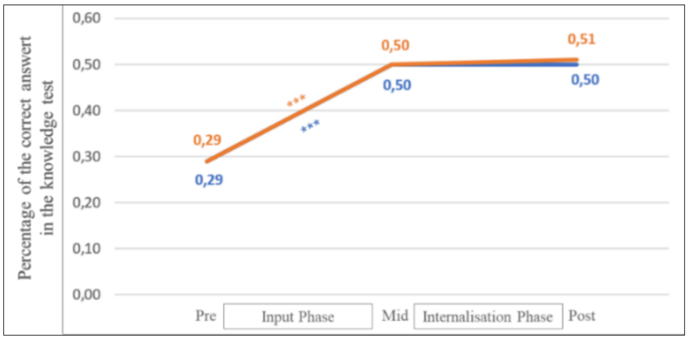

Figure 13. Means of the Knowledge Test (Explanatory Video Group = blue, Task Group = orange).

How are (1) the digital learning environment, (2a) the creation of explanatory videos and (2b) the digitally supported task processing assessed from the students in terms of attractiveness?

The results of the attractiveness test are presented in Table 10 and Figure 14. Both groups rate the digital learning environment on a 6-point Likert scale from 1 = negative to 6 = positive as very attractive in the mid-test. In the post test, this attractiveness decreases significantly for the students of the task group with a medium effect. In contrast, the attractiveness of the explanatory video group after the internalisation phase does not differ significantly from the attractiveness after the input phase. Moreover, the residual comparison between the two groups shows no significant differences between the two groups. Nevertheless, a medium effect indicates that the students of the explanatory video group rate the internalisation phase more attractive than the students of the task group.

Table 10. Results of the Attractiveness Test.

	n	M^*_{mid}	M^*_{post}	Mid - Post		Residual comparison	
				p	d	p	d
Explanatory Video Group	26	4.96	5.03	.609	.093	.076	.550
Task Group	21	5.11	4.75	.040	.524		

*6-point Likert scale from 6 = positive to 1 = negative

How do (1) the digital learning environment, (2a) the creation of explanatory videos and (2b) the digitally supported task processing affect the cognitive load of the students?

The third question deals with the effect of the teaching materials on cognitive load (see

Table 11, Figure 15). For this, a 6-point Likert scale was used, with value 1 corresponding to a high cognitive load and value 6 to a low cognitive load. The students of the task group perceive the internalisation phase more cognitive burdensome than the input phase (significant effect, medium effect size). The cognitive load of the students in the explanatory video group remains constant. However, the residual comparison shows no significant differences between the two groups.

Table 11. Results of the Cognitive Load Test.

	n	M^{*}_{mid}	M^{*}_{post}	Mid - Post		Residual comparison	
				p	d	p	d
Explanatory Video Group	25	5.15	5.11	.873	.028	.079	.522
Task Group	22	5.38	4.95	.007	.669		

*6-point Likert scale from 6 = Low Cognitive Load to 1 = High Cognitive Load

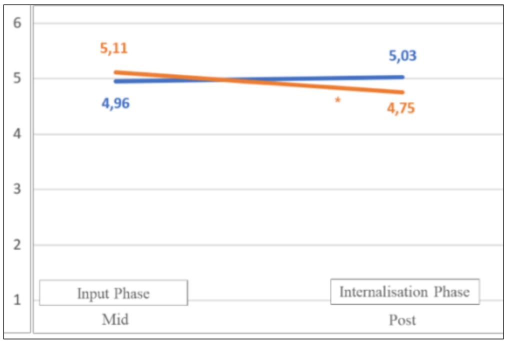

Figure 14. Means of the Attractiveness Test (Explanatory Video Group = blue, Task Group = orange; 6-point Likert Scale from 1= negative to 6 = positive).

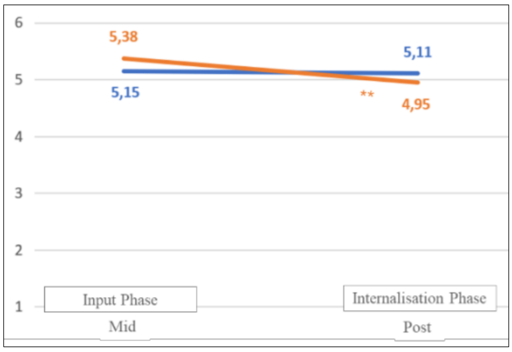

Figure 15. Means of the Cognitive Load Test (Explanatory Video Group = blue, Task Group = orange; 6-point Likert Scale from 1 = high cognitive load to 6 = low cognitive load).

DISCUSSION AND CONCLUSION

Based on the results presented above, it can be stated that the expertise of the students in both groups can be significantly increased by the input phase, while no additional increase in knowledge can be detected after the internalisation phase. Furthermore, both, the input phase and the internalisation phase are considered to be attractive for the students of both groups. However, there are tendencies that the creation of an explanatory video is rated more attractive by the students than the work on iPad-based tasks. The cognitive load is not too high for both groups.

Following the pilot study, the teaching materials and the test instruments will be revised. As a consequence of the results just presented, the knowledge test will be optimised. To this end, the cognitive level of the test is to be raised in order to determine differences between the two groups on the higher cognitive level of application. In addition, we will add open questions to the knowledge test in order to check if there are any differences between the two groups regarding these more difficult questions. Further, we will optimise the learning environment (e.g. due to curricular changes renaming the chapter "Oxidation" to "Oxide formation"). Moreover, the usage behaviour has not yet been evaluated. Hence, an evaluation using specific coding manuals is planned. Furthermore, possible differences between the different cognitive levels of the students will be analysed. Consequently, another pilot study will be carried out with a sample of $N \approx 80$ students. Finally, the main study with a sample of about $N \approx 275$ students will take place.

ACKNOWLEDGEMENT

We thank the participating students and teachers. The learning software was developed as part of the project DoProfiL. This project is part of the "*Qualitätsoffensive Lehrerbildung*", a joint initiative of the Federal Government and the *Länder* which aims to improve the quality of teacher training. The programme is funded by the Federal Ministry of Education and Research.

EXPLORING DIFFICULTIES IN THE USE OF MOBILE DEVICE SENSORS IN THE SCIENCE CLASSROOM: THE CASE OF ACCELEROMETERS

Pavlos Tzamalis [1], Alexandros Kateris [2], Panagiotis Lazos [3], Tsoukos Serafeim [4], Athanasios Velentzas [5]

[5] National Technical University of Athens, Athens, Greece

In recent years, the educational community has shown a keen interest for the use of mobile devices (smartphone and tablets) in the school science lab, and particularly for exploiting the potentialities offered by the sensors of these devices. The present paper reports parts of the findings from a broader study into the difficulties that a teacher might encounter when trying to implement proposals from the physics education literature. These difficulties are primarily related with the variation in technological capabilities of the different models. Specifically, we investigated whether the variety of students' personal mobile devices may cause significant differences in the results of experiments, utilizing the acceleration sensor of those devices. Details of smartphones model belonging to 1,083 students were recorded, and the most popular devices of this population were identified, with the seven of them selected for use in the study. The selected smartphones simultaneously recorded the acceleration of a moving body to which they all were attached. The findings indicated that the differences in the values of the acceleration measured by the various devices are not statistically significant in the context of experimentation in the school lab. Therefore, in our view, students' use of their personal mobile devices would in no case be a deterrent to a lesson plan involving the measurement of acceleration.

Keywords: Technology in Education, Laboratory Work in Science, Teaching Practices

INTRODUCTION

The use of smartphones and tablets seems to provide, for science teachers, an easy solution both for real-time data collection (via the various sensors available in all mobile devices), and the on-site processing of these data as well. The literature on this subject is rapidly expanding (e.g. Kearney et al., 2012; Kuhn &Vogt, 2013; Zacharia et al., 2016; Gonzalez & Gonzalez, 2016; Iliaki et al., 2018), but it does not address yet all aspects of this technology in the classroom. Most of the papers describe experiments in which the use of mobile devices is required, and only few of the studies deal with technical problems involving the mobile device sensors (e.g. Monteiro 2015). However, there are no significant studies on the practical problems that may arise in the classroom when using these devices.

As a first step in our research, we considered that it would be useful to investigate the possible practical issues that might arise during the implementation of experiments using students' personal mobile devices in the school lab. On the one hand, the practical issues might arise from students' potential difficulties in using their mobile devices in ways that might be unfamiliar to them, while on the other hand, the devices themselves could create a problem, i.e., the differences between (i) the technological capabilities of the different models, (ii) the device's operating system (iOS –Android), and (iii) the applications (Apps) which the devices utilize.

In the present study, we are investigating the possible differentiation between the results of experiments using the acceleration sensor of different models of mobile phones or mobile phones with different operating system (iOS / Android).

METHODS

Initially, the number and the models of students' mobile phones (MPs) to be used for recording measurements had to be determined. Our goal was to use a number of devices sufficient to permit simultaneous measurements from the same experiment. Towards this end, information about the MPs of 1,083 students from three Greek secondary schools was recorded and the most popular devices were identified, resulting in seven different smartphone models being selected for use in the experiment. Two, of these seven selected MPs, use the iOS while the rest the android operating system.

The experiment focused on the use of the accelerometer, a sensor with which all MPs are equipped and for which there are many suggestions in the literature for use in the classroom (e.g. Vogt & Kuhn, 2014). One of the proposed experiments was performed, namely the use of the accelerometer sensor to measure the acceleration (a) of a sliding body (Fig.1) in order to calculate the coefficient of friction (μ) between two surfaces (Equation 1).

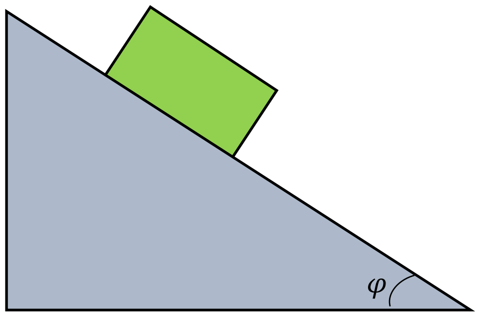

Figure 1. The sliding body on an inclined plan

$$\mu = \frac{g \cdot sin\varphi - \alpha}{g \cdot cos\varphi} \quad (1)$$

This specific experiment was chosen because it was possible for all seven MPs to be attached onto the same moving object (a wooden parallelepiped) and afterwards to study its motion (Fig.2), thus ensuring that possible variations in acceleration values will only be due to the type of device and not to other parameters.

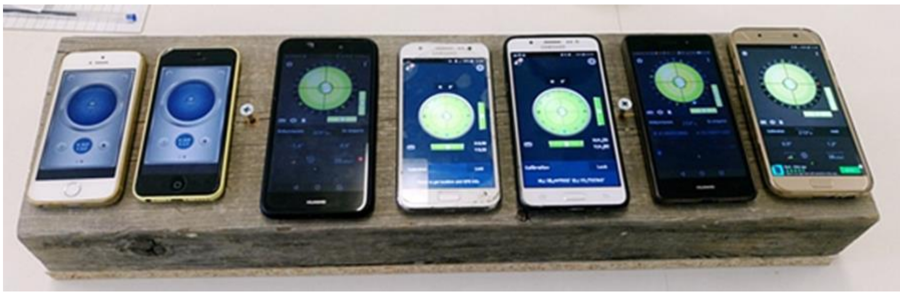

Figure 2. The smartphones on the wooden parallelepiped.

For measuring the value of acceleration, the application "SPARKvue" was used by all devices (https://www.pasco.com/sparkvue/). The selection of this App was made on the basis of the following criteria: (i) It is available free of charge for mobile devices, (ii) It has the same format and handling in both the iOS and Android platform, (iii) It automatically creates graphs and allows them to be handled on the device, (iv) It allows data to be extracted on spreadsheets, and finally (v) It allows a wide range of sampling frequency (0-1KHz).

In addition to the measurement of acceleration, the measurement of the slope angle of an inclined plane was also required during the experiment. Unfortunately, we could not find the same App for both the Android and iOS platforms, so we had to use the "compass level" application (https://play.google.com/store/apps/details?id=com.jee.level&hl=en) for the Android devices, while the "surface level" application was used for devices with the iOS platform.

Finally, it should be noted that the experiment was carried out by the researchers with the participation of the students who were the owners of the selected MPs. However, data on the ability of these students to use the devices during the experiment and on the learning processes were not recorded as these were not among the aims of the present study.

FINDINGS

In the first phase of the study, the models of the MPs owned by 1,083 students were recorded. The findings showed 303 different smartphone models from 32 manufacturers, with both iOS and Android operating platforms. The total number of the selected seven most commonly used MPs corresponds to 22% of the valid responses.

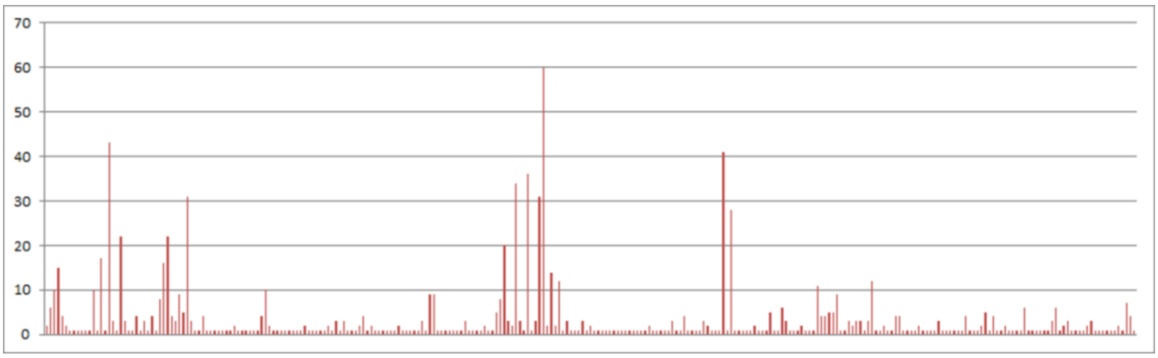

Figure 3. The number of each type of smartphone.

This highlights the wide range of MP models belonging to students (Fig.3) and, therefore, indicates the importance of undertaking a study concerning the reliability of the measurements of all these different devices.

In the experiment carried out, the following measurements were taken:

(i) The gravitational acceleration (g) was measured by the accelerometer of the MPs in order to gain knowledge not only about the reliability of the measurements, but also about their accuracy (Table 1).

Table 1. Measurements of the acceleration of gravity from the seven MPs.

Measurements of g in m/s^2						
MP 1	MP 2	MP 3	MP 4	MP 5	MP 6	MP 7
9.91	9.83	9.76	9.84	9.91	9.96	9.63
Mean: 9.83		SD: 0.10		C.V: 1.02%		

(ii) The angle (φ) of inclination of the inclined plane was simultaneously measured by all MPs (Table 2).

Table 2. Measurements of the slope angle of the inclined plane from the seven MPs.

MP 1	MP 2	MP 3	MP 4	MP 5	MP 6	MP 7
24°	24.5°	23.3°	24.4°	24.2°	23.8°	24.6°
Mean: 24.1°		SD: 0.4°		C.V: 1.67%		

(iii) The acceleration (α) of the moving body on the inclined plane was simultaneously measured by all MPs.

As it is shown in Figures 4 and 5, there is an area in the graph were the acceleration is approximately constant (plateau), corresponding to the duration of the sliding of the wooden parallelepiped along the inclined plane. From this area, a section (shaded section in Figure 4) was selected in which the minimum, the maximum and the mean value of the acceleration, as well as the standard deviation and the coefficient of variation, were calculated (Table 3). As it is mentioned above with the SPARKvue application, the extraction of these values is possible directly on the screen of the MPs (figure 5) or with the use of a computer and an appropriate software (figure 4).

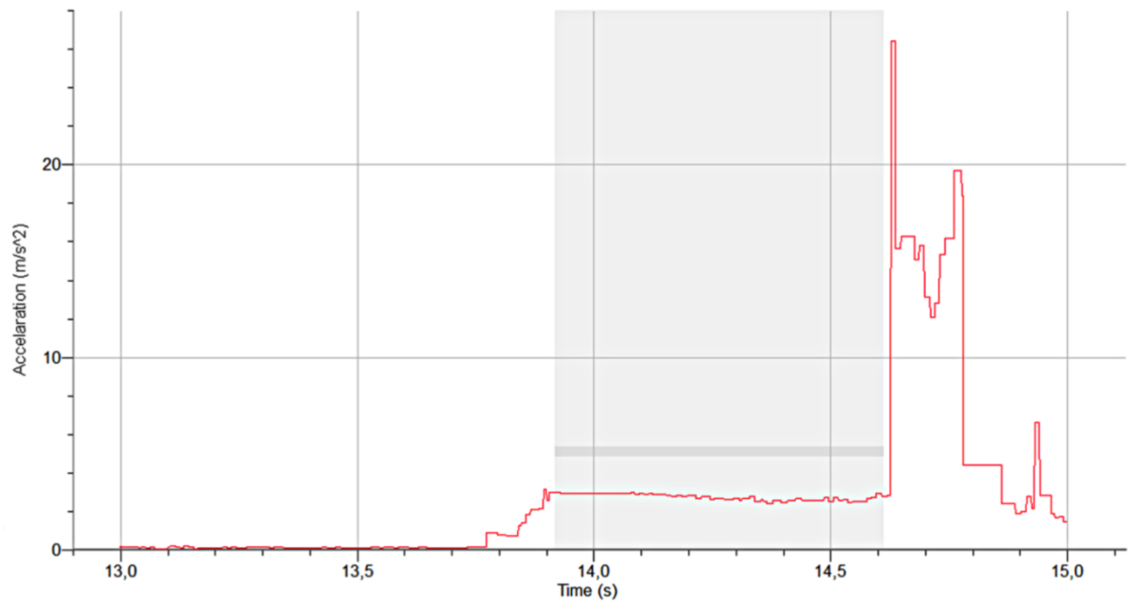

Figure 4. The graph of the acceleration in relation to time from the downloaded data of a MP in a PC using the Logger pro software.

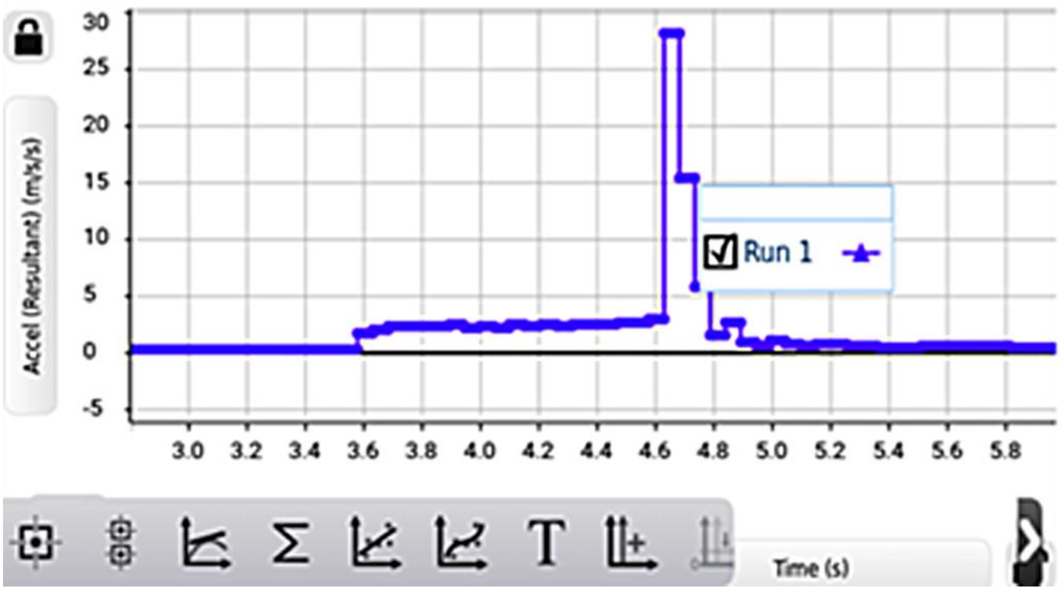

Figure 5. The graph of the acceleration in relation to time directly from the screen of a MP using the SPARKvue application.

Table 3. Characteristic values of the acceleration (in m/s^2) in the plateau area.

	MP 1	MP 2	MP 3	MP 4	MP 5	MP 6	MP 7
a_{min}	2.408	2.403	2.600	2.651	2.603	2.603	2.552
a_{max}	3.166	3.109	3.174	2.956	3.079	3.071	3.117
a_{mean}	2.776	2.736	2.792	2.774	2.820	2.826	2.815
SD	0.173	0.172	0.188	0.117	0.171	0.153	0.168
C.V.(%)	6.23	6.29	6.73	4.23	6.05	5.41	5.98

Finally, based on the measurements, the kinetic coefficient of friction (μ) between the body and the inclined plane was calculated by using the corresponding theoretical formula (Equation 1) (Table 4).

Table 4. The kinetic friction coefficient as it was calculated using the data from each MP.

MP 1	0.13
MP 2	0.15
MP 3	0.12
MP 4	0.14
MP 5	0.13
MP 6	0.13
MP 7	0.14

CONCLUSIONS AND IMPLICATIONS

As the present study confirms, students own a wide variety of mobile phone models. This means that the teacher who plans to implement the "Bring Your Own Devices" (BYOD) process (Stavert, 2013; Song, 2014) in the classroom or in the science lab will be faced with many different types of mobile devices and operating systems. Therefore, he/she should not only choose an App compatible with different operating systems, but he/she also should be aware of the range of measurement variation among the different devices. The results of the present study may contribute to this end.

With regard to App selection, there is a wide variety of suggestions, possibly ephemeral due to the rapid rate of technological development. In the present study, the "SPARKvue" App proved to be an appropriate choice for use in devices with different operating systems (iOS and Android). This specific application is free of charge, easy to use, allows the processing of data directly on the device and, finally, the data can be extracted for further processing with the appropriate software.

The main question addressed in the present study is whether measurement experiments in which the accelerometer of different mobile devices are used result in differences which render the use of these devices unsuitable for educational use. According to our findings, direct measurements with the MPs – such as the angle of the inclined plane, the acceleration of gravity, as well as the mean value of the acceleration during the sliding of a body – show differences which are not statistically significant. This makes the mobile devices useful educational tools for implementation in the school classroom or lab.

GAME OF THRONES TO LEARN SCIENCE. AN EXPERIENCE WITH SPANISH PRE-SERVICE SCIENCE TEACHERS

Antonio-Joaquín Franco-Mariscal[1], *María-José Cano-Iglesias*[2] *and José-Manuel Hierrezuelo-Osorio*[1]

[1]University of Málaga, Department of Science Education, Málaga, Spain

[2]University of Málaga, Department of Civil Engineering, Materials and Manufacturing, Málaga, Spain.

The most consumed media in Spain in 2018 was television, with fiction series being the favourite among young people. This paper shows how this medium can be used as an educational resource in science education by studying problematic situations of interest, presenting the results of an experience carried out with 52 pre-service science teachers (PST) who worked with the television show Game of Thrones in an educational innovation subject of the Master's Degree in Secondary Education Teaching at the University of Málaga (Málaga, Spain). The PSTs watched several sequences from the TV show, from which they had to select frames and propose driven questions on physics, chemistry, biology and geology for secondary school students, explaining how to approach them in the classroom. The researchers categorized the proposals in the scientific disciplines according to the contents used and the PSTs´ explanations. To assess the experience, the researchers used a questionnaire that included items about the learning achieved, the educational possibilities of the resource and the emotions felt. On their learning, they highlighted how a playful resource could be converted into an educational resource to motivate students. The resource was well received with a score of 8.53 out of 10.00, increasing the average knowledge of the PSTs of their educational possibilities from 1.96 to 4.54 (on a scale of 5.00 points) before and after the experience. The PSTs highlighted interest, satisfaction and concentration as the main emotions felt during the experience. This study is considered novel since it applies this strategy to teachers in training, analysing their capacity to teach and their perceptions. Finally, it should be noted that the educational use of television as a resource in the classroom allows us to connect scientific and school knowledge, can motivate disinterested students and provide a pedagogical tool that enhances instruction.

Keywords: teaching innovations, initial teacher education (pre-service), science education

INTRODUCTION

Teaching-learning science is often boring and difficult for high school students. To overcome this difficulty, some authors have formulated proposals with different educational resources to motivate and improve the learning of science and scientific attitudes of students. Among these is the media as a source of knowledge, and particularly television, a medium which, along with the Internet, is one of the most widespread in the current population due to its diffusion, power, influence and consumption (AIMC, 2018). TV consumption data show the influence of this type of media on students' conceptions, as well as the image presented of science on TV, which does not usually coincide with reality (Dudo et al., 2011).

Different studies have explored the use of fictional resources (films, television shows or novels) in formal and informal science education settings to teach science concepts or enhance critical-thinking skills (Li & Orthia, 2016). The educational use of TV shows, as the main preference of adolescents, is shown as an attractive alternative since it can make science learning more effective and motivating; namely, it can be a good way of getting students interested in science (Allday, 2003; Sánchez, 2010) and can contribute to the scientific and television literacies of teenagers by connecting the domains of scientific and school knowledge. Famous TV shows such as The Bing Bang Theory (Li & Orthia, 2016), CSI (Cass, Grazier, Thompson, & Marrinan, 2013), Prison Break (Franco-Mariscal, 2009), Bones (Milanick & Prewitt, 2013) or House (Millard, 2009), or cartoons such as The Simpson (Orthia et al., 2012) or Peppa Pig (Franco-Mariscal, 2016) have been used to learn science.

Despite its potential, the number of researches carried out to educate in the excellent use of television and the Internet, and more particularly, to teach and learn science or to create positive attitudes toward it are considered insufficient. Therefore, we face with two literacies (scientific and television) considered as important objectives of today's education.

The teacher’s role in implementing the resource into practice is also crucial, as he or she must be aware of its educational possibilities in order to get the most out of it, as well as know-how to guide the students discussing the science implied in the TV show sequences. In this sense, the works presented in this line with pre-service science teachers (PSTs) are very limited. For this reason, this paper presents the results of an experience with PSTs, which aims to study their ability to teach science through the TV show Game of Thrones and their perception of the resource to transfer it to the classroom as future secondary school teachers.

METHOD

A total of 52 Spanish PSTs of the Master’s Degree in Secondary Education Teaching of the University of Malaga (Malaga, Spain) participated in this study. The 59.60% were women and 40.40% men, aged between 22 and 44 years. The PSTs studied a subject of innovation and educational research in the specialities of Physics-Chemistry and Biology-Geology during the academic year 2018-2019. The experience presented here is framed within a teaching unit dedicated to educational innovation where different resources for the classroom were shown, including the use of TV shows to teach science.

The method used in the classroom is based on the use of fictional series in science teaching through the study of problematic situations of interest (King, 2012; Ültay y Çalik, 2012). Game of Thrones was the TV show chosen by a large number of followers in the ages of the participants in this research. According to *The Guardian,* Game of Thrones is the “most talked about show on television” (Hughes, 2014).

PSTs watched several sequences from the episode 7x06, totalling no more than 3 minutes of duration, including the ambush of the white walkers on Jon Snow in a frozen lake, the arrival of Daenerys with her dragon to help them, and the rescue of the dragon from the bottom of the lake by the white walkers. Working in groups, the PSTs should prepare a report explaining how they could use this resource in secondary science class. To do so, they should select different frames and propose scientific driven questions to pose to the students. They had to work three contents of physics, chemistry, biology and geology, clearly explaining how to approach them in the class. The researchers categorized the results according to the contents used in the different disciplines and their explanations.

In order to know their assessment of the activity, each PST completed a questionnaire after the experience where they had to explain what they had learned, the evolution of their knowledge of the resource before and after on an ordinal scale of 1 to 5 (1: I do not know anything, 2: I know a little, 3: I know it well, 4: I know it very well, 5: I can explain it to a friend), assess the best and the worst aspects of the task, give it a score over 10, and choose between several emotions how they had felt in their development justifying why. Evolution of their knowledge and emotions were taken from the *Knowledge and Prior Study Inventory* (KPSI) questionnaire (Jiménez-Liso, Martínez-Chico, Avraamidou, & López-Gay, 2019), with the PST being able to choose more than one of them.

RESULTS

PSTs' proposals

The PSTs made numerous proposals to bring this resource into a secondary classroom. Table 1 shows several examples of sequences, the associated scientific content and the driven questions.

Table 12. Examples of scientific contents and driven questions.

Discipline	Sequence	Scientific content	Driven question
Physics	Jon Snow´s group crosses the icy lake. In their chase, the horde of walkers fails and break the ice	Forces	Why Jon Snow and his friends manage to cross the frozen lake and when the white horde walkers pass the ice breaks?
Chemistry	Jon Snow seems to be having difficulty breathing during the chase	Oxygen concentration	Why Jon Snow has difficulty breathing in the mountains?
Biology	When rescuing the dragon from the ice, you can see that the colour of his eyes has changed to blue	Genetic	Why do some dragons have blue eyes and other blacks?
Geology	The horde of walkers appears from a narrow gorge	Formation of relief	How could a crack have formed in the middle of the mountain? Why isn't a mountain a perfect, smooth, seamless mass?

Two sequences (figures 1 and 2) related to the dragon are explained in detail below, which allowed to discuss different contents through driven questions in the field of biology.

Sequence 1: The eye of the dragon rescued from the ice has changed to blue.

Figure 1. The eye of the dragon

Content 1: Mendel's Laws.

Some PSTs proposed to work the laws of genetics to explain the colour of the eyes and how the transmission of characters takes place. Some driven questions were:

Driven question 1: Why do some dragons have blue eyes and another brown?

Educational approach: The aim is to address in the classroom that the colour of people' and animals' eyes is genetically determined, with DNA being responsible for defining this colour. Also, there are other objectives to address in class such as the belief that eye colour is a mixture of the colour of the parents is not valid; introducing the concepts of dominant character and recessive character by giving examples of the formation of eyes of different colour using the laws of genetics.

Driven question 2: Can two dragons with brown eyes have a dragon with blue eyes? If so, why?

Educational approach: To address this driven question, the student must first propose which is the dominant and recessive gene of eye colour in dragons. He/she can assume that the blue colour of the dragon's eyes, as in humans, is due to a recessive gene concerning his/her allele for the brown colour. Thus, if the dragon's parents have brown eyes and the offspring blue eyes, it is because the dragon son is homozygous recessive (aa), and his/her parents in order to pass on the gene “a” must be “Aa”.

Dragon parents genes: Aa x Aa

Dragon son genes: aa

Driven question 3: What colour do you think their parents and grandparents have?

Educational approach: It is about discussing through Mendel's laws the possible eye colours that the dragon's parents and grandparents could have so that theirs are blue.

Content 2: *Anatomy of the eye.*

The driven questions 4, 5 and 6 are oriented to know or identify the eye anatomy and the functions of its parts.

Driven question 4: What are the different parts of a dragon's eye?

Educational approach: The aim is to identify each of the parts in the dragon's eye: a lens called the crystalline lens, with adjustable focus according to distance; a "diaphragm" (the pupil), whose diameter is regulated by the iris (coloured area), and a light-sensitive tissue (the retina).

Driven question 5: How is the dragon's pupil initially located (dilated or contracted)?

Educational approach: This involves understanding that the pupil changes size depending on the amount of light the eye receives. Thus, through the phenomenon of myosis, the pupil decreases in size, while with mydriasis, it increases in size. The pupil is contracted in the sequence analysed (figure 1). Also, the pupil is vertically elongated and torn like a cat, allowing for a higher capacity for dilation and the ability to have a good depth of objects, which makes the dragon a good hunter.

Driven question 6: Why does the dragon have a second lateral eyelid? Is it fiction?

Educational approach: It will be indicated that this is not fiction since other reptiles have two eyelids, even some animals such as camels have three. As in humans, the eyelids have a protective function. A second function is related to the use they can give them in the air. This situation allows students to ask if they have ever ridden on a motorcycle or rolled down the window of a car, and what is wrong with their eyes, with the idea that they will identify that it is both to protect the eyes from anything getting in them and to keep them hydrated.

Sequence 2: The dragon.

Figure 2. The dragon.

Content 3: Taxonomic classification of the dragon.

The following driven questions allow us to know better the different kingdoms of life and their characteristics.

Driven question 7: To which kingdom of living beings would a dragon belong? Within the animals, what class?

Educational approach: This driven question allows us to approach the kingdoms of life, focusing on the animal kingdom and within it the vertebrates and the chords. It also explains the importance of classifying living beings in science.

Driven question 8: Does the dragon resemble any animal we know? What characteristics do they share and how do they differ?

Educational approach: This driven question aims to introduce the evolution of reptiles and their characteristics, a paraphyletic class of amniotic vertebrate animals with epidermal keratin scales.

PSTs' Assessments

On the learning achieved:

The PSTs highlighted how a playful resource could be converted into an educational resource to learn or explain science by making a good selection of scientific contents, attracting the students with means that they enjoy.

About the evolution before and after the knowledge of the PSTs about the resource:

The average knowledge of the PSTs of the educational possibilities that the resource can offer increased from 1.96 points (before its use) to 4.54 (after) (figure 3) on a scale of 5.00 points (1: I do not know anything, 2: I know a little, 3: I know it well, 4: I know it very well, 5: I can explain it to a friend).

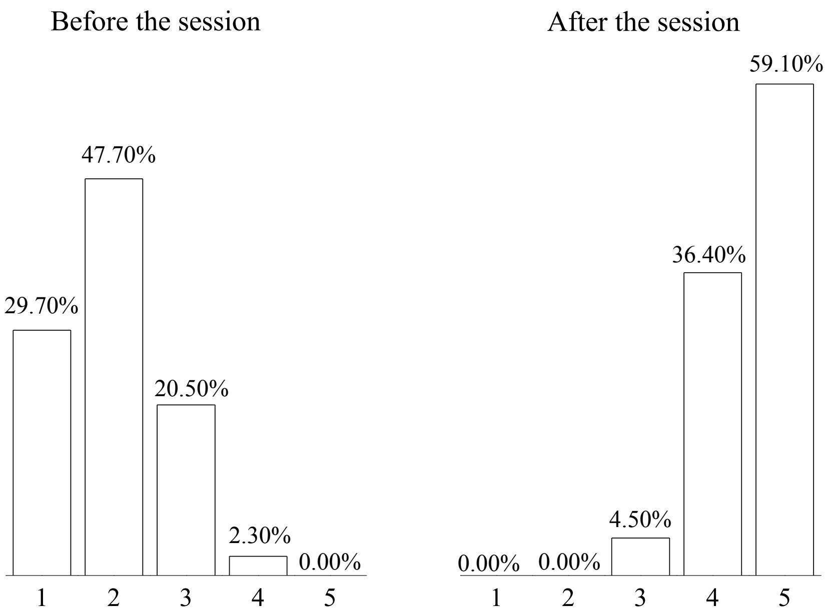

Figure 3. Evolution of the educational possibilities of the resource before (left) and after (right) its use.

About the score given to the resource and the best and worst rated aspects:

The average score of the resource was very good (8.53 out of 10.00 points). The most highly rated characteristics of the resource were its ability to motivate and innovate, its simplicity or its connection with everyday aspects. As negative aspects, they cited the previous knowledge required by the students to solve some driven questions o that the motivational capacity of the show will depend on whether it is known to the students.

Regarding the emotions felt:

81.80% of the PSTs showed interest as the main emotion felt during the activity (figure 4). Satisfaction (59.10%) and concentration (56.80%) were other major emotions. Only 2.30% felt bored, and 4.50% rejected the use of the resource.

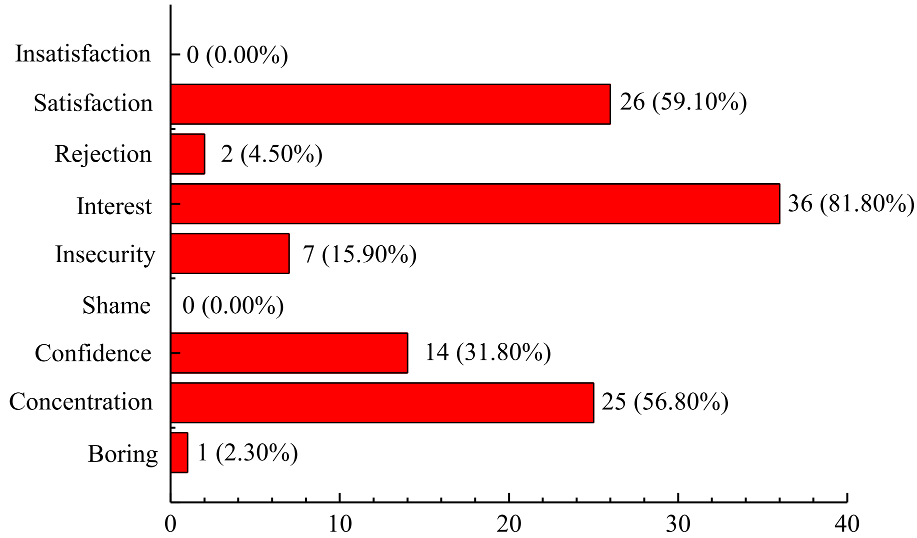

Figure 4. Emotions (%) felt by the PSTs during the activity.

CLOSING REMARKS

We agree with Raham (2004), Perales and Vílchez (2005) and García-Borrás (2008) that the results obtained from this kind of experience are encouraging and show the effectiveness of this resource, although they also highlight the obstacles encountered by secondary school students in explaining phenomena.

This experience has attempted to provide the PSTs with the necessary training to take the resource to the classroom, stressing the possible difficulties of the secondary students. Likewise, the method used does not intend to make an exhaustive follow-up of each chapter of the TV series, but only tries to analyse some situations from the perspective of science. Finally, the fact of having used an adult series does not imply that it will also be used with high school students and the PSTs are aware that they must use a TV series according to the preferences of their students.

ACKNOWLEDGEMENT

This work is part of the 'I+D Excelencia' Project EDU2017-82197-P funded by the Spanish Ministry of Economy and Finance through its 2017 research call and del PIE17-062 de la Universidad de Málaga.

SCIENCE PRE-SERVICE TEACHERS TPACK AND BELIEFS ABOUT LEARNING WITH DIGITAL MEDIA

Julian Küsel[1], & Silvija Markic[1]
[1]Ludwigsburg University of Education, Ludwigsburg, Germany

Even if the technical possibilities of ICT are given, the biggest obstacles for teachers in using digital media are a lack of expertise and competences. To prepare future science teachers for teaching science with digital media, a concept for a seminar for pre-service teachers of chemistry and primary science is developed, implemented, and evaluated. The main goal is to develop the pre-service teachers' skills and knowledge about the use of digital media in science classes and to change – if needed – students' beliefs about the usage of digital media in a positive way. Our seminar is based on a blended learning approach. It discusses new organisational possibilities and new learning media in science classes. The conceptual focus of the seminar is the development and production of educational videos on a certain topic. Besides the feedback for further development of the seminar, the evaluation focuses on pre-service teachers' beliefs and their TPACK regarding digital media in science education.

Keywords: ICT Enhanced Teaching and Learning, Higher Education, Computer Supported Learning Environments

INTRODUCTION

As the world in which we live and work becomes increasingly digital, the demands placed on school and higher education have changed. Parents, politicians, and learners see great potential in the digital society and demand learning with digital media. In various strategy papers, the Ministers of Education of Germany call for the digitisation of education in Germany, which could contribute to addressing several challenges (e.g. KMK 2017, 2019). It has been shown that the use of digital media or Information and Communication Technologies (ICT) has positive effects on teaching and learning (e.g. Hattie, 2008; Hillmayr, Reinhold, Ziernwald, & Reiss, 2017). Furthermore, researchers, especially in science education, see great potential, e.g. in process and model visualisation, in experimentation and knowledge acquisition as well as in inquiry-based learning (e.g. Meßinger-Koppelt, Schanze, & Groß, 2017; Maxton-Küchenmeister & Meßinger-Koppelt, 2014; Hogarth, Bennett, Lubben, Campbell, & Robinson, 2006).

In order to use digital media in a didactically meaningful way in school and, thus, to exploit their potential, a number of prerequisites must be met: in addition to a suitable and usable digital infrastructure, digital learning concepts and teachers trained in media didactics are required (Becker & Nerdel, 2017; Schmid, Goertz, Radomski, Thom, & Behrens, 2017).

Unfortunately, only a small number of teachers in general and science teachers in particular use digital media in their classrooms. Studies have shown that teachers in Germany use digital learning concepts rarely (e.g. Gerick & Eickelmann, 2017). The reasons for this, which have been identified in several studies, are that only 15 % of the teachers see themselves as qualified and only 25 % see the potential of digital media in class (Schmid et al., 2017). Thus, the lack of digitalisation of teaching and learning in schools is partly based on the lack of teachers' expertise, competence, and knowledge in designing learning settings with digital media (Initiative D21, 2016). To fulfil the demand for implementing digital technology, teachers need to professionalise in teaching with digital media.

THEORETICAL BACKGROUND

Concerning this need for professionalisation, it is important to identify the factors that influence teachers to use digital media in teaching. In general, the teachers' actions in class are influenced by two factors: (i) their knowledge and (ii) their beliefs about the subject, such as their beliefs about the use of digital media (Goodman, 1988). Knowledge and beliefs are seen as filters for all activities, and the processing of new information and are often difficult (Eilks & Markic, 2007). They can only be changed in a long-term learning process (Huberman, 1993).

With the TPACK framework, Koehler and Mishra (2008) have provided a model for the (i) knowledge the teachers need for using digital media in teaching in a didactically meaningful way. They refer to Schulman's concept of professional knowledge (1986) and expand it to include Technological Knowledge (see figure 1) which is the knowledge about technology, tools, and resources as well as the productive use of it at work and in everyday life. TPACK describes complex relationships between pedagogical knowledge (PK), content knowledge (CK), and technological knowledge (TK). The term TPACK stands for *Technological Pedagogical and Content Knowledge* and describes the knowledge about the selection and use of technologies for the promotion of learning processes in a subject matter. In this way, TPACK conceptualises the knowledge that teachers need to integrate digital media didactically meaningfully and effectively into their teaching (Schmidt et al., 2009). Guzey and Roehrig (2009) also conclude that the appropriate and effective use of digital media in science teaching depends largely on the TPACK of teachers.

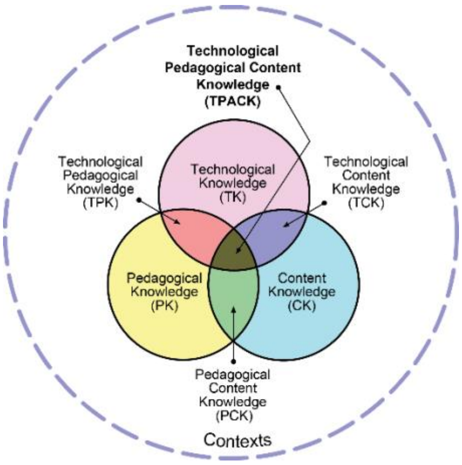

Figure 1. TPACK, Reproduced by permission of the publisher, © 2012 by http://tpack.org

Besides knowledge, teachers need positive (ii) beliefs to use digital media in their class. These beliefs depend on various internal variables of the teacher. The Social Cognitive Career Theory (SCCT) by Lent, Brown, and Hackett (2002) attempts to capture the complex interdependencies of these intrapersonal variables and to find out how these variables influence decision-making processes in the context of a profession. These variables, such as self-efficacy, outcome expectations, and interest are interdependent and influence the formation of personal goals as well as the selection, practice, and execution of behaviours, such as the use of digital media (Lent et al., 2002; Niederhauser & Perkman, 2008).

To sum up, to professionalise teachers in teaching with digital media, they need TPACK and positive beliefs about the integration of technology into their classroom. In order to develop this knowledge and beliefs, pre-service teachers need specific education at a very early stage of their university teacher education program. Thus, in our seminar, pre-service teachers of primary science and chemistry are supposed to obtain knowledge about usage of digital media, as well as expertise and competences in designing learning settings based on digital media for their future teaching. We developed, implemented, and evaluated a seminar for pre-service teachers of chemistry and primary science, that aims for the development of their TPACK, and beliefs and that teaches future science teachers the usage of digital media in class.

DESIGN OF THE SEMINAR

To reach the goal, a new concept for a seminar was developed at our university which follows a blended learning approach (Kerres & de Witt, 2003). The structure of the seminar is presented in figure 2.

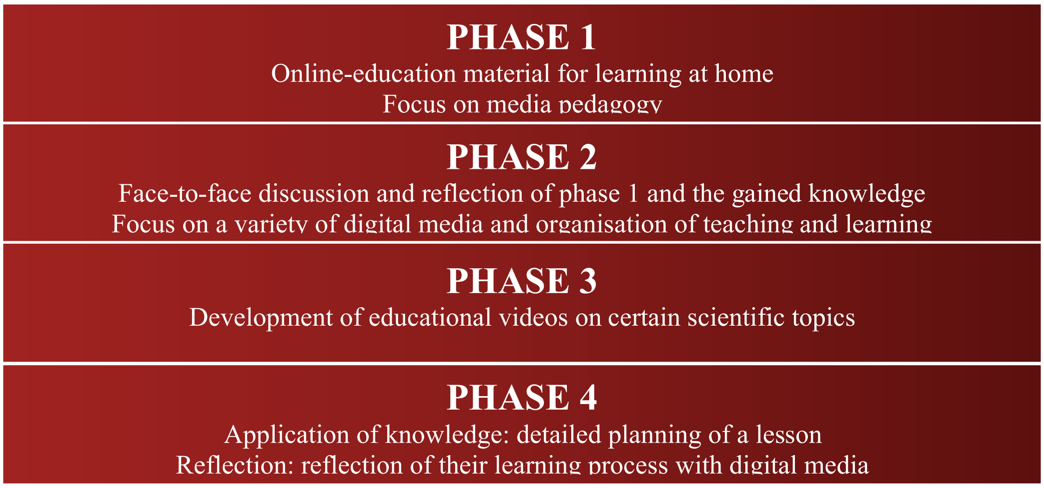

Figure 2. Design of the seminar

In phase 1 the pre-service teachers prepare individually and self-directed with learning materials, assignments, and further information at home. They learn with videos, texts, podcasts, and short online courses with assignments. The focus is on media pedagogy.

Phase 2 works strongly with cooperative and digital learning methods and is strongly learner-centred. The students meet two full days to discuss and reflect on the preparation and their gained knowledge. In this In-Class-Activity, the seminar focusses on the variety of digital media and the organisation of teaching and learning in science education. In these two days, the students work a lot with tablets, apps, and digital whiteboards, so the pre-service teachers can become familiar with these technologies and gain an impression of their productive use in class. They learn to plan lessons with digital media with a didactical concept. One of the topics is criticism of digital media in school and challenges that need to be faced if they want to implement digital media in school. Furthermore, the students will get to know general and scientific learning apps and, in particular, apps with gamification and serious game elements. They will discuss the chances of their use in class.

Finally, the central point of the seminar was in phase 3 the development of educational videos on a specific scientific topic. Educational videos are the most popular digital learning medium for students in their free time (Medienpaedagogischer Forschungsverbund Suedwest [MPFS], 2018). Explanatory videos can be of great use for the students. Especially videos with scientific experiments are considered because laboratory equipment and laboratories are sometimes not available in schools and, therefore, the experimental part of the subject is often insufficiently represented. Through the use of videos, chemical experiments can be integrated into everyday school life. The pre-service teachers need to design a lesson plan and think about how to integrate their video into the learning process. Following this, they develop a script and produce the video.

After the In-Class-Activity, in phase 4, the pre-service teachers in our study need to apply and reflect on their new gained knowledge. Each student creates a portfolio on the topics of the seminar and works on short lesson plans using different digital media in different settings. They reflect on their learning process and beliefs regarding digital media in their future teaching. With this knowledge and these experiences, students will hopefully be able to inform themselves about learning with digital media independently in the future.

RESEARCH QUESTION

Based on the insights from the literature, the goal of the seminar was to improve the pre-service teachers' TPACK and – if needed – to influence their beliefs in a positive way. Thus, three main research questions are raised for the evaluation:

(RQ1) How do pre-service teachers experience the developed seminar and what are their wishes and ideas for its improvement?

(RQ2) How does the concept of the developed seminar change the *technological pedagogical and content knowledge* of pre-service teachers of science and primary science regarding the usage of digital media in their future classes?

(RQ3) How does the concept of the developed seminar change the *beliefs* of pre-service teachers of science and primary science regarding the usage of digital media in their future classes?

METHOD AND SAMPLE

To answer these questions, a pre-post-follow-up-research-design was employed using qualitative and quantitative data. The post-test took place a few days after the seminar and the follow-up test took place four months after the seminar.

Regarding the first research question, the final evaluation of the seminar was based on open questions such as "What did you like about the seminar?", "What did you learn in the seminar?", and "What could be improved?". For answering the second research question, we used a questionnaire yielding quantitative data (Schmidt et al., 2009; translated by Mahler &

Arnold) which measures the pre-service teachers' perceived TPACK. For answering the third research question, a Likert-type questionnaire about pre-service teachers' beliefs about the usage of digital media was employed (Hulleman, Godes, Hendricks, & Harackiewicz, 2010; Hulleman & Harackiewicz, 2009; Davis, 1989; Lent et al., 2005; translated and slightly modified).

24 pre-service teachers of chemistry and primary science participated in the seminar. 20 of them were enrolled in a bachelor's program in primary science and in the first semesters of their degree. The remaining four students were enrolled in the master's program of chemistry for secondary school and in the final stage of their degree. Approximately 80 % of the pre-service teachers were female, which is typical for a University of Education in Germany. We analysed the data with a paired-samples t-test.

RESULTS

In the following, the results will be presented to answer the research questions.

RQ1

The pre-service teachers of chemistry and primary science in this seminar had fun producing the educational videos and liked that they could test a lot of devices and apps and learn that way. They stated that they discovered many possible applications and suggestions for their future classes and got a good overview. They said that the seminar had a good structure and that they liked the blended learning approach. They value the hands-on-activity and the active parts of the seminar. They had hardly any experience with digital media in learning scenarios before the seminar, except for educational videos, which they use to learn in school and higher education. We also asked for suggestions for improvement. After the first round of the new seminar, they only suggested a better timing of the working-phases and more practical examples in class. Based on the evaluation after the second round, we improved in both points.

RQ2

Regarding the second research question, the results are presented in figure 3.

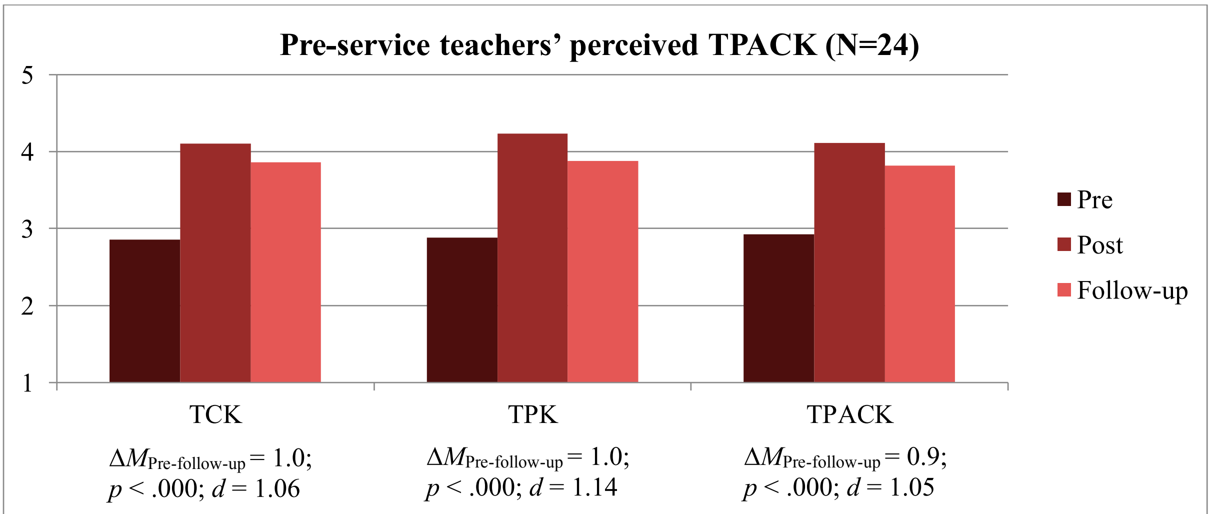

Figure 3. Pre-service teachers' perceived TPACK

The diagram shows the development of the pre-service teachers' perceived TCK, TPK, and TPACK in the pre, post, and follow-up tests. These are the intersections in which the technological knowledge is combined with the other domains and therefore this is interesting for the development of the pre-service teachers. The bars of the pre, post, and follow-up tests have almost the same height regarding the three TPACK intersections. The value in the pre-test is around 2.9 and it increases to a value of around 4.1 in the three cases in the post-test. In the follow-up-questionnaire the value decreased to approximately 3.8 in TCK, TPK, TPACK. The increase of the perceived TPACK is significant and has a large effect size with a Cohen's d > 0.8 (Cohen, 1988).

RQ3

The results regarding the third research question are presented in figure 4.

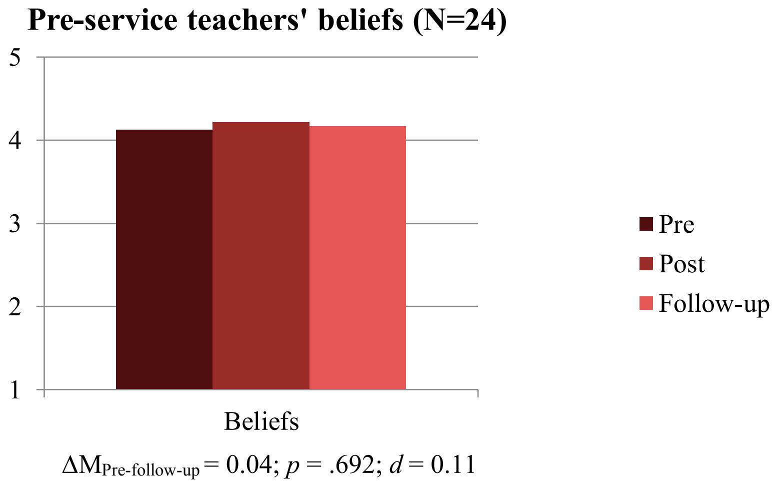

Figure 4. Pre-service teachers' beliefs

In the diagram, the development of the pre-service teachers' beliefs in the pre, post, and follow-up tests is displayed. The bars of the pre, post, and follow-up tests have almost the same height. The value in the pre-test is 4.1 and it increases to a value of 4.2 in the post-test. In the follow-up-questionnaire the value decreased to 4.15. Thus, there is a slight increase, but the differences are not significant. Overall, the beliefs remain on a high level with a value of around 4.1 on a Likert scale from 1 to 5.

DISCUSSION

The present study shows the impact of a specialised seminar on the development of pre-service teachers' perceived TPACK and beliefs about the usage of digital media in science lessons. To summarise our results, the pre-service teachers in this study have a positive impression of the seminar and the feedback became even more positive after the 2nd and 3rd round. A blended learning concept with digital media seems suitable for two full-day seminars in higher education. We recommend giving the pre-service teachers enough time to get to know the technology, such as tablets and apps. A great way to do that is to let them work on creative assignments in groups. They are engaged and will come up with thoughtful and appropriate ideas. Moreover, we suggest discussing criticism regarding digital media in school.

Regarding the perceived TPACK of the students, a significant increase could be observed, with the highest value in the post-study. Thus, we conclude that the seminar leads to an increased perceived TPACK. Here, the seminar reached the goal to develop the pre-service teachers' TPACK.

In contrast, the pre-service teachers' beliefs didn't change significantly but remained at a high level. We think that these results are due to the students' willingness to participate in the course. The course is optional in their study program and we believe that the majority of the students choose the course because they already have strong positive beliefs about the usage of digital media in learning. Furthermore, in Germany, the topic is trendy because there are important governmental campaigns for supporting the digitalisation of learning in schools. Thus, we assume that this could have increased the pre-service teachers' beliefs to this high value already before the seminar. The constantly high values of the beliefs can be interpreted as a positive result because we didn't discourage pre-service teachers with a realistic view of the implementation of digital media in class. Based on the evaluation, we believe that this type of seminar can help pre-service teachers to implement digital media in their future teaching in school. However, this question needs to be addressed in further studies.

USE OF A COMPUTER TOOL IN SCIENCE TEACHING TO SUPPORT THE DESIGN OF EXPERIMENTS

Claire Wajeman[1], Isabelle Girault[1], Cédric d'Ham[1], and Maelle Planche[1]
[1] Grenoble-Alpes University, Grenoble, France

The computer supported environment LabNbook has been proposed to high school and university teachers to support the production of experimental reports or lab notebooks by students. Our focus is on activities where students have to design experiments including a formalisation part through the writing of the experimental protocol. LabNbook provides a protocol editor, Copex, to support students in this formalisation of their experiment. We investigate the pedagogical strategies developed by teachers to make students write protocols using the Copex tool. Forty-nine activities from twenty-one teaching units are analysed. While some teaching units do not spend much on the writing of the protocol, various creative strategies are proposed by the teachers with Copex. An insight on the use of Copex by students shows that the spontaneous use of Copex by the students for writing a protocol is encouraged by the value teachers give to the writing of the protocol and to the use of Copex, in previous activities. Two teachers' interviews show that the structuring power of the writing of the protocol supported by Copex, is used in particular to make students structure their work and thus better understand and connect, the strategy and the details of the experiment.

Keywords: Computer Supported Learning Environments, Laboratory Work in Science, Learning by Design

INTRODUCTION

Literature shows added values and benefits brought by active learning based education (e.g. inquiry learning, problem- or project-based learning (PBL), in terms of conceptual learning (Freeman et al., 2014). Among the possible activities associated to active learning, we are specifically interested in the design of experiments by students that helps them acquire new scientific skills (Etkina, Karelina & Ruibal-Villasenor, 2010).

LabNbook (labnbook.fr) is an online learning environment, which has been initially designed for researchers, to study the design of experiments by the students. LabNbook supports students (and teachers) who are committed to active learning based education and need to write either a lab notebook or a scientific report (e.g. inquiry learning, problem- or project-based learning (PBL), experimental process). For the means of designing experiments, LabNbook includes a protocol editor, named Copex, an original tool to support the writing of structured experimental protocols. This tool is based on one main hypothesis, valid for both high school and university learning: the design of an experiment is at the centre of the experimental process and can be related to each step of this process. This design task is complex and demanding and requires guidance in order to make it feasible by the students. This is supported by several researches in science education (Etkina et al., 2010; Girault, d'Ham, Ney, Sanchez & Wajeman, 2012; Girault & d'Ham, 2014; Arnold, Kremer & Mayer, 2014; van Riesen, Gijlers, Anjewierden & de Jong, 2018; Xenofontos, Zacharias & Hovardas, 2018). Most of these studies do not pay a particular attention to the experimental protocol which describes the experiment and belongs to the experimental process.

The experimental protocol

In our research, we put emphasis on the experimental protocol, in the belief it can play an important role for scientific learning through the design of an experiment. The protocol is a true scientific object that fulfils several functions in the experimental process. Despite an experimental protocol is compulsory in an experimental process, scientific publications seldom deal with it on epistemological issues. Discussions are mostly limited to repeatability and reproducibility questions, and to communicability for assessment by experts (see for instance Dean & Voss, 1999; Selwyn, 1996). This corresponds to an underlying practice: a protocol is a memory of what has been done during the experiment and it describes how the collected data were produced. A protocol carries thus essential information for data analysis and interpretation and for subsequent discussions. In books about the design of scientific experiments (Dean & Voss, 1999; Selwyn, 1996), the protocol is mentioned as a writing part that describes the procedure of an experiment (actions to carry out the experiment) and have to include objectives, information about material and apparatus and the data processing can have to be described as well. Selwyn underlines the necessity of writing a protocol before carrying out the experiment because "experiments that are designed on the fly are rarely successful". Thus the writing of a clear and structured protocol obliges to think, formalize and make clear what one is willing to do; it has to be assessed and improved. The protocol contains theoretical terms and is directed by concepts. The designer has thus to build links between the world of ideas and the world of facts (Tiberghien, Psillos & Koumaras, 1995).

What is the place and role of the experimental protocol in scientific education? For instance, the French upper secondary school curricula (ending 2020) often mention "run a protocol, sometimes "design and run a protocol" and once “propose a critical analysis of a protocol”. Following Chevallard’s framework (1985) to describe knowledge in an ecological context, the protocol can be considered as a para-scientific object: it is a scientific tool that a student must be able to use, but it is not a subject to be taught in itself and it is never defined nor described. In a previous study (Girault et al., 2012), laboratory manuals were analysed at high school level and at the first years of university. It showed that the protocols given to students in cookbook labs have various forms and do not resemble protocols as scientists would write them. The students may thus have difficulties to build a clear image of a protocol.

The protocol editor Copex

After performing several experiments where students design an experiment and write the protocol, we have built a model of a protocol (Bonnat, Marzin-Janvier, Girault & d’Ham, 2019). The model is simple and flexible in order to make it usable for a variety of protocols and suitable at upper secondary school level and for university students. This model was implemented in a protocol editor Copex. A high gain of Copex is to foster the writing of short sentences that are easy to understand, to include drawings, comments and tables and organise the procedure in a hierarchical way. The Copex model is composed of four introductory rubrics followed by the procedure. These rubrics are: Experiment objectives or research question, Experiment hypotheses or expected results, Experiment principle, List of material. The procedure is the description of the experimental actions to be carried out when running the experiment. The procedure is organised in steps, sub-steps and actions. Thus, Copex model supports a structured vision of the experiment that can be built by articulating a global view through the rubrics and the procedure main steps, with the details through sub-steps, actions (there is a possibility to add actions comments). Furthermore, looking ahead for what the experiment should produce (expected results) and connecting it with the hypotheses, requires reflecting on the relevance of the experiment and should foster problem solving.

Copex is available on the LabNbook platform (d'Ham, Wajeman, Girault & Marzin-Janvier, 2019), where students produce scientific reports collaboratively. Since LabNbook does not include content and do not address any pedagogy, the teachers have freedom to design the activity they wish for their students with the pedagogy they want. The teacher configures a template of the students' working space, named “mission”. The students work in collaboration in their own shared working space, named “report”: they write down their report by using four LabNbook editors, including the original protocol editor Copex. Copex can be fine-tuned by the teacher to structure the activity of experimental design at different levels. The teacher can include in the students' workspace a predefined Copex document, i.e. a protocol template which can be totally or partially filled, or empty. She/he can add instructions in the mission to assign a task to the students and to guide them. However, using a protocol editor is not a usual scientific or a teaching practice. Therefore teachers and students may use the LabNbook text editor for writing protocols instead of Copex editor.

Research questions

From 2017, LabNbook has been used by about 140 teachers. In this paper, we address the question of how the protocol editor Copex is used by teachers and students during experimental design activities to make students work on the experimental protocol. There could be a variety of uses of Copex by the teachers since they can structure the activity of experimental design at different levels. We specify two research questions (RQ) through the analysis of teachers' productions and of students' activity:

- RQ1: Which activities regarding the protocol do teachers propose to their students using the Copex protocol editor? What guidance do they implement within LabNbook to help their students in these tasks? Which pedagogical roles/values do teachers assign to these tasks?
- RQ2: When students have to design an experiment, do they spontaneously use Copex to write their experimental protocol? In which teaching circumstances?

DATA AND METHOD

Around 250 pedagogical activities have been created with LabNbook and used for teaching from September 2017 to January 2019, both at high school level (students aged 15 to 18) and at University level (age 19 to 23). The pedagogical activities are diverse, some teachers use LabNbook for one activity that lasts between two and four hours, while others use it through one semester for a project-based learning or for a collection of laboratory works during the two consecutive years of our study. Two kinds of data are used in this study: first we collect the template of working spaces, called missions, that have been built by the teachers for their students. Then, for collecting more information about the teaching process and the teacher's intentions, we conducted an interview with two teachers who designed a mission.

Missions

To answer RQ1 we analyse the 25 missions (10 at high school level and 15 at university level), that include predefined Copex documents (*i.e.* protocols given by the teachers in the template), spread over 12 teaching units (set 1). We collect 24 extra missions (set 2, organised in 9 teaching units) that have no predefined Copex document, while a Copex document was added by students in their LabNbook report. This reveals that students are expected to write a protocol. Among these 24 missions, 15 are connected to missions with predefined Copex documents, so they can be part of a guidance strategy.

For the selected missions, we use an analysis grid to analyse the predefined Copex documents (set 1 only) and the instructions within a mission, in order to identify the tasks that are demanded to the students regarding the experimental protocol. We thus seek for

1. the written instructions within the missions that are related to Copex or/and to a protocol.
2. information that is given or that is to be completed by the students within a predefined Copex document (set1), regarding the rubrics (objective, hypotheses, principle, material), and the procedure (steps, actions).

Students

To answer RQ2, we analyse the second set of selected missions (set 2). For each mission, we calculate the ratio of students who use Copex to write a protocol on all the students who work on the same mission.

Teachers' interviews

We choose two teachers who give an important and original place to the protocol within the missions they designed. These teachers do not use the protocol in the same way and they teach in different contexts.

Teacher 1 is an upper secondary school teacher in chemistry and physics for K12 level students (30 per year). He designed three missions for his own use, following his own will to improve his teaching.

Teacher 2 is teaching laboratories in electronics in an engineering school (L3 level, 360 students per year), and is part of a team of teachers. There is an institutional will to renew and improve all the laboratories. The interviewed teacher designed two missions belonging to two different teaching units, each one taking place at a different semester of L3. In fact, his students follow each semester other teaching units (labs in physics) using LabNbook.

The two teachers are interviewed in a semi-open mode (Planche et al., 2019), to make them express their motivation and objectives, tell what they did to make their students work with the protocol, what was successful and what has to be modified. We want to figure out the epistemological and pedagogical role they give to the protocol in the laboratory work they designed.

ANALYSIS OF MISSIONS

Guidance through Copex

We analyse the protocols in the predefined Copex documents of the 25 missions of set 1, to identify what kind of information is given by the teachers or is to be completed by the students: objective, hypotheses or expected results, principle, material, procedure (steps and tasks). We also look for instructions related to the production of the experimental protocol(s).

	Number of missions (a total of 25 missions)
Presence of predefined Copex documents with only a title	11
Teachers fill at least one rubric among research questions, hypotheses or expected results, principle	19
Steps and actions are given	7
Only steps are given	9
Only actions are given	0

Table 1. Types of information given by the teachers in predefined Copex documents. There can be more than one predefined Copex document in a mission.

The teachers use several guidance strategies to guide the students in the design of a protocol.

- The minimum of guidance is to give students an empty Copex document in the mission. This way, teachers push the students to use Copex to write a protocol. When creating a new document, giving a title is mandatory, this explains why there is at least a title. This is the case in 11/25 missions.
- Another type of guidance is to give students the context of the procedure that will be written by them. This corresponds to one, two or three rubrics filled with research questions or objectives, hypotheses or expected results and the principle of the experiment. This is the case in the majority of protocols (19/25).
- Regarding the procedure itself, some teachers give steps and actions (7/25) or only the steps (9/25). Our analysis shows that there are no missions (0/25) where the teachers would give the actions and the students would have to organise them by adding the steps.

We seek for instructions (in the mission and/or in the teachers' interviews) to associate the type of guidance with intended pedagogical activities. For this we also take into account the the 15 missions within set 2 (no predefined Copex documents) that have a connection with missions that do include predefined Copex documents.

We highlight several pedagogical activities. Some of them correspond to an activity inside a Copex document, while other activities imply an evolution throughout several Copex documents inside a single mission or through several missions. We are able to relate some activities to a pedagogical scenario that we describe in relation to the activities.

- A procedure (steps and actions) is given and the students have to infer the problem to be solved and the expected results (1/25 mission). The teacher expects students to have an overview of their protocol.
- The teacher gives the principle in the dedicated area and through the steps, and the students have to give the details by writing actions (1/25 mission). This gives the students an opportunity to detail the experiment that will be done, to force them to face the complexity of an experiment.
- A Copex document is given with steps and/or actions in an alphabetic order and students have to organise them (3/25 missions, 3 teaching units).
- Students are expected to write the entire protocols with no visible guidance (3/25 missions, 2 teaching units). These missions only propose an empty Copex document. For two of them, the students are working in a project at master level and probably have a degree of autonomy to write their protocol and get feedback from the teacher.
- Students are expected to write the entire protocols with guidance available in a resource area of the mission (1/25 mission). This is a sheet telling how to write a protocol.
- A Copex document is filled by the teacher and given as an example in a mission. Then, students have to write new protocols based on the given example. Combining the two sets of missions, we can describe different cases:
    - students have to learn from one example in a first mission, there is no predefined Copex document in the next missions of the same teaching unit (1/25 mission);
    - there is a fading throughout one mission with several Copex documents having less and less information (2/25 missions, 2 teaching units); or the fading happens throughout several missions (8/25 missions, 3 teaching units). The guidance is strong at the beginning and gradually fades to end with no scaffolds at all. Details are given in the next part, since the two interviewed teachers practice such fading guidance.

Detailed description of the teaching of the two interviewed teachers

Teacher 1: he designed three missions in LabNbook, all related to a transverse theme, the calibration of measuring tools, with a fading effect in the guidance. In the first mission, the teacher offers students a procedure with only steps that can be converted to actions and then steps and actions need to be ordered. In the two other laboratories, students are given only steps to order and must add the actions and the knowledge has to be transferred to a new experimental situation. According to the teacher, the last situation, which is not guided anymore, is significantly more difficult than the previous ones.

Teacher 2: the students have to write protocols in 15 missions within five teaching units during three consecutive semesters: semester 1 (teaching units T1 and T2), semester 2 (T3 and T4) and semester 3 (T5). Teacher 2 designed two LabNbook missions in teaching units T1 and T3, always with predefined Copex documents.

In T1, Teacher 2 designed four laboratories, but only one with LabNbook. The guidance appears through a sheet to be filled for the three paper-and-pencil labs, and with several predefined Copex documents with a fading effect along the LabNbook mission.

He designed one mission in T3, where several protocols are demanded to the students. The students have to exchange one set of data with another group of students (they give one data set and get one); they have to provide the protocol they designed and used to collect the data, and on the other hand they have to analyse and interpret the data set they receive.

These students experience guided protocol writing in two other teaching units: the guidance in T2 is faded through three missions, with predefined Copex documents only in the two first missions. Students use Copex in the third mission without being told. In the 6 missions of teaching unit T4, no predefined Copex documents are given but the students are reminded of Copex with an instruction giving the exact names of its rubrics.

In the 4 missions of T5, taking place the next year, students have to write protocols too, but nothing is done to remind them of Copex. However, the students continue using Copex.

Spontaneous use of a Copex document

Engineering school students do use Copex when there is no predefined Copex document in a mission (RQ2): when there is guidance almost all students use Copex (112/118 reports (95%) for the last mission of T2; 80/90 (89%) for the 6 missions of T4). The next year, students go on using Copex with no guidance at all (15/31 reports (50%) for the 4 missions of T5).

It can be compared with 4 other teaching units (within set 2) for which students are asked to write a protocol but with nothing to encourage the use of Copex in the mission or in connected missions. Some students do use Copex however. The number of students' reports using Copex spontaneously is between 5 to 20% (2/41 to 33/159). This suggests that students seldom use spontaneously Copex to write a protocol when they have not been taught and encouraged to use it.

TEACHERS'INTERVIEWS: DISCUSSION

Acquiring structures for a better understanding

Despite the different contexts, there are similarities between the two cases. First the two teachers have a common major trigger: they are struck by the fact that students do not understand what they are doing and are always focused on a single task at a time without any idea of where it should lead them. Thus they both want to guide their students into a structuring process that will help them to overcome this difficulty and for this they implement guidance with a fading effect. The work with experimental protocols takes a large part in this structuring process. Both tell to have succeeded and that some students said that they better organise their work and thus better understand what they are doing. Teacher 2 says that most students keep on structuring without being told the next year (Master 1) as is observed from our analysis. As described previously, the students were guided for structuring their work through four teaching units and 11 missions, all along the first year (Licence 3). According to the teacher, it is necessary to keep these guidance effort and stringent requirement for a year.

Teacher 1 comments the exercise he proposes in the first mission: this exercise engages all the students, whatever their achievement level, into a rich and collaborative cognitive activity. Students are asked to organise the procedure: they decide the status of each items, step or action, and discuss their position in the procedure and the meaning of it. They deeply experience the hierarchical nature of the protocol and the teacher does observe it "I almost watch the wheels in their brains rotate". Students are autonomous in conducting the process for the third mission despite a strong increase in the difficulty. The students do build a solving path, they link the global view to the detailed actions, identify the global objective, and they do not lose it anymore. It must be underlined that the procedures designed by both teachers include data processing and sometimes elements for data analysis and interpretation (such as "compare to the theoretical model or value"), and thus covers a large part of the experimental process at stake.

Paper pencil versus numerical tool

However, both teachers express reservations. Teacher 1 says that he was not able to check, and thus that he was not convinced, that his students would be able to transfer this know-how to another type of contents. But he said too that the exercise with the protocol cannot be achieved without Copex, and furthermore, when asking his students to write protocols in paper pencil mode, he is unable to guide and check the writing of the protocol before the students carry out the experiment. Teacher 2 thinks that it is necessary to combine both pencil paper and numerical mode for the writing of the reports. He fears that the use of the numerical support only could drive the students to think that the demanded structure of the report could be related to the numerical tool. Then they may not understand this structure as a general resource for laboratories and could not reuse it.

Role of the protocol

The two teachers do not consider the main role of the protocol in the same way: at high school, students have to build a structured description of what has to be done in order to carry out the experiment. The role of the protocol is mainly the design of the experiment, thus thinking and structuring the experiment ahead. This role, even if teacher 2 does not put emphasis on it, exists for the engineering students who have to write the protocol before the laboratory. Teacher 2 says that he wants them to reflect and organise the experimental work prior to the laboratory. However, the main point for him is that the protocol tells how the data are collected. This is required to interpret the data and to find out what is wrong when there is a problem with the data. This requires a high quality and detailed procedure. He designs one specific mission (in T3) in order to make the students feel this point and deepen their analysis, making them experience how much data processing and interpretation depends on how data are collected. During the laboratory, he initiates a discussion with the students in a feedback loop between the protocol and the experimental curves obtained from the collected data: he makes the students analyse, check and complete their data and correct and complete the protocol. But he thinks that the protocol writing skills of the students remain fragile.

Copex rubrics (objectives, hypotheses …) do not have the same pedagogical and scientific status for the two teachers. Teacher 1 does not value the rubrics, focusing on the procedure part. However, he tells that some students do fill the rubrics very seriously without being asked, include pictures or use the comments fields to include explanations. On the contrary, the engineering students have to fill the rubrics, and teacher 2 puts a high value on the "hypothesis or expected results" rubric. This is consistent with the role of a protocol as a description of the data.

CONCLUSION

Twenty one teachers, or teams of teachers, have designed on LabNbook platform the 49 pedagogical activities analysed in this paper that propose students to work on the experimental protocol. These scientific activities belong to a variety of teaching units that are meant for very different populations of students, from K10 to M1, at technical and general high school, university, engineering school ... In twelve teaching units, the teachers make use of the protocol editor Copex which seems to provide an appropriate medium. For instance, engineering school teachers go on using Copex protocol model to guide their students. However, our results suggest that students seldom use spontaneously Copex to write their protocols when they have not been taught or encouraged to use it.

The teachers express a true creativity in the building of exercises about the experimental protocol with Copex. A number of teachers seem to want their students to learn how to write an experimental protocol. But the role of the protocol in these activities goes far beyond just telling what one has to do to run the experiment, as it is usual in cookbook laboratories. Students have to use the protocol as a tool for data analysis and interpretation and to discuss data quality. The protocol is used to think and organise the experiment ahead: the students have to write the protocol, to re-organise or analyse the procedure… Both interviewed teachers consider the protocol as an indispensable element of the report. They both highlight the structuring potential of the experimental protocol in fostering understanding. They find here a solution to an initial and common behaviour they both underline as highly problematic: students focusing on a single task they perform, hindering any understanding of the experiment and more generally of their doings.

The analysis of the pedagogical activities with the protocol also carries original pedagogical strategies. For instance some teachers scaffold the students' learning of a structured approach by using a fading effect in the guidance of the activity. Asking the students to structure and organise a protocol within Copex is used successfully to foster the students understanding of the experimental process at stake by building a global view of the process and connecting it to the detailed parts.

The new French secondary school curricula (starting 2018 to 2021) better highlight the scientific role and the pedagogical potential of the experimental protocol. A wide variety of exercises are recommended, such as "discuss the influence of the measurement device and of the protocol with reference to the data accuracy", "test the limit of usage of the protocol", "identify steps in a protocol", "understand the importance of reproducibility of sampling protocols", "do a critical analysis of protocols and justify the techniques used", "compare the pro and cons of protocols". The experimental protocol should thus take a more important place in teaching. This, together with the presented results, supports that the experimental protocol as a key element of experimental processes, is worth to be learnt and could be used as a powerful tool for learning experimental science.

ACKNOWLEDGEMENT

APPROACHING MODERN PHYSICS THROUGH A VIDEOGAME

Maria Guida[1] *and Alessia Giampaoli*[2]
[1]Indire, Florence, Italy,
[2]LNGS - INFN, L'Aquila, Italy

Gran Sasso Video Game owes its name to the national physics laboratory located under the mountain of Gran Sasso (LNGS), which is the largest operative underground laboratory in the world carrying out a research activity at the frontier of science. The main plot of the game takes place inside the lab, where it really was conceived and developed thanks to a collaborative teamwork made of researchers, science communicators and videogames experts. It is meant as a way to approach young students to modern physics with the curiosity and passion of a researcher. The game environment faithfully reproduces every single detail of the experiments, with the pixel art design, in the following areas: Dark Matter, Double Beta Decay, Solar Neutrino and Nuclear Astrophysics. In this framework, Zot the alien, the video game protagonist, has been catapulted in our Universe due to an unexpected time–space singularity. In order to come back home he needs to repair the four experiments with the help of scientists. The video game, developed in HTLM5, is usable on PC, Mac, Linux or iOS or Android mobile devices, as tablet or smartphone. Next step for authors, due to the collaboration between LNGS and Indire, is to investigate the impact of the game on young students and their learning.

Keywords: Educational Technology, STEM Education, Teaching Innovation.

INTRODUCTION

The purpose of this contribute is to describe a still ongoing project aimed at using the video games to bring 14-19 year old students to study physics and, furthermore, to approach a general public to the scientific culture.

A collaborative teamwork made of researchers, science communicators and videogame experts has developed a game named Gran Sasso Videogame (www.gransassovideogame.it) because it is set in the Gran Sasso National Laboratories (LNGS), the largest operative physics underground laboratory in the world.

The final goal of this project is to study and identify, through a collaboration between LNGS and Indire, a particular kind of learning obtained by exploiting videogames dynamics to approach young people closer to physics. This game was created in the framework of the PILA project (Physics In Ludic Adventure), winner of a call from the Italian Ministry of Education for "Initiatives for scientific culture dissemination". In the next paragraph, the theoretical background that suggested and encouraged this work will be outlined.

In the following paragraphs, after a description of the process of the game development and an explanation of the choices made by the team, authors will illustrate some very early evidences and indicate future work perspective.

THE THEORETICAL BACKGROUND.

In the last forty years, the video game industry has integrated the traditional play experience with a new kind of games that, in this period, have undoubtedly become part of our culture. (Esposito, 2005). However, it is only in the first years of the new millennium that this field of study began to be considered as an emerging academic field at an international level, so that 2001 is considered (Aarseth, 2001) the Year Zero of the study of videogames. Since then, several scholars have developed classifications of the new type of games (Garris, Ahlers and Driskell, 2002, Malone, 1981, Prensky, 2001) based on the characteristics they show in addition to those borrowed from their non-electronic precursors (Huizinga, 1938, Caillois, 2000, Sales & Zimmerman, 2003).

The game is described as an activity or a voluntary occupation performed within fixed limits of time and place, according to freely accepted but absolutely binding rules, having its purpose in itself and accompanied by a feeling of tension, joy and awareness that is "different" from ordinary life (Huizinga, 1938).

So the game is separated from the routine of life, occupies its time and space and its rules suspend ordinary laws and behavior. It involves imaginable realities that can be compared with "real life". (Caillois, 2000).

Sometimes the game enacts an artificial conflict that ends in a quantifiable result (Sales & Zimmerman, 2003), sometimes it has a narrative background.

The game is also the ideal condition for experiencing the flow that is being completely involved in an activity that is an end in itself. "The ego slips away. Time flies. Every action, movement and thought inevitably descends from the previous one, like when you play jazz. Our whole being is involved and we use our skills to the fullest ". (Csikszentmihalyi, 1990).

Scholars talk about serious game when the goal of the game is not to entertain the player, which could be an added value, but to use its funny feature for training, education, health, public policies and strategic communication (Zyda, 2005). The interactive aspect favors the active cognitive processing of educational material, and this is a prerequisite for effective and sustainable learning (see Wouters, Paas, & van Merriënboer, 2008).

However, the learning principles that good games incorporate are all strongly supported by contemporary research in cognitive sciences. The good games give information "on demand" and "just in time", not out of the context of actual use or outside the gamer's objectives and goals, as it happens too often in schools. People are rather poor in understanding and remembering the information they have received out of the context or far too long before they can use it (Barsalou, 1999; Glenberg and Robertson 1999).

Good games operate at the outer and growing edge of a player's competence, remaining challenging, but affordable, while schools often operate at the lowest common denominator (diSessa, 2000). Since games are challenging but affordable, they are often also pleasantly frustrating, which is a very motivating state for human beings.

Several theories underline the potential of serious games to positively influence intrinsic motivation (Garris et al., 2002; Malone, 1981). This means that players are willing to invest more time and energy in the game not because of extrinsic rewards, but because the game itself is rewarding. Several features of serious games have been identified for this motivating appeal. Malone (1981) has proposed that the most important factors that make playing an intrinsically motivating computer game are challenge, curiosity and fantasy.

Two other essential factors associated with computer games, autonomy (ie the opportunity to make choices) and competence (ie, a task is experienced as difficult but affordable), derive from the theory of personal determination and are known to positively influence expert motivation (Przybylski, Rigby, & Ryan, 2010; Ryan, Rigby, & Przybylski, 2006).

Lastly, a particular kind of serious games are the so-called "games for learning" considered by Mayer as all those games or those simulations that intentionally have the objective of favoring learning, which therefore produce a measurable change in the academic knowledge or in the cognitive abilities of the students.

METHODS

The underground structure of the Gran Sasso National Laboratory (LNGS) represents a unique setting for a physics game. The mission of the laboratory is to address the open questions in the astroparticle field, through its main research lines: properties of neutrino, dark matter and nuclear astrophysics.

In order to involve the players in the life of experiments a series of interviews with the researchers working in the various experiments were recorded. The interviews were aimed at understanding scientists' activities, motivations, passion and competition and so suggestions and ideas for the video game story emerged. In particular, the elements that could stimulate curiosity in the players were analyzed; the knowledge and technology challenges; the charm of the setting in the huge underground halls.

Thus, the idea of an adventure-type game was born, an exploration of the underground labs in which interacting with objects and characters to achieve the goals set. In the writing of the screenplay, the different points of view of the working group have converged to get enjoyable gaming experience for students, but also fully satisfactory for insiders and for researchers working in the laboratory.

The fictional component of the game is entrusted to the main plot. The alien Zot, who happened in our Universe due to a space-time singularity, has to restore four LNGS experiments in order to reactivate the damaged circuits of his spaceship and return home. At the end of each experiment, a minigame is unlocked, with a simple game dynamics (i.e. touching some objects and not others) in which quick reflexes come into play. This minigame was introduced to make the continuation of the game interesting.

In the early stages of game design, a series of sketches were made. All the game setting were realized based on available photographic references and on the visit of the working group team in the LNGS experimental halls, like the control room of the Xenon experiment, shown in fig. 1, reproduced in the video game using the pixel art design.

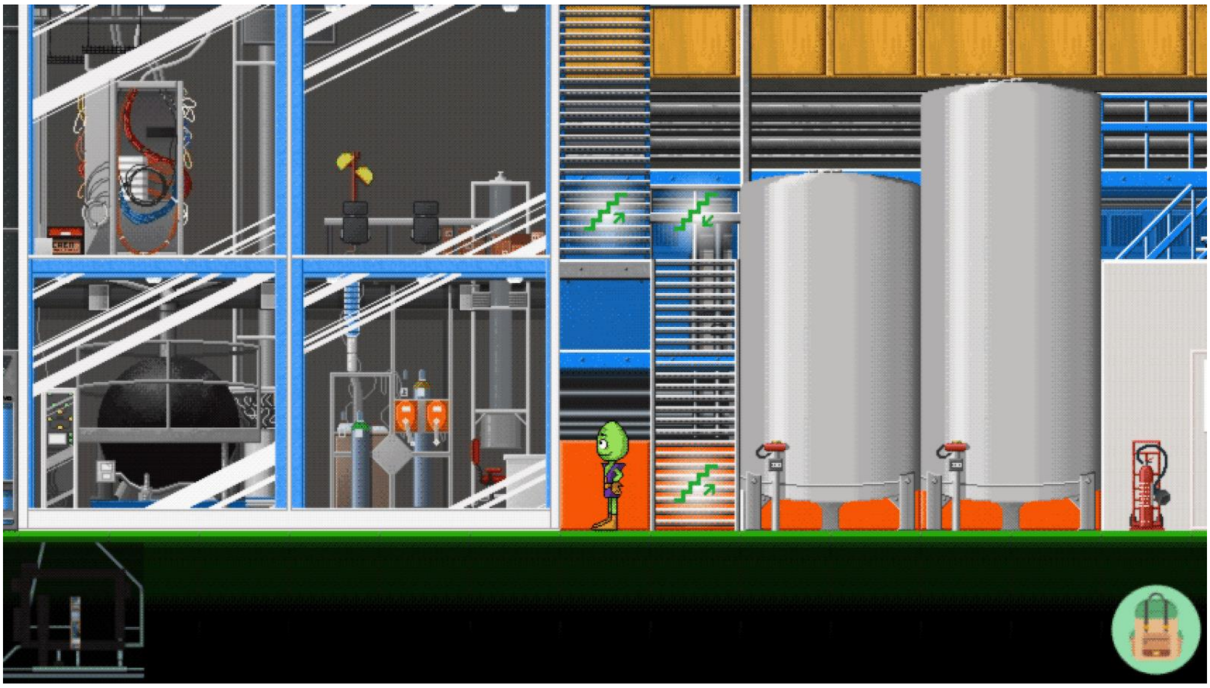

Figure 1. An experimental control room reproduced using the pixel art design.

In the development of the videogame, objects and actions have been chosen to underline important experimental concepts and approaches such as the pure target preparation, the 3D printer to realized detector frames without contaminant, ect.

Each experiment and the related objects are connected to a short card that the player is free to read or not. The card has a dual function: on one side contains a suggestion to be used in the game, on the other it is a way to stimulate curiosity on the particular topic and to eventually direct the user to a more in-depth information sheet, external to the game and hosted on Gran Sasso videogame website.

Gran Sasso videogame is also imagined to be used in schools, within a single class, in a scheduled time duration between half an hour and two hours, in one or more sections of the game.

In this regard the PILA project, mentioned above and proposed by LNGS-INFN together with the communication agency *formicablu srl*, takes advantage from the collaboration with INDIRE, the National Institute for Documentation, Innovation and Research in Education, especially in the phase of experimentation in schools, which only the pilot has been carried out until now. However, the deep knowledge and competence of LNGS researchers in physics is completed and enriched, for the purposes of this project, by Indire competence in the pedagogical field and for its knowledge of the schools located throughout the Italian territory, with which it has a consolidated relationship built over the years through well-known projects and national teacher training plans.

The innovativeness of the proposal, moreover, is not only inherent in the chosen medium, but also in the treated topics, which are not normally included in the school physics curriculum neither in the final years of the scientific high school. The topic are the neutrino physics, the existence of non-visible matter, the fascinating evolution of the stars reproduced in the laboratory with nuclear astrophysics. The videogame tries to put students in front of these themes, without trivializing them but instead honoring their complexity, trying to leverage them to fascinate girls and boys thus stimulate students' interest in further study of physics.

The PILA project has a duration of 24 months and includes, in addition to the creation of the videogame, the production of a website with downloadable materials to support teachers.

In the second year (2018-2019) of the project, a user experience evaluation has been conducted in order to fine-tune the final version of the videogame and the related teaching materials. The experience evaluation was foreseen in testing the game in a number of schools located in the Abruzzo region, the same where LNGS are set, involving their teachers as co-researchers. The project team referred to the literature in this field in order to identify and understand the possible benefits and outcomes deriving from the use of games in school. The team planned to extend the test in a wider territory in Italy in the third year of the project.

RESULTS

At the LNGS Open Day 2018 the beta version of the videogame was presented and an evaluation questionnaire was submitted to the participants in the event, where they were asked to express their appreciation for the gaming experience on a likert scale.

The users were not the ones defined in the project, even if mostly young people, but it was interesting to observe the reactions to the use of the game for the first time and a great interest for a deeper involvement in the physics topics was recorded.

Some good insights emerged from the analysis of the website accesses too. In addition, during Didacta educational faire 60 STEM teachers participated in a workshop based on the game and they filled in a survey, answering the questions if they would use this video game in their teaching activity and what possible advantages they expected to gain. The great majority of them replied that they would gladly use the game in their classroom, especially the ones who teach in the upper secondary, while the others were afraid that the topics were too difficult for younger pupils. Among the advantages of using the game in the classroom, teachers mainly indicated the following. The game can stimulate the interest in physics and the in-depth study of the theoretical lesson, due to a graphic language close to the world of teenagers. It stimulates the curiosity that leads to the continuation of the game. Teachers saw the possibility of using it as a first approach to complex topics to be studied and the possibility of stimulating collaboration between players, avoiding competition among those with more or less playing skills. They consider the game even useful to prepare a visit to the real LNGS. Finally, they consider the logical sequence of the steps to be taken in the game, a formative aspect for students.

In spring 2019, the beta version was played in 23 classrooms, involving 382 students of high schools in an average age of 17, but the analysis of the results of the evaluation questionnaire is still in progress. A preliminary analysis shows that the 45% of the students are interested in scientific matters, and they found this videogame helpful to getting closer to physics.

CONCLUSION AND FUTURE PERSPECTIVES

After the release of the beta version, the game has been improved. Additional elements have been introduced such as bonus elements that push players to complete the exploration of underground laboratories in every hidden door or corridor. The English version has been implemented to allow the game fruition even outside the Italian territory. The insertion of new sub-works and new scientific experiments have been evaluated. In 2019, due to the involvement of INDIRE further 8-10 classes of upper secondary schools located in the Abruzzo Region, participated in the evaluation of the videogame by testing its functionality and the real usability of the didactic materials for dealing with topic related to modern research in physics. The evaluation sections with the classes had a duration of 2 hours. The user experience evaluation, made in the second year of the project and the tests in schools, will allow adapting the didactic contents to the real needs of students and teachers.

In 2020 with the final version of the video game and material ready, further inquiry can take place, involving schools from all over Italy. After the first exploratory phase, the future research will go into more detail about the possible effects on students of the use of video games in physics classes. Measurable change in the academic knowledge or in the cognitive abilities of the students (engagement increase or intrinsic motivation, development of cognitive processes, or understanding and retention of content over the long term) will be the subject of future study.

EVALUATION OF A FEEDBACK-SUPPORTED EDUCATIONAL APP TO PROMOTE STUDENTS' UNDERSTANDING OF PCR AND GEL ELECTROPHORESIS DURING HANDS-ON EXPERIMENTATION

Markus Bergmann, Angela Sandmann and Christine Florian
University of Duisburg-Essen, Essen, Germany

An educational app was developed including feedback on learning tasks to support students' conceptual understanding of PCR and gel electrophoresis during hands-on experimentation in an out-of-school laboratory. N = 134 secondary students learned and carried out experiments based on the information and instructions in the app. Moreover, the students conducted a knowledge test on PCR and gel electrophoresis before and after using the educational app. The Biology grade and information on the Cognitive Load were asked. The reliability of the knowledge test was satisfactory. Scores of the pretest and the posttest were compared in order to derive evidence that indicates validity of the app. The results showed a significant increase of knowledge on PCR and gel electrophoresis after using the educational app. Furthermore, correlations between Biology grades and pretest scores as well as correlations between Cognitive Load and posttest scores were conducted. The results support the idea of validity of the measures of the knowledge test. To investigate the appropriateness of the learning tasks failure frequencies were analysed. The results show that the number of students who need additional support as they were not able to respond to the learning tasks correctly, was in an acceptable range. Beyond that, students who failed to give the correct response to the learning task often had Biology grades that indicates a low level of expertise. All in all the results of the analysis consistently indicate acceptable validity of the learning environment. The next step is to vary different types of feedback in a pre-post-intervention study.

THEORETICAL BACKGROUND

Learning PCR and gel electrophoresis in out-of-school laboratories

PCR and gel electrophoresis (GEL) are essential methods in Science and therefore an obligatory learning content in schools in various countries (OECD, 2007). Out-of-school laboratories offer opportunities to conduct experiments including PCR and gel electrophoresis. The understanding of the underlying concepts requires prior content knowledge, instruction and is highly cognitive demanding (e.g. Duncan & Reiser, 2007). Therefore, a multimedia learning environment representing abstract molecular concepts in multiple external representations could support students' conceptional understanding of PCR and gel electrophoresis (Mayer, 2014; Sweller, 1994). Moreover, as students differ concerning their prior content knowledge (Ceci & Chi, 1987) learning environments that provide individual support are held to be even more effective. Against this background a well-designed tablet-supported educational app with integrated automated feedback offers the potential to reduce cognitive load and enhance the learning outcomes for students during experimentation including PCR and gel electrophoresis in an out-of-school laboratory.

Feedback

Feedback is reported to be one of the most enhancing factors concerning individual learning (Hattie, 2009). In the context of computer supported and automated feedback we define feedback as “any kind of information provided to students about their actual state of learning or performance in order to modify the learners thinking or behavior” (Goldin, Narciss, Foltz & Baauer, 2017, pp. 384-386).

The interactive tutoring feedback model (Narciss, 2013) describes different types of feedback. Two of them are Knowledge of Response (KR) and Knowledge of Correct Response (KCR). KR gives information about the correctness of a respond to a learning task while KCR provides the correct respond. Modern information technologies, such as tablets, allow utilizing the advantages of immediate feedback in multimedia learning environments (van der Kleij, Feskens, & Eggen, 2015). More complex types of feedback are described as elaborated feedback. Elaborated feedback combines all types of feedback that provide additional information besides KR and KCR.

The effect of feedback on the learning outcome is affected by the the cognitive processes that are needed to solve a task. A meta-analysis shows that KR and KCR has a positive effect on lower order learning outcomes. Elaborated Feedback, however, has a positive effect on lower order learning outcomes and higher order learning outcomes (van der Kleij, Feskens & Eggen, 2015).

AIM AND RESEARCH QUESTION

In this preliminary study we evaluate a self-designed and programmed educational app, which includes multiple information, instruction and learning tasks as well as KR and KCR feedback for students who visit an out-of-school-laboratory to learn the concepts of PCR and gel electrophoresis and conduct experiments including these methods. Hence the aim of this preliminary study is to derive evidence about the reliability and validity of a feedback-supported educational app to promote the understanding of PCR and gel electrophoresis during hands-on experimentation in Biology. The following research question is addressed:

RQ: To which extend do measures of reliability and validity indicate the quality of the educational app including the integrated learning tasks?

RESEARCH DESIGN AND METHODS

Development of the educational app

First a laboratory course in an out-of-school-laboratory was developed, where students of secondary schools conduct hands-on experiments including PCR and gel electrophoresis. Then, to support the conceptual understanding of PCR and gel electrophoresis and to guide the students through the steps of experimentation, an educational app for iPads was developed. Students’ knowledge about the concepts of PCR and gel electrophoresis was derived within a single-choice test before and after using the educational app and conducting the experiments. At the same time the structure of the app and the test (Figure 1) organises the laboratory course.

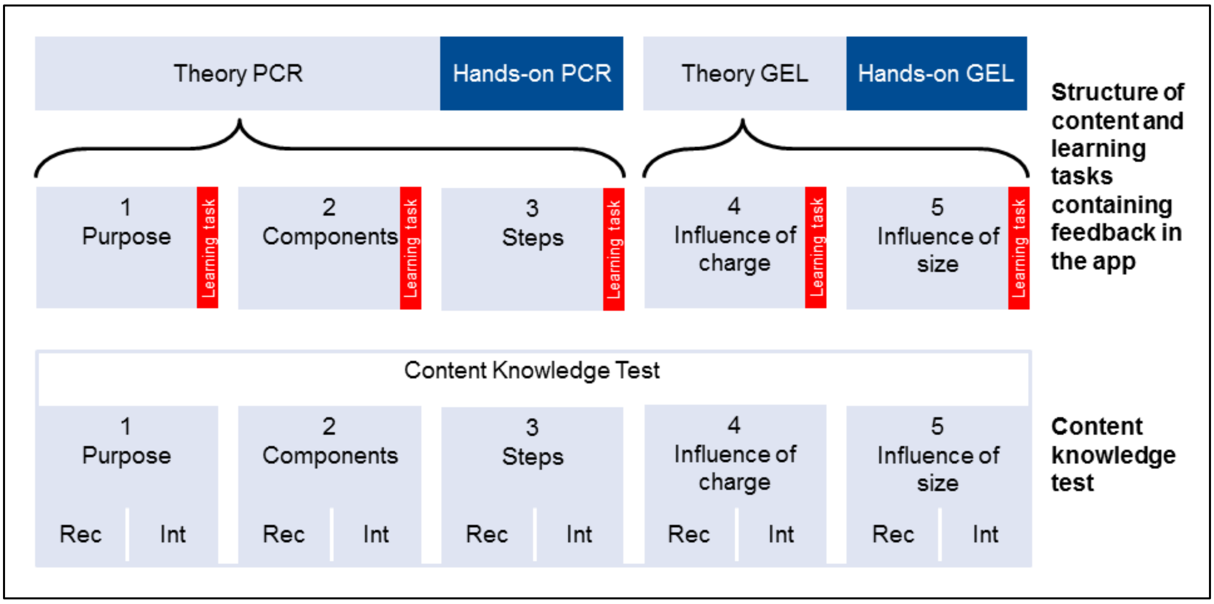

Figure 1. Structure of the app and the content knowledge test.

Note. Rec = Recognition of facts. Int = Integration of facts. GEL = Gel electrophoresis.

In the developing process we oriented to the national curricula and interviewed Biology teachers. They were asked for crucial aspects in understanding PCR and gel electrophoresis as well as for aspects students often trouble to understand. Based on a qualitative analysis five sub concepts were derived, which are key for understanding PCR and gel electrophoresis in the given context (PCR: *purpose*, *components*, *steps*; GEL: *influence of charge*, *separation by size*). Each of the concepts represents one chapter of the app.

At the end of each chapter we integrated a learning task in a single-choice format with four answer options that covers the concept of the chapter. Students had to respond to the tasks and received immediate feedback. In this study the types of feedback were KR for correct responses, KR and KCR for incorrect responses.

The structure of the app is also the basis for the content knowledge test that consists of 27 items. On a first level the test is structured by the five derived sub concepts of PCR and gel electrophoresis (s. a.). On the second level it includes two cognitive processes (compare Anderson, 2014): *recognition of facts* and *integration of facts*. Recognition of facts means that only a single fact is needed to complete a task, whereas integration of facts means that a minimum of two facts has to be integrated to complete a task.

During the app development we applied principles of the Cognitive Theory of Multimedia Learning on instruction in e-Learning (Mayer, 2014; Mayer & Clark, 2016). We, for instance, based on the Multimedia Principle, used text and graphics instead of words alone. Based on the Segmenting Principle we divided the app into chapters with each chapter being subdivided into coherent sequences. The order of the chapters is structured and students can unlock new chapters by completing the previous one. Students can navigate between the sequences at their own pace and in a free order. This level of guidance offers sufficient structure in an open learning environment. Since engagement can support learning we added a few prompts for students to interact with and engage in the prompted contents (Figure 2).

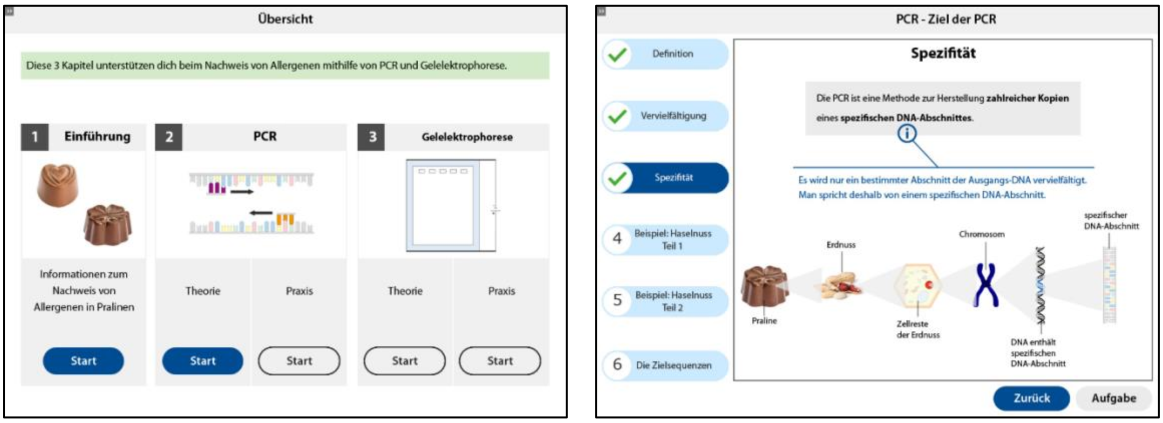

Figure 2. Examples pages of the app. On the left side there is the main menu. On the right side there is a typical content page.

In the following we will describe the appearance of a typical page representing a chapter in the app (Figure 2). At the top there is a headline that describes the chapter. A content box takes up the majority of the page. Buttons on the left allow for navigation and provide control over the content box. Each of the numbered buttons represents one sequence of the chapter and is activated by touch. Once a student touched one of the buttons the content box displays the related information. After touching the buttons a checkmark replaces the number, which indicates that the sequence has already been viewed. We placed a button to navigate to the following chapter in the bottom right, but they remain inactive until the student selected all sequences of a chapter. In the top left there is a button to expand and collapse a table of contents, but chapters are not accessible before they have been unlocked by completing the previous one.

Design and Sample

In this preliminary study 134 students (69% female) with an average age of $M = 16.8$ years ($SD = .90$) took part. Content knowledge on PCR and gel electrophoreses was assessed in a pre-post design using a 27-item self-developed content knowledge test. The sub concepts of PCR and gel electrophoresis as well as the two cognitive processes of recognition of facts and integration of facts structure the test.

In Addition to the content knowledge test the students' Biology grades were asked in the pretest and their Cognitive Load (CL), measured as mental effort on a 11-point rating scale (Leppink, Paas, van der Vleuten, van Gog & van Merriënboer, 2013), was asked in the posttest. The Biology grade was on average in the middle range (*Mdn* = 3/C).

RESULTS

Content knowledge test

Table 1 presents the Cronbachs α values for all scales and subscales of the content knowledge test. The reliability of the overall test was good ($n = 27$ items; $\alpha = .80$). Moreover, the reliabilities of its subscales were calculated. All measures were satisfactory ($.50 < \alpha < .73$) with the exception of the scale GEL x recognition of facts (6 items; $\alpha = .36$). Furthermore we checked reliability of the Cognitive Load Scale, which shows good internal consistency ($n = 8$ items, $\alpha = .80$).

Table 1. Item number and Cronbachs α of subscales of the content knowledge test.

Scale	Items (n)	Cronbachs α (post)
Overall	27	.80
Recognition of facts	16	.69
Integration of facts	11	.68
PCR	15	.73
GEL	12	.60
PCR x Recognition of facts	10	.66
PCR x Integration of facts	5	.54
GEL x Recognition of facts	6	.36
GEL x Integration of facts	6	.50

The mean knowledge increase for the whole test is M = 10.20% (SD = 13.09%), for the items of recognition of facts M = 12.41% (SD = 15.74%), and for items of integration of facts M = 6.99% (SD = 18.82) (Figure 3).

Since integration of facts is meant to be a higher cognitive process than recognition of facts, items on integration of facts should be answered correctly less frequently. Posttest-scores of items of integration of facts were significantly lower than the posttest-scores of items of recognition of facts ($t(133) = 9.02$, $p < .001$, $d = .58$) (Figure 3). This indicates construct validity of the test.

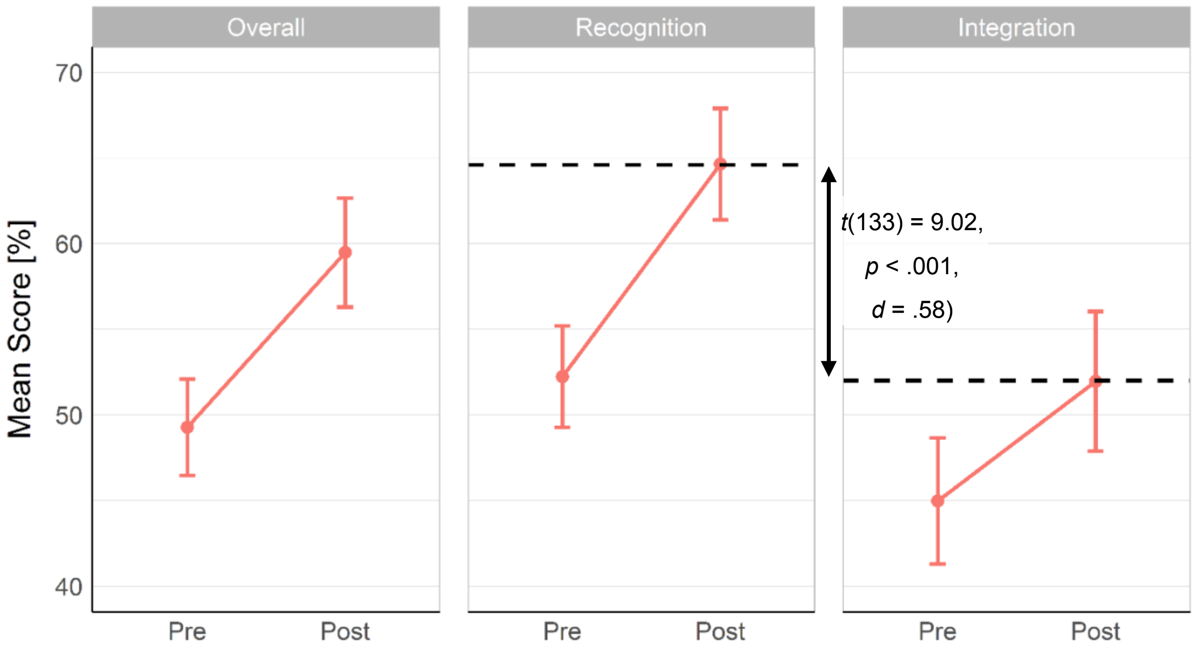

Figure 3. Increase in content knowledge overall and for the cognitive processes separately.

We further investigated correlations between the test scores and other criteria. Spearman correlations between the Biology grade and scores of the pretest were conducted. The better the Biology grade of the students the higher they scored in the pretest ($r_s(132) = -.49$, $p < .001$). Since the Biology grade points to the level of students' expertise in Biology and in Germany lower grades represent better performances, we see this as indicator for criterion validity.

Additionally negative correlations between CL (M = 2.04, SD = 1.48) and scores of the posttest indicated the higher students reported on their CL the lower they scored in the posttest ($r_s(132) = -.30$, $p < .001$). This again indicates criterion validity of the test.

Learning tasks

According to the analysis of the learning tasks the failure frequencies were within a range of $.13 < M < .47$ (Figure 4). Three learning tasks had intermediate failure frequencies and two had a lower one. The low failure frequency on learning tasks 3 and 5 indicate that only few students needed support on these tasks. As a result these tasks are not suited to measure the effect of feedback on learning outcome and therefore need revision.

The distribution of failure frequency over all tasks is fairly normally distributed (Figure 4). The analysis shows that 9.7% of the students answered no learning task wrong. Therefore, it is not possible to investigate the effect of feedback on these students. In addition to that, 11.9% of the students answered four or five of the learning tasks wrong. It is at least questionable if those students are even able to profit from feedback considering their low conceptual understanding.

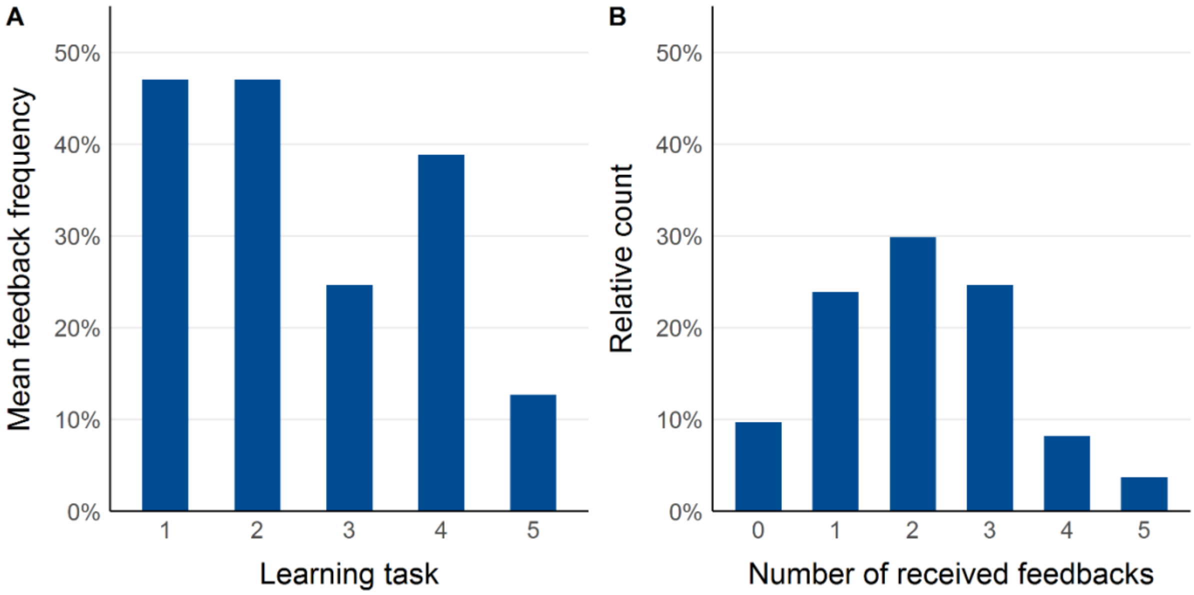

Figure 4. A: Feedback frequency per learning task. B: Distribution of feedback frequency over all learning tasks.

Finally correlations show: the worse the Biology grade the higher was the failure frequency in the learning tasks ($r_s(132) = -.28$, $p < .01$). This connects the learning tasks with the content knowledge test and indicates criterion validity.

DISCUSSION

In this preliminary study the aim was to derive evidence about the reliability and validity of a feedback-supported educational app. To do so we developed a knowledge test on PCR and gel electrophoresis. The reliability of the content knowledge test is acceptable and only one subscale needs revision. Items should represent the cognitive process of either recognition of facts or integration of facts. The higher difficulty of items that were constructed for integration of facts in comparison to items that belong to recognition of facts indicates construct validity of the test. Studies show that in tests that are designed for large-scale assessment it can be difficult to post-hoc operationalize items towards the cognitive processes that are needed to solve them (Kauertz & Fischer). However, interventional studies often aim for considerably smaller and more homogeneous samples. That is why we think, despite using simple but common methods, the content knowledge test meets the requirements satisfactorily. Based on correlations between outcome related criteria, such as Biology grade and CL, and learning outcomes we found several indicators for criterion validity.

Some limitations should be noted. Firstly, we used a short content knowledge test with only 27 items. Therefore, the test might not represent the concepts of PCR and gel electrophoresis in every detail. However, by doing so we could ensure a time-effective data collection during the laboratory course. Short tests are widely used for assessing students' abilities in interventional studies, because their concentration and attention is limited. Secondly, we assessed the Biology grade and CL as self-reports. Although self-reported CL seems questionable many studies demonstrated that students are capable of reporting on their mental effort (Paas, Ayres & Pachmann, 2008). This is why measuring CL as self-reported mental effort is a common practice in educational research. Because the results are consistent with our theoretical framework we conclude that there are sufficient and reliable arguments to use the instruments in combination with the app in further studies with focus on the effect of different types of feedback on the learning outcome.

Feedback is only useful when it is needed. All students needing feedback on every learning task, however, would indicate a mismatch between the learning prerequisites of the students and the learning environment, because content knowledge as well as abilities that are necessary to use the app for learning, e. g. reading, should be normally distributed in the population. Therefore, most learning tasks showed an appropriate failure frequency while two of them need revision. The failure frequencies of the learning tasks indicate that the number of students who need further support concerning crucial concepts of PCR and gel electrophoresis is appropriate. The correlation between the Biology grade and the failure frequencies of the learning tasks indicates that especially students on a lower level of expertise may profit from feedback.

At this point we do not know which types of feedback foster students understanding of PCR and gel electrophoresis on a lower order and on a higher order level during experimentation in an out-of-school laboratory. For this reason, we plan to investigate the effect of different types of feedback in a pre-post-intervention study based on the evaluated learning environment and test in this preliminary study. So far, the used feedback covers only KR and KCR. Elaborated feedback is supposed to be more effective on tasks that require higher order learning skills. The next step is to integrate elaborated types of feedback into the educational app. We consider that by doing so especially a deeper understanding of PCR and gel electrophoresis is promoted. Students who receive elaborated feedback might then score higher on scales that cover the cognitive process of integration of facts.

MEANINGFUL LEARNING AFTER USING MULTIPLE MEDIATIONS TO TEACH BOHR ATOM IN SECONDARY SCHOOL IN BRAZIL

Savana dos Anjos Freitas[1], Agostinho Serrano de Andrade Neto[1]

[1] Universidade Luterana do Brasil (ULBRA), Canoas, Brazil

The present research sought to investigate the main ways to approach the teaching of the Bohr atom model to secondary school students of a high socially vulnerable neighbourhood in Brazil. The theoretical framework used is the CNMT (Cognitive Networks Mediation Theory) to find out which mediations may contribute to a better learning of the Bohr atom model four mediations used within a PMTU (potentially meaningful teaching unit) teaching sequence. Our results indicate that the hypercultural mediation stood out among the students interviewed; However, all mediations have contributed to the understanding of the Bohr atom in some specific facet, and many combine different mediations to better understand Bohr Atom.

Keywords: Computer Based Learning, Physics, Video Analysis.

INTRODUCTION

Many obstacles can be manifested in physics teaching in 9th grade, which represents the end of the Elementary School (ES) in the Brazilian educational system (1st to 9th school year). Many teachers are not trained in this area of knowledge, that is, they are not graduates in Physics or Chemistry, which technically does not qualify them to work with these disciplines and generates problems in teaching. The lack of laboratories is also a factor mentioned by the authors, since it can negatively affect the motivation of teachers and students to teach-learn science.

Given the panorama of the teaching of physics in PE in Brazil and due to so many questions, this research aimed to investigate and analyze the mental images acquired or modified by PE students after using extracerebral tools for the study. learning concepts relevant to the study of the Bohr atom model. This research has chosen as its theme the Bohr atom model, because this content can be approached jointly in the disciplines of Chemistry and Physics. Since the guidance is for these last year of the ES to work together, Bohr's Atom enables this initiative. The concepts expressed in this atomic model can be developed in both disciplines, as evidenced by some 9th grade science textbooks.

Bohr's atom can contribute to the explanation of many phenomena observed in people's daily lives, such as lights and lamps, flame testing or fireworks. In his master's research, Silva (2013, p. 158) describes that many students believe that fireworks had different colors due only to the use of dyes, that this "is not related to the electronic jumps that occur in the metals that make up this firework. artifact, but because of the presence of dyes ".

Fluorescence and phosphorescence are other phenomena that can be discussed in the classroom with students approaching everyday examples when working on the Bohr atom (Silva et al., 2014). Accordingly, Parente, Santos and Tort (2014) state that when developed on the Bohr atom in the classroom, it contributes to its being a gateway to the world of the internal structure of the subject for students, a subject that often brings the curiosity of the students.

The theme was explained using a didactic sequence elaborated by the researchers-teachers of this research. The didactic sequence, entitled Didactic Sequence from the perspective of the UEPS-based TMC, was proposed after the use of seven Potentially Significant Teaching Units (UEPS), a concept proposed by Moreira (2011), prior to the PIBID Physics subproject. The didactic sequences elaborated in this research were based on extracerebral tools applied during the proposed activities, such as a computer simulation or the making of the Bohr atom model, for example.

Therefore, we elaborated this research considering the reality of physics teaching in PE and the context of the school community. The research was conducted in partnership with the Physics subproject of the Institutional Teaching Initiation Scholarship Program (Pibid) of the Lutheran University of Brazil, in Canoas, RS. The college in which the project was conducted is the João Paulo I State Elementary School, located in a neighborhood near the University. The students participating in the project were from the 8th and 9th grades of EF. The two classes were chosen based on the fact that they are in the final stretch of the ES, in preparation for the beginning of high school (MS).

To analyse the results, we used the Cognitive Networks Mediation Theory (CNMT). In his CNMT, Campello de Souza, Silva, Silva, Roazzi, & Carrilho (2012) indicates that cognitive development involves the interaction of an individual with objects and systems that have the ability to perform computations, being a process that involves the simultaneous emergence of internal and external mechanisms of mediation. The individual not only allocates the same computational resources, but also gains new concepts, where the new internal mechanisms present in the cognitive structure of the individual are named *drivers* (as employed in computation) that make possible the use of external mechanisms.

For Campello de Souza, Silva, Silva, Roazzi, & Carrilho (2012), also detailed in Serrano et al. (2018), there are four levels of mediation: Psychophysical Mediation, related to the physiological characteristics of the subject with the composition of the object; Social Mediation, when interaction occurs with different people in the same environment; Cultural Mediation, implying the language and the capacity of society to report events involving categorizations of ideas and concepts; And Hypercultural Mediation, which uses access to technology, to the computer, to simulations, that is, there is use of technological tools. Therefore, our research question is which mediations best help the FE student to understand the concept of the Bohr Atom?

METHODOLOGY

For the sake of clarity, the methodology has been divided into two parts: research methodology and didactic methodology. The research methodology brought results through interviews conducted following the Report Aloud protocol and the Pibidian logbook. After the descriptive gestural analysis the students were separated into three categories based on the four TMC mediations. Significant learning was verified through observations from the Pibidians and interviews with students in 2017 and 11 months later, with the project ending in 2018.

The didactic methodology was based on the work together with Pibid with the elaboration and application of a didactic sequence from the perspective of TMC based on Potentially Significant Teaching Units (UEPS).

The classes were explained using a didactic sequence elaborated by the teachers-researchers of this research. The didactic sequence was proposed after the use of seven Potentially Meaningful Teaching Units (PMTU), a concept proposed by Moreira (2011), in the previous moment of the PIBID subproject of Physics. The didactic sequences elaborated in this research were based on extra cerebral tools applied during the proposed activities, such as a computer simulation or the construction of a Bohr atom model (using Styrofoam, colored pencils, led bulbs, for example). This research was applied during the whole year of 2017, the first semester dedicated to create and test the PMTUs and the second semester was dedicated to gather the data presented in this article (31 meetings with the students). A total of 31 students started in the classes (themselves scheduled to the counter-shift of their regular classes) but only 11 students remained till the end of the research; this study is based on those 11 students.

Therefore, we elaborate this research considering the reality of the teaching of Physics in the FE and the context of the school community. The research was conducted in partnership with the Physics subproject of the Institutional Scholarship Initiative Program (Pibid) of the Lutheran University of Brazil, in Canoas, RS. The school in which the project was conducted is the State School of Primary Education João Paulo I, located in a high social vulnerability neighbourhood near the University. The students participating in the project were 8th and 9th year FE students. The two classes were chosen based on the fact that they were in the final stretch of FE, in preparation for the beginning of High School.

The students had contact with the four mediations (social, cultural, psychophysical and hypercultural), which had different durations. Social mediation took place during all monitored classes by interaction with the teachers. Psychophysical mediation took place during four classes mostly by building a Bohr Atom model with led lights of different colours representing the different wavelengths of the absorbed/emitted radiation; cultural and hypercultural mediations took place in one class each, the first by using books (including didactic books) and the second by using a computer simulation of the Bohr Atom model. After the study, the students were interviewed where they were asked to explain the Bohr Atom (what it is? How does it works? What happens when a photon is absorbed and how a photon is emitted and the relationship between wavelength and the distance between orbit radii?). For the interviews we applied the Report Aloud technique, where the student first solve the questions by themselves and then explains in the interview how he solved them (Trevisan, Serrano, Wolff and Ramos, 2019). For Depictive Gesture Analysis, we employed the method used by Monaghan & Clement (1999) and Clement & Stephens (2010).

RESULTS AND CONCLUSION

Given the results that were obtained in the research it was possible to highlight what Erickson (1986) portrays in his research on abstract universals and concrete universals. “Universal” suggests that it was possible to identify certain concepts in more than one student, not just one. In this research it was observed that the use of the four mediations was useful for teaching certain concepts.

According to Erickson (1986), the researcher has the chance to perceive the universality that occurs with all students, as well as the possible particularities in each one.

In this research we obtained four abstract universals:

I. The atom image comes in many forms, and may come from psychophysical mediation or cultural mediation (as in books or television series);

II. The idea of photon is related to hypercultural mediation and the image of the electronic layers related to psychophysical mediation;

III. The color associated with the specific emission of light within the Bohr atom model (different colors related to different hops) is the result of interaction with psychophysical mediation;

IV. Hypercultural mediation was also responsible for providing drivers that allowed students to understand the mechanics of the Bohr atom model (more precisely to understand that bouncing causes photon emission or absorption);

The concrete universals that, according to Erickson (1986, p.130), form a “specific case in great detail and then comparing it with other cases studied in equally great detail”, reveal that, in this research, it was possible to perceive the particularities of each student. We divided the students into categories, which evidenced a different mediation, or combined mediations, in their learning process. Following are four concrete universals resulting from this research.

I. When asked what he knew about the Bohr atom, student A4 mentioned the Bohr atom model of LED (psychophysical mediation).

> E: When you talk about Bohr atom, what are you imagining?
> A4: Oh, I can't tell you, but in her mind she thinks a lot.
> E: What are you imagining?
> A4: You can remember that thing [00:46, GLA] that we did, in this case in the last Styrofoam class.

Student A3 quoted a television series (cultural mediation) as answering how he imagined Bohr's atom

> A3: The atom I imagine ... (Student draws)
> E: You saw it somewhere right? Remember where you saw it?
> A3: In The Big Bang Theory Series

II. Regarding the notion of the photon, student A1, for example, portrayed the image he retained from computer simulation (hypercultural mediation).

> E: And this photon, what does his face look like, what do you imagine?
> A1: Lightning.
> E: A lightning bolt, a lightning bolt that appears there or elsewhere?
> A1: Which appears on the computer image.

Already student A2 mentioned the electron jumps he thinks occur in the Bohr atom model of LED (psychophysical mediation).

> A2: When we took the ball [10:52, #E] and put it, let's say from the smaller orbit and jump let's say to the third layer and take the drums and put it in the light, that caught my attention, which I thought that would have been, like I thought ah, that I thought so, since since the color is changing then each one, each color must be something different then I started to remember the other materials as well.

III. Regarding the association of different colors for different jumps, student A3 explained his ideas when asked what he remembered about electron jumps from one orbit to another.

> E: Ah, so why do you remember more? That's right, and did you remember any different colors when he jumped from different orbits?
> A3: Yes.
> E: But do you know why or when?
> A3: It's because one color has more energy than the other.
> E: Ah, so yeah, the color that has the most energy happens when the jump is bigger or smaller?
> A3: Larger.
> E: Bigger, that's right then. And you remember, when you remember that you remember the computer or you remember others?
> A3: Of the colors?
> A3: From there? (LED)
> E: From that one, talking about different heels and different colors do you remember that one from there?
> A3: Of colors from there, jumping with colors.

IV. During the interview students A3 and A2 stated the importance that the computer had for their understanding regarding the emission and absorption of photons. Student A3 says that:

> E: Everyone, everyone or is there a preference?
> A3: I think more about the computer, in case I had it ... I used the computer a lot and I was playing with it a lot, so he jumped up and down.

E: Ah, so why do you remember more? That's right, and did you remember any different colors when he jumped from different orbits?
A3: Yes.
E: Okay, the jump itself do you see the computer?
A3: Yes.

Thus, given these results, answering the research question, after the data collection indicate that the hypercultural mediation stood out from the other mediations and that mediations are complemented in the teaching of the Bohr atom model (Figure 1). The results also indicated that each of the mediations was used to explain some specific facet of the Bohr atom.

According to the logbook of the teachers and the observations made by the teacher-researcher of this work, the students felt more at ease after the proposed didactic sequence, as it enabled them to carry out activities that helped them to remember previous contents, arousing curiosity about the subject that would be taught in class. The activities involving experiments enabled ES students to feel they were learning physics, when they themselves carried out the experiments and debated the process, learning, at each class, based on experiences that they realized with their own hands.

Figure 1. The same sequence of depictive gesture was made by one student in Nov/2017 (a) and Oct/2018 (b) the experiment.

Considering the data collected during these two years of research, the students' contact time with each mediation did not influence the comprehension of the content addressed. Although the computational (hypercultural) simulation activity was shorter and performed shortly before the interview, it was the most frequently mentioned by all students. The same can be said of the activity involving the LED model (psychophysics), which was used on average in four classes, not being mentioned very often. Each student used a "different combination" of mental images that came from different mediations to explain the Bohr atom model; some students used two mediations together, others used a single mediation for a particular concept.

Student A1 being questioned during the interview about what Bohr's atom was to him, the student uses the image of the atom of computer simulation in the psycho-physical model made of LED. That is, in his mind explaining about the model of the atom and Bohr era imagines the hypercultural mediation atom in psychophysical mediation, bringing this combination to his learning (Figure 2).

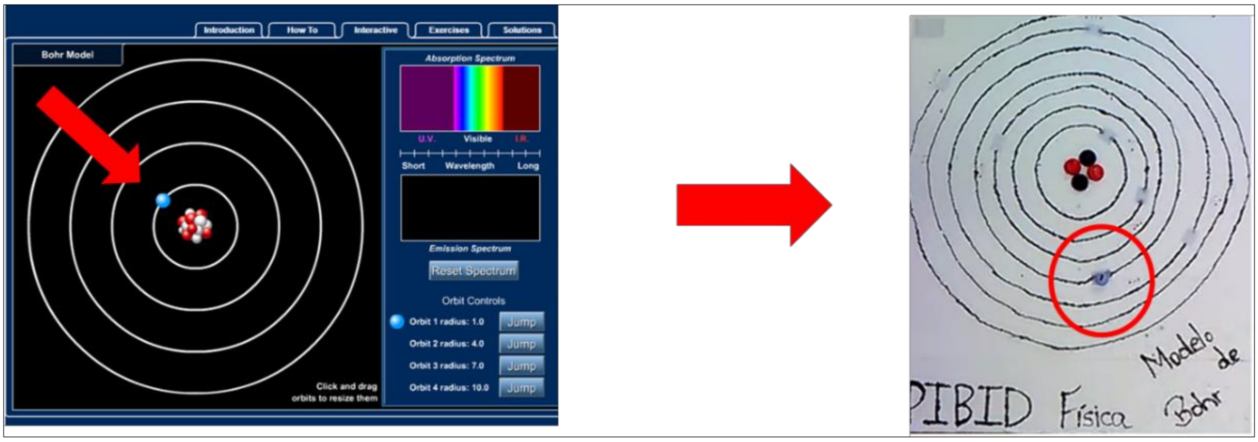

Figure 2. The student imagined the Bohr atom of computational simulation (hypercultural) in the LED model (Psychophysics).

The image of the atom has been associated with cultural mediation, sometimes students reported mental imagery that were from television series or some book; the image of the photon emerged only after the use of hypercultural mediation; finally, the electronic layers gained a representation soon after the students had used psychophysical mediation (Figure 3).

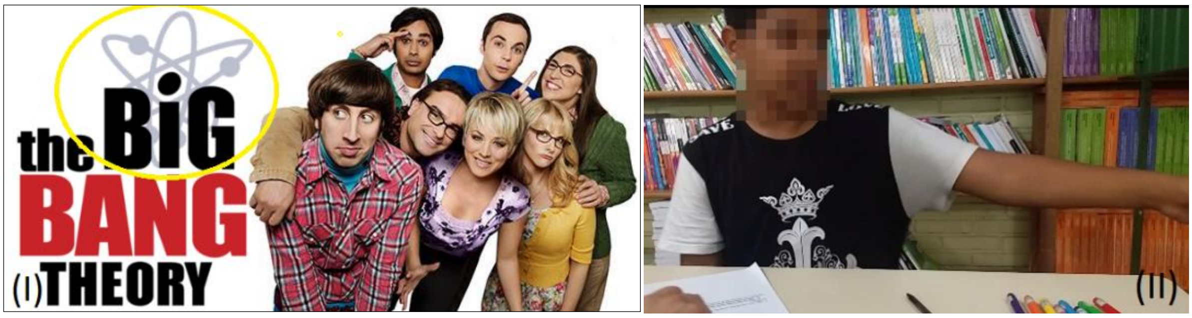

Figure 3. The student (II) recalled a television series (I) when asked about Bohr's atom

All mediations helped to understand the Bohr atom model, but hypercultural mediation was evidenced by most students, even those without daily access to computers and the internet (Figure 1). These students come from low-income families, but the format of the classes led them to become more involved in the study of science. Considering the process of this research in its totality, from its conception to the data collection, we believe in the relevance of the findings observed in the teaching of Physics in the FE in socially vulnerable areas. In addition, after 6 months of finishing the activities, the students were interviewed one more time and we were quite surprised to learn that they could recall the previously discussed, being able to correctly explain the Borh Atom, and even instigating them to learn from their questions through the experiences proposed (see figure 1).

Social mediation was mentioned by student A2 when the interview was conducted. Student A2 began by gesturing what would be Bohr's atom to him (Figure 4). When asked about the origin of this image, he pointed to the picture placed beside him, as well as the other mediations. That is, at first he claimed to remember the picture on the board to explain what he understood about the Bohr atom model. A2 stated that he had forgotten the leap from one layer to another. But at the 33rd meeting, he recalled the content and mentions that in his mind he saw the teacher explaining.

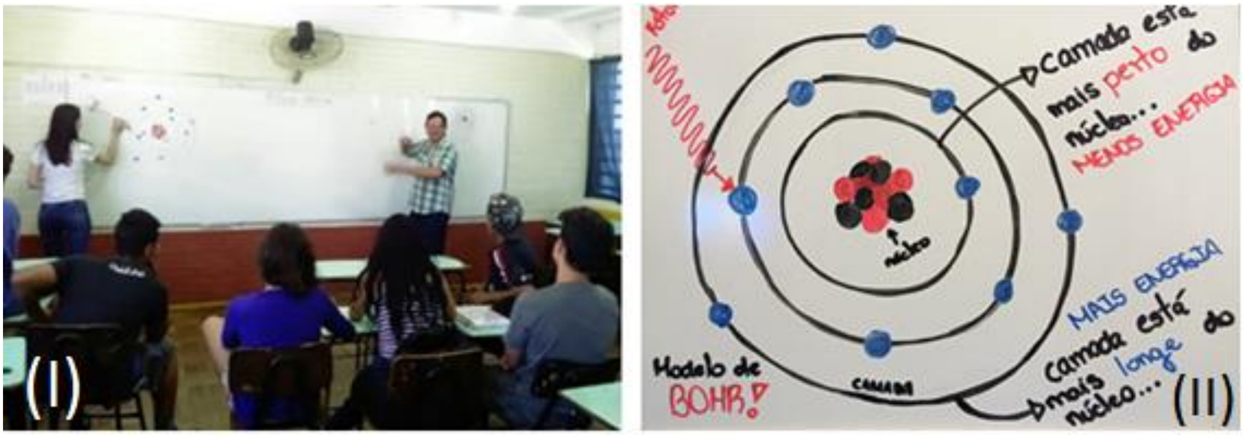

Figure 4. Image of teachers explaining on board (I) and interacting with students and the image of Bohr's atom on board (II).

_Hypercultural mediation was essential for students to understand the mechanics of the Bohr atom model: interviews showed that hypercultural mediation was essential for students to complement what they imagined about the Bohr atom.

This research also highlighted three important points: how teaching Modern Physics in fundamental school contributes to motivation and learning, the importance of using the four mediations combined to enhance learning even in fundamental school and, especially, the relevance of the use of the didactic sequence from the perspective of PMTU. The four mediations aided learning of the proposed theme, but the computational simulation was the most important and, in a way, was able to fill the students' comprehension gaps based only on the teacher's explanation, essentially allowing them to build mental images to model the Bohr Atom.

USING FLIPPED CLASSROOM WITH DIGITAL MEDIA FOR PRE-SERVICE PRIMARY SCIENCE TEACHER EDUCATION

Julian Küsel[1], & Silvija Markic[1]
[1]Ludwigsburg University of Education, Ludwigsburg, Germany

Based on various reasons, it is demanded to use digital media in higher education. For the present study, a flipped classroom module for pre-service primary science teachers at the Ludwigsburg University of Education (Germany) was developed. Following the approach of a flipped classroom, information about the content on the specific topic are provided by online education resource before the lecture. After this preparation, the students work learner-centred during an in-class meeting, discuss and reflect on their gained knowledge and actively used it in, e.g. problem-solving tasks. Finally, after the in-class meeting, students deepen their knowledge on the topic. Most of the methods – especially the first phase – are based on digital media, which are used in the learning management software. The evaluation focuses on the students' feedback on the used flipped classroom concept and the development of pre-service teachers' TPACK and beliefs regarding the use of digital media in education. The results of the evaluation will be used for the improvement of the concept and the development of open educational resource.

Keywords: ICT Enhanced Teaching and Learning, Higher Education, Computer Supported Learning Environments

INTRODUCTION

With the digitalization of the every-day life, demands are placed on education and especially in higher education. Students and politicians expect that lecturers in higher education exploit the great predicted potential of digital media in teaching. The Ministers of Education of Germany call in various strategy papers for the digitisation of education in Germany, which could contribute to addressing several challenges in higher education (e.g. KMK 2017; 2019). Furthermore, several studies have shown positive effects on teaching and learning with digital media (e.g. Hattie, 2008; Hillmayr, Reinhold, Ziernwald, & Reiss, 2017).

Teaching with digital media can make higher education more attractive, more individual, more practical and more flexible, enabling it to partly respond to qualitative and quantitative changes in the student population. (Dittler & Kreidl, 2018). However, Dittler and Kreidl (2018) and Schmid, Goertz, Radomski, Thom, and Behrens (2017) show that the possibilities of digitization in higher education have so far been insufficiently and only selectively realized. Germany-wide student surveys show that only 50% of courses at universities use audiovisual media (Bargel, Müßig-Trapp, & Willige, 2008). Students would like to see more digital media in teaching (Bargel, Multrus, Ramm, & Bargel, 2009; Kreidl & Dittler, 2018) and expect digital media to enrich university courses and offer new and meaningful opportunities (Kreidl & Dittler, 2018). University lecturers also wish to use digital media and concepts in their seminars and lectures (Alvarez, 2012; Bergmann & Sams, 2012), but mostly only use presentation software (e.g. Microsoft Powerpoint) and learning management platforms (e.g. Moodle) to provide digital text documents. Lecturers state, that they face multiple challenges, e.g. legal issues, high technological innovation dynamics, higher teaching load, high costs and lack of IT- and didactical-support. Related to students, they see the risk of student' distraction, disruption and fraud (Schmid et al., 2017).

THEORETICAL BACKGROUND

Flipped-classroom-concept

One of the most used concepts to reach the goal of digital learning in higher education is the blended learning approach with the focus on flipped classroom. The flipped classroom is an instructional model, which uses the advantages of learning at home and in-class. Students learn basic contents self-controlled at home asynchronously and independent of location. The selected learning materials can have different formats, such as online videos, texts, podcasts, interviews and illustrations (Bergmann & Sams, 2012; Strayer, 2012). In the lecture, the learning activities are student-centred, collaborative and interactive (Strayer, 2012). These two phases of the lecture are - in contrast to the traditional and teacher-centred lecture concept - flipped or inverted (Bergmann & Sams, 2012). The implementation of a flipped classroom in higher education is used to promote students' engagement, perceptions and attitude, different forms of metacognition, performance, understanding, achievement, and self-efficacy (Al-Samarraie, Shamsuddin, & Alzahrani, 2019). The development of students' deep understanding of the materials by providing them with more control over what and how they learn, is one offered opportunity. Another goal is to facilitate students' acquisition of information, ideas, and reflection on their self-learning experiences (Al-Samarraie et al., 2019).

Several studies validate the potential of a flipped classroom in different learning contexts. Overall, the studies show the potential of the flipped classroom concept in support specific learning outcomes, e.g., engagement, attitude, understanding, metacognition, performance (Strayer, 2012), and self-efficacy (Al-Samarraie et al., 2019). Students take responsibility for their learning and are better prepared for in-class meetings (Alvarez, 2012). Flipped classroom encourages the synthesis of material, critical thinking and higher-order thinking skills (Bergmann & Sams, 2012). The potential of a flipped classroom in higher education has gradually increased across disciplines (Al-Samarraie et al., 2019).

In education courses, most of the previous studies found that the flipped classroom concept is used to enable students to process higher level of reflection and inquiry (Vaughan, 2014). In this area, the flipped classroom can also promote students' creativity through fluency, flexibility and novelty (Al-Zahrani, 2015) and foster the development of learners' self-efficacy and knowledge (Hao & Lee, 2016). The concept promotes students' positive perceptions towards the course (Zainuddin & Attaran, 2016). It enables students to develop positive attitudes (Xiu, Moore, Thompson, & French, 2018) and increase satisfaction (Ritzhaupt & Sommer, 2018) toward the learning process. When students are exposed to learning problems using supportive materials that are consistent with their learning styles, they are likely to develop positive attitudes towards the way of instruction they have experienced (Al-Samarraie et al., 2019).

Although the concept offers several positive opportunities, there are also challenges in the implementation. The main obstacles that need to be faced when using the flipped classroom concept are the time spent and technical difficulties. Furthermore, design efforts, limited practical sessions, lack of immediate feedback and course structure have a negative influence on the perception of the teaching (Al-Samarraie et al., 2019; Hotle & Garrow, 2015). In education courses, difficulties related to the requirement for discipline-specific skills and pre-preparation to implement the flipped learning model were stated in the literature (e.g. Al-Zahrani, 2015).

DEVELOPMENT AND DESIGN

To implement a flipped classroom in our university, we developed a new concept for the lecture "Introduction to science teaching". To sum up, the contents of the lecture are principles of science teaching, constructivism, diagnostic in science teaching and inquiry-based learning as well as dealing with students' misconceptions and language-sensitive teaching. One lecture addresses learning with digital media in science teaching as well. The structure of the single meetings is presented in figure 1. Phase 1 is the preparation at home based on online educational materials. Here the students work on educational videos, texts, interactive presentations (e.g. Prezi, www.prezi.com), tests and collaborative tools. The learning media are accompanied by assignments to work on. In phase 2, the students meet for the in-class actions at the university. Here they discuss, repeat and reflect on their preparation and get short theoretical input from the lecturer. They need to implement the gained knowledge in a practical task, such as the development of diagnostic-instruments and language-sensitive working sheets, jigsaw classroom activities, experiments in the lecture and other practical tools for their future teaching. In phase 3, the pre-service teachers reflect and/or deepen on the topic at home with the help of the mentioned digital education materials.

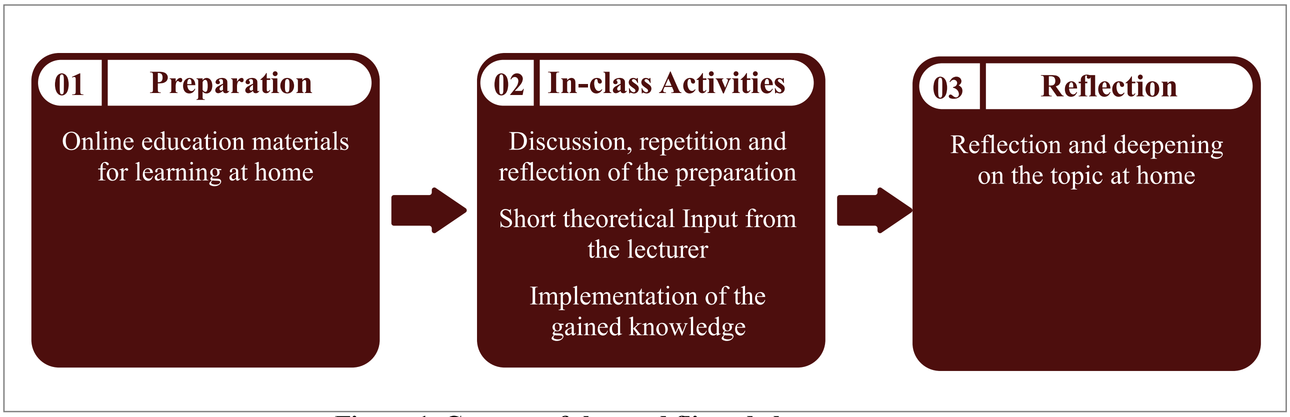

Figure 1. Concept of the used flipped classroom

Impact on pre-service teachers' media knowledge and beliefs

Pre-service teachers observe how lecturers in higher education behave when using media, how they use it, and how they evaluate social change and the changes it brings to their future schools. Because of that, we tried to design a lecture with didactically appropriate use of digital media in all learning phases and that way to introduce various forms of digital learning to the pre-service students. The lecturer and the lecture itself can be seen as a model, as defined by the social learning theory by Bandura (1977), which influence the student's knowledge, behaviour and beliefs. Thus, they could gain active experience as a learner and see how digital media can be successfully deployed in education. This way, they can learn about application scenarios, characteristics, advantages and disadvantages of digital learning concepts. This knowledge can be used in their future teaching with digital media. In conclusion, we suppose that the successful use of digital media in higher education for pre-service teachers could lead to the learning of media knowledge (e.g. TPACK) and the change of beliefs regarding digital media in teaching.

The term TPACK stands for *Technological Pedagogical and Content Knowledge* and describes the knowledge about the selection and use of technologies to support learning processes in a subject area (Schmidt, Baran, Thompson, Koehler, Mishra, & Shin, 2009). Koehler and Mishra (2008) have provided this framework for the knowledge that a teacher needs in order to use digital media successfully in class. They refer to Schulman's concept of professional knowledge (1986) and expand it to include technological knowledge, that is the knowledge about technology, tools and resources as well as productive use in work and everyday life. *TPACK* describes complex relationships between pedagogical knowledge (PK), content knowledge (CK) and technological knowledge (TK).

Teachers beliefs regarding the use of digital media in learning scenarios are essential if they ought to use them. These beliefs depend on various internal variables of the teacher. The Social Cognitive Career Theory (SCCT) by Lent, Brown and Hackett (2002) attempts to capture the complex interdependencies of these intrapersonal variables and to find out how these variables influence decision-making processes in the context of a profession. These variables, such as self-efficacy, outcome expectations, and interest are interdependent and influence the formation of personal goals as well as the selection, practice, and execution of behaviours, such as the use of digital media (Lent et al., 2002; Niederhauser & Perkman, 2008).

RESEARCH QUESTIONS

Starting from the theory, we raised three main research questions for the evaluation:

(i) How do pre-service primary science teachers experience the developed lecture, and what are the wishes and ideas for the improvement of it?

(ii) How does the concept of the newly developed lecture change TPACK of pre-service primary science teachers regarding the usage of digital media in their future classes?

(iii) How does the concept of the newly developed seminar change the beliefs of pre-service primary science teachers regarding the usage of digital media in their future classes?

METHODS AND SAMPLES

Regarding the first research question, students evaluate the concept following open and closed questions in an online survey after the lecture. In the closed-ended questions, the students respond to the statements, if they liked the interaction and the structure of the lecture as well as the variety of used methods. Furthermore, they rate their effort and learning outcome. In the open-ended questions, we asked for comments on the methodical concept of the lecture and opinion on the used digital media. The pre-service teachers are requested to give ideas for improvement of the lecture and name, which topic they liked the most.

For answering the second research question, the evaluation of pre-service teachers` perceived *TPACK* bases on a quantitative questionnaire (Schmidt et al., 2009; translated by Mahler & Arnold). For answering the third research question, a Likert-type questionnaire about pre-service teachers' beliefs about the usage of digital media was employed (Hulleman, Godes, Hendricks, & Harackiewicz, 2010; Hulleman & Harackiewicz, 2009; Davis, 1989; Lent, Brown, Sheu, Schmidt, Brenner, & Gloster 2005; translated and slightly modified).

131 pre-service primary science teachers participated in the study. They were aged 19 - 38 (*M* = 23). The pre-service teachers were at the beginning of their teacher training, visiting the second or third semester in a bachelor's program. Approximately 80 % of the pre-service teachers were female, which is typical for universities of education in Germany.

RESULTS

In the following, the results will be presented to answer the research questions.

RQ1

The quantitative results (figure 2) show that the participants like the used variety of methods (M = 4,08 on a 1-5 Likert-scale) and that the lecture was designed with interaction (M = 3,79). They pointed out the better structure of the lecturer (M = 3,88) and that they took a lot of the lecture (M = 3,66). They had an average effort (M = 3,23) in this lecture.

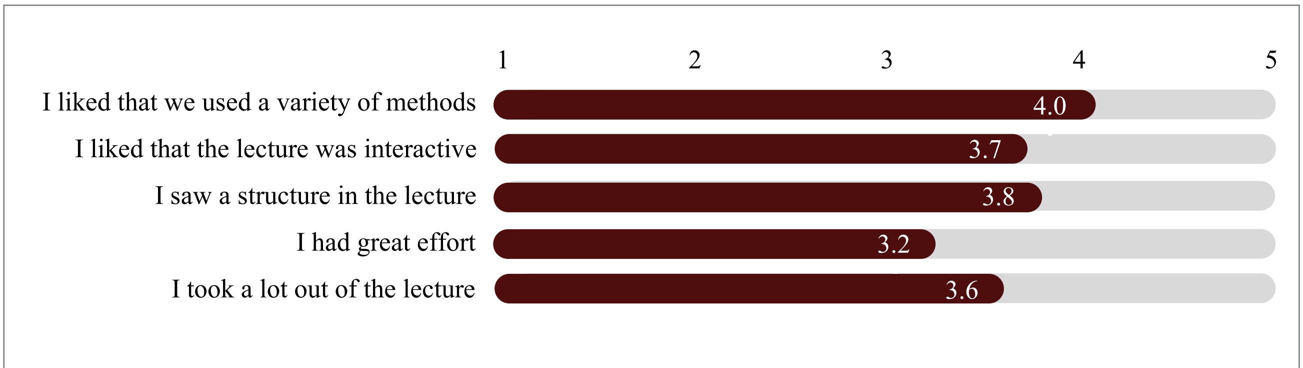

Figure 2. Closed-ended questions (N=131)

The qualitative data supported these results and put them into context. For most of the pre-service primary science teachers in this study, this was the first touch with a flipped classroom. About 20 % stated that they worked more comparing to a traditional lecture. However, the vast majority pointed out that they learn more compared to the traditional lecturer by the combination of theory in preparation at home and practical application in the lecture. Only some of the pre-service teachers in this study felt overstrained and wished for a traditional lecture with theoretical input from the university educator and only a few digital learning settings. The great majority of the pre-service teachers highlighted the work with a variety of digital media in this lecture was new and attractive, and they stated that this primarily facilitated their learning. They mentioned that they got a good overview as well as inspiration and knowledge for their future digital teaching.

Furthermore, for a majority, the cooperative group activities facilitated their learning. These active learning opportunities with the development of practical tools were labelled as useful for their future profession. Overall, they evaluate the flipped classroom concept positive and got a good overview as well as inspiration and knowledge for their future teaching.

RQ2 and RQ3

The results regarding the third research question are presented in figure 3.

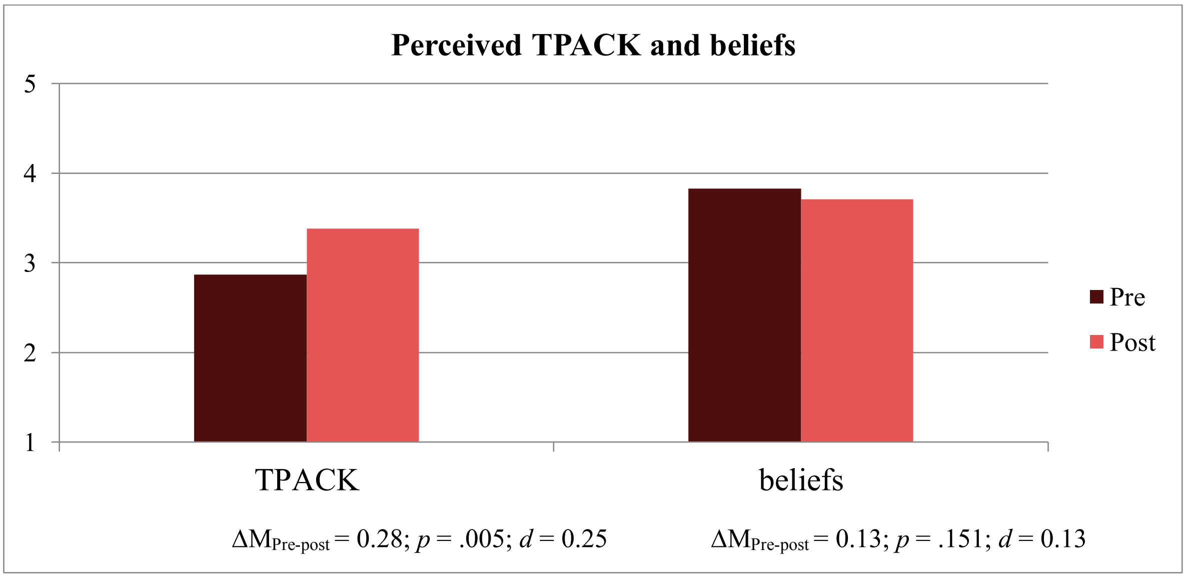

Figure 3. Pre-service teachers' perceived TPACK & beliefs (N=131)

The diagram in figure 3 shows the development of the pre-service teachers' perceived TPACK in the pre- and post-test. The value in the pre-test is 3.1, and it increases to a value of around 3.4 in the post-test. The pre-service teachers` perceived TPACK increased significantly ($\Delta M_{Pre\text{-}post} = 0.28$; $p = .005$; $d = 0.25$). The increase of the perceived TPACK is significant and has a small effect size with a Cohen's $d > 0.2$ (Cohen, 1988). The development of the pre-service teachers' beliefs in the pre- and post-tests is also demonstrated in figure 3. In comparison to the TPACK, the pre-service teachers` beliefs regarding the learning with digital media decreased, but not significantly (ΔMPre-post = 0.13; p = .151; d = 0.13). Overall, the beliefs remain on a high level with a value of 3.8 on a Likert scale from 1 to 5.

DISCUSSION

The present study shows the evaluation of a flipped classroom based on digital media in higher education from the perspective of pre-service primary science teachers. For our group of pre-service primary science teachers, a flipped classroom seems to be a fitting opportunity to combine theoretical and practical elements in a lecture and lead the students to work effectively. The pre-service students liked the concept and learning activities in the lecture. Though it was the first experience for them, it was easy to work this way. The participants see the value and the advantages of the flipped classroom for their professional development.

Regarding the perceived TPACK of the students, a significant increase could be observed, with the highest value in the post-study. Thus, we conclude that the lecture leads to an increased perceived TPACK. On the opposite, the pre-service teachers' beliefs slightly decreased insignificantly but remained at a high level. In Germany, the topic of digitalization in trendy because of the overall digitalization of society and a massive governmental campaign for supporting the digitalization in schools is set up. Thus, we assume, that this could explain the high level of beliefs before the lecture, especially because they stated, that they did not come in contact with digital media in an educational scenario before this lecture. The remaining of the beliefs at a high level can be interpreted as a positive result since the lecture did not discourage pre-service teachers with a realistic view on the implementation of digital media and the learning with and in this digital concept.

Interestingly, pre-service teachers can develop perceived TPACK and get a more realistic view, eventually mainly through the frequent use of digital media together with one specific session. In the debate about the responsibility for the education of pre-service students in media knowledge in higher education, frequent usage of digital media could be one practical and influential way for every participating domain. However, this requires further studies.

PART 5: STRAND 5

Teaching-Learning Sequences as Innovations for Science Teaching and Learning

Co-editors: *Nikos Papadouris & Italo Testa*

CONTENTS

STRAND 5: INTRODUCTION

TEACHING-LEARNING SEQUENCES AS INNOVATIONS FOR SCIENCE TEACHING AND LEARNING

This chapter gathers the contributions to the ESERA 2019 e-proceedings for STRAND 05. The strand focuses on Teaching Learning Sequences (TLS), namely structured sequences of instructional activities, with well-documented suggestions for teachers and expected student reactions. In other words, studies in this strand are prominently empirical, including small-group interventions, with emphasis on the evaluation of students' learning and affective outcomes.

At the ESERA 2019 conference, 26 oral contributions and 36 posters were presented in this strand. 10 of the oral contributions and 4 posters have been included in the e-proceedings.

Amongst the studies that were presented as oral contributions, three concern physics topics, three address modelling approaches, two report on biology topics whereas the last two were presented in a symposium about the MultiCO Project.

Amongst the three studies that addressed physics topics, Kardaras and Kallery present a TLS about the continuous spectrum of the stars and specifically blackbody radiation. Results show a significant impact on the students' learning about this specific topic. Meli and Koliopoulos describe a TLS that focuses on the first law of thermodynamics. Results suggest that the proposed activity sequence lead to a sufficient level of student's understanding of the addressed topic. In the third paper about physics, Rico et al., present the design and development of a TLS about sound for prospective primary teachers. The third study focuses on learning objectives and the key ideas about sound emerging from an epistemological analysis.

The three contributions about modelling present different methods and contents. Bermudez et al. present a TLS about biological diversity. Results show that after the TLS the students' representations of biodiversity increased in abstraction and complexity. Koukioglou & Psillos describe how a TLS on optical properties of materials increased students' epistemological beliefs regarding models in science. Sadidi & Pospiech, discuss about how a particle physics scenario helped to increase students' skills in likelihood and uncertainty analysis as well as their critical thinking.

The two contributions about biology topics address animal physiology and evolution theory. Manzoni-de-Almeida et al. discuss how an open inquiry TLS in a non-formal teaching environment provided students with the possibility to collect and analyze data in biology. Papadopoulou & Ntinolazou use the Ideas, Cosmos and Evidence framework to develop a TLS on evolution theory. Results show positive results on students' understanding of evolution concepts.

Finally, two papers are taken from the symposium on the MultiCO project. This EU funded H2020 project aimed to raise students' awareness about knowledge and skills in STEM careers using specific career-based scenarios. The study by Connolly & Simon investigates the use of a scenario of a female Nuclear Medicine Technologist. Results show that the activities promoted interest in the proposed physics topic. Drymiotou & Constantinou discuss how a scenario focused on Polar Bears helped to generate and sustain students' situational interest and raise their awareness about science-related careers.

The four remaining papers concern the poster sessions of the conference. In the De Ambrosis et al. paper, the Feynman's sum over paths approach is presented. Data analysis shows that the TLS was effective in uncovering students' difficulties about introductory quantum mechanics. Malgieri et al. discuss a TLS on the micro-macro relationships in thermodynamics. A qualitative analysis shows an overall effectiveness of the TLS on students' participation in the activities. The study by Sakamoto et al. aims to examine the potential of a TLS on genetically modified organisms to enhance students' socio-scientific decision-making. Results suggest that the activities promoted students' reasoning about trade-offs taking multiple perspectives. The last paper by Ueno-Guimaraes et al. discusses a laboratory-based TLS on the inclined plane. Results are encouraging as students improved their experimental skills after being engaged in the TLS.

Overall, this chapter of the e-proceedings brings together studies that confirm that the TLS research field is active in several international contexts and continues to provide insights about how to innovate teaching practice in a variety of context.

TEACHING THE CONTINUOUS SPECTRUM OF THE STARS WITHIN PHYSICS COURSES: A MODULE AND THE STUDENTS' LEARNING OUTCOMES

Ioannis Kardaras and Maria Kallery

Aristotle University of Thessaloniki, Greece

Continuous spectrum generated by a blackbody, such as incandescent bulbs and stars, is interpreted with fundamental quantum laws and concepts that are also important for the understanding of contemporary physics. Teaching them within the frame of astrophysics can motivate students for learning and help them obtain a more profound and qualitative understanding of the blackbody's properties and their application in the laboratory in astrophysical settings. In the present study we present a module for the teaching of continuous spectrum of the stars within physics courses and specifically blackbody. The design of the module was based on the model of educational reconstruction. Students' previous ideas were investigated, and textbook analysis was carried out. Students of the upper secondary education engaged in a combination of computer simulations and hands-on activities. The approach was structured inquiry. In order to evaluate students' learning outcomes interviews, questionnaires and worksheets were administered. The data were qualitatively and quantitatively analyzed. The results showed that the intervention had a significant impact on the students' learning outcomes.

Keywords: blackbody, spectrum, stars

INTRODUCTION

In upper secondary education the teaching of concepts related to the starlight properties and the fundamental quantum concepts is insufficient and fragmented as indicated by the literature research. School textbooks offer few relevant information and the connection between these subject areas is neither clear nor explicit as these are studied in different units and chapters of textbooks. Teaching these concepts with coherence and cohesion may increase the understanding of individual concepts and all-around knowledge of the phenomena. In literature, relevant studies in the cognitive region of the celestial bodies usually refer to the motion of these bodies and few of them concern the physics of the stars (e.g. Colantonio, Galano, Leccia, Puddu, & Testa, 2017). In view of all the above, we designed a module and implemented it in the 2nd grade of Lyceum (students aged 17), where we combine the concept of the blackbody and the laws that describe it (Planck, Wien, Stefan-Boltzmann) with the concept of the continuous spectrum through the use of experimental activities, aiming at the deeper understanding of both concepts. In the experimental activities we consider the incandescent bulb (Bonnet & Gabelli, 2010) and the Sun as blackbodies. In this work we present a short description of our module as well as the students' learning outcomes after the implementation of the module.

METHODOLOGY

Design and implementation of the module

The study was carried out in Greece. The design of our intervention considered the country's curriculum and the physics concepts it includes. Accordingly, the duration of the intervention was 4 hours. The approach adopted in the intervention was that of structured inquiry.

The intervention was carried out on 41 students aged 17 years during the school year 2018-2019. This was the 1st main implementation of the intervention since the pilot of the year before. The design of the module was based on the model of educational reconstruction (Duit, Gropengießer, Kattmann, Komorek, & Parchmann, 2012, Viiri, J. & Savinainen, A., 2008): it is iterative, with three intertwining components (i) analysis of the content structure, (ii) empirical investigation (textbook analysis and students ideas) and (iii) construction of instruction.

The design of the module was guided by the following research questions:

(1) How can we design a teaching module based on a sequence of activities that helps students understand blackbody radiation within the frame of continuous spectra?

(2) What is the impact of the designed teaching module on students' learning outcomes and on their understanding of physics concepts and laws related to continuous stellar spectra?

The first steps towards an educational reconstruction of blackbody radiation and its continuous spectrum consisted of identifying key concepts and laws and reviewing students' conceptions of this topic**.**

Key concepts of blackbody radiation and continuous spectra

In order to identify key concepts and laws for the description of the continuous spectrum and blackbody radiation and also to acquire knowledge about how these are presented, we analyzed school textbooks and introductory university physics books (Young et al. 2014, Hewitt 2014). According to our analysis the key features of teaching blackbody radiation within continuous spectra are:

- Phenomena: analysis of the light, thermal radiation
- Concepts: photon, continuous spectrum, temperature, energy, wavelength, blackbody radiation, intensity, index or refraction, heat
- Laws: Wien, Stefan-Boltzmann, Planck.

Students' conceptions

As stated by the National Research Council (2005) students' ideas play important role for their future knowledge acquisition. Moreover, the framework of Educational reconstruction places great emphasis on the investigation of students' misconceptions, previous knowledge and understanding of their basic ideas in order to make the complex and abstract scientific knowledge meaningful to them. This way it influences the construction of instruction (Duit et al., 2012).

Drawing from literature review, students face difficulty in understanding fundamental concepts such as heat and temperature (Harrison et al.1999). They also give incomplete or erroneous responses regarding the black body (Sadoglu, 2015) and demonstrate misconceptions about photons, stellar temperature, stellar spectra and stellar energy (Bardar, 2006).

To find out our students' previous knowledge of blackbody radiation and its spectrum we had them complete a questionnaire with multiple choice and open-ended questions. We observed that some students were not aware of the relationship between radiation – energy and they mix up the types of radiation. Many of them also hold the view that red color of radiation is related with greater energy, express the conception that colors of visible light are attributed to the intensity of light and do not have sufficient knowledge about stars.

Module content and activities

The module consists of two units, in which fundamental laws and concepts for describing continuous spectra are gradually introduced. In unit 1, the driving questions that lead students to encounter fundamental concepts and laws, are 'What is a continuous spectrum?', 'Which physical quantities are necessary for describing and interpreting a continuous spectrum?', 'What is the emitted power distribution for a given temperature in different wavelengths?' In Unit 2 'Which are the mathematical equations that relate the quantities of temperature with wavelength of maximum power output and total power output?', 'How can we apply these equations in describing stars' temperature, color and luminosity?'. The structure and content of the module is presented in Table 1.

Table 1. Description of the module's content and activities.

Duration	Units	Content	Activities
2h	Continuous spectrum,	Properties of continuous spectrum	Observation of Sun and incandescent light bulb's spectra
	Plot of the ligh intensity versus wavelength	Planck's law	Process and plot of the Sun's spectrum with software
2h	Concepts describing	Wien's law	Variation of Bulb's voltage-variation of the spectrum
	blackbody, wavelength	Stefan-Boltzmann's law	Experiment study of Stefan-Boltzmann's law
	of maximum power		with measurement of light bulb's resistance and its light intensity

output, temperature	Calculation of the Sun's photosphere temperature through temperature measurement of a liquid in a can

A fundamental feature of the module is that it is based mainly on experimental activities and students engage in a combination of computer simulations and hands-on activities. Students carried out activities, two of which we describe below, wrote down their observations and the results, processed them and finally discussed them in the class.

An important experiment that students performed in order to study the Solar spectrum and confirm its similarity to the corresponding spectrum of blackbody radiation as described in theory, was the analysis of the sun's spectrum spectral chart obtained by a spectroscope, with NASA's HEASARC software (Figure 1).

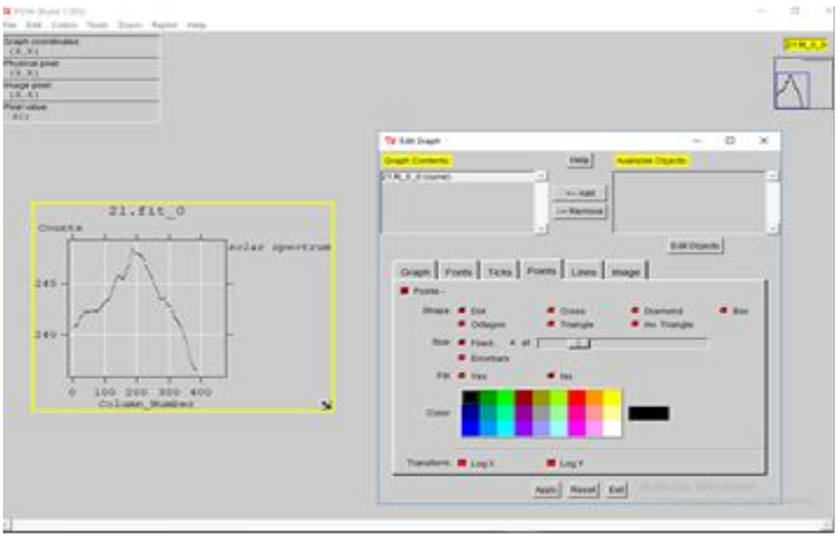

Figure 1. Screenshot, showing on the left the graph of the solar light's intensity in different wavelengths of the visible spectrum obtained by students with NASA's HEASARC software, available (http://heasarc.nasa.gov/lheasoft/ftools/fv/fv_download.html).

This way students became familiar with the Sun's spectrum and ascertained that its spectral emittance has many similarities with those predicted from the Planck's law. They also realized that the maximum power output occurs at about 510 nm, which corresponds, applying Wiens' law, to 5800 K, that is the temperature of the photosphere of the Sun. Moreover, they understood why Sun appears white-yellow since its maximum emitted energy is in the yellow part of the visible spectrum.

Another experimental activity, in order to probe Stefan-Boltzmann's law, was the measurement of the dissipative power, at different temperatures, of a tungsten filament light bulb which was used as the emitting source of the blackbody radiation (Bonnet, I., & Gabelli, J. 2010, Wellons, M., 2007) (Figure 2). Students measured the voltage and the current and subsequently calculated the temperature and the emitted power of the filament knowing that the resistivity ρ is a nonlinear function of the temperature. Then, by plotting a graph of lnP versus lnT, students tested whether the relationship between P and T is a power law and the exponent of that power law is the slope of the curve.

Figure 2. Experimental setup to measure the emitted power of an incandescent lamp, by calculating filaments' temperature of the lamp.

Assessment of students' learning

To evaluate students' learning progress we administered, among other assessment tools (observations, worksheets and interviews), two questionnaires. One of them consisted of ten multiple choice items, three of which are presented in Table 2.

Table 2. Sample questions for the evaluation of students' learning outcomes

Questions
1. Antares is a red star, Sun is a yellow-white star and Vegas is a blue star. Which one has the higher surface temperature
a) the Antares b) the Sun *c) the Vegas*
2. Warmest stars emit most of their energy in the region of a) infrared b) ultraviolet c) visible *d) X-rays*
3. A continuous spectrum is emitted by
a) a hot solid *b) a hot gas* c) a cool gas

Students were also asked to complete a questionnaire with open-ended questions, (Young et al. 2014, Hewitt 2014), in order to test if they acquired deep understanding of the topic and developed critical and scientific thinking of this subject area. They should justify their responses in writing by explaining their reasoning in words and by mathematical calculation. The level of understanding of each response was evaluated as correct, partially correct, or incorrect. Two of the questions are presented in table 3.

Table 3. Sample of open ended, explanation type questions in order to evaluate the quality of students' argumentative discourse.

Open ended questions
Q1. Could you explain why do we perceive a "green-hot" star not as green but as white?
Q2. Could you explain why a lamp filament that is made of tungsten emits a continuous spectrum rather than a tungsten line spectrum when light from an incandescent lamp is viewed with a spectroscope?

Implicit in the question Q1 is the idea that the objects don't emit a single wavelength of light but they emit photons in a range of wavelengths and in the question Q2 the idea that the otherwise well-defined energy levels of outer electron shells are smeared by mutual interactions among neighboring atoms.

RESULTS

Questionnaire with open ended questions

The qualitative assessment of the data showed that before the intervention none of the students gave correct answers and only a small percentage of them were able to give partially correct answers. This was due to their lack of knowledge. After the intervention, students were able to answer correctly and partially correctly, achieving average scores of 26% and 32% respectively to question Q1 and average scores of 32% and 36% respectively to question Q2, as presented in Figures 3 and Figures 4. Therefore, we observe that teaching blackbody radiation within the frame of continuous spectra and with a variety of experimental activities helps students develop a more sophisticated view of the complexity of the blackbody radiation.

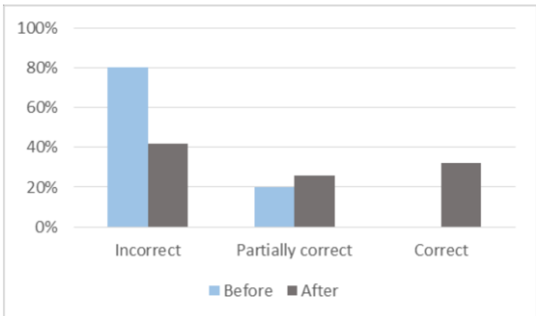

Figure 3. Quantitative assessment based on students' answers to the question Q1 before and after the implementation of the teaching module.

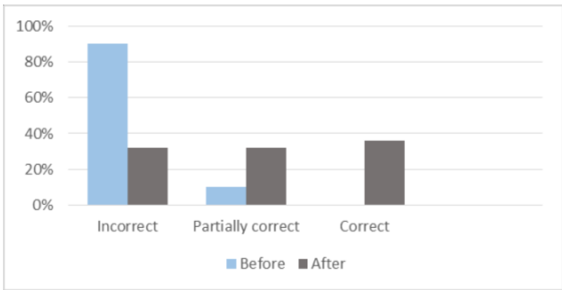

Figure 4. Quantitative assessment based on students' answers to the question Q2 before and after the implementation of the teaching module.

Multiple choice questions

The results of students' responses to three questions of the multiple choice questionnaire are presented in figure 5.

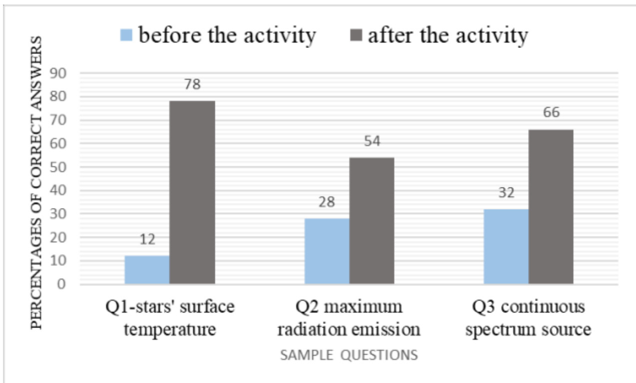

Figure 5. Percentages of students' correct answers to three questions before and after the teaching intervention.

The results obtained from these three questions, before and after the intervention, are shown in Figure 5. High scores were attained after the intervention and a noticeable improvement can be seen. After gathering data from all the questions, we proceeded to the statistical analysis using SPSS 23 statistical package. Initially, we conducted the normality test which indicated that the data were normally distributed and then we performed a dependent t-test that compares the mean difference between our samples (Field, 2009). The test consisted of ten multiple choice questions, where each correct answer was assigned 1 point and thus, for a student who had answered correctly all the questions, the total maximum score was 10.

Figure 6. Distribution of students' score for the overall test before and after the intervention..

The statistical analysis of the responses showed that the impact of the intervention on students' understanding was noteworthy since the mean value and the standard deviation before the main implementation were M=2.82, SD=0.93, while after M=5.80, SD=2.21 respectively. The difference in performances between pre-test and after-test (Figure 6), as evaluated using the statistical package SPSS 23, is statistically significant (t=10.78, df=40, $p<10^{-4}$). For the item analysis, for each question after the implementation, we calculated the indices of difficulty (proportion of correct answers) and discrimination (how well an item distinguishes students with high scores from those with low scores) (Ding & Beichner, 2009). The acceptable item-difficulty values range from 0.3 to 0.9 and for the item-discrimination index are greater than or equal to 0.3. The average value of the difficulty index and the average value of the discrimination index for all items was 0.58 and 0.68 respectively, therefore within the accepted criteria values.

DISCUSSION

The structure and content of the implemented module that bridges blackbody's laws and concepts with the continuous spectrum of star light as well as the approach used, seem to have had a positive impact on students' learning outcomes and also on their understanding of physics concepts and laws related to continuous stellar spectra. The findings of the study create perspectives that the combination of the specific content with hands-on activities, simulations and software and their application in the laboratory in astrophysical settings can be effective for the teaching of such complex and difficult concepts and laws in secondary education. Nevertheless, our study continues with further applications for the improvement of the intervention as well as with investigations of the students' attitudes towards the experimental procedures used.

RESEARCH-BASED DESIGN OF A TEACHING AND LEARNING SEQUENCE FOR THE FIRST LAW OF THERMODYNAMICS

Kalliopi Meli[1], Dimitris Koliopoulos[1]
[1]University of Patras, Patras, Greece

In this study, we present the design principles and the respective development of a Teaching and Learning Sequence (TLS) in the field of introductory thermodynamics, with particular focus on the First Law of Thermodynamics (FLT), for upper secondary school students. The TLS design takes into account the poles of knowledge, learning and teaching that correspond to three theoretical domains; (a) epistemological aspects related to the FLT, (b) students' cognitive capacity for dealing with the various features of the FLT and (c) pedagogical approach of this topic. Regarding the epistemology of the field, we analyze the historical framework in which the FLT emerged and the textbook approaches for the introduction of this law. The cognitive analysis includes the categorization of the multi-dimensional alternative frameworks and the reasoning patterns that the students put forward in explaining phenomena related to the FLT. About the pedagogical aspects of the TLS, we analyze the constructivist approach as a learning alternative for the traditional approach, which prevails among science curricula. The conclusions drawn by the three-level analysis formulated the design principles for a medium-level TLS (12 sub-sections) that covers the FLT along with several introductory thermodynamic topics. The results from the implementation of the TLS are presented briefly.

Keywords: Science Education, Teaching Learning Sequences, Physics

INTRODUCTION

In science education contexts, the development of a Teaching and Learning Sequence (TLS) aims to students' facilitation in their pursuit of understanding the established scientific knowledge. The design of a research-based TLS relies particularly on the results of preceding studies for a chosen topic (Ruthven, Laborde, Leach, & Tiberghien, 2009). In this study, we present the design principles and the respective development of a research-based TLS that addresses the First Law of Thermodynamics (FLT) as an introductory physics thermodynamics topic.

The FLT suggests an expression of energy conservation throughout a thermodynamic system and its surroundings. It also describes the distribution of energy through the conversions of the implicated energy entities (heat, work, and change in internal energy). Therefore, it is considered a fundamental principle of thermodynamics and its understanding is crucial for all experimental scientists, technicians and modern citizens.

In this case, we design a TLS for the FLT addressing the second year of secondary school. For this educational level, the research regarding the teaching and learning of thermodynamics, beyond the understanding of basic concepts such as temperature and heat, is rather limited (Meli, Koliopoulos, Lavidas, & Papalexiou, 2016). Our main goal is the improvement of students' representations regarding energy conservation. This design takes into account three basic pivots; knowledge, learning and teaching. Each of these pivots corresponds to a theoretical domain; these are respectively epistemology, cognition, and pedagogy (Buty, Tiberghien, & Le Maréchal, 2004). In the following sections, we elaborate on these domains and we present a sample of the TLS as the product of this analysis.

DESIGN PRINCIPLES OF THE TEACHING AND LEARNING SEQUENCE

Epistemological analysis: historiographical and textbook analysis regarding the FLT

By the end of the 17th century, scientists had fully realized that materials at a gaseous state behave like any other fluid and conducted experiments for the investigation of the thermal properties of gases. At first, their main focus was on the interpretation of the nature of heat, which involved microscopic issues that could not touch just yet; the fundamental work of John Dalton (1766-1844) was about a century away from being established and representations of the micro-level world were unattainable (Cardwell, 1971). Although a few scientists, like Daniel Bernoulli (1700-1782) worked toward a Newtonian-like explanation for thermal properties, the absence of material points inevitably gave rise to a new branch of physics that developed aside from the dominating Newtonian system (Harman, 1982). In that sense, “physics of heat” was the first scientific revolution that emerged after Isaak Newton’s (1643-1727) era.

One additional particularity of this new physics was that its applications preceded its theoretical establishment for about a century. In 1712, Thomas Newcomen (1663-1729) constructs the first functional steam engine, which plays a substantial role in the Industrial Revolution. The urgent need for the improvement of its efficiency shifted scientists’ focus from the nature of heat to the conservation of heat. Many prestigious scientists, like Sadi Carnot (1796-1832) made a clear distinction between microscopic hypothesis and developments at the macroscopic level (Meli & Koliopoulos, 2019). Through their work, the initial statement of heat conservation evolved to the notion of heat-work equilibrium and finally to energy conservation, which was expressed with the complete form of the FLT by Rudolf Clausius (1822-1888) in 1854 (Clausius, 1854, p. 484).

The principle of energy conservation in a qualitative and quantitative form through the explicit formulation of FLT affected all scientific fields. Each discipline introduces the FLT under its particular scope and therefore diverse textbook approaches are describing the same thermodynamic law (Christiansen & Rump, 2008). Physics and engineering textbooks offer many interesting perspectives that are often in agreement and complement each other. These refer to multiple statements of the FLT in terms of wording, mathematical expressions, and alternative representations.

One major strategic choice for a textbook suggests the “macroscopic vs. microscopic” approach of the FLT (Tarsitani & Vicentini, 1996). While macroscopic approaches reflect the classical theory as developed during the 19th century (e.g. Baehr, 1973), the microscopic approaches introduce the statistical mechanical theory that was developed during the 20th century in a vastly mathematical way (e.g. Landau & Lifshitz, 1976). However, in some cases, elements of both approaches can co-exist in the same textbook (e.g. Young & Freedman, 2012). Another strategic choice for the architecture of a textbook refers to the “applications vs. axioms” approach of FLT (Christiansen & Rump, 2008). The first one unfolds the theory through a deductive methodology (e.g. Carathéodory, 1909), while the second gives prominence to the presentation of specific models and systems (e.g. Moran, Shapiro, Boettner, & Bailey, 2014).

The convergence of macroscopic-applications approaches is particularly evident in technical thermodynamics textbooks, that usually address novice and expert engineers. Such textbooks offer semi-quantitative energy distribution representations of theoretical and real engines, such as Sankey diagrams (e.g. Young & Freedman, 2012, p. 655). These representations are in-line with the historiographic analysis that illustrates the role of steam engines for the emergence of the FLT. At the same time, they allow the discussion to expand to crucial issues, such as engine efficiency and energy dissipation.

Cognitive analysis: students' alternative frameworks and reasoning patterns for the FLT

First- and second-year university students and upper secondary students hold similar conceptual frameworks regarding the FLT, as a result of their comparable reasoning patterns (Rozier & Viennot, 1991; Tiberghien, 1994). Students seek interpretations for the thermodynamic processes they encounter under the umbrella of linear causal reasoning. Linear causality leads them towards systematic neglect of variables, creation of preferential relations among variables and oversight of the symmetry between variables (Rozier & Viennot, 1991). Due to this reasoning pattern, students land on alternative frameworks that can belong in energy and/or non-energy frameworks.

The energy approach of a thermodynamic phenomenon through the FLT is adequate for the description of all thermodynamic processes. However, its use is limited and often inaccurate (Leinonen, Raesaenen, Asikainen, & Hirvonen, 2009; Meli et al., 2016). Within energy frameworks, students have difficulty in recognizing the energy entities that play a role in a thermodynamic process and also in identifying the increase or decrease of these entities (Meltzer, 2004; van Roon, van Sprang, & Verdonk, 1994). The above findings can be related to an inadequate representation of the thermodynamic system and its surroundings (Meltzer, 2004; van Roon et al., 1994).

In non-energy frameworks, students typically use the Ideal Gas Law or microscopic level approaches as stand-alone explanations or complementary to their perception of the FLT. The Ideal Gas Law is particularly favored, although it is inadequate in interpreting adiabatic processes. State entities are much more appealing to students than energy entities (Kautz, Heron, Loverude, & McDermott, 2005; Leinonen et al., 2009; Loverude, Kautz, & Heron, 2002; Meli et al., 2016) Micro-level descriptions are also used, as the "ultimate" explanation students can offer. However, due to their intrinsic complexity, it is difficult for students to handle them properly and provide an accurate and complete explanation for thermodynamic processes (Kautz, Heron, Shaffer, & McDermott, 2005; Leinonen et al., 2009; Meli et al., 2016; Meltzer, 2004). It should be noted that both the above non-energy frameworks are usually taught long before the FLT, undermining the exploratory power of the latter (Leinonen et al., 2009; Meli et al., 2016).

Pedagogical analysis: constructivism as a pedagogical approach of the FLT

Traditional instruction, in the sense of attempting to "transfer" knowledge to students, has poor learning outcomes in the field of thermodynamics (Meli et al., 2016). One feature of the traditional approach, that may influence these outcomes, is the presentation of many and diverse frameworks for the same section, without an in-depth analysis for any of them. Another feature is the "conveying" of this knowledge on an abstract basis, with no reference to real-life situations, thus jeopardizing students' engagement to the subject (Koliopoulos & Constantinou, 2005).

To deal with these issues, constructivism proposes teaching that facilitates students in constructing their own meaningful, yet scientifically accurate, representations (Tiberghien, 1997) in a restricted framework with cultural context. For achieving this, three interrelated levels for the teaching and learning of science should be taken into account: phenomena, theory, and models (Tiberghien, Psillos, & Koumaras, 1995).

The phenomenological field of introductory thermodynamics mainly refers to thermodynamic processes. These should be organically integrated into a phenomenological field that is relevant to students, pertinent to what they usually face, free of technical challenges and capable of developing a "cognitive need" (Devi, Tiberghien, Baker, & Brna, 1996). The theory describing the phenomena should be both in a qualitative and a quantitative form. Qualitative form refers to the proper use of wording for describing entities and principles, while quantitative form refers to mathematical formulas and/or diagrams.

However, even if students form the mathematical expression of the FLT correctly, this does not necessarily reflect a sufficient understanding of the processes at hand (Kautz, Heron, Loverude, et al., 2005). The levels of phenomena and theory should be properly linked for students to seamlessly match phenomena to theory and the other way around. This link refers to the level of models that intervene between phenomena and theory to create smooth, yet meaningful, connections. For the FLT, the Energy Chain Model (ECM) can work towards this direction, since it suggests a semi-quantitative model representing energy distribution between the thermodynamic system and its surroundings during a process.

The convergence of the epistemological, cognitive and pedagogical analysis for the design principles of the TLS

We make decisions informed by the above-described three-dimensional analysis (Ruthven et al., 2009) and we seek intersections that should lead to a coherent design of the TLS and also a feasible implementation of this TLS for the upper secondary school level. Based on the threefold "theory-phenomena-models" as the levels for the teaching and learning of science, our main conclusions unfold respectively as follows:

(a) *We exclusively employ the macroscopic (classical) approach of thermodynamics.* The epistemological analysis illustrates that this framework can efficiently describe the theory and applications of thermodynamics, as it was historically developed before the appearance of the microscopic (statistical) one and it often stands alone in contemporary textbooks (Meli & Koliopoulos, 2019). Cognitive analysis confirms the appropriateness of this choice for novice learners, as the microscopic approach is the source of various misinterpretations and it hinders the energy-related explanations of thermodynamic processes (Kautz, Heron, Loverude, et al., 2005; Leinonen et al., 2009). Finally, sticking to a single framework and deeply examining it is consistent with the pedagogical analysis (Koliopoulos, Adúriz-Bravo, & Ravanis, 2011).

(b) *We organically integrate the steam engine as a study object.* Historiographical analysis suggests that steam engines had a great contribution to the development of thermodynamics (Cardwell, 1971; Kuhn, 1977), while textbook analysis shows that they used to be and still are a standard component for physics and engineering education. Employing them as our basic phenomenological reference, students' frameworks can be more accurate and energy-oriented (Cochran & Heron, 2006). Additionally, steam engines bring thermodynamic processes in a real-life context, within which students can find common ground with the respective theory (Koliopoulos et al., 2011).

(c) *We give prominence to energy distribution representations of thermodynamic processes, through the ECM.* Epistemological analysis confirms the representational power of such models, especially in reference to steam engines. From a cognitive point of view, these representations are in-line with students' intuitive linear causal reasoning pattern (Rozier & Viennot, 1991), but they can also pave the road for students to overcome it. Versions of the ECM, like the one we propose, can work efficiently towards the meaningful connection between the levels of theory and phenomena (Delegkos & Koliopoulos, 2018; Tiberghien, 1996).

CONTENT OF THE TEACHING AND LEARNING SEQUENCE

Table of contents of the TLS

The TLS consists of three broad-sections (BS) that include twelve sub-sections (SS). Throughout the TLS we examine Newcomen's steam engine and we focus on the gas in its motor as an example of a thermodynamic system. On this account, we introduce the FLT as an energy explanation for the description of adiabatic, isothermal and isobaric processes. Lastly, we use these components to assemble the cyclic process and discuss the efficiency of the engine. Several additional elements are also examined during this course, such as the properties of thermodynamic systems and the Carnot cycle.

Table 1 presents the contents of the TLS. The "activity problem" column describes the issue students attempt to address throughout each sub-section. The "conceptual components" column refers to the thermodynamic concepts and processes that are being introduced in a sub-section. Finally, the "conceptual negotiation" column mentions the representations that students are expected to construct during the instruction of the sub-section.

Table 1. Sample of the TLS content table.

	ACTIVITY PROBLEM	CONCEPTUAL COMPONENTS	CONCEPTUAL NEGOTIATION
BS1	**Thermal engines and thermodynamic explanation**		
SS01	What is a thermal engine and how does it work?	Structure/function of Newcomen engine	Activation of pre-energy conceptions Qualitative representation of energy distribution Semi-quantitative energy distribution Introduction to the ECM
SS02	How can we explain the function of the Newcomen engine in terms of energy?	Work and heat	
SS03	How does the Newcomen motor work?	Thermodynamic system and surroundings	
BS2	**Gas processes and the first law of thermodynamics**		
SS04	Why did an ignition take place in the tube?	Adiabatic compression/ Change in internal energy	Qualitative and quantitative representation of energy distribution and conservation: • phenomenon ➞ ECM • phenomenon ➞ ECM ➞ mathematical expression • mathematical expression ➞ ECM ➞ phenomenon
SS05	Why was the air in the tube liquified?	Adiabatic expansion/ Work/ FLT	
SS06	Why did the piston move (I)?	Isothermal expansion/ Heat/ FLT

Activity sheet: Which part is the motor of the engine?			
Discussion: Motor as a thermodynamic system/ system's surroundings	Discuss the concepts of the system and its thermal-mechanical surroundings	Thermodynamic system and thermal-mechanical surroundings	Construction of the concepts of system and surroundings / Semi-quantitative ECM
Activity sheet: The motor's cycle is one uniform process or several diverse processes?			
Discussion: Components of a cyclic process - examples	Discuss the features of a cyclic process	Cyclic process in a steam engine	Construction of a qualitative approach of the cyclic process

RESULTS FROM THE IMPLEMENTATION OF THE TLS

In this paragraph, we briefly describe the results of the research in reference to the conclusions that were drawn from the convergence of the epistemological, cognitive and pedagogical analysis. This TLS was implemented as a case study in a class of 19 students of the second grade of upper secondary school in Athens (Greece). The results reported here derive from the qualitative and quantitative analysis of pre- and post-tests.

(a) The restriction of the TLS in macroscopic thermodynamics and with special focus on the energy framework was very much reflected in students' final explanations of thermodynamic processes. While in the pre-test they used a variety of alternative frameworks, including the microscopic one in significant percentages, in the post-test almost every student employed the FLT framework and many among them provided explanations at a high-efficiency level.

(b) Newcomen's steam engine suggested a functional phenomenological field for the introduction and application of the FLT. The quest for the operation of the engine facilitated the organic integration of several thermodynamic processes; through this real-life situation, representations that otherwise would be abstract, became meaningful and approachable. In the post-test, students provide energy explanations for thermodynamic processes by assessing their utility in the engine's motor.

(c) The ECM as a representation for the energy distribution between the targeted thermodynamics system (gas in the engine's motor) and its surroundings was at great extend used by students for explaining thermodynamic processes in the post-test. Therefore, it appears as a proper model for bridging the phenomena to the theory of the FLT that describes them.

DISCUSSION

For the design of a TLS addressing the FLT for the upper secondary school level, we thoroughly analyzed preceding works on the field of introductory thermodynamics (Ruthven et al., 2009). This analysis was unfolded in three different domains: epistemology, cognition, and pedagogy (Buty et al., 2004). We drew our basic design principles for the TLS through the convergence of these domains. All parts of the analysis agreed on the use of (a) the macroscopic thermodynamics approach (Meli & Koliopoulos, 2019), (b) steam engines (Cochran & Heron, 2006) and (c) energy distribution models (Koliopoulos et al., 2011). Based on these design principles, we formed and implemented a medium level TLS (12 sub-sections) with related conceptual components and issues for negotiation with students, for them to improve their respective representations. The quantitative and qualitative analysis of pre- and post-tests confirmed our choice of design principles, as students' representations were in-line with them and their representations achieved satisfactory levels of sufficiency.

Acoustic phenomena are closely related to our daily lives and many decisions related to health, the environment or technologies faced by citizens are related to sound. Sound is also a key concept in physics. Therefore, in accordance with most Primary Education curricula, acoustic phenomena must be understood, at least as far as their phenomenology is concerned. In that sense, many proposals and teaching materials to learn about sound in early childhood and primary education are available, but the differences in context and learning objectives to be evaluated make it difficult to apply them directly in pre-service primary science teacher education. We present a proposal for the design of a teaching-learning sequence (TLS) about sound in the aforementioned context. This proposal follows a Design-Based Research (DBR) methodology. We adopt the DBR methodology because of its characteristics: an iterative process of design, implementation, evaluation and refinement, in an attempt to get a specific product - in our case a TLS - explicitly based on research results. Furthermore, we chose DBR because it is a widely-used approach for tackling informed designed research in educational research in general and, increasingly, in science education research. In this paper, we present results derived from the design phase, which involves the analysis of the school context, definition of learning objectives and learning demands, of our TLS about sound using the DBR methodology.

Keywords: Teaching Learning Sequences, Physics, Teacher Education, Primary Education

INTRODUCTION

Sound is a common phenomenon that we experience every day and plays an important role in understanding physical phenomena that are relevant to students. In fact, sound properties and sound effects are typically covered in all stages of Science Education curricula (Eshach & Schwartz, 2006; Mazens & Lautrey, 2003; West & Wallin, 2013). However, students display numerous difficulties regarding this concept, specially when explanatory wave models and the particulate nature of matter are incorporated in sound conceptualization as shown by the extensive research on secondary and university students' difficulties on the concept of sound (Hrepic, Zollman, & Rebello, 2010). Interestingly, fewer studies asses Primary Education students' or pre-service primary teachers' (PSPT) ideas about sound. Nevertheless, pervading issues, such as, identifying and differentiating the properties of acoustic vibrations, assigning materialistic properties to sound or difficulties to use the wave model were also identified in PSPT (Rico et al., *submitted manuscript*).

Despite the fact that research-based innovative products, which follow a socio-contructivist approach and take into account student's ideas to approach the teaching of sound have been produced over the years, the majority of them are for Secondary Education (Hernández, Couso, & Pintó, 2012; West & Wallin, 2013) and they do not provide enough insight to translate the approach to other context. Science education research provides fundamental insights into the cognitive, social, and emotional processes involved in learning, and contributes to the generation of new techniques, strategies, and materials for classroom instruction. These works include sequences of teaching activities with the aim of improving the students' learning of specific topics at a small-scale level (for instance a few teaching sessions) or at a medium-scale level (a whole sequence of lessons on a particular topic) but typically not addressing the large-scale level of a whole programme (of one or several academic terms). The literature refers to such teaching activities as Teaching-Learning Sequences (TLS). A distinctive characteristic of the TLS is its dual character that implies both research and development, pointing at a strong link between the teaching and the learning of a particular topic. A TLS can be broadly defined as "both an interventional research activity and a product, like a traditional curriculum unit package, which includes well-researched teaching-learning activities empirically adapted to student reasoning" (Psillos & Kariotoglou, 2016). We, thus, propose a Teaching-Learning Sequence (TLS) for the context of PSPT education.

TLS design reflects the interlink between the development of learning tools and environments and the development of theory. This interlinkage is a complex, cyclical process in which general education principles are applied to the teaching of specific topics in specific contexts. As a consequence, researchers have elaborated frameworks, to be used by designers, as interfaces between grand theories and the needs associated with developing a TLS on specific topics (Lijnse, 2004). We will present our design process as an implementation of Design Based Research (DBR) methodology (Easterday, Lewis, & Gerber, 2014; Guisasola et al., 2017). An argument in favour of using DBR in TLS design is that it provides help in solving some methodological issues, such as deepening the theoretical considerations that inform the TLS design, specifying the teaching strategies to overcome students' learning difficulties and clarifying the relation between criteria of design and the evaluation and re-design process (Guisasola et al., 2017). The literature shows the benefits of DBR in science education research since it reports how DBR provides the basis for a scientific approach to science education research by overcoming some of problems in the design of the TLS. For example, Trna & Trnova (2014) argued that by providing a methodology that includes the evaluation of the efficacy of the TLS, DBR is part of the teachers' Pedagogical Content Knowledge toolkit. These examples, among others, support our proposal of DBR as a methodology to improve TLS and TLS research in science education. The DBR methodology of design, evaluation and iteration for TLS comprises three general phases: i) Design, ii) Teaching experiments, and iii) retrospective analysis (evaluation and refinement of TLS) (Guisasola et al., 2017).

As part of an ongoing project, which aims to use the DBR methodology as a process to design, implement and evaluate a TLS about "Foundations of sound" in the context of PSPT education at the university, we hereby present data derived from the design phase of our TLS, which include the analysis of the school context and definition of learning objectives and learning demands (Leach & Scott, 2002). The general theories that support the design phase include the social-constructivist cognitive psychology, the epistemology of physics curriculum for the context of teaching and the results of Physics Education Research on teaching and learning. In particular, we think that from the aforementioned elements that are critical to the success of the process of design, these are the ones deserving further research: i) the influence of the context of application of the TLS, ii) the definition of learning objectives based on epistemological analysis and iii) the gap between these objectives and students' alternative ideas (i.e. learning demands; Leach & Scott, 2002).

METHODS:

In this paper we will exclusively focus on the first phase of the process (i.e. TLS design), as shown in the following sections.

Definition of Learning Objectives and Identification of Learning Demands

This is a primordial step in the TLS design and several elements were taken into account in order to define the learning objectives: i) analysis of the Primary Education curriculum and educational context, which justifies the need to teach our PSPT in this topic, ii) an epistemological analysis of the concept of sound by looking at its historical development and the explanatory models that have been developed in accordance with current scientific theories.

Regarding the first point, the analysis of the school context determines the conditions in which the TLS will be implemented. This goes beyond a mere analysis of curriculum standards to be achieved by the students in a particular educational stage, but it includes as well the students' feedback and the socio-cultural parameters of the educational setting. This is paramount if results are going to be compared between different schools or countries. In fact, the lack of definition of the factors influencing the design and evaluation of the TLS has been highlighted in the literature as one of the barriers to generalize such TLS designs (Guisasola et al., 2017). In our case, our PSPT are third year undergraduate students from a 4-year BA on Primary Education at a public university, enrolled in a compulsory 9 ECTS course on Natural Sciences teaching, which covers pedagogical content knowledge about physical and chemical sciences for primary education. Students attend different type of sessions, including lectures in big groups of students (ca. n=40) and seminar or lab sessions (n <25).

Regarding the epistemological analysis of the theory of sound, it is relevant to consider not only the state of the art and current definitions about sound, but also the historical context where such concepts were developed and validated (Izquierdo-Aymerich & Adúriz-Bravo, 2003). In other words, scientific concepts and theories do not emerge miraculously but are the result of an arduous process of problem solving and rigorous testing of initial hypotheses.

Consequently, knowing the development of the explanatory ideas that gave rise to the current scientific model can provide important information when designing teaching sequences. Research supports the inclusion of History of Science in Science teaching, but there are fewer studies that explore the use of History of Science to select the knowledge to be included in a TLS (Izquierdo-Aymerich & Adúriz-Bravo, 2003). In this work we use the History of Science as an effective tool to examine the problems that arose in the development of concepts and theories and, thus, we can identify epistemological barriers that needed to be overcome, ideas that allowed moving forward and technological repercussions of the newly acquired knowledge. This allows defining learning goals based on the epistemology of the discipline, instead of relying on school tradition. Obviously, the historical analysis has to be carried out with an educational approach by taking into account students' difficulties on the topic. A clear and explicit definition of learning goals is a key step i) in order to evaluate effectively the achieved outcomes by the students and, ii) to obtain valid results from the evaluation of the TLS for future designs.

The second element in the design phase of our TLS, is the analysis of the gap between the defined learning goals and the students' learning difficulties, as shown in the literature. Leach and Scott (2002), define this gap as the learning demands. They are defined through an analysis of the ontological and epistemic differences between students' ideas and the scientific concept to be taught (Leach & Scott, 2002). These differences will guide the teaching layout of our TLS, by defining the type and level of difficulty that we expect the students to encounter. In consequence, the identification of learning demands is a useful guide in the design of activities, because a big learning demand should require a specific treatment in number of activities and structure, compared to a learning demand that is small. Figure 1 shows a flow chart depicting the design and didactic tools used in this phase.

The sequence was organized around a scenario that enquired about how sound is produced in a music box. After the engaging scenario was presented, driving problems were designed in order to guide the students to learn around three concepts: a) the nature of sound, b) sound's propagation; c) the sound wave model. According to the social perspective of learning, the teaching strategy involves posing situations to students, with directions that guide them to find solutions. The solution must be achieved in accordance with scientific practices that we want students to become familiar with (Guisasola et al., 2017). In the case of our TLS about sound for PSPT, it provides an interactive learning context that has four characteristics: (1) students were organized in groups of four, and they were asked to record all their observations and work in pairs in the tasks that involved predicting outcomes, designing and carrying out experiments; (2) the TLS is structured around several driving questions about the key ideas about sound; (3) in each driving question, there is a number of activities that guide students to make explanations for each key idea. They have opportunities to make argued decisions in the small group; (4) Different ways of solving the task are discussed, guided by the teacher, and a classroom summary is formulated. By carrying out these activities, students engage in scientific practices because we expect that students i) start assessing the question using a qualitative approach, avoiding straight mathematical operations; ii) design an experiment and predict the outcome before carrying it out; iii) collect data and explain the results; iv) Discuss the results.

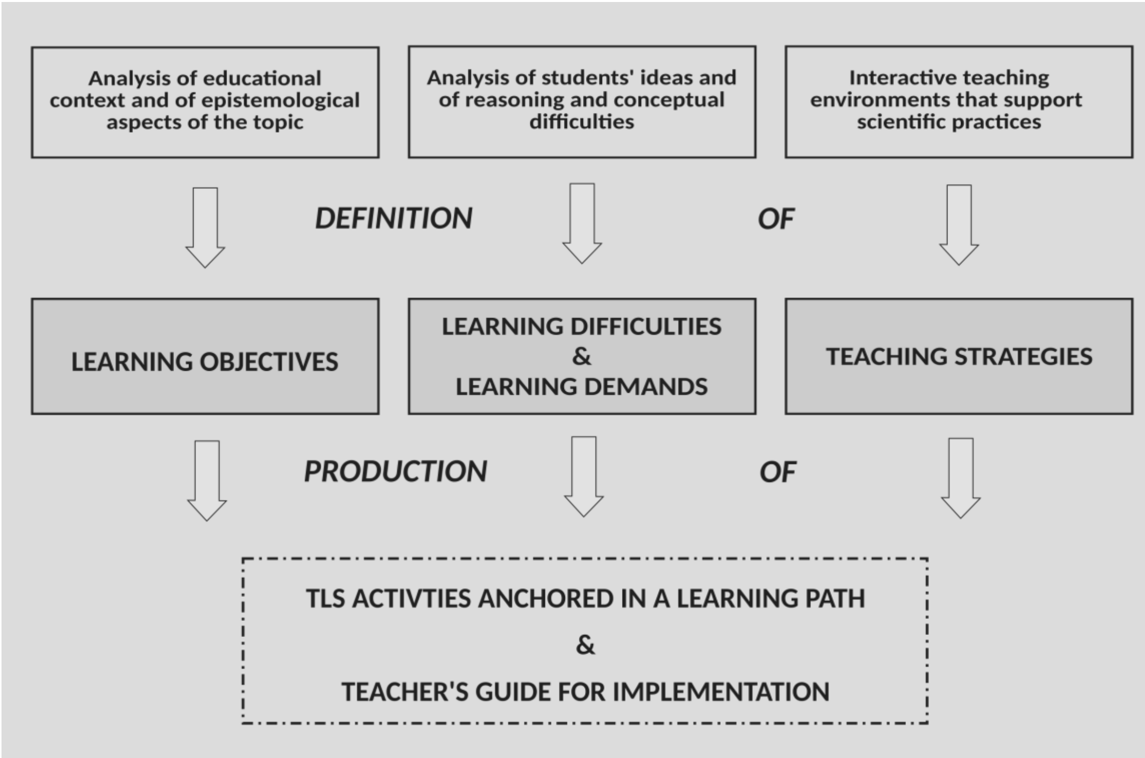

Figure 1. Flow chart depicting the didactic and design tools used in the Understand and Design Phases to sketch a TLS about sound for PSPT based on DBR methodology.

RESULTS

The results obtained with our educational tools will be shown in this section: i) epistemological analysis of school content and ii) Learning demands. It is important to highlight that not all the materials for the TLS are derived from these two educational tools, and hence, teachers that may use the TLS should be informed about which aspects come from previous research and which are personal contributions based on the designers' Pedagogical Content Knowledge.

An analysis that takes into account the epistemology of the theory of sound indicates that sound is defined as the event produced by the vibration of a body perturbed by an energy source. These vibrations cause a disturbance in the elastic medium in the form of a change of pressure or density without the transport of matter. As all waves, sound waves transport energy from one point to another but require some material medium for propagation (Rossing, Moore, & Wheeler, 2001). A deeper scientific understanding of sound involves the identification of its intrinsic properties, that is, loudness, pitch and timbre. Loudness depends mainly on sound pressure. Pitch, depends mainly on frequency, which is a magnitude that states the number of times that an event is repeated over a second and is measured in Hertz (Hz). Timber includes all those attributes that serve to distinguish sounds with the same pitch and loudness. In this sense, the theory of sound explicitly distinguishes: (i) between amplitude and volume; (ii) between frequency and pitch; and indicates (iii) that when evaluating sound energy it is necessary to take into account both properties (amplitude and frequency); (iv) that intensity, tone and timbre are interdependent properties.

Another fundamental aspect to be understood is that what is propagating through the elastic medium is the vibration itself (Hernández et al., 2012) and sound waves are disturbances that propagate through the air in a longitudinal way. Longitudinal means that the back-and-forth motion of air is in the direction of travel of the sound wave (Rossing et al., 2001). The case of sound and its propagation is an example of emergent process. Many patterns in the world are usually the result of the interactions of large numbers of smaller pieces that somehow combine in different ways to create the large-scale pattern. This mechanism is known as emergent process (Fazio et al., 2008).

Table 1 shows the key ideas about sound emerging from this epistemological analysis: 1)Sound and its properties; 2) Propagation of sound and 3) The wave model. A brief definition of each idea is shown in Table 1. Each key idea forms the basis for the definition of our learning objectives and constitute measurable indicators, which will inform the design of specific open-ended questionnaires and teaching strategies to evaluate students' learning.

Table 1. Learning objectives that define the concept of sound for a TLS in PSPT education.

Elements from the epistemology of physics	Learning objectives
Sound and its properties	
E1. Understanding that sound is generated when a typically audible vibration propagates through a medium and that the source of sound comes from a vibrating object. E2. This allows using the two properties of vibrations to characterise sound: the intensity (amplitude) and tone (frequency) of the vibration.	O1. The vibration of an object produces a sound, although not all sounds are perceptible to the human ear. O2. Objects of different shapes and materials generate different sounds. O3. The sound vibrations can be differentiated by their intensity (high/strong and low/soft) and pitch (low and high).
Propagation of sound	
E3. This vibrations are propagated through an elastic medium without transport of matter. E4. When a source vibrates, the surrounding air molecules do not go from the source to the detector during disturbance transmission, but oscillate back and forth over their electronic balance position and then return once the disturbance has passed. E5. Matter is composed of discrete particles (i.e. the particulate nature of matter).	O4. Sound vibrations need a material medium to propagate. O5. The speed of propagation depends on the medium (proof that it is the vibration or wave that is propagated).

The wave model E6. The propagation of this vibration is represented through the abstract concept of pressure wave.	O6. A sound can be represented by a wave (wave model) by establishing relationships between a) the intensity of the sound and/or the amplitude of a wave; b) The pitch of the sound and/or the frequency of a wave.

Table 2 shows how the definition of learning objectives and the identification of learning difficulties from a previous literature review allows for the identification of our student's expected learning demands. This is a pre-requisite to design appropriate teaching strategies and activities and evaluation tools, which will be used in the implementation phase. We show some examples illustrating the rationale behind the assigned level of the learning demands (Leach & Scott, 2002).

Table 2. Alignment of Learning Difficulties with learning objectives and identification of Learning Demands for a TLS about *Foundations of sound* for PPT**.**

Learning difficulties	**Learning objective**	**Learning Demand**
D1. An explanation that links sound with vibration is context-dependent (clear in a guitar string, confusing when hitting stones). Some students may not understand what "vibration" means (Küçüközer, 2009)	O1 (*vibration*)	Low
D2. Difficulties on differentiating tone from intensity or relating the sound's tone with its frequency and sound's intensity with its amplitude (Awad & Barak, 2018)	O2, O3 (*properties*)	Medium
D3. Sound does not need a medium to propagate (electromagnetic wave application; Linder, 1993) D4. Students associate materialistic properties to sound (e.g. carried entity by medium particles; Eshach & Schwartz, 2006; Hrepic et al., 2010) D5. Students cannot represent compression-rarefaction zones during sound transmission (Sözen & Bolat, 2016)	O4 (*propagation*)	Medium-High
D6. Difficulties in understanding/explaining sound propagation in solids (West & Wallin, 2013) D7. The louder the sound, the faster it propagates (Sözen & Bolat, 2016) D8. The denser the medium, the slower it propagates (Hernández et al., 2012)	O5 (*speed of propagation*)	Medium
D9. Confusion between longitudinal and transverse waves (Linder, 1993) D10. Sound and light are the same type of waves because their wave equation is identical (Linder, 1993) D11. Sound is not identified as a process (energy transfer) (West & Wallin, 2013)	O6 (*representation* of a *pressure wave)*	High

D12. Sound's properties are not correctly interpreted in graphic representations of the sound wave (Sözen & Bolat, 2016)	
D13. Coexistence of the wave model with the "entity" model (Hrepic et al., 2010)	

Regarding the first learning objective (O1, Tables 1 and 2), the literature on students' difficulties shows that the understanding that sound is originated due to the vibration of an object is context-dependent in primary students or PSPT (Küçüközer, 2009). We consider that this objective poses a low learning demand because providing different contexts for sound production and linking sound with everyday situations can help understanding sound phenomena (West & Wallin, 2013). We also predict that all learning objectives that involve understanding sound propagation (Learning Objectives O4 and O5) will present medium to large learning demands (Table 2), due to the persistent "materialistic" conception of sound in students of all ages (Hrepic et al., 2010). Lastly, we also predict that the representation of sound as a pressure wave or as a sinusoidal wave (Learning Objective O6, Table 2) can pose a high learning demand due to the mathematical abstraction and the confusion with transversal wave representations (Linder, 1993).

DISCUSSION

We have presented an application of the DBR methodology for a TLS of sound for pre-service primary teacher education that will form the basis of a research program on the validity of evidence-based TLS in PSPT science education. As stated previously, the first phases of the DBR methodology allow to anchor robustly a TLS addressed to a specific audience, which takes into account the historical development of the concept to be studied and the reported difficulties in the literature (Guisasola et al. 2017). Taking into account current paradigms of science education, the designed TLS should give opportunities for the students to engage in scientific practices, with the aim to provide strategies that foster both learning of science and about science. Further work, that will be presented in the future, involves the definition of guiding problems and strategies to foster learning about sound in pre-service Primary teachers. In the subsequent phase, the obtained results regarding the quality of the sequence and the evaluation of learning will inform the refinement of the proposed TLS and provide empirical evidence regarding pre-service teacher's understanding of sound.

BIODIMOD: A DIALOGIC PROCESS OF MAKING SENSE OF BIODIVERSITY THROUGH MODELLING-BASED TEACHING IN SECONDARY EDUCATION

Science education has acknowledged the need to consider modelling as a key process in teaching and learning. Despite scientific modelling has been gaining traction within science education studies, there is relatively little research on the modelling of biological diversity. Our goal was to better understand teacher and students' modelling-related talk when constructing and reaching consensus on subrogant representations of biodiversity. We further aimed to identify how the teacher allowed the construction of a shared understanding and the occurrence of metamodeling talk. We report on four recursive analytical categories that were inductively identified in our registers of an instructional unit, which included fieldwork and classroom biodiversity modelling (32 students, 17-18 years old). The findings show that the representations of biodiversity became increasingly complex, integrating more and more components, and bridging the abstract, material and real planes of the model through different pathways. Teacher's role was characterised by a continuous guidance and dialogic inquiry, by which students were able to hypothesise, predict, describe and explain phenomena related to ecosystem processes in the context of a socioscientific issue.

Keywords: Modelling-based learning, Socioscientific Issues, Classroom Discourse

INTRODUCTION

Modelling and models are important scientific activities and products for scientific disciplines. Constructing, testing, and revising models is at the heart of the scientific endeavour, since models can be used descriptively, as a means of showing or explaining something, and predicatively, as hypothetical entities and research tools (Gogolin & Krüger, 2017). One of the best-known positions within the semantic view of theories is Giere's constructive realism (Koponen & Tala, 2014), that defines models as any subrogant representation, in any symbolic medium, which allows us to think, speak and act with rigor and depth on the system being studied (Giere, 1988). Hence, the purpose of theories, which is composed of a set of models, is to describe the phenomena within their "expected scope", so that one can answer questions about the phenomena under study and their underlying mechanisms (Koponen & Tala, 2014). Subrogant representations may consist not only of highly-sophisticated abstract models, but also of mock-ups, images, drawings, graphs and analogies. However, there is a need to avoid reducing these representations to mere phenomenological "traces" of the subrogated objects (Adúriz-Bravo & Aymerich, 2009).

From an educational perspective, models can be conceived of as intermediaries between children's capacity of interpreting natural facts and the multiple aspects of these facts that substantially work by representing hidden semantic connections and organising them in a comprehensive meaning (Acher, Arca, & Sanmartí, 2007). Therefore, modelling requires adjusting the imaginary or *abstract plane* (AP) with the observed objects (*real plane*, RP) by means of representations (*material plane*, MP), which allow sharing and negotiating semiotic registers with others (Chamizo, 2010; Gómez Galindo, 2013). Nonetheless, teachers tend to refer to the representational forms of the material plane as "models" themselves, rather than referring to representational systems as a whole (Passmore, Gouvea, & Giere, 2014).

Biological diversity was defined as "the variability among living organisms" by the Convention on Biological Diversity (CBD) (1992, p. 3). Since then, biodiversity conservation has been acknowledged to be a socioscientific issue (SSI) due to the intricate and complex links between social concerns (moral, ethics, etc.) and conceptually-influenced scientific practices (Evagorou, Jimenez-Aleixandre, & Osborne, 2012). Empirical research on SSI-based instruction has shown learner gains in ecology concepts, science practices, and learners' epistemic engagement around environmental topics (Kinslow, Sadler, & Nguyen, 2019). Following CBD's definition, biodiversity includes three components, *i.e*., genetic, species and ecosystem diversity ("*biodiversity trilogy*"), but recent contributions have further specified its meaning to include other components, such as species evenness, species composition, functional composition, and landscape units (Bermudez & Lindemann-Matthies, in press). Although students have a range of frameworks related to biodiversity, with some of them being in agreement with scientific conceptualisations (Bermudez & Lindemann-Matthies, in press; Campos et al., 2012), research on teaching and children's understanding of biodiversity has seldom addressed the material or representational challenges that modelling pose for students or how modelling might be used in conceptually fruitful ways (Manz, 2012; *cfr*. Kampourakis & Reiss, 2018).

From a sociocultural perspective, the classroom discursive interaction has gained great relevance as a mediator and privileged indicator of teaching and learning processes (Edward & Mercer, 1987). Language and talk enable us to understand the world around us, communicate with peers, express and share ideas and experiences, as well as to knowledge-building (Evagorou & Osborne, 2013). Therefore, the development of mental contexts, terms of reference and shared forms of speech through which participants construct senses and meanings gain importance in order to achieve a *shared understanding* (Edward & Mercer, 1987; Gray & Rogan-Klyve, 2018).

In this framework, we aimed to fill the gap in the knowledge of modelling of biodiversity and the features of teacher's and students' talk in a teaching and learning sequence (TLS) by answering the following questions: 1. What characterises modelling activities of biodiversity and which is the teacher's role? 2. Which are the functions of teacher's talk and how shared understanding is achieved? 3. How teacher and students reach consensus on the semiotic registers? 4. Are metamodeling ideas explicit or remain implicit throughout modelling activities?

METHODS

In order to analyse the process of biodiversity modelling, a didactic unit or TLS was designed and implemented. These are used as research and innovation tools, and are included in the so-called *developmental research* (Méhuet & Psillos, 2004). The TLS was centred on the meaning-making of an updated concept of biodiversity and getting to know local plants and animals. We implemented the TLS in the last course (32 students aged 17-18) of a state secondary school in the city of Córdoba (1.5 M inhabitants), Argentina. All of the students came from families of low socioeconomic status. Three lessons out of 8 of the TLS were dedicated to the modelling of biodiversity (80 min/lesson). The TLS was co-designed by the first and the third author, who was also the teacher, holds a degree in biology and a M.Sc. in environmental impact assessment, and has 15 years of experience in secondary schools. The first author was the research team's primary liaison with the teacher and class, designing lessons and often coteaching. This researcher's role has also been the case in Gómez Galindo's (2013) and Mans' (2012) developments. Our school reference scientific model of biodiversity was an adaptation of the conceptualisation put forward by the Intergovernmental Platform on Biodiversity and Ecosystem Services (IPBES, www.ipbes.net; Bermudez & Lindemann-Matthies, in press).

Data collection included audio recordings of all sessions, photographs of classroom dynamics, students' and teacher's productions (written and material), and the researchers' (first and second author) field notes. Conversations were audio-taped and transcribed verbatim by the second author. We have also punctuated the transcribed speech, in accord with our own intuitions, to make it easier to read. The approach of analysis of the modelling activities followed by the secondary-school students, the generated material representations and the teacher's role was qualitative (Patton, 2014), with a method of discourse analysis (Acher et al., 2007; Bahamonde & Gómez Galindo, 2016; Edwards & Mercer, 1998; Gómez Galindo, 2013).

Based on a descriptive and analytic account of the sequentiallity of the communication, we dialogued with our research registers aimed to characterise the modelling process and then generate assertions for this particular case that were grounded in the data. The research registers were treated as "situated." The analysis was developed respecting the sequentially of the oral communication conducting qualitative discourse analysis (Acher et al., 2007).

Through discourse analysis (Edwards & Mercer, 1998) the ideas introduced during the modelling activity and the role of the teacher were identified. For each representation the entities, represented relationships and properties were identified. Considering the totality of the data, a first proposal of categories was generated after a *recursive analysis* (Patton, 2014) in which all the analytical units were considered and, giving meaning to the modelling activity, they were reformulated. The analytical categories that we established are: (i) Modelling opportunities: contexts, entities and their relationships; (ii) semiotic registers bridging the planes of the modelling of biodiversity: A platform of common understanding; (iii) teacher's role and talk: From a guide to a dialogic inquirer; and (iv) metamodeling talk: Explicit reference to modelling. This particular selection has been made in order to illustrate the ways we observed participants constructing and manipulating models. We report the most representative sequences, including photographs and oral expressions, so as to produce a characterisation of the key aspects that lead to the modelling process in each of these units (Acher et al., 2007).

FINDINGS

Modelling opportunities: From the real to abstract and material planes of biodiversity

In order to analyse the process of modelling, this category describes the teaching activities that allowed the introduction of model entities and the construction of more and more abstract subrogant representations of biodiversity. The first modelling task took place in an urban park (lesson 3), after students had used dichotomous keys to identify native plants, and started with students' identification of high and low-biodiversity areas (HBA and LBA, respectively), within which 2 one-square-meter quadrats were selected. Inside of them, rubber tokens of different colours, forms and textures were provided by the teacher and used by the students in order to represent biodiversity components. By starting with this activity, students used the RP (i.e. plant individuals) with a subrogant representation of biodiversity (semiotic register of the MP, *i.e.* tokens), according to their conceptual understanding (AP, *i.e.* species richness) (Figure 1). Hence, *species richness* was explained, in terms of the initial model, as the number of tokens of different colours. Later, *functional groups* were conceptualised by the teacher as an emergent category of a set of species, based on shared significant characters because of their effect on ecosystem functioning or their response to environmental changes. The same tokens that students had used to represent species richness allowed us to represent functional groups, by the usage of the token shape. Therefore, the hexagonal and square shapes (MP) was interpreted to be the analogical bridge to the growth-form functional group (AP), and allowed us (cognitive agents) to distinguish between elements of the RP (e.g., grasses and forbs, with the latter being all herbaceous dicotyledonous species that are not graminoids). Trees and shrubs were not tackled with the MP, but we talked about them as part of the ideational AP of biodiversity. Finally, *genetic diversity* was also recognised as a component of biological diversity, with important links to species interactions, but we ran out of time to represent this feature with the MP in the fieldwork (Figure 1).

Back to the classroom (lesson 4), we continued the modelling of biodiversity. We decided to refer to HBA and LBA as "scenarios" of high and low biological diversity (HBS and LBS, respectively), since we started using photographs of the RP and because this approach considers plausible alternative situations that are based on particular assumptions (Bermudez & Lindemann-Matthies, in press). As a first step, students had to represent photographs of the same quadrats of HBA and LBA identified in the fieldwork (lesson 3), by the use of rubber tokens on an expanded polystyrene sheet, where two separate places had been previously delineated for HBS and LBS (Figure 2). The second task consisted of the modelling of a brand new component of biodiversity (species evenness), by presenting and discussing a pair of photographs of the same studied area (RP), each showing high and low *species evenness* (HBS and LBS), Figure 2). Both activities provided the opportunity to describe actual biodiversity scenarios, conjecture about the causes of their current condition, make predictions about the future and past events of the scenarios (retrodictions), and decide which scenario was better for protection. In order to gain complexity in the AP, other components of biodiversity were also represented, such as *genetic diversity*, *functional divergence* (richness and variability) and species *interactions*. It is also worth noting that HBS and LBS were always associated with ecosystem processes (such as rainwater infiltration, soil formation and fertility, biotic pollination, etc.) and the influence of ecosystem disturbances (e.g., biological invasions, human trampling, forest fires, etc.) (Figure 2).

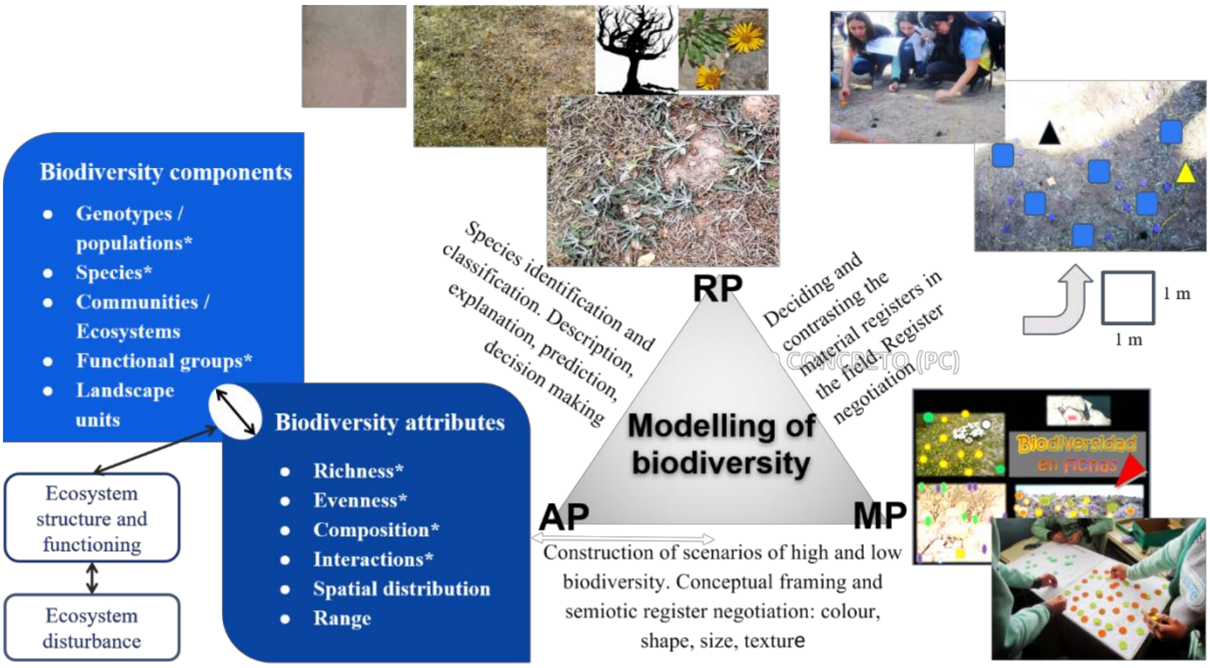

Figure 1. Triadic structure of the modelling of biodiversity in a teaching-learning sequence (TLS), linking the Abstract (AP), Real (RP) and Material Planes (MP) of the model. * Indicates the components of biological diversity that were dealt with in the current TLS.

Semiotic registers bridging biodiversity modelling planes: A platform of common understanding

With this analytical category we identify and describe the material and symbolic representations that were put into play during the modelling of biodiversity, according to teacher's specifications and agreements *with* and *between* students in small-group work and entire-class discussions. We were able to recognise three different *pathways* by which the abstract, material and real planes (AP, MP and RP) were bridged together:

a) AP→RP→AP: At the beginning of lesson 3, students defined biodiversity as the number of species. After a small talk by which the teacher introduced the genetic variability and discussed about the ecosystem processes implicated in forest fires (a patch of the park had recently burned) and droughts, students had to identify areas of high and low biodiversity in the field, and to delimitate and compare quadrats within. After a while, the teacher asked the students how many species were there in each quadrat. References: T = teacher, S = Student (Arabic numbers are used to differentiate them, e.g. S1), numbers before S and T indicate the talk turn within the same lesson.

56 A4: Oh! There are about a million [species]!
57 T: Let's see.
58 A4: But I'm not going to count grass by grass!
59 T: [Towards other students] He tells me if we to count grass by grass [...]
61 T: There may be grass of more than one species but we are confusing, it seems to me, species with individual.
62 A6: What is an individual?

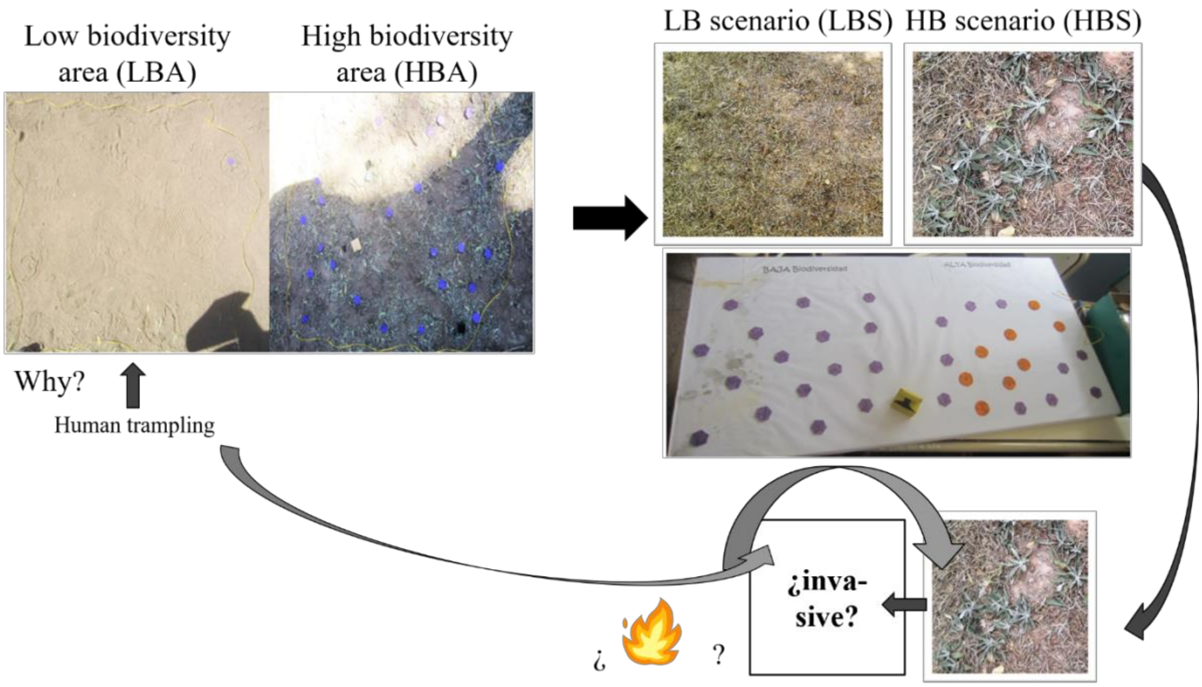

Figure 2. Biological diversity modelling sequence: From real areas in the field (upper left corner) to the construction of material subrogant representations in scenarios of high and low biodiversity (right). See description in the main text.

b) AP→MP→RP: After the aforementioned sequence in 'a' (lesson 3), the teacher presented the material representation of biodiversity by the introduction of rubber tokens. Students had to represent species richness within.

119 T: "What I want now is for us to represent […] We are going to use the tokens to put on top of the species, of the individuals, actually, to make a representation of the biodiversity we can see within these quadrats. [...]
130 A7: […] [You said to] Put the tokens on top of each individual, using different colours.
131 T: Exactly.
132 A3: We have to use one color per species.

c) AP→RP→MP: In lesson 3, after conceptualising the plant growth-form as a functional group (AP), the teacher promoted the recognition of different expressions of this component within the quadrats (RP). Later, a certain quality of the tokens (MP) would be used to represent HBS and LBS:

223 T: Now, that we have differentiated these two categories of plants called forbs and grasses, how can we represent them in the quadrat with our tokens? [5 sec] Well, until now we have concentrated on the color…
224 S1: With token form, then.
225 T: Exactly! Tokens have circular, hexagonal, square shapes…

d) MP→AP→RP: In the classroom, the teacher discussed with a group of students, after they had modelled species evenness, about the semiotic register of genetic diversity (lesson 5).

426 T: Well, how can you represent genetic diversity within a species with your tokens?
427 S4: By the size or colour of the tokens?
428 S3: The color.
429 S4: No, no, the colour corresponds to the species. That's why I said we could use size.
430 T: Well, let's say that we have assigned color to another component of biodiversity: the species one. [...]
435 S3: With the design of the tokens. Because some of them have a smooth surface and others have...
436 S7: … and others have those black wrinkles!
437 S3: Yeah ... they have those stripes!
438 T: Well, we can call that 'texture' [...].

Teacher's role and talk: From a guide to a dialogic inquirer

The teacher had the role of *organising* the activities, *moderating* students' interventions and *guiding* the modelling activities, constantly taking up the existing relationships among the modelling planes (RP, AP, and MP). Of special interest were teacher's interventions that helped to set the relationships among the semiotic registers and facilitated the reaching of consensus. Two subcategories teacher's role have been identified:

a) Teacher as a *guide*: When the teacher gave orientations for the modelling assignment, specifying what to see, compare and experiences to recall. For instance, lessons (L) 3 and 5:

L3. 97 T: All right. If we compare this sector [2 sec], what do you see?
L3. 98 S6: Soil… not much, stones... and may be two clumps of grass.
L3. 99 T: Yes, very few indeed. And what do we have to identify here within this quadrat? [4 seconds] What are we watching, indeed?
L5. 158 T: What did colour mean according to our previous activities?

b) Teacher as a *dialogic inquirer*. This role was found when the teacher identified difficulties in representing components and attributes of biodiversity due to material constrains, inquired students' comprehension of their statements and of academic knowledge under construction, talked about and compared the entities in the subrogant representations (asking for explanations, predictions and retrodictions), synthesised students' contributions and translated them from everyday formulations to academic terms. For example in lesson 4, when talking about the possible influence of human trampling on the modelled scenarios, the following dialogue was registered at a whole-class level:

345 T: Ok then, we could take out the "creeping daisies" [*Trichocline reptans*]. What would that mean?
346 S4: That there is only one species left.
347 T: Which means that…, in terms of biodiversity...

348 S5: That biodiversity is lower.
349. T: That biodiversity is lower than... [2 sec] Well, that's what probably happens when there is a disturbance like [2 sec] human trampling. [After the conceptualisation of "ecosystem disturbance"] Now, let's think what could happen if it rains torrentially here and here? [Talking about a LBS and a hypothetical condition].
350 S4: The water could be infiltered here and not there.
351 S6: That [...] will have better infiltration since biodiversity is higher. […]
360 T: Ok, then, how could you represent that hypothetical scenario with our tokens?

Metamodeling talk: Explicit reference to modelling

Metamodeling talk points out teacher's explicit reference to what is being done with the models and their representations, in order to understand the activity implications. For example (lesson 4):

188 T: […] Last session we used these tokens in the fieldwork, because biologists often use a tool called modelling to work on or make representations of nature, with objects that allow them to explain or predict certain things. For example, have you ever made a mock-up of the cell or the digestive system?
189 S: Yes. [Numerous students]
190 T: Ok, all these are ways of creating models... those models that one builds allows the recognition of the components and the studying of placement, size, structure and functions of the organs. Sometimes the colours have a specific meaning based on certain agreements. Right? Biologists use models very frequently as scientists do, including models of biodiversity, and that's what you have started constructing the last session. So now we will move forward with our modelling processes by using some photos I took in the fieldwork… Have you taken photos of your own?

DISCUSSION AND CONCLUSIONS

Throughout the modelling sequence, representations of biodiversity increased in abstraction and complexity, given that the students moved away from the experiential observation in the fieldwork (Manz, 2012), integrated and re-signified concepts through progressive representations (Bahamonde & Gómez Galindo, 2016; Gómez Galindo, 2014) by including more and more components of biodiversity. This progressive abstraction was at the centre of the modelling activity and implied going from/to the material - abstract - real planes (Chamizo, 2010) along different circuits: AP→RP→AP, AP→MP→RP, MP→AP→RP, and MP→AP→RP, among others not presented here.

In agreement with Passmore et al. (2014), we kept focus on reasoning and making sense *with the model,* as a dynamic entity along the didactic sequence, rather than reducing our model to just another thing to be learned by rote. This is why the distinction between the modelling *of/for* was used to construct situated models that were evaluated in the context of cognitive activities, toward a clear sense-making goal (Passmore et al., 2014). With this regard, teacher's talk through modelling activities allowed students to formulate hypotheses, predictions, explanations and to justify claims (Acher et al., 2007). These processes were framed by the usage of talk, the main teacher's support to achieve shared understanding (Bahamonde & Gómez Galindo, 2016; Edwards & Mercer, 1998).

Teacher's guidance as modelling directions was associated with setting and negotiating registers, keeping track of the task and promoting small-group- and whole-classroom interactions (Gray & Rogan-Klyve, 2018; Gómez Galindo, 2013). Related to this, classroom dynamics seemed to be constructed on the basis of constant questioning, shifting attention toward what was being analysed (Acher et al., 2007). Teacher's inquiry moves seemed to be guiding students to evaluate the value of a specific point of view, providing opportunities to problematise and deepen the understanding of biodiversity and the interconnected ecological processes (Gómez Galindo, 2014; Manz, 2012).

The experiences introduced throughout this study allowed the students not only to manipulate objects, observe properties and changes, and recognise similarities and differences, but also to do so by constructing subrogant representations which conditioned both their perceptions and their explanations (Svodova & Passmore, 2013). These experiences can thus be described as a process from which the students manipulate, talk, and think according to a school science model that is under permanent construction (Acher et al., 2007).

The treatment of biodiversity as a socially-situated modelling practice builds from and extends perspectives on engaging students in disciplinary practice (Manz, 2012). Scarce explicit metamodeling talk indicated few conceptualisations of modelling itself (Gray & Rogan-Klyve, 2018; Schwarz & Gwekwerere, 2007), possibly because of teacher's focus on modelling directions and task fulfilment (Krell & Krüger, 2016). This emphasises the need of modelling training for teachers, especially for the teaching of biodiversity in innovative and conceptually fruitful ways (Blanco-Amaya, Justi & Díaz de Bustamante, 2017). In light of the present findings, we recommend that teachers use modelling-based teaching in order to conceptualise more up-to-date biodiversity definitions than the traditional concept stated by CBD (1992), and as an attempt to deal with students' centrism in species richness (Bermudez & Lindemann-Matthies, in press).

ENHANCING STUDENTS' EPISTEMOLOGICAL BELIEFS ABOUT MODELS IN SCIENCE THROUGH A MODEL BASED TLS ABOUT THE OPTICAL PROPERTIES OF MATERIALS

Stavros Koukioglou[1], *Dimitrios Psillos*[2]
1 School of Primary Education, Aristotle University of Thessaloniki, Thessaloniki, Greece
[2]School of Primary Education, Aristotle University of Thessaloniki, Thessaloniki, Greece

Models and modelling practices have been systematically and extensively used in Physical Sciences curriculum for more than three decades. Yet students' epistemological beliefs about their nature, role, change and multiplicity often deviate from the scientifically acceptable ones. This research aims to enhance their epistemological beliefs regarding models in science with the use of an inquiry, model based, Teaching Learning Sequence as an intervention method. The latter contains modelling processes and practices of expressive, experimental and exploratory modelling pedagogies which are formed in a cyclic manner. The activities incorporated consist of real world and virtual experiments all of which explicitly adopt the geometrical optical ray model for the interpretation and prediction of light phenomena. In addition, it is this study's goal to unveil the criteria by which students distinguish and categorize images representing science models from non-science models representations. Results indicate an increase in students' performance regarding their epistemological beliefs about science models. Moreover, they reveal three criteria -axes- which provide us with an insight into students' ideas about models in science.

Keywords: scientific, models, TLS

INTRODUCTION

Despite models' significance in Science and Science Education, students hold a variety of misconceptions towards them. Accordingly, researchers are investigating approaches to enhance their awareness of features of scientific models and particularly their purpose, nature, multiplicity and change (Oh & Oh, 2011). From a number of studies it appears that engaging students in modelling activities is not sufficient for enhancing their model awareness unless metacognitive activities are embedded in teaching concerning these features of models (Schwarz & White, 2005). In another study these effects were investigated by an inquiry model based Teaching Learning Sequence (TLS) in optics, enriched with metacognitive activities and found significant improvements on student teachers' epistemological beliefs about models (Soulios & Psillos, 2016). In this research the abovementioned TLS is further adapted to junior high school students' level in an attempt to enhance their epistemological beliefs about the nature, purpose, multiplicity and change of models. In addition, an issue that warrants investigation is the ability of students to distinguish visual representations of scientific models from images portraying non-scientific models e.g. technological devices (Grosslight, Unger, Jay, & Smith, 1991). Within this context the research questions of the present study are:

Research questions

- What are the changes on students' epistemological beliefs about the nature, purpose, multiplicity and change of models?
- What are the changes on student's ability to recognize and distinguish images depicting non-models from images representing obvious and non-obvious models?

METHODOLOGY

The Teaching Learning Sequence

The TLS used in this research is the product of iterative modifications of a previous one focusing on the optical properties of optical fibers originally developed during a European program on Materials Science (Testa, Lombardi, Monroy, & Sassi, 2011). After its adaptation to the Greek curriculum the TLS was enriched by incorporating cyclic modeling practices suggested in the literature (Campbell, Oh, & Neilson, 2013). These consist of exploratory modeling practices in which students use pre-designed models, inquiry modelling practices in which models are used to make predictions which later on will be submitted to tests for validation and a continuous process of designing, testing and revising the models created. Moreover, metacognitive episodes are also embedded as a means of reflection and feedback to students (Soulios & Psillos, 2016). For the purposes of the present investigation, the TLS is further modified in terms of expression regarding the metacognitive questions and their content. Regarding the second matter, the basic conversions include adding more reflection questions and integrating the "Bending Light" application from Phet Website ("Bending Light," 2019). The notion of the scientific model is introduced explicitly throughout the TLS with the use of the geometrical optical ray model. The TLS intervention lasted 8 weeks in a total of 12 teaching hours. The sample consists of 35 second grade junior high school students (8th grade), from two classes of a public school in Greece, who share the same cognitive skills and difficulties thus similar didactic approaches were followed.

Instrumentation

Two questionnaires are used both before and after the implementation of the model-based TLS. The first questionnaire is a closed-ended one which consists of 18 visual representations (Table 1). Below each image students can fill in either the "yes" or the "no" box as to whether the image depicted represents a scientific model or not. The pictures are divided into three clusters; the first one consists of images that do not represent scientific models but rather technological devices. The second cluster comprises of visual representations of static scientific models such as a human cell replica while the third cluster consists of images of abstract scientific models usually that of a procedure, e.g. the photosynthesis mechanism. The classification of the these representations in three different clusters is based on previous studies (Grosslight et al., 1991; Schwarz & White, 2005).

The second questionnaire consists of seven open-ended questions regarding the nature, purpose, multiplicity and the ability of a scientific model to change. The questionnaire was been developed and used in a previous study (Soulios & Psillos, 2016). Apart from the two questionnaires, semi-guided interviews were also conducted between the researcher and a random sample of 15 students, before and after the completion of the TLS.

Table 1. Visual representations classification into clusters

Cluster 1	Cluster 2	Cluster 3
Camera	Globe	Graph
F1 race car	Human skeleton 3D representation	An equation
TV personalities	Cell 3D representation	Water molecules simulation
TV set	Earth's interior sketch	Blueprints
Cell phone	Sketch of plant's parts	Chemical compound simulation
House	Functional miniature of a car	Photosynthesis sketch

RESULTS

Students' answers to the open-ended questionnaire and interviews are categorized according to the hierarchical three-level classification framework which was developed and utilized in earlier studies (Crawford & Cullin, 2004; Grosslight et al., 1991; Soulios & Psillos, 2016). The first level includes answers that deviate from the scientifically acceptable ones whereas the second level consists of intuitive answers that tend to approach the scientifically correct ones. Third level's answers are those that are in compliance with the scientifically acceptable ones. Students' failure of presenting an answer is categorize in a different level that of "No Answer" (NA). Students' answers percentages in the aspects of nature, purpose, multiplicity and change of scientific models before and after the implementation of the TLS are presented on Table 2.

Table 2. Percentage of students' answers per epistemological level

Level of epistemological beliefs	% Before TLS				% After TLS			
	NA	**1**	**2**	**3**	**NA**	**1**	**2**	**3**
Nature	5,7	68,6	25,7	0,0	0,0	40,0	48,6	11,4
Purpose	5,7	65,7	25,7	0,0	0,0	28,6	71,4	0,0
Multiplicity	5,7	11,4	74,1	11,4	0,0	20,0	68,6	11,4
Change	11,4	22,9	62,9	2,9	2,9	11,4	57,1	28,6

The abovementioned results are treated with paired sample parametric T-test and bootstrap method with 1000 sample Bias Corrected and Accelerated (BCa) at 95% confidence intervals. Their analysis reveals that students' epistemological beliefs are improved in three out of four aspects of scientific models after the completion of the model-based TLS (Table 3). In specific, students understanding of the nature, purpose and the ability of a scientific model to undergo changes are enhanced except for multiplicity which appears impervious to the effects of the TLS.

Table 3. Paired sample t-test about epistemological beliefs

Paired sample T- test	Scientific model's aspects			
	Nature	Purpose	Multiplicity	Change
T-statistic	**-4,29****	**-3,90****	-0,63	**-4,06****

*p ≤ .05, **p≤ .001

The analysis of students' answers on the closed-ended questionnaire reveals a 22% decline in students' positive answers regarding first cluster visual representations, a 6% rise in the second cluster ones and a 16% increase in the third cluster images (Table 4). A paired sample parametric T-test with bootstrap method was conducted on the abovementioned answers. The test confirms statistically important improvement in the cases of cluster 1 and 3 visual representations (Table 5). These results suggest that the TLS has a profound effect on students' ability to discard the visual representations of cluster 1 as scientific models. Simultaneously it enables students to acknowledge cluster 3 visual representations as scientific models. Finally, despite the increase of the correct answers percentage in cluster 2 images no statistically significant improvement is identified.

Table 4. Average percentage of positive answers per cluster

	% Before TLS	**% After TLS**	**% Change**
Image cluster 1	50,48	28,10	-22,38
Image cluster 2	66,19	71,90	5,71
Image cluster 3	57,62	73,33	15,71

Table 5. Paired sample t-test per image cluster

Paired sample T- test			
	Cluster 1	Cluster 2	Cluster 3
T-statistic	**3,36***	-1,10	**2,90***

*p ≤ .05, **p≤ .001

Moreover, students' transcribed interview analysis unveils certain criteria -axes- by which they recognize and sort images into obvious science models, non-obvious ones and non-science models. To begin with, the first axis takes into consideration a model's purpose meaning that students categorize images into models according to what models are supposed to do. Students who mistakenly accept visual representations of cluster 1 as scientific models believe that models are technological devices that help us in our everyday life. On the other hand, the same criterion-axis is used by other students in order to justify their answers in cluster two and three images. According to those students' answers a scientific model is used as a means of understanding, interpreting physical phenomena and teaching.

The second criterion -or axis 2- takes into consideration the nature of a model and its construction. According to students, scientific models are sophisticated designs that only scientists can construct. Therefore, many technological devices depicted in the visual representations are considered as such. On contrary, students who reject images of technological devices as scientific models claim that a model presents a theory, an idea or even a process which helps us discovery something else. In addition, some students explicitly stress that models are simulation of reality rather than the reality itself.

Finally, a third criterion is identified as combination of the first two axes and the notion of evolution meaning that students attribute to scientific models the ability to change. On one hand students who mistakenly consider technological devices as scientific models propose that upgrades can be made to "models". On the other hand, students who reject the abovementioned visual representations as scientific models support the view that models can change when they contradict experiments or when a new, more suitable theory is presented.

DISCUSSION AND CONCLUSIONS

By comparing students' pre and post answers in the open-ended questionnaire it is evident that their epistemological understanding of scientific models is promoted in all aspects except for multiplicity. It is our belief that this inconsistency could be attributed to an intrinsic design feature of the TLS; the single use of one and only scientific model for light propagation i.e. that of geometrical optical ray. By analyzing students' answers on the closed-ended questionnaire, we conclude that their ability to discriminate scientific models from non-model representations is also improved (cluster 1). Furthermore students appear more capable of acknowledging abstract visual representations of scientific models (cluster 3). Yet no statistically important effect is recorded about cluster 2 visual representations. Interview analysis also reveals three main axes regarding students' reasoning about models' nature, purpose and ability to change. Further investigation into these axes and students' reasoning is required.

In conclusion, we consider that the application of this inquiry model-based TLS in the field of optical properties of materials promotes students' epistemological beliefs about scientific models. In addition, the TLS enables students to recognize and distinguish visual representations of non scientific models from images depicting such while it also enhances their ability to identify more sophisticated and abstract scientific models from relatively understandable ones. In line with other studies (Soulios & Psillos, 2016), current results suggest that it is feasible to enhance secondary students' awareness about certain aspects of scientific models by using an inquiry model-based TLS related to a specific content.

ACKNOWLEDGEMENT

The authors would like to thank Dr E. Petridou and Dr I. Soulios for their permission to use the original closed-ended questionnaire and Dr A. Taramopoulos for his insight and comments regarding data analysis.

DEVELOPING STUDENTS' CRITICAL THINKING: LIKELIHOOD AND UNCERTAINTY ANALYSIS IN PARTICLE PHYSICS

Farahnaz Sadidi[1], Gesche Pospiech[1]
[1]Technische Universität Dresden, Dresden, Germany

Likelihood and uncertainty analysis (LU) is an important aspect of critical thinking (CT). It is relevant in everyday life, but also in science outside and inside the classroom. However, students have difficulties in applying the LU skill. We tested this skill before and after a teaching intervention, investigating how our content-specific instruction can promote this important aspect of CT. The topic is antimatter and the target group is German high school students of grade 10. To develop and optimize our instructional design, we use a Design-Based Research (DBR) cycle. Here, we focus on the design of a worksheet about alternative interpretations of a cloud chamber photograph. To assess the effectiveness of the design of the worksheet in teaching LU skill, we compare the hypothetical learning trajectory (HLT) with the actual learning trajectory (ALT). Furthermore, we introduce a content specific critical thinking test was developed to assess the extent to which students' LU skill improve during the intervention. Our example from particle physics may help physics teachers to develop students' LU skill in other contexts.

Keywords: Cognitive Skills, Design-Based Research, Training and Development

INTRODUCTION

Very few events in life can be known with certainty. Teaching students to use likelihood and uncertainty analysis (LU) skill for making a decision about uncertain events is very important. Furthermore, it is important to differentiate between the general LU skill, which requires knowledge of everyday life (Ennis, 1989), and the domain-specific LU skill, which requires content-specific expertise (McPeck, 1990), e. g. in a particular domain of physics.

LU in mathematics is called "probability". High school students learn the necessary rules and skills to calculate probability in a mathematical context. However, it might be hard for students to transfer their mathematical knowledge about probability to other subjects, such as physics. For example, in a cloud chamber experiment, a given track can be caused by a muon or an electron. Without further data, the scientist can only make a probability judgement about these two hypothetical processes. Thus, particle physics is a suitable topic for teaching the LU skill. Our aim was to design (and re-design) teaching activities about antimatter to increase students' general and domain-specific skills in Critical Thinking (CT). One of the 5 CT skills is likelihood and uncertainty analysis on which we focus.

METHODS

The lack of concrete guidelines for designing a high quality intervention in the abstract area of particle physics encouraged us to choose Design-Based Research (DBR) approach to develope our content-specific instruction in an iterative cycle of design-enactment-analysis-redesign (Collins, Joseph, & Bielaczyc, 2004; Nieveen, 2010). We have already designed a content-specific instruction for training Critical thinking (CT) skills. The instruction comprises 10 lessons about antimatter for high school students of grades 10, 11 &12 (Sadidi & Pospiech, 2019). Here we focus on the evaluation of the instruction with respect to LU skill. As an example we present the design of a worksheet about the “discovery of the positron” and we analyes students’ discourse to get insight into how the teaching-learning activities promote students’ LU skill. To support our qualitative analysis, we also present an analysis of pre- and posttest data.

Design of worksheet

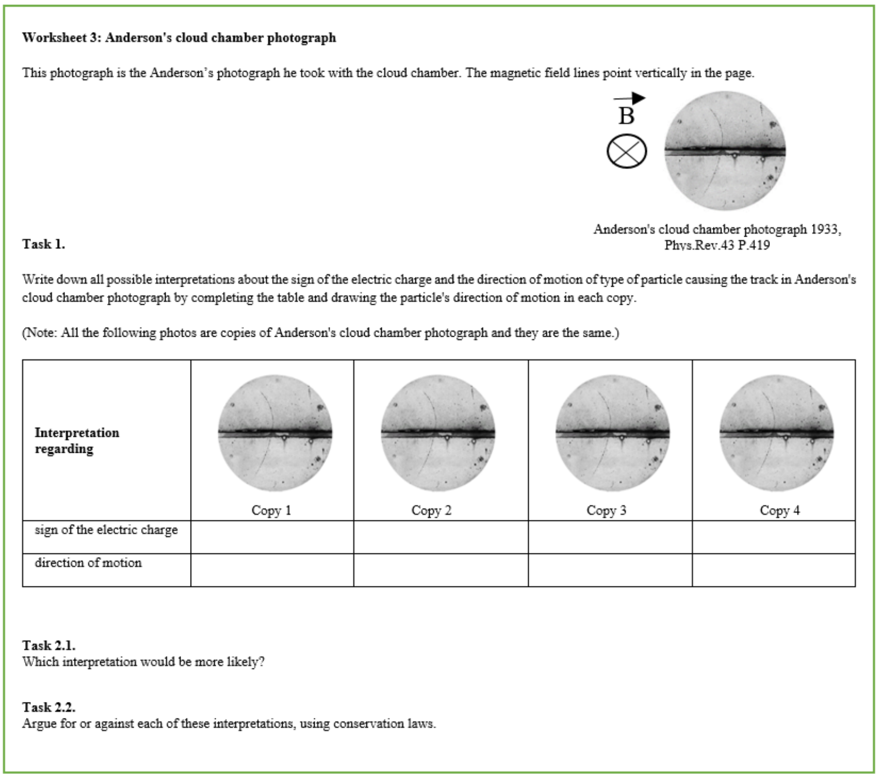
To design teaching-learning activities for promoting LU, we needed first to generate hypothetical learning trajectories (HLTs). This implies to specify students’ prior knowledge, define learning goals, outline a hypothetical learning process, and design a task (Simon & Tzur, 2004). Regarding learning goals, we focused on the 4 outcomes of applying LU skill in everyday life defined by Halpern (2009) and made them domain-specific (see learning goals in table 1), *cf.* Tiruneh et al. (201**6**). Halpern (2009) defines these LU-related outcomes as: (1) estimating the probability of occurrence of an event, (2) using probability judgement to improve decision making, (3) understanding the limits of extrapolation, and (4) understanding the need for relevant and valid information for being able to conclude about the most probable event in everyday life. To provide a task for the students, we designed a worksheet about Anderson’s cloud chamber photograph of the positron. The design of the worksheet was inspired by Anderson’s discussion of four ways in which his photograph might be interpreted (Anderson, 1933).

Table 1 shows an example of a generated HLT to design a worksheet about “Anderson’s photograph” which was used in teaching about the “ discovery of the positron”.

Table 1. Hypothetical learning trajectory (HLT) to design the “Anderson’s photograph” worksheet.

Students’ prior knowledge	Lorentz force, conservation of energy and momentum, relationship between radius of the track and momentum and energy of particles, and definition of range in particle physics.
Learning goals	Making multiple possible interpretations. Estimating the likelihood of occurrence of an event(s). Making decision about the most likely event. Recognizing the need for relevant and valid information to be able to conclude about the most likely event.
Hypothetical learning trajectory	<u>HLT 1</u>: Students will apply their knowledge about the Lorentz force and the right-hand rule to **make different interpretations** about the sign of the charged particle and the direction of particle motion. <u>HLT 2</u>: Students will apply their knowledge about conservation laws to **evaluate their interpretations** and to **discuss the likelihood** of a certain type of particle causing the track. <u>HLT 3</u>: Students will **make decision about the most likely event**. <u>HLT 4</u>: Students will discuss and reflect on the activity to **realize the importance of having relevant and valid information for final conclusion**.
Tasks (for the worksheet)	This photograph is the Anderson’s photograph he took with the cloud chamber. The magnetic field lines point vertically in the page. **Task 1.** Write down all possible interpretations about the sign of the electric charge and the direction of motion of type of particle causing the track. **Task 2.** Which interpretation would be more likely? Argue for or against each of these interpretations, using conservation laws.

Figure 1 shows the worksheet about "Anderson's photograph" designed based on the hypothetical learning trajectory.



Worksheet 3: Anderson's cloud chamber photograph

This photograph is the Anderson's photograph he took with the cloud chamber. The magnetic field lines point vertically in the page.

$\vec{B}$ ⊗

Anderson's cloud chamber photograph 1933, Phys.Rev.43 P.419

Task 1.

Write down all possible interpretations about the sign of the electric charge and the direction of motion of type of particle causing the track in Anderson's cloud chamber photograph by completing the table and drawing the particle's direction of motion in each copy.

(Note: All the following photos are copies of Anderson's cloud chamber photograph and they are the same.)

Interpretation regarding	Copy 1	Copy 2	Copy 3	Copy 4
sign of the electric charge				
direction of motion				

Task 2.1.
Which interpretation would be more likely?

Task 2.2.
Argue for or against each of these interpretations, using conservation laws.

Figure 1. Worksheet about "Anderson's photograph".

In the *"discovery of the positron" lesson students did not receive the first and the second task simultaneously. After completing the first task and an in-group and in-class discussion, students learned the necessary content knowledge e.g. calculating the radius of the track, relationship between radius of the track and energy of particle, and definition of range in particle physics. Next they receive the task 2.*

Participants

The course has been implemented with 10 students from grade 10 in a high school for particularly gifted pupils in mathematics and science. The teacher had been teaching for 35 years and she had experience in teaching particle physics. The teacher was given a teacher package provided by the researcher including content knowledge, worksheets, guidelines for teaching, students' difficulties, and the most common student questions. The teacher package is the result of data analysis of the last implementation in our Design-Based Research project. The teacher was informed during several meetings and discussion with the researcher about the goal of the project as a whole and each session specifically.

Data sources and analytic methods

We refer to two types of data here. One data source includes video-recording of teaching sequences, audio-recording of students' discussions, and students' answers on the worksheet during *teaching the "discovery of the positron" lesson (45 minutes) in May 2019. Analysis of these data enabled us to observe* the actual learning trajectories (ALTs). Comparing the ALTs with the HLTs (Dierdorp, Bakker, Eijkelhof, & Maanen, 2011) gives us an impression of how students' LU skill develops during the lesson and an insight into the effectiveness of the teaching-learning activities. *We considered two criteria to analyze the ALTs. The first was the extent to which students use LU skills and the second was to evaluate the quality of students' reasoning when using LU skills (Thinking in discipline). The other data source includes pre- and posttest items. The results from pre- and posttest are used to answer the question of whether or not students' LU skill improved over the course of 10 lessons.*

Pre- and posttest

As alluded to before, to *investigate whether our content-specific instruction can promote general and domain-specific LU skill, we assigned a pre- and posttest.* We used the Halpern Critical Thinking Assessment (HCTA) (Halpern, 2016) as pre- and posttest, with 4 items for evaluating LU skill in everyday life. It is necessary to mention that we translated the original version of the HCTA from English to German. We validated the German version of the HCTA by retranslating it to English for the purpose of this study. The purpose of this study was not to check the validity of the German version of the HCTA test in a large scale.

Furthermore, to evaluate the development of students' LU skill in particle physics, we needed to develop a content-specific critical thinking test as posttest. To design a Particle Physics Critical Thinking (PPCT) test, we used the structure of the HCTA as a framework. The PPCT contained 17 items, from which 3 items evaluate the LU skill. We also defined a relevant scoring rubric for the PPCT test. To validate its content and practicality, we used expert reviews, small-scale paper-pencil administration with physics teacher students (N= 8) and a cognitive interview with high school students (N= 4) (Adams & Wieman, 2010). To check the reliability, we calculated the internal consistency of these 3 items, Cronbach's $\alpha = .97$. In addition, 8 students' answers have been selected and corrected independently by two raters. Table 2 shows the results of calculating inter-rater reliability and item difficulty of the 3 LU-related items.

To assess the convergent validity of the PPCT items evaluating LU, we calculated Pearson's correlation coefficient between the PPCT test and the HCTA test as a standard test. Therefore, the participants' performance on the LU-items of the PPCT was compared to their performance on the corresponding items in the HCTA test. The result showed a positive correlation between the two sets of the scores ($r = .35$, $p = .04$, N= 34).

Figure 2 shows a sample item of the PPCT test for evaluating LU. The item objective is that students understand the limits of generalization and the need for relevant and valid information to make a more accurate prediction.

Table 2. Inter-rater reliability (Cohen's kappa coefficient) and item difficulty of 3 items of Particle Physics Critical Thinking (PPCT) test to evaluate Likelihood and Uncertainty Analysis (LU) skill.

Item related to LU skill	Cohen's kappa coefficient (n=8)	Item difficulty

7	.60	.32
9	.82	.50
12	.71	.53

In one lecture at CERN you hear about the GBAR experiment. GBAR measures free fall acceleration of neutral antihydrogen atoms in the terrestrial gravitational field with the accuracy of 1% of g.

You ask yourself:
if we release a neutral Anti-Apple above our Earth, does it fall up or fall down?

You share your question with your friend.
He says: "As neutral antihydrogens fall down in the GBAR experiment, we can conclude that Anti-Apple will fall down."

Task 7.1: Would you agree with your friend?

- ☐ Yes, I agree
- ☐ No, I do not agree.

Task 7.2: Explain your reason.

Figure 2. Sample item 7 of the Particle Physics Critical Thinking (PPCT) test.

Table 3 shows the corresponding scoring rubric for item 7 of the PPCT test.

Table 3. Corresponding scoring rubric for the sample item of the Particle Physics Critical Thinking (PPCT) test.

Item weight: 5 points

The complete answer that we expect from students is:
Gravity acts only on mass. There is no negative mass for antimatter and antimatter has the same mass as matter. Therefore, the Anti-Apple will fall down. However, this generalization has some limitations e.g. GBAR experiment was run in a vacuum while here, annihilation of falling Anti-Apple in the air is a challenge. Furthermore, we should differentiate between antihydrogen and the complex system of Anti-Apple.

Scoring rubric:

<u>Task 7.1</u>
Yes: if there is consistency between "Yes" and the answer to the task 7.2: 1 point, otherwise 0.
No: if there is consistency between "No" and the answer to the task 7.2: 1 point, otherwise 0.
<u>Task 7.2</u>

- Did the student mention that gravity acts on the Mass explicitly?
  # Yes: 2 points.
  # Not explicitly: e.g. gravity exists, 1 point.
  # No: 0 point.
- Did the student mention the limitation of generalization?
  #Yes: 2 points e.g. annihilation or difference between antihydrogen and Anti-Apple.
  #No: 0 point. Go to the next question.

• Did the student make assumption like "if antihydrogen behave like matter, all antimatter would behave like this"? Or "anti-apple contains anti-hydrogen"? # Yes: 1 point. # No: 0 point.

RESULTS

Here, we present the results of a comparison between the HLTs and students' ALTs (Dierdorp, Bakker, Eijkelhof, & Maanen, 2011) during working on the "Anderson's photograph" worksheet. Ultimately, we report students' performance in pre- and posttest.

Making different interpretations

In the first task the teacher gave students 4 copies of Anderson's photograph and asked them to make different interpretations about the sign of the charged particle and the direction of the particle motion causing the track. First all 4 groups of students did apply content knowledge to make two interpretations but not more. Data analysis showed us the overconfidence problem defined by Halpern (2009) as that "people tend to be more confident in their decision about probabilistic events than they should be." Here the teacher encouraged students to overcome this problem and make more interpretations. This is a big step that requires students' persistency in solving complex tasks. During brainstorming for making more interpretations different ideas including students' misconceptions were discussed and the teacher as facilitator encouraged students to reflect on their own ideas to correct their understanding of particle physics. Finally, one group ended with 4 interpretations, 2 groups with 3 interpretations and one group did not go further and stopped after making 2 interpretations. It might be interesting to analyse more deeply why this group did not develop further interpretations.

Figure 3 shows different students' interpretation about the particles cause the track in the cloud chamber photograph.

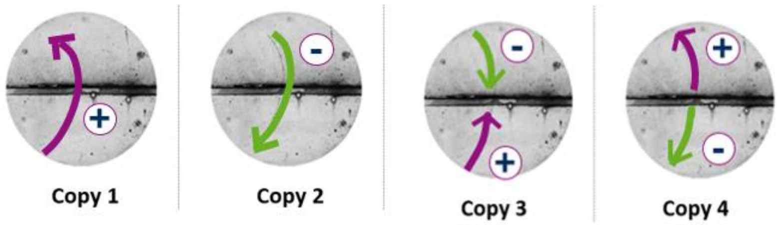


Figure 3. Different students' interpretations in the cloud chamber photograph.

Evaluating interpretations and discuss the likelihood

Tasks 2.1. & 2.2. (see the worksheet) asked students to make a decision about the most probable event. But before making the decision we expected that students apply their content knowledge to evaluate their interpretations (see figure 3) and understand that two of the four interpretations could be correct but the probability of occurrence of one is very low.

Analysis of transcripts from video and audio data and students' answers on the worksheet showed us that students made efforts to evaluate their interpretations. Some wrong ideas were changed along discussion and reflection in the group and with time students came up with more reasonable ideas. Moreover, analysing students' dialogues showed us that they used more frequently the words related to applying probability in making decision e.g. most likely, likely, unlikely. This showed us that the goal of the task that is developing LU skill was clear for students and was accepted by them.

Table 4 presents an example of student' argument for or against different interpretations in figure 3 to answer the task 2.2. on the "Anderson's Photograph" worksheet (The student's answer was translated from German to English). The student was in the group with 4 interpretations.

Table 4. An example of student' written answer to the task 2.2. on the "Anderson's photograph" worksheet.

Interpretation	*Student's answer*	*clarification*
Copy 1	The positive particle loses energy passing through the lead plate, so the radius gets smaller.	The student argued **for** interpretation 1.
Copy 2	I had considered unlikely that the negative particle gain energy passing through the lead plate.	The student argued **against** interpretation 2.
Copy 3	Why would two particles meet at exactly the same point?	The student considered the **probability** of occurrence of this event **low**, therefore she argued **against** interpretation 3.
Copy 4	Particles would have to split in the lead plate and were not before in the alcohol vapour.	The students argued **against** interpretation 4. The argument does not sound reasonable. **Note:** The concept of pair production was taught after this lesson. Therefore, the student did not use the correct terminology.

Making decision about the most likely event

All students concluded that the interpretation 1 is the most likely event. They argued for this interpretation by discussing about changing radius of the particle in two sides of the plate and energy loss of the particle passing through the plate.

Realizing the importance of having relevant and valid information for final conclusion

Analysis of students' discussion during evaluating different interpretations showed us that students realized the importance of focusing on the relevant information. When an idea came up in a group students looked for reasons, discussed and reflected on their reasons to collect relevant and valid information to evaluate their interpretations. Some ideas were rejected and at the end the ideas reported in the worksheet remained as accepted ideas by the group.

As considering the credibility of a source of information is an important topic for developing critical thinking skills and in this context LU skill, an in-class discussion was planned to emphasize explicitly on the topic.

Pre- and posttest scores

Preliminary analysis of the HCTA pre- and posttest (N=9) showed us different trends in the development of students' general LU skill: progress, stand-still, or regress for each individual student. Furthermore, on average, there was no significant difference in the score of LU skill (**Pretest** *M=11.33, SD=2.50*; **Posttest** *M=11.11, SD=2.08*).

Moreover, the PPCT results were good, with an average of 8.22 out of 12 points. Table 5 shows an overview of sample student responses and awarded scores for item 7 of the PPCT test.

Table 5. Sample student responses and awarded scores for item 7 of the Particle Physics Critical Thinking (PPCT) test.

Student 1	Yes, I agree. Because it is shown, that antiparticles have mass like particles, so the gravity acts on them. Therefore, the Anti-Apple would fall towards the earth. • Awarded 3 points (consistency between "Yes" and the reason= 1, gravity acts on the mass= 2)
Student 2	Yes, I agree. The charge has no effect on the gravitational force. • Awarded 0 point.
Student 3	No, I do not agree. We cannot conclude from neutral antihydrogen atoms to Anti-Apples. • Awarded 3 points (consistency between "No" and the reason= 1, considering limitation of generalization= 2)

DISCUSSION

The aim of this study was to learn whether, and how, students' LU skill develops during working on the "Anderson's photograph" worksheet. From a comparison between the HLTs and ALTs (Dierdorp, Bakker, Eijkelhof, & Maanen, 2011), it became clear that the "Anderson's photograph" worksheet provided students with the opportunity to work on the likelihood and uncertainty analysis skill. In addition, the students' results in the Particle Physics Critical Thinking (PPCT) test confirmed that they have learned the LU skill and could apply the skill in a specific domain of particle physics. Although we cannot conclude from the results of the HCTA pre- and posttest that the design of teaching-learning activities was appropriate to promote students' general likelihood and uncertainty analysis (LU) skill, the analysis of the students' difficulties in the test will allow us to reconsider the HLTs, and to re-design the teaching-learning activities within our Design-Based Research cycle. However, the time distance of 6 weeks between working on the "Anderson's photograph" worksheet and the assignment of the HCTA posttest may explain the ambiguous results of the HCTA posttest.

As alluded to before, we realized that students in one group were unable or unwilling to provide more than two interpretations of the given photograph. Conducting further analysis of video and audio data of this group can give us hints for making teaching-learning strategy more practical and efficient. Furthermore, when interpreting Anderson's cloud chamber photograph, some students strove for a single, definite answer. Thus, the teacher should emphasize the importance of considering alternative interpretations, even if they seem less likely.

The teaching materials proposed here can also be used in grades 11 and 12. Teachers can implement the proposed activities to develop students' domain-specific LU skill. Teachers should be aware of the complexity of the task and of their essential role as motivator and facilitator to appreciate students' efforts, to encourage them, and in this way to promote students' persistency.

We investigated the production of scientific projects by undergraduate biology students concerning the theme of animal physiology using the structure of a sequence of open-ended investigative classes. The analysis of the final reports of the students showed that the open inquiry-based sequence provided a significant mobilization of abilities and the construction of qualitative and quantitative methods for research in physiology and their relationship with living beings and the environment.

Keywords: biology inquiry-based teaching, open inquiry-based activities, non-formal education in zoo.

INTRODUCTION

Science education is necessary and important in people's lives at all stages of human development and can occur in different spaces and modalities, among which non-formal education spaces (Rocha & Terán, 2010). Generally, the interest of science and biology teachers in using these spaces, such as the zoo, for example, has some connection with what is developed in class (Marandino, 2001) and with the possibility of having a more active participation and an engagement of the students in scientific practice. Non-formal education can be defined as an organized approach to provide formal school content learning in spaces outside the formal education system or beyond school boundaries. The non-formal spaces of education are characterized by a more flexible educational proposal and show themselves able to attend, at least in part, some school deficiencies, such as direct contact with nature that can stimulate learning. Examples of these spaces are institutions such as museums, science centers, aquariums and zoos. Especially in zoos, in recent years, the social role of these places has shifted from a space for viewing, leisure and recreation to a place that is also concerned with conservation, research and education. Nevertheless, there is a need for studies that show the potential of using zoos for scientific education (Vieira, Bianconi & Dias, 2005; Marin, Carvalho & Freitas, 2017).

Regarding the Brazilian educational system, statistics have shown that it has failed to provide adequate scientific learning to its students. Some of the difficulties found in Brazilian schools are related to a misconception about science, often presented as reductionist, decontextualized, infallible and absolutely true. There is a need to provide realistic and meaningful scientific education, leading to the development of critical individuals. Due to the high impact that scientific education has in social development, the use of different approaches of science teaching in Brazilian schools may contribute to the advance of scientific knowledge and social development in the Brazilian society (Santos, 2007).

To the school and universities, in turn, different positions have been required in order to include their students in the scientific culture of the contemporary world, so that these institutions could not only transmit knowledge but also form critical and conscious individuals. It is from this epistemological perspective that inquiry-based teaching is inserted, an active problem-solving methodology in which students can mobilize scientific practices and use relevant data and information to find scientific solutions and explanations for practical problems. Since it is not restricted to a purely theoretical approach, research-based learning has a great significance in teaching comparative animal physiology, since this discipline, due to its high complexity, is often uninteresting and monotonous to students due to the use of traditional and exclusively theoretical methodologies (Almeida, Marzín-Janvier &Trivelato, 2016; Marin, Carvalho and Freitas, 2017).

In fact, for a long time it has been sought to innovate in animal physiology classes through practical demonstrations with the use of live animals in laboratories. Although the number of animals used in teaching is lower than in the research, this practice has been discontinued in several countries due to new laws and policies considering that nonhuman animals are sentient beings. Several legislations have emerged around the world restricting the use of animals in education and promoting the adoption of alternative methods of comparable efficacy. Thus, we believe that the development of inquiry-based learning methodologies using the resources of non-formal educational spaces and not using animal manipulation is essential, not only to minimize animal suffering, but also to develop responsible postures toward other animals and to provide a more meaningful learning process (Valk et al., 1999; Oliveira et al., 2018).

Our research problem is defined in this article through the following question: how can we teach complex subjects of biology, e.g. physiology, in non-formal spaces of education? Thus, the aim of the present study was to evaluate the construction of research projects and instruments in physiology by undergraduate students of the biological sciences course in the non-formal science education space.

METHODOLOGY

The present study is an analysis of a case study. The development of the inquiry-based learning sequence was based on Banchi and Bell (2008) that establish four levels of inquiry-based activities. For the authors, level one consists of the question, methods and conclusions provided by the teacher; level two consisting of the question and methods provided by the teacher and the conclusion made by the students; level three composed of the question provided by the teacher, but method and conclusions constructed by the students; and level four consists of all steps proposed from the student engagement. Here, our option was to work with level 4, also known as “open research”, to provide students with greater freedom, engagement and creativity in research proposals. Thus, the inquiry-based learning sequence was structured for application in 6 weeks (6 steps),3 hours of classes each week, given to two different classes (total of 42 students) in the course of Practices in Biological Systems for undergraduate Biological Sciences students. This course consists of several practical laboratory classes and field activities with diverse subjects in biological sciences. Practical classes with subjects of comparative physiology of living beings is one of the topics covered in the classes of this academic course. It was only established the biological theme - comparative physiology - and the place of data collection - the zoo of the city of São Paulo.

In step 1 the students read texts of animal physiology and environment. At this stage, important concepts were discussed about the relationship of the physiological functioning of living beings (vertebrates) and their relationship with the environment and biological evolution. In step 2, the students were informed of the field activity in the zoo and engaged in building hypotheses and scientific questions involving animal physiology for the zoo visit. In step 3, students were encouraged to think creatively to construct methodological ways to study the physiology of living zoo animals. In step 4, the students made a 3-4-hour visit to the São Paulo Zoo to collect data using the methodological tools designed and developed in Step 3. In step 5, in the classroom, the students re-analyzed the data collected during the zoo visit. In Stage 6, the last phase was divided into 3 classes in which the students orally presented their projects in poster presentations, communicating their scientific results to the classmates (Table 1).

To record students' findings during the investigative activity throughout the classes, field research notebooks were developed for students. These notebooks were structured on three levels. The first level consisted of notes and hypothesis development, scientific questions and research methodologies by the students. The second level consisted of research field notes, visiting the zoo. The third level consisted of the analyzes performed by the students from the data collected in the field classes.

The students' final written reports were used for analysis in this study (total of 42 reports). The students' writings were analyzed under two perspectives: i) regarding the physiology subtheme chosen and approached as a research theme and the justification for choosing the subtheme. The objective of this analytical perspective was to verify how the students chose the subject of study in physiology for the study of living beings in a non-formal space. The subthemes used as categories of our analysis of animal physiology were: Nervous system, Digestive system, Cardiac system, Respiratory system, Excretory system, Locomotor system and Reproductive system; the second perspective of analysis: ii) What were the data collected and the methodological analysis used by the students to perform the research in physiology? The purpose of this analytical perspective was to understand the creativity and development of methodological tools that students mobilized to study the physiology of living beings without the use or direct contact with animals. Thus, the final reports were analyzed individually with a focus on the analysis of the subjects of physiology. In addition, it was categorized the methodological tools of research that were mobilized by the students and the percentages of appearance of the subthemes and methodologies in the reports were computed.

Table 1. Steps of classes, activities e learning goals.

Steps of classes	Activities	Learning goals
1	Class on physiology and adaptations of vertebrates to the environment	Discuss key concepts in physiology and adaptation of vertebrate animals to the environment
2	Engagement in research questions and hypothesis	Mobilizing the emergence of scientific issues in students
3	Planning in research methods	Provide the construction of methods for data collection by students
4	Collection of data in the São Paulo Zoo	Visiting and providing data collection by students
5	Analysis and discussion of data collected	Organize the collected data and produce explanations for the phenomena observed
6	Presentation of the final report	Report the results found

RESULTS AND DISCUSSION

Analyzes of the student's writings showed that the open inquiry-based activity sequence allowed the students to articulate subjects of physiology with alternative methods of collection, without manipulation of living beings, and data analysis in non-formal spaces of education, for example, in a visit to the zoo.

A characterization of the reports was performed as the first analysis of the students' written reports. The first set of results shows the diversity of subjects of physiology that was mobilized by the students, having the subjects about digestion the highest percentage of research projects built with this theme. The projects proposed by the students with this theme touch the interest on the feeding habits of vertebrate animals in captivity with comparison with their wild territory; or another example of animal eating habits and their anatomical and physiological structure. The second theme most approached on student's projects is related to the vertebrate nervous system, for example, the state of sleep-wake and sense organs of animals in captivity and their relation to the wild environment of these groups of animals; Another example is the possible damage to the nervous system of animals kept in captivity. (Figure 1). The second set of results shows the diversity of instruments mobilized by the students to collect, analyse and support the establishment of the relations of different physiological systems among vertebrates with the environments they live in. We can see that in order to answer research questions the students mobilized a variety of instruments to collect data, such as photography, filming and observation of the animals and their captivity in the zoo (Figure 2). The decision making of the students in choosing and creating the methodological tools for studying the subjects of animal physiology was variable (Table 2). This data set shows the mobilization of important scientific practices, for example, linked to the production, communication and assessment of knowledge for decision making. For example, to study the eating habits of birds, a student opted for filming at specific times and catalogue the foods sought by these animals and related them to their digestive physiology. Another student interested in the cat's sleep-wake habits interviewed animal handlers regarding feeding times. Using video record, she analysed the behaviour of different groups of cats during a day of visitation in the zoo and finally correlated it with the wild habits of these animals described in specialized literature. In this same set of results, it can be observed the comparison of data collection methodologies: photographs, videos, questionnaires, observations of animals, body structures, locations, eating habits, modes of locomotion, etc. This data is interesting because the comparison of data between distinct groups of animals is a common epistemic practice in the scientific culture of biology researchers in comparative physiology. Another important methodological practice used by the students is the comparison of the data collected during the visit to the zoo with published data in scientific literature: a basic scientific practice. In resume, it suggests that the research activity promoted the incorporation of this logic of research practice by the students.

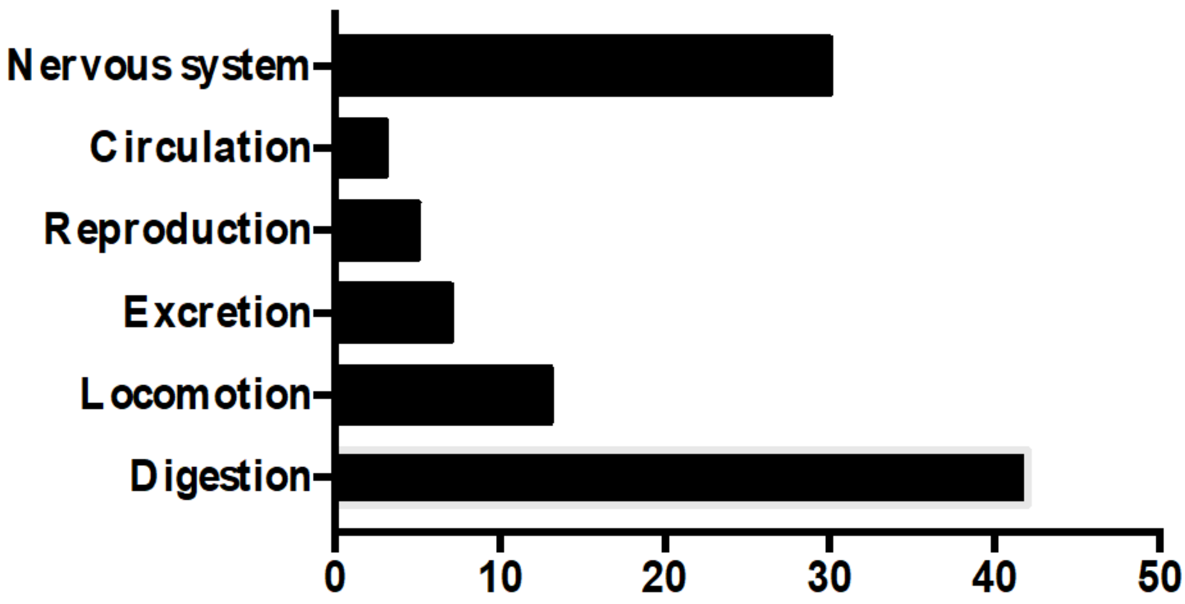

Figure 1. Percentage of subjects of comparative physiology mobilized in the research projects of the students during the open inquiry-based sequence.

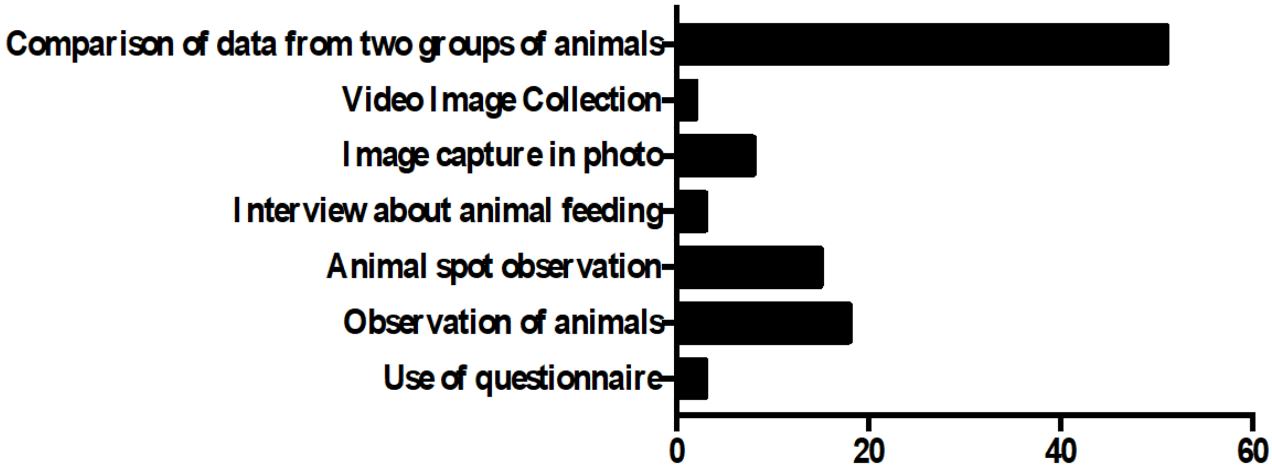

Figure 2. Percentage of research instruments constructed or mobilized by students in the research projects for the open inquiry-based sequence in comparative physiology.

Table 2. Examples of justifications used by students to use the instruments formulated for research.

Research instruments constructed or mobilized by students in the research projects	**Summary of the justification of the methodological approaches made by the students**
Comparation of data from two groups of animals	Animals have different anatomical and physiological structures.
Video image collection	The possibility of capturing sounds, behaviors and animal movements.
Image capture in photo	Recording images of animals, food and enclosures.
Interview with the keeper on the animal's feeding behavior	Habitat capture and animal behavior
Animal spot observation	Notes on the environment and its influence on habitats and behavior of captive animals.
Observation of animals	Notes on the habits and behavior of captive animals
Use of questionnaire	Registration of scientific knowledge about habitats and behavior of captive animals.

A second analysis of the reports was performed to describe the research carried out by the students. Here we will show three significant examples that can contribute to the physiology inquiry-based learning.

Research on the digestive system of animals in the zoo

The first most prevalent sub-theme in the students' final reports was research on the theme of animal digestive system (40% of research projects). The projects developed by students with this theme focused on investigating the food habits of vertebrate animals (mammals in their entirety) and relating them to the physiological mechanisms of digestion of these animals. To carry out this research, the projects had as methodological tools the use of photography of the food available to animals (e.g., lion, zebra and elephant), interviews with people who distribute food to the animals about the types of food provided, and the comparison between food and eating habits between groups of animals. For example, the project of a student had the research question: "What is the difference in the digestive system between monkeys and zebras?" For this, the student observed and recorded the eating habits and foods that were provided in the monkey cage (chimpanzee) and in the zebra's enclosure. In these places he noticed and recorded that chimpanzees were provided with fruits and vegetables, but for zebras they were provided with foliage and grasses. He also found that zebras were allocated in pasture enclosures which allowed these animals to consume grasses. With these data, the student researched anatomical and physiological differences between these groups of animals, making comparisons that allowed him to realize significant differences in architecture and physiology between these groups of animals.

Research on the nervous system of animals in the zoo

The analysis of the reports showed that the students also showed interest in investigating the theme of the vertebrate nervous system (30% of the projects carried out). The projects developed by students with this theme focused on studying the nervous system of vertebrates, mostly mammalian animals, using the observation methodology, video recording and interviews with the staff responsible for the care of the animals' cages, behavior of the captive animal, think about possible alterations or damage to the nervous system of the animals. For example, large cats that need large physical space for their living are kept in cages that reduce the locomotion of these animals. One student had the following research question: "Why does the jaguar move in circles inside the cage?". The student watched the animal inside the cage for approximately forty minutes and recorded videos of the animal's movements in the enclosure. He interviewed veterinarians and confronted the video with researched videos about the animal's locomotion in the enclosure. He conducted theoretical research in physiology, argued and concluded in his report that the behavior of the animal in the enclosure was due to captive breeding that could cause significant changes in the animal's nervous system.

Research on the Animal Locomotion System at the Zoo

The third research theme in which 12% of the projects were engaged is about the locomotion system of vertebrate animals (mostly mammals). For this theme the projects used, mainly, the recording of videos in the zoo enclosures and comparison between groups of animals. For example, two students developed a project in which the research question was the speed of displacement of the "spider monkey" using the tail as a form of locomotion. This species of monkey lives in a tree canopy and uses its tail as a form of support and locomotion through the tree branches. In the zoo, these monkeys are housed in a high-tree enclosure and are located on an island in the center of an artificial lagoon. This geography enables the isolation of these animals. Thus, the students observed and recorded in the camera of their cell phones for about 30 minutes the interaction of these animals in the trees. The students, by means of the analyzes, calculated the average velocity of displacement of these animals when they used the tail to move around the tree canopy compared to those that displaced otherwise, for example, using their paws. They then conducted a research on the importance of the tail for these monkey species as an aid to feeding and locomotion. The students, with their common project, concluded that this species of monkey moved faster using the tail through the tree canopy compared to other forms of locomotion.

In conclusion, the open inquiry-based sequence in physiology in a non-formal teaching environment provided students with the creative possibility and immersion in the scientific culture of the biological sciences, especially physiology and environment, with the construction of instruments for the collection and analysis of data in biology, important in literacy and scientific training in higher education. In addition, the activity made it possible for students to mobilize knowledge in different themes (which conferred genuine interest and engagement in the studies of each student); the proposition and use of research strategies and methodologies (which represents the sharing of specific scientific practices and also the creative search for ways to solve selected research questions); and finally, the articulation with theoretical knowledge already established by the scientific literature (which occurred according to the interests of the students, allowing the appropriation of this knowledge to establish explanations for their research questions).

THE IDEAS-COSMOS-EVIDENCE MODEL AND THE TEACHING OF THE EVOLUTION THEORY: A FIRST APPROACH

Pinelopi Papadopoulou, Christina Ntinolazou
University of Western Macedonia, Florina, Greece

The purpose of this paper is to analyze educational activities based on the Ideas-Cosmos-Evidence (ICE) model and to search for a correlation between the effectiveness of an activity and the links between the individual entities of the model the activity promotes. A Teaching Learning Sequence (TLS) was designed, implemented and evaluated for the teaching of the Evolutionary Theory (ET) in junior high school students. All TLS activities were analyzed based on the ICE model. The analysis of the results obtained from the evaluation of the TLS shows that the most successful activities, both in the course of their implementation and in achieving their learning objectives, were those that promoted connections of all types between the individual entities of the model

Keywords: Teaching Learning Sequences, Ideas-Cosmos-Evidence Model, Evolutionary Theory

INTRODUCTION

The teaching of the Evolutionary Theory (ET) presents a number of problems that are related both to the students' alternative ideas (Driver et al., 2000, Zogza et al, 2009, Zabel & Gropengiesser, 2011, Wallin & West, 2013) and to the respective ideas of the teachers, as well as to the issues of acceptance both face (Berkman & Plutzer, 2010). Systematic educational interventions aiming at conceptual change require the organization of inquiry-type activities in the framework of a Teaching Learning Sequence (TLS) (Psillos & Kariotoglou, 2016). According to the proposal of Tselfes (2003), the choice of educational activities in designing a TLS can be guided by the Ideas-Cosmos-Evidence model (ICE) based on Hacking Laboratory Classification (1992). As reported by this classification, the activities of laboratory sciences are characterized by an almost autonomous "inner life" in which three individual entities - Ideas, Cosmos and Evidence - are in constant interaction and subject to constant transformation as a result of this interaction. Ideas include theoretical concepts and models, theories, and beliefs. In the Cosmos category, physical entities such as the sample, data capture devices and raw data are included. Data of all types that have undergone any form of processing are referred as Evidence. Conforming to Hacking the practice of scientists is to link the individual entities of the model together. The adjustment of the model for the teaching practice is based on the hypothesis that if students become familiar with scientific practices, it will be easier for them to understand scientific texts, since the concepts contained therein make sense only in this context. To this end, specific teaching activities are suggested that will guide students to create links between all the individual entities in the ICE model (table 1). Since science is doing (intervening) as well as knowing (representing), in the same way teaching activities may be interventional or representational.

Table 1: Activities that promote the creation of links between entities (Kallery, Psillos, Tselfes, 2009)

Linked entities	Link Type	Didactical activities
Ideas - Evidence	R	Linking Ideas with expected Evidence. Predictions of Evidence based on one's own ideas
Evidence - Ideas	R	Linking of Evidence with Ideas. Explaining specific Evidence in terms of some specific Ideas. These Ideas can be scientific or common
Cosmos - Evidence	R	Linking a piece of Cosmos with a piece of Evidence. Description of what is happening in Cosmos in terms of observed or recalled Evidence
Evidence - Cosmos	I	Linking Evidence with a piece of Cosmos. Constructing, intervening or modifying a specific segment of the material world on a basis of a specific piece of Evidence
Ideas - Cosmos	I	Linking Ideas with Cosmos. Interventions to the material world. Using scientific ideas, construct a piece of Cosmos with specific characteristics
Cosmos - Ideas	R	Linking Cosmos with Ideas. Describing a piece of Cosmos on the basis of one's own ideas

R: representational - I: intervational

In this study, we sought to relate the effectiveness of an educational activity to the number and type of links between the individual entities created during its implementation. The ICT model has been used in the past on two occasions (Psillos et al, 2004, Kallery et al, 2009). In both cases the model was used to analyze a posteriori the teaching activities and attempted to correlate their effectiveness with the type and number of connections of the model entities included. The first research group (Psillos et al, 2004) came to the conclusion that a long, persistent, empirical effort to develop improved teaching activities on a given topic gradually leads to the implementation of the expected links from the model. This fact is considered proof of its validity.

METHOD

A TLS of 5 teaching hours was designed, implemented and evaluated for the teaching of the ET to junior high school students. A parallel visit was also made to a Museum of Palaeontology. The participants of this developmental research were 20 ninth grade high school students in northern Greece. All activities were epistemologically analyzed on the basis of the ICE model and the links of all individual entities created were recorded (Table 2).

Description of the TLS

Each activity of the TLS' s scenario (Table 2, 1st column) dealt with a central concept that was basically approached through an inquiry type activity. Of the 5 activities included in the TLS, two were observations and 3 were simulations.

At the introductory activity (observation), biodiversity was the central concept. The students were asked to look for similarities and differences between the organizations given to them in the photographs and to compare their specific hereditary characteristics with those of their classmates and the teacher. A discussion followed in which they expressed their thoughts, ideas, and concerns about the origins of all of these organisms that resemble and differ at the same time.

The sequence was followed by a simulation activity, focused on the randomness of the mutations. It was essentially the well-known and popular "chinese whispers" game. One phrase was transferred from one student to another and its information changed as was the case with genetic information when it was passed down from generation to generation. The purpose of the activity was to help students understand that any reproduction mechanism involves the possibility of errors occurring at random.

The third activity had natural selection as a central concept. The students represented the birds with different beaks. Some had a beak like a spoon, a knife, a fork or a toothpick. Each group of birds was each time in a different seed environment. Candies were used as seeds that differed in shape, size and texture and students had one minute to compete for the "seed" collection. The worksheet helped students record their data, compare them and, through appropriate questions, arrive at the desired conclusions about how natural selection works.

The next activity, which was also simulation, was about random genetic drift. Through an initial population of pom pom of different colors, students chose at random to create their own subpopulations. They then compared their subpopulations with both the original population and that of their peers, and through appropriate worksheet questions were guided to conclude that something similar happens in nature when under certain conditions, e.g. in a natural disaster, chance chooses which organizations will survive and give the next generation, not the natural selection, whose role is traditionally exaggerated in teaching evolution.

The last activity (observation) took place inside the Museum of Paleontology and involved the recording of specific exhibit information. It was framed by pre- and post-visit activities to enhance learning outcomes. Specifically, prior to the visit, the students searched for information about the museum's exhibits and recorded questions that they would like to address to the guide, and after the visit they presented in the classroom in a manner of their choice two of the exhibits that impressed them.

Evaluation method

The main tool of the TLS's evaluation was a questionnaire with closed and open-ended type questions filled out by the students before and after the teaching, which was created for the purposes of the present study. Especially it included 7 closed type questions and 3 evolutionary phenomena for interpretation, while in its final form as it was given after teaching it was enriched with 7 additional questions aimed at recording students' views on ET and teaching. The design of the main evaluation tool was based on two questionnaires - by Price et al. (2014) and Anderson, Fisher & Norman (2002) - which measure the degree of understanding of random genetic drift and natural selection respectively. Information on the course of activities was mainly recorded in the teacher's diary: whether the time was sufficient, if language, conceptual or other difficulties arose, data that could be formative assessment material. The worksheets completed by the students provided some initial clues as to whether they understood the concepts they were dealing with. The whole set of data collected from the assessment tools was analyzed qualitatively, based on 5 main axes: The scientific concepts that students correctly refer to in their justifications, the alternative ideas that students rely on in their interpretations, the improvement of understanding the role of chance in evolution, the way natural selection works, the minimum unit that can evolve, and the existence of intraspecific diversity. The last points of analysis were the students' views on the ET and the method of teaching followed.

Results

Activities' analysis with ICE model

The results of the activities' analysis on the base of ICE model are shown on table 2. It was found that each activity had a different number and kind of relationships, and only representational (knowledge) relationships were included.

Table 2. Analysis of activities in the I-C-E model.

Teaching scenario (TS) / Activity	Ideas	Cosmos	Evidence	Links
1. Comparison of hereditary features	Intra-species diversity, common descent Characteristics of organisms	Photos of organizations, people in the classroom, cupboards	similarities, differences of organisms	C → E; I
2. A phrase is transferred from student to student (chinese whispers game)	Generations, mutations, transfer of genetic information, alleles	Students, the phrases being transferred from one student to another	sentence' s change from one student to another	C → I, C → E, E → I
3. Simulation of natural selection (students represent birds with different beaks)	Different survival rate, different conditions, competition, diversity	candies, spoons, forks, knives, toothpicks	Different number of candies collected from each "tool"	C → I, C → E, E → I, I → E
4. Create subpopulation by random choice from original population (pom pom use)	Random genetic drift, sampling error, drastic reduction in population size	different colors' Pom pom	Initial population formation, subpopulation formation, Subpopulation differences	C → I, C → E, E → I, I → E

5. Visit to the Museum of Palaeontology - observation of exhibits	Common descent, evolutionary relationships	Fossils	similarities of organisms	C I E

C-E= Cosmos – Evidence, I-E= Ideas-Evidence, C-I= Cosmos - Ideas

The evaluation of TLS

After TLS' s implementation the reinforcement of certain scientific concepts that the students use correctly in their justifications (Figure 1) and the retreat of most of their alternative ideas (Figure 2) were observed. The main reinforcement was observed in the use of the concept of mutations (TS 2) while a more significant retreat occurs in the alternative idea related to the survival of the strongest (TS 3).

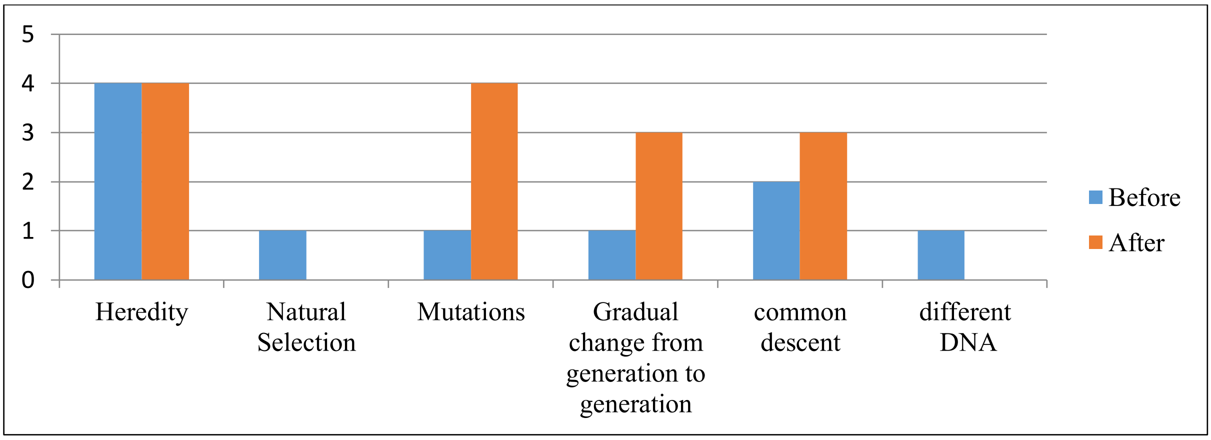

Figure 1. Frequency of reference for each scientific concept

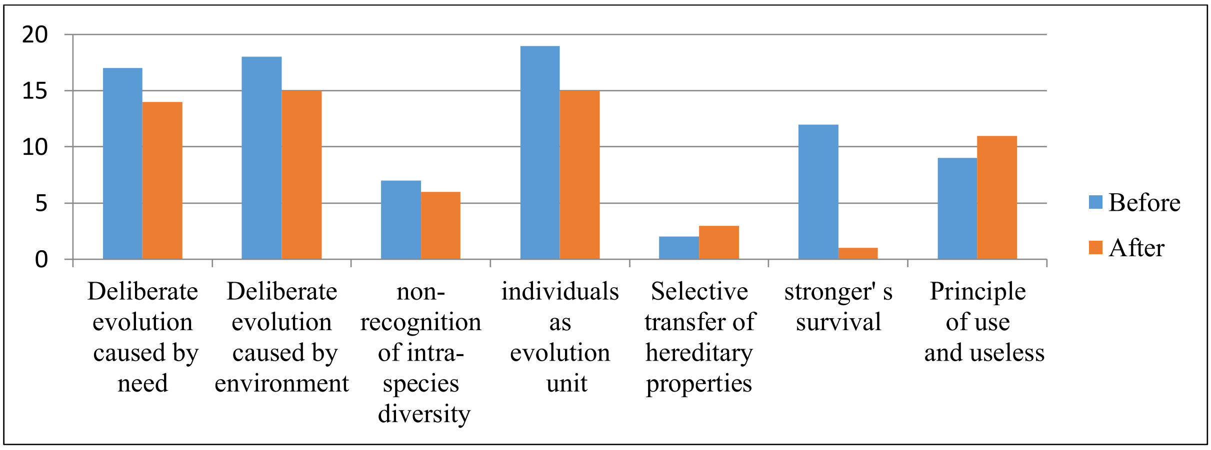

Figure 2. Frequency of reference for each alternative idea

Of the 20 students, 7 increased the number of scientific concepts they use correctly in their explanations. Among these, 5 used for the first time a scientific concept in the right way after teaching (Figure 3). Taking in mind that all of the alternative ideas found in the students' responses had been taken into account while designing TLS, it seems that their teaching management was rather effective and indeed for the majority of the students, since 13 of the 20 have reduced the number of their alternative ideas since the implementation of the TLS (Figure 4).

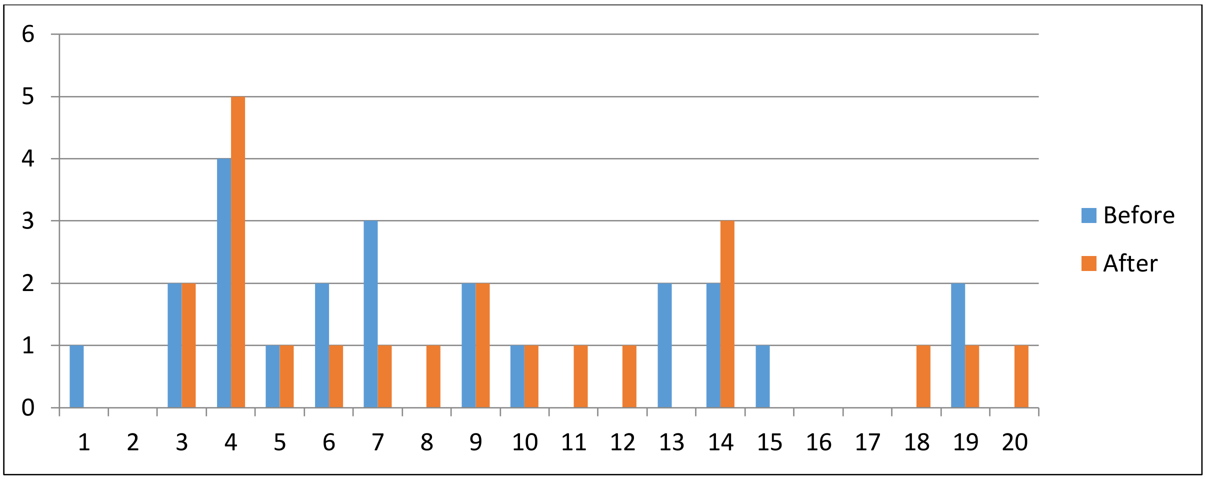

Figure 3: Number of scientific concepts used by each student in their explanations

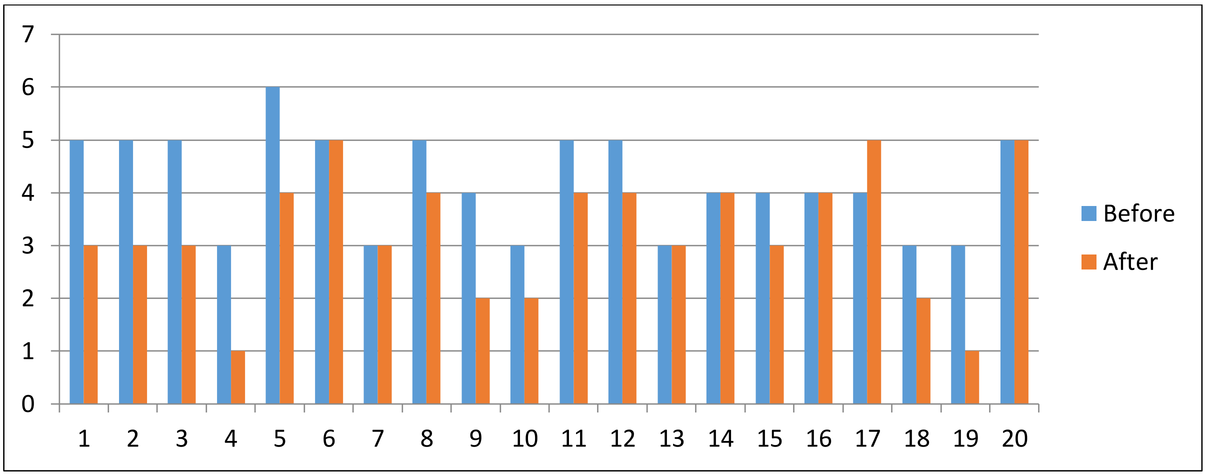

Figure 4: Number of alternative ideas per student, before and after teaching

Most of the students understood the role of chance in evolution - through random genetic drift (TS 4) – as it was clear from the analysis of the answers to the relevant questions (Figure 1 & 2), while they showed a superficial understanding of the way natural selection works and the existence of intraspecific diversity, since similar questions with different contexts resulted in contradictory responses. As far as the evaluation of teaching is concerned, the students distinguished the most interesting activities of inquiry nature that promoted connections among all the individual entities.

Discussion – Conclusions

The general finding drawn from the analysis of the results was that the TLS had an overall positive impact on improving understanding of evolutionary phenomena. Going further, with a closer look at the results, one finds that some of the teaching scenarios were more effective in achieving their learning goals. In particular, teaching scenarios 2,3,4, in the course of which were created links between all the individual entities, according to the ICE model (Table 2), were more successful in their implementation. They motivated students and stimulated their interest, and they seemed to improve their understanding of the concepts they were dealing with. On the contrary, activities 1 and 5 which lacked links were not performed by the students with the same willingness and did not substantially influence the understanding of the concepts with which they were related.

The short duration of the TLS, due to the limitations imposed by the Curriculum, did not allow for delving deeper into important concepts related to the ET. However, the evaluation of its pilot application revealed that the teaching had some encouraging results. In the next stage of the research empirical data will be used for the development of the TLS and the adaptation of activities to students' thinking (Psillos & Kariotoglou, 2016). The activities will be enriched with new types of links between individual entities - such as interventional ones - to investigate their impact on increasing the effectiveness of the TLS. Our results indicated that the ICE model could be an effective tool for evaluating activities at the design and development phase of a TLS. Although further research is needed to analyze a larger number of activities and to determine the kind of links that may be associated with better learning outcomes of a teaching activity. This process will reveal whether the model could be used as a tool to predict the effectiveness of an educational activity for the teaching of the ET, based on the number and type of connections created.

USING A PHYSICS BASED CAREER SCENARIO TO PROMOTE FEMALE SCHOOL STUDENTS' INTEREST IN PHYSICS AND PHYSICS CAREERS

John Connolly[1], *Shirley Simon*[1]

[1]UCL Institute of Education, London, England

Studies have shown that students' interest in physics at secondary school tends to decline as they get older. The number of students, particularly female students, who participate in further study of physics is worryingly low. Interest has been found to be an important determinant for students when they make their choice of subjects for post-compulsory education in the UK. The decisions they make are also related to their ideas about how useful a subject is for a particular career. Contextualisation in school science has been shown to promote interest in science. The Horizon 2020 MultiCO project aimed to raise awareness about knowledge and skills used in STEM based careers and how they are linked to the science curriculum through intervention lessons using a STEM career-based scenario. This study investigates the use of a scenario of a female Nuclear Medicine Technologist for a class of 15 years old school students. The results show that the majority of students gained knowledge about the working skills and use of nuclear radiation in a real-world setting that promoted interest in the physics topic, particularly that of the female students.

Keywords: Physics, Student Interest, Context-Based Learning

INTRODUCTION

Students' deteriorating interests in science subjects as they progress through compulsory secondary school science education has been well documented in the UK (Osborne, Simon and Collins, 2003) and internationally (Sjøberg and Schreiner, 2010). Participation in Science, Technology, Engineering and Mathematics (STEM) subjects has been categorised as a leaky pipeline (Clark Blickenstaff, 2005). This has created, what media in the UK describe as, a STEM skills deficit (Morris, 2016) that may threaten national prosperity due to the reduction of qualified specialists involved in STEM industries. Vidal Rodeiro's (2007) survey into students' reasons for choosing A-level subjects in England found that students rated interest in a subject and a subject's usefulness for a future career as the primary factors in deciding what subjects to choose. DeWitt, Moote and Archer (2019) state that the utility value of a subject in relation to a future career was the most common reason for choosing a subject for post-compulsory education at school from the results of a survey of 13,000 students in England. The number of students choosing to study to A-level physics in England in 2018 was 37,806 representing 4.7% of the total entrants into A-level studies. The approximate ratio of male to female physics entrants was 4:1 which has been a consistent proportion for many years (since 2001) despite attainment in GCSE physics for females being equivalent to that of males (IOP, 2018).

In order to reverse the decline in interest, DeWitt and Archer (2015) emphasise the importance of teaching physics in a way that highlights its relevance to students' lives to promote interest in physics, particularly amongst female students, in order to help students to consider choosing a career in physics. Potvin and Hasni's (2014) findings recommend contextualised learning, i.e. relating science content to students' real-world experiences, as a way to promote students' interest in science. Students are generally unaware of science related occupations and can tend to have stereotypical conceptions of scientists and science related work (Cleaves, 2005). The EU Horizon 2020 MultiCO project investigated if students' interest in science and science careers could be enhanced by using context-based science learning interventions using STEM career-based scenarios that linked science curriculum content to the knowledge and skills required for a variety of careers.

In relation to young people choosing STEM careers, Sadler et al. (2012) report that the biggest factor for children is their initial interest in science when they start secondary school. Tai et al. (2006) affirm this notion for people in science-based careers remembering the influence that an interest in science careers from primary school age had on their choice of career. However, Hidi and Renninger (2006) contend that this perspective of an early developed interest expounds a misconception that interest in STEM subjects or careers cannot be developed in older students, especially as young people frequently change their minds about their futures. If the utility value of a subject is a factor in students' choice of subjects the information and guidance that they obtain about careers is very important.

Careers advice in schools

School career guidance provided by state funded organisations in England has suffered cuts in funding in recent years and the responsibility for providing such guidance has been placed on individual schools. However, Moote and Archer (2018) report that there is concern over the lack of career guidance resources on offer in schools and that more support is required to help teachers develop their skills and confidence to deliver careers education and advice. According to Hutchinson et al. (2011), school students who are interested in science/STEM careers are more likely to make enquiries about careers to their science teachers than any other source. Hall et al.'s (2011) study in the US found that students felt that their teachers' encouragement to pursue STEM based courses, as well as the teachers' knowledge about careers, were important factors in their consideration of future career paths. However, the teachers involved in the study felt that they only held limited knowledge of possible STEM careers. Hutchinson et al. (2011) noted that careers advice provided to students tended to be limited and focussed on traditional choices. Similarly, Cleaves (2005) reported how students are generally unaware of careers related to their science education and can tend to have stereotypical conceptions of scientists and science related work which is echoed in surveys of school students' knowledge of science careers (Porter and Parvin, 2008). One way of increasing teachers' knowledge and confidence about

STEM based careers is to have resources that link the science curriculum to STEM based careers which can also highlight the utility of the subject content to students who will be considering their subject options after compulsory education.

MultiCo project

The EU project, 'Promoting Youth Scientific Career Awareness and its Attractiveness Through Multi-Stakeholder Cooperation' (MultiCo) aims to develop: students' knowledge, understanding of, and interest in, STEM-related careers; the skills and qualifications required for STEM-related careers; the links between career knowledge and skills and the science curriculum in secondary schools. MultiCo is based on the development of career-based scenarios that focus on STEM-related careers that are primarily linked to the European Challenge Areas, i.e. energy, water, waste, climate change, food, health, technology and transport. Each scenario provides contextual information about people working in a particular STEM career that includes the factors that interested them to work in their field, their route through education to work in that profession, and the types of knowledge and skills required in their career. Each scenario is designed to provide a platform in which students engage in an investigation or an enquiry that links curriculum content with the science career during a series of intervention lessons.

RESEARCH AIMS

This case study of a science class in a London school details the use of a physics-based career scenario involving a female Nuclear Medicine Technologist in intervention lessons to investigate the impact of the scenario on students' (particularly female) interest in a nuclear radiation topic as well as a novel and unfamiliar physics career. Using a mixture of observation and a questionnaire, quantitative and qualitative data were collected about the students' interest in, and relevance of, the career used in the scenario.

METHODS

The scenario-based intervention was conducted in the science lessons of a London secondary school with a Year 10 class (15 years old) of 31 students (12 female and 19 male). The intervention lessons coincided when the teacher, a biology specialist, had scheduled to teach the nuclear radiation topic of the school's GCSE scheme of work. The scenario and intervention lessons were developed by the lead author in conjunction with the biology teacher. The scenario introduced students to a female Nuclear Medicine Technologist (NMT) highlighting her educational pathway by detailing the subjects she studied in school and university which included physics at A-level. It also included information about the typical activities she conducted on a day to day basis and the students were asked to consider the working skills required for her profession as well as the physics knowledge that would be useful. Students were tasked with developing a role play where the NMT interacts with a patient to inform them about an upcoming procedure to diagnose and treat a tumour in the patient's thyroid using radiotherapy. Students chose a partner to work with to develop a script for the role play that had to utilise technical terms from the physics content as well as showcasing the working skills of the NMT and how they dealt with the patient's concerns. Once the students had developed their script, three pairs were invited to either read or enact their script to the rest of the class. The students also researched the types of radioisotope that would be suitable for a variety of procedures based on the penetration, ionisation and half-life characteristics of radioisotopes. Although the scenario with the female NMT was introduced in the first intervention lesson, the teacher made constant reference to the scenario and the NMT throughout.

This study used a mixed methods approach to collect data about students' interest in the physics topic and the physics-based career. The intervention lessons were observed by a UCL MultiCo researcher who made fieldnotes during the lessons providing a narrative of the lesson as well as providing comments relating to interest and engagement of the students throughout. The lessons were also video recorded for posthumous analysis by the authors using a framework devised by Andersen and Nielsen (2013) for video-based analyses of students' motivation and interaction in science classrooms. The entire lessons were observed and divided into episodes (e.g. role-playing activity) that were analysed and coded. A transcript describing the episodes was made separately by each author and codes were linked to dialogue and actions. The video was watched together by the authors and the analyses were compared and triangulated with the fieldnotes of the UCL MultiCo researcher (see Table 1).

At the end of the second intervention lesson, students were asked to complete a Scenario Evaluation of Relevance and Interest (SERI) questionnaire that was devised to measure students' knowledge, engagement and interest in relation to the scenario (Kotkas, Holbrook and Rannikmäe, 2017). The questionnaire consisted of 28 items with 3 and 4-point Likert scales to state their level of agreement regarding cognitive and affective aspects of the scenario including interest levels with space to elaborate on their responses for the final five items. Descriptive statistics from the evaluation questionnaire were used with independent t-tests utilised to discover any statistically significance differences between the female and male responses.

RESULTS

Table 1 shows the results of the analyses of the fieldnotes and the video of the role-playing activity of the first intervention lesson.

Table 1 Analysis of students' motivation and engagement for the NMT scenario using Andersen and Neilsen's (2013) framework.

Categories		Code	
Students' actions and engagement	Content of students' talk	Subject matter	Students confidently discussed the physics content and related it to the NMT career correctly (role play and scripts). Demonstrated understanding of the links between the physics curriculum content and the physics knowledge required for the NMT career.
		Social organising	Development of character roles. Enacting their role play.
	Indicators of motivation	Students generating ideas	Used correct physics knowledge to inform the conversation between the NMT and the patient (scripts).
		Content related questions	Questions about the NMT career and nuclear radiation and its uses in medicine.
	Initiative and Engagement	Non-procedural display	Students weren't just "doing school". No indications of boredom or off-task behavior. Students enjoyed the lesson.

The students demonstrated that they were able to apply their knowledge of nuclear radiation and the working skills of the NMT to develop their scripts for the role-playing activity. They utilised correct knowledge of the physics and the procedures used to diagnose and treat a thyroid condition of a patient. The students demonstrated their understanding of the personal skills required by the NMT to assuage a patient's fears and concerns of the procedures using nuclear radiation. Throughout this activity the students were motivated and were judged to not to have just gone through the motions of completing the activity; they demonstrated enjoyment and an eagerness to engage in the role-playing activity (most pairs were keen to read or enact their role-playing scripts) as well as the rest of the intervention lessons. There was no perceived difference in motivation, engagement and enjoyment between female and male students.

Table 2 shows the students' evaluation questionnaire responses for the scenario used in the intervention lessons. Only the items that are pertinent to this study in relation to interest in the topic and the career have been used. The mean and standard deviation for each item is displayed as well as the proportion of female and male students who agreed with each item. Table 3 shows the written response of female students to the item 'I found this scenario interesting'.

Table 2 Results of the evaluation questionnaire

Evaluation statement	**Mean**	**SD**	**% agree (F,M)**
The knowledge I gain from the scenario may be useful in the future.	2.83	0.58	100, 68**
From this scenario, I am able to gain new knowledge about possible career(s).	2.94	0.72	100, 53**
This scenario enables me to understand the skills that are necessary in this profession.	3.03	0.65	83, 79
I found this scenario topic helped me develop understanding of subjects studied at school	2.65	0.70	75, 47
I feel my future career may be related to the topic covered in the scenario.	1.93	0.83	42, 11*
I think my future studies at university level may be connected to the topic covered in the scenario.	1.97	0.90	42, 16*
I predict that I will need to perform skills described in the scenario in my future career.	2.13	0.87	58, 16 **
I predict I will need to use the science related skills described in the scenario in my future career.	2.13	0.83	58, 21*
	Yes (F, M)	**No (F, M)**	**Not Sure (F, M)**
I found this scenario interesting	8, 10	0, 5	4, 4
This scenario makes me want to learn more about the topic	5, 4	2, 6	5, 9

*$p<0.05$, **$p<0.01$

It is notable that all the female students agreed that they gained knowledge that may be useful for the future as well as about a new career. Both these items had a statistically significant difference for the female students compared to the male students. Three quarters of the female students agreed that the scenario helped them to understand the physics content covered in the intervention lessons. Though the majority of students did not agree that the topic covered would be one that they would study or relate to their work in the future, a higher proportion of females did agree with these questionnaire items which was a statistically significant difference. The majority of female students also identified that the skills (working and physics based) would be useful for their future careers. Though it is difficult to discern what the students were considering when responding to the questionnaire, the scenario introduced the students to a novel career that was able to promote a positive representation of physics content. Of the 58% of students who found the scenario to be of interest, 8 were female (66% of total females) and 10 were male (53% of total males). Table 3 shows a selection of comments from the female students about why they found the scenario interesting.

Table 3 Female students' written responses to the questionnaire item, 'I found this scenario interesting'.

Yes	Not Sure
It helped me to understand the topic and it helped to know what happens, which is interesting.	It didn't appeal to me personally, don't know when I will use it, but it wasn't too bad.
I like science and feel my future career may be linked to it.	I don't know if I found it interesting.
Because I got to learn about nuclear medicine.	
Because it was intriguing to learn about it. I wasn't already aware of this.	
As I have never thought about this line of career and it was quite interesting knowing about how it is used to diagnose and treat.	
Because it gives good examples of real-life situations and informs of new things.	
I was intrigued as it gives you good information and a good insight on what radioactive atoms can help with.	

The variety of responses shown in table 3 indicates how the use of scenario based teaching focussed on a new career that promotes practical applications of physics and links topics to the real world can promote students' interest in physics as well as physics based careers. Some students were unaware of the practical application of radioisotopes in diagnosis and treatment and some had already considered this to be an area that they would like to work in. Of the 10 students who responded that they felt motivated to learn more about the topic, five were female. This highlights the possibilities of promoting physics to overcome the anachronistic and stereotypical representations and views of physics and physics based careers as masculine and engineering focussed.

In developing the scenario and the intervention lessons, the class teacher learned about a new career and gained confidence in discussing relevant information about pathways to become a NMT to the students. Anecdotally, the teacher commented that the scenario provided a novel and interesting way of teaching nuclear radiation that they had previously taught using slides about the characteristics of radio isotopes and their uses.

DISCUSSION

The career-based scenario of the nuclear medicine technologist and the associated intervention lessons provided participating students with an opportunity to explore the working skills and knowledge used in this career as well as the links between the career and the pertinent physics curriculum content. By using the context of someone using physics in their day to day working life, it is possible for teachers to provide relevant career information in lessons as well as providing a real-world context to teach physics topics. The results from this study support the findings of Hazari et al. (2010) regarding the use of contextualised learning to promote the students' interest in physics. The Relevance of Science Education (ROSE) report (Sjøberg and Schreiner, 2010) states that girls tend to be more interested in health and medicine aspects of science whereas boys are more interested in technology and dramatical aspects of physics. Research has also shown that girls tend to aspire to medical careers more so than boys (Shapiro et al, 2015). This study tends to support these findings about girls' being interested in topics associated with health and medicine but it also shows that it is possible to use this interest to promote girls' interests in physics and a physics based career.

Due to the relatively limited time of the intervention lessons and use of the scenario, it is only likely that the students are expressing a situational interest (Hidi and Renninger, 2006) towards the scenario and its contents relating to the NMT career and the nuclear radiation topics covered. This interest is unlikely to be sustained unless more lessons are focussed on this same topic. However, recent empirical evidence indicates the importance of triggering situational interest in science lessons in order to allow for knowledge acquisition (Ayotte-Beaudet, Potvin and Riopel, 2019). Gaining knowledge about new careers associated with the physics curriculum has the potential for more students to consider physics for future study due to students being able to perceive the utility value of physics and a wider range of career prospects in physics.

LIMITATIONS

The evaluation questionnaire used in this study was designed to evaluate the career-based scenario. However, by completing the questionnaire at the end of the intervention lessons, it is unclear if the students were evaluating just the career-based scenario or the whole intervention. Whether students disaggregated ideas about medicine from the physics content is unclear but there was scope for female students to see a practical application of physics to medicinal careers. The sample size in this case study was too small to be able to generalise the findings but is useful to highlight the impact of a career related scenario and intervention on this particular class.

CONCLUSION

This career-based scenario and intervention lessons used in this study allowed students to gain knowledge about a STEM-related career that was new to the majority of the students. The novelty of the career along with the contextualization of the nuclear radiation concepts involved in the career appeared to be the factors that sparked the students' (particularly the female students) interest, as it allowed them to relate acquired physics knowledge to a real-world situation. The results from this case study highlight the potential of increasing interest in physics in secondary schooling, particularly female students' interest by connecting fields of interest, in this case medicine, to school physics content. This corresponds with the findings of Haussler and Hoffman (2002) who reported the benefits of linking physics concepts to contexts of interest to female students to augment their relevance. The findings also demonstrates the potential of ensuring that the practical applications of physics can be used to support students' ideas about working life beyond school and provide a conduit that connects the physics curriculum content to the skills and practices of working lives with the intention of promoting physics as a subject for further study and a future career.

STRENGTHENING STUDENTS' INTEREST IN SCIENCE: THE CASE OF 'SAVING THE POLAR BEARS'

Irene Drymiotou and Costas P. Constantinou
Learning in Science Group, University of Cyprus, Nicosia, Cyprus

Increasing students' interest in science remains a critical issue in efforts to address the mismatch between demand and supply for professionals in Science, Technology, Engineering and Mathematics (STEM). As part of project MultiCO, this study aims to explore the impact of career-based scenarios, on students' situational interest in science and career awareness. Career-based scenarios are teaching innovations which when integrated in science classrooms can enhance the potential to influence students' future study choices and career aspirations. The study adopted a design-based approach implementing the same scenario in three classrooms (14-15 year-old students) using a variety of data collection methods for quantitative and qualitative analysis. The main sources of data included two questionnaires and interviews with students and teachers reflecting on the scenario implementation. The findings illustrated that career-based scenarios succeeded in generating students' interest and improving career awareness when active engagement was promoted and connections between theory and practice were established fostering meaningful interaction with experts. These findings hold important implications for educational practice in science education as they offer insights into how to design career-oriented instructional material in order to have an impact on students' interest, career awareness and aspirations in science.

Keywords: Science education, Situational interest, Career awareness

INTRODUCTION

Interest in science has been considered a fundamental attribute influencing decisions on future science-related study and career choices (Potvin & Hasni, 2014). In contrast, young people's declining interest in science is a predictor of future shortages in the STEM sector. Recent policy papers have issued an urgent call to increase the proportion of STEM graduates and confront the mismatch between supply and demand, especially in Europe and the US (OECD, 2017). A review of the literature in science education highlights empirical evidence showing a number of interrelated factors that influence students' study and career aspirations in relation to science. These factors relate to the individuals per se - intrinsic factors - as well as their surrounding environment - extrinsic factors. Intrinsic factors concern affective reaction towards science (i.e. positive feelings and fascination), being interested in science, as well as self-efficacy beliefs and are related to race, gender and science identity (e.g., Lykkegaard & Ulriksen, 2019; Gottlieb, 2018; Holmegaard, Madsen & Ulriksen, 2012; Cleaves, 2005). On the other hand, extrinsic factors pertain to socio-economic status, the role of significant others, school-related factors such as the teacher's expertise and the teaching practices and most importantly the lack of career counseling (Vincent-Ruz & Schunn, 2018; Stets, Brenner, Burke & Serpe, 2017; Blotnicky, Franz-Odendaal, French, & Joy, 2018). Research has shown that middle school students' knowledge of STEM careers is limited, and this might impact their interest in pursuing a STEM career (Taskinen, Schutte & Prenzel, 2013; Blotnicky et al., 2018). Towards this end, science education research suggests several teaching strategies that result in fostering positive attitudes towards science and related careers. In an endeavor to contribute to this effort, this study aims to explore the impact of career-based scenarios, as teaching innovations integrated in secondary science classrooms, on students' interest in science that may serve as an option for further studies and a career.

The study draws on three theoretical domains: the Social Cognitive Career Theory (SCCT) model, Situational Interest (SI) and Problem-based Learning (PBL) (Drymiotou, Papadouris & Constantinou, 2018). The SCCT model derives from Social Cognitive Theory (Bandura, 1986) and suggests that interest is a predictor of career goals and choices and can be developed within a learning environment (Brown & Lent, 1996). Interest is conceptualized as "a psychological state and a predisposition to re-engage particular disciplinary content over time that develops through the interaction of the person and his/her environment (Hidi & Renninger, 2006). Based on this conceptualization, this study aligns with Hidi and Renninger's (2006) four-phase interest development model according to which SI is initially triggered and maintained (Phases 1 & 2) and then individual interest emerges and develops (Phases 3 & 4). The emphasis is on SI defined as a short-term form of motivation elicited by aspects in a specific situation that stimulate focused attention and consists of affect (Phase 1) and value components (Phase 2) (Hidi & Renninger, 2006). PBL could be considered as an environment that is conducive to utilizing stimuli in the form of career-based scenarios as driving questions to advance learning. More specifically, based on the assumption that students' aspiration to pursue science-related careers is highly related to their interest, and given that regular experiences of SI can be the starting point for individual interest in science (Palmer, Dixon & Archer, 2016), this study aims to answer the following research questions: Under what conditions and how does the integration of career-based scenarios in science class:

(a) generate students' situational interest and,

(b) raise students' awareness about science-related careers?

METHODS

The case study involved 67 student participants attending the 9th grade (14-15 years) from three secondary schools in Cyprus. School A is a private secondary school located in the capital of the island and it follows the National Curriculum of England Key Stage 3 up to the end of Year 9. School B is located in West Cyprus and School C in the centre of the capital. Both are public secondary schools (grades 7-9) that follow the national curriculum established by the Cyprus Ministry of Education and Culture.

The classroom interventions were extended over 3-4 teaching periods (35-50 minutes each) using the same scenario titled 'Save the Polar Bears'. Framed in the context of PBL, the scenario was integrated in the teaching unit of Heat transfers in Physics and concerned the issues of climate change stressing the need for energy efficiency as a possible solution. In particular, the scenario presented how climate change threatened the lives of polar bears due to the rise in temperatures and the melting of polar ice caps. This was illustrated by showing a video from National Geographic. The scenario helped classroom discussions to make the case that climate change threatened not only the lives of polar bears, but it also affects the entire planet (e.g., photos from floods, droughts, fires). It had established the link that the extensive energy needed for heating and cooling our houses came largely from fossil fuels making a connection to the increase in global temperatures due to the increase in carbon dioxide levels in the atmosphere. At that point, the mission of the students was to test energy-efficient model-houses to address global warming and save money by assuming the roles of architects and engineers who specialized in energy-efficiency.

The classroom interventions were structured as follows: scenario presentation as an introduction to the unit, scenario link to the teaching unit and a reflection/consolidation phase that wraps up the teaching unit and revisits its connection to the scenario. In each classroom case there were some adjustments based on the teacher's perspective about the achievement of the learning objectives as well as curriculum and time constrictions. Table 1 summarizes each case and scenario adaptations following a design-based research approach.

Table 2. Description of each Classroom Intervention in Chronological order

Structure	Case A (School A)	Case B (School B)	Case C (School C)
Focus	Link between theory and practice though the scientific method		& interaction with experts
Scenario presentation: Introduction to the teaching unit	National Geographic video showing a starving polar bear and follow up discussion about climate change consequences focusing on how energy can be saved: link to energy efficiency		
	Text-based career-related information (PP slides)	Video showing interviews with the experts	Video was trimmed
Scenario link to the teaching unit: Experimentation	Mission: to test energy-efficient model-houses and address global warming assuming the role of architects and engineers specialized in energy-efficiency. Students divided in groups test the insulation of different materials using temperature sensors and a software program.		
	Each group tests out 3 materials	Each group tests out 1 material (different in each group)	
Reflection phase: Revisit of the scenario link to the teaching unit	Experts' visit to school: PP Another lesson followed to continue experimentation	No experts' visit Discussion about the best material to use for insulation	Experts' visit to school: planned in collaboration with the researchers

For this classroom-based research, both quantitative and qualitative data were collected. The primary data collection methods included (a) two questionnaires consisting of Likert scale items and open-ended questions and, (b) interviews with 22 students and 3 teachers reflecting on the scenario implementation and the added value in terms of triggering interest and raising awareness about science-related careers. In addition, field notes served in both facilitating the triangulation of the primary data and supplementing interpretation. The first questionnaire (MultiCO Scenario Evaluation) was administered at the end of Lesson 1 consisting of items related to the two phases of SI: Triggered (measuring students' affective reaction to the scenario) and Maintained (measuring the value/importance/relevance of the scenario), as well as career-related items. The second questionnaire (Lesson Questionnaire) was given at the end of each lesson to measure the intensity of SI throughout the intervention and consisted of four items regarding students' focused attention and affection (Rotgans & Schmidt, 2011). Quantitative data were analyzed using descriptive statistics and qualitative data were coded based on the Triggered and Maintained SI developing a coding tool according to SI sources emerged from the literature (RQ1a) and career awareness-related information (i.e. job duties, skills) (RQ1b). The analysis of qualitative data with respect to whether the career-based scenarios generate students' SI (RQ1a) aim to give further insights on the sources of triggering and sustaining SI.

FINDINGS

Regarding the first research question, Table 2 depicts the descriptive statistics of students' SI emerged from the analysis of students' responses to MultiCO Scenario evaluation questionnaire with respect to Triggered SI (TSI) and Maintained SI (MSI). Table 3 displays the frequencies of students' responses in the open-ended questions in the MultiCO scenario evaluation questionnaire and the interviews based on the content analysis. Hence, from the content analysis derived four (4) sub-categories and thirteen (13) codes under the categories of TSI and MSI denoting affective and value-related facets respectively.

Table 3. Descriptive Statistics in terms of Triggered and Maintained SI

	Situational Interest	Case A[a]		Case B[b]		Case C[c]	
	Items[e]	Mdn	Mode	Mdn	Mode	Mdn	Mode
TSI	The scenario was fun	3.00	3	3.00	3	3.00	3
TSI	I like the format of the scenario	3.50	4	3.00	3	3.00	3
TSI	I find the topic of the scenario interesting[d]	2.00	2	2.00	2	2.00	2
MSI	I find this topic important for me personally	3.00	3	3.00	2	3.00	3
MSI	I find this topic important for learning at school	4.00	4	3.00	3	2.00	2
MSI	I find this topic important for the society	4.00	4	3.00	3	3.00	3
MSI	The topic has something to do with me	3.00	3	2.00	2	2.00	2

Triggered SI

As can be seen on Table 2, in all the cases the students expressed positive feelings towards the scenario (mdn≥3.00, mo≥3) and found its topic interesting to the highest degree (mdn=2.00, mo=2). The statement 'I like the format of the scenario' tended towards a positive extreme in all the cases (mdn≥3.00, mo≥4). The content analysis of the qualitative data collected from the questionnaire, indicated that *novelty* was considered by the students as the main source of triggering SI (52 times). In particular, in Case A the most frequent code was *setting the goal* (11 times) which refers to students' responses indicating that they liked the idea to take on a mission as 'experts' (e.g. *"The mission seems very fun to do!"*). In Case C, *visual aids* was the most frequent code that refers to the use of the video to introduce the scenario (e.g. *"I liked the video with polar bear"*) followed by the *interaction with experts* (e.g. *"Most of all, I liked it when the architect came and talk to us. We were talking to an expert and he answered to all the questions."*). On the other hand, the sub-category of *topic interest* (24 times) was less common throughout all the cases whereas emphasis was given on the *interest in the careers* (8 times) in Case B (*"I liked the jobs, the architect and the civil engineer"*). *Practical activities* and particularly *experiments* (16 times) were also reported by the students in all the cases especially in Case C (7 times) (e.g. *"I liked it a lot because we did experiments, practical activities"*).

Maintained SI

All the students agreed that the scenario topic was quite important for the society and for learning at school though there was a negative trend in terms of the latter in Case C (mdn=2.00, mo=2). The statement 'I find this topic important for me personally' that denotes personal value was endorsed by all the students to the positive extreme (mdn≥3.00). Nevertheless, the statement 'The topic has something to do with me' that signifies personal relevance had a negative trend in Cases B and C (mdn=2.00, mo=2). According to the content analysis, the students' responses showed that *learning* and *relevance* were the common sources of sustaining SI with the former being more frequently reported (47 times) than the latter (35 times). *Learning* was mostly reported in Case B focusing on *career-related information* (13 times) gained from the career-related videos and the follow up discussion with the teacher (e.g. *"I liked best that we learned about jobs because we might choose one of these jobs in the future"*). Moreover, the most frequently reported code in all the cases was *learning in general* (21 times) probably indicating that the students valued learning and gaining information about the practical aspect of science in everyday life (e.g. *"Yeah I never considered the shading they put over the window and I haven't actually thought of why …*

and I never thought the angles of the sun and stuff like that. That was interesting", Case A). *Learning about social issues* was the least reported code (7 times). In terms of *relevance*, the most frequent source of SI reported by the students was *global value* (21 times) that was mostly endorsed by the students in Case A (15 times) (e.g. *"The subject of global warming is intriguing and a very important worldwide issue"*). On the other hand, the scenario topic was not perceived as having a *personal value* (14 times) for the students which contradicts the findings derived from Table 2 reflecting on Lesson 1 (e.g. *"It is important for people in general cause the architects are people which have the plan for you to make a house but for me personally it's not really relevant to me but it's important"*). The students who perceived the scenario topic as personally important they usually attributed this value to the career aspect because of its alignment with their aspirations (e.g. *"Yes because I like architecture and it is something I want to do in the future"*).

Intensity of SI

Table 4 shows that students' SI overall tended towards the positive extreme in all the cases (mdn>3). However, some fluctuations are identified in each case. In particular, in Case A students' SI was relatively decreased in Lesson 3 (mdn=3.25) from the previous lessons (Lesson 1: mdn=4.38, Lesson 2: mdn=4.25) whereas an increase can be seen in Lesson 4 (mdn=4). In Cases B and C there were slight differences indicating that the least interesting lessons were Lesson 3 and 1 correspondingly (mdn=4, mdn=3.50).

Table 4. Students' Situational Interest in each Intervention per Lesson

Cases	**Case A (N=14)**				**Case B (N=25)**			**Case C (N=25)**		
SI/Lesson	**L1**	**L2**	**L3**	**L4**	**L1**	**L2**	**L3**	**L1**	**L2**	**L3**
Median	4.38	4.25	3.25	4.00	4.13	4.50	4.00	3.50	4.00	4.00
Mode	4	5	3	4	4	5	4	4	4	5

Further insights from the interviews support these findings. In Case A, a student claimed that the expert's visit was not interesting due to the lecture-type presentation and that it could had been more engaging (*"Perhaps they could have done more hands-on things to get more involved, engaged"*). Nevertheless, the experimentation with the use of the computer as a novelty aspect promoted self-regulated learning and there are indications that it had succeeded in sustaining students' SI (e.g. *"I really liked it when we experimented on our own"*). Considering Case B, although the students showed interest in the introduction of the scenario, field notes and teacher's interview indicated that some students' attention was withdrawn during the career-related videos because of their length and sound problems. Two students also noted that *"the experts in the video were not talking clear"* and that *"the lesson was boring"*. Regarding Case C, students' SI was seen to gradually increase. More specifically, the teacher stated that *"students' engagement was enhanced once they got ownership during testing materials"*. Likewise, the majority of the interviewees expressed their excitement while doing the experiment (e.g. *"We understood better the topic, it was more creative and it triggers your interest more."*). According to the teacher, during the expert's visit the students were engaged *"once the architect managed to establish a connection with students"* and the climate became friendlier and personally relevant.

Career Awareness

Following the presentation of career-related information in Lesson 1, Table 5 below indicates that students' knowledge gained about job and opportunities and the understanding of skills necessary in the job of the architect tended toward the positive extreme in all the cases (mdn=3.00). Regarding the statement 'This career might be an option for me', students in Cases A and B responded negatively (mdn=2.00; mo=3 and mo=1 respectively) opposed to the students in Case C (mdn=3.00; mo=3).

Table 5. Descriptive Statistics with respect to Students' Career Awareness

Career awareness	Case A[a]		Case B[b]		Case C[c]	
Items[e]	Mdn	Mo	Mdn	Mo	Mdn	Mo
From this scenario, I gained new knowledge about jobs and career opportunities	3.00	3	3.00	3	3.00	3
This scenario enables me to understand the skills that are necessary in this profession	3.00	4	3.00	3	3.00	3
This job/career might be an option for me	2.00	2	2.00	1	3.00	3

a. N= 14, b. N= 25, c. N= 25
d. 1= totally disagree, 2= disagree=, 3= agree, 4= totally agree. The findings are discussed with respect to the two extremes.

Findings from qualitative data indicated that the students perceived knowing more about careers at the end of each intervention. In particular, the interviewees in Case A reported knowing the architect as a job title but not where architecture and engineering could branch out to. Reflecting on the career-related video and the follow-up discussion in Case B and the expert's visit in Case C respectively, the interviewees stated that the intervention enabled them to get an idea of the basic studies and sector-specific knowledge related to how the theoretical concepts in the teaching unit of heat transfers can be applied in architecture (e.g. *"I learnt that it's more complicated than just having to figure out what material is better to use, other factors come in place, from the temperature of the room, whether it's sunny, humidity also affects it"),* the opportunities to gain expertise and to understand the difference between the architect and civil engineer (e.g. *"I learned that the architect designs the building whereas the civil engineer is responsible for the foundations of the building to be stable and insulated"*). It was also seen that the informal interaction with the experts (Case C) was more engaging for the students instead of the lecture-type one (Case A) (e.g. *"It was interesting because we could ask anything and you don't usually have opportunities like that to talk to an expert"*). In addition, there were some references to the general responsibilities of the job, working conditions and specific skills (e.g. design & IT skills). A common finding was that the students considered learning about careers very useful (e.g. *"It's interesting because we don't learn about jobs. The teacher focuses on the lesson and many of us don't know what subjects to choose and the available jobs"*).

DISCUSSION AND CONCLUSIONS

The findings presented in this paper showed that the use of career-based scenarios as an introduction to science teaching units can serve as a mechanism to generate students' SI and raise their awareness about science-related careers under some conditions. What vividly stands out in sustaining students' interest throughout the scenario implementation and providing them with knowledge about careers relates to specific features of the scenario and how these are supported in the teaching sequence.

According to the findings from the three cases described above, focusing on students' SI, the students expressed positive feelings (e.g. enjoyment, excitement) towards the scenario and foremost the novelty aspect. More specifically, visual aids (i.e. video), 'setting the goal' tasks using PBL and interaction with experts were the most frequently reported sources of triggering SI. The mission assigned to the students and thereby the experimentation, as well as the interaction with the experts, seemed to have had facilitated students' active engagement in class. On the other hand, someone could share Rotgans and Schmidt's (2012) argument that the feeling of being curious about something that is new and unknown fades away at some point and then the students become less engaged and active. What it is worth mentioning here though, based on the reflection from our previous work (Drymiotou et al., 2018), is that the novelty aspect was repeatedly presented throughout the intervention to provide constant stimulations of SI and it presumably succeeded in 'holding' students' interest.

Moreover, considering the interaction with the experts, the measurement of the intensity of SI, indicated that interacting with experts is not always serving the purpose to trigger and/or sustain SI unless it occurs in an informal setting offering a fertile ground for the development of 'friendly' conversations. The lack of good planning and collaboration between the expert and the teacher which was looped by the researcher in Case A seemed to have failed developing an environment that could host fruitful discussions and promote students' engagement. Conversely, in Case C, the expert managed to establish a connection with the students which prompted them to ask more personal questions and get to know information about his out of work life and how this was affected by his work. In accordance with the findings presented by Kudenko, Simarro and Pintó (2017), the minimal contribution from industry representatives in initiatives to develop learning resources and support STEM curriculum often ignored personal and social attitudinal issues. The findings of this study perhaps highlight the significance of having a more personal interaction with the experts.

The results of this study also revealed that the students valued the fact that the scenario implementation provided them with general knowledge and information about careers and everyday social issues. Even though the majority of the students were not personally interested in the topic or the career, they perceived the scenario experience important and useful due to the transfer of science concepts to a real-life-personally-relevant context. This perhaps enabled them to establish connections between theory and practice. Similarly, findings from a study conducted by Palmer, Burke and Aubusson (2017) suggested that providing opportunities to create relevance to everyday life now and in the future would make the students understand its usefulness and probably increase their enjoyment in science and the possibilities for a relevant future study and career choice.

Although many of the students expressed positive feelings towards the scenario, only few chose the career of architect or civil engineer as a possible future option. This finding supports a previous study by Dorph, Bathgate, Schunn and Cannady (2017) in which fascination was found to be negatively correlated with having a career goal at all. However, in all the cases, it was revealed that the students gained information about the careers presented and were able to share what the experts' job entails emphasizing sector-specific knowledge and how this relates to their teaching unit. Perhaps even more noteworthy is that the students perceived learning about careers very useful for their future subject and career choices claiming that it is something missing from school lessons. Consisted with Archer, DeWitt and Dillon's (2014) findings, even though the intervention did not radically change students' career choices, it had a positive effect on broadening their understanding of the careers related to their teaching unit.

Overall, the scenario features that could possibly generate students' SI and raise career awareness pertain to primarily (a) promoting students' active engagement and self-regulated learning using PBL and novelty aspects, (b) establishing connections between theory and practice by transferring science concepts to a real-life-personally-relevant context and, (c) carefully integrating the career aspect by promoting a more personal interaction with experts and gain a more nuanced understanding of its practical aspect and the theory behind it. This study shares some interesting empirical evidence in terms of certain principles that may facilitate the design and implementation of career-oriented curricula in science classrooms with the potential to enhance students' interest in science and foster related career aspirations. These findings could be used to further theorize about the development of SI and career-oriented instruction adding to the existing body of literature.

AIMING FOR AN INTEGRATED PERSPECTIVE ON MODELS OF LIGHT IN THE SECONDARY SCHOOL

Anna De Ambrosis[1], Massimiliano Malgieri[1] and Claudio Sutrini[1,2]

[1] Department of Physics, University of Pavia, Pavia, Italy

[2]IS Taramelli-Foscolo, Pavia, Italy

We discuss a teaching experiment on the introduction of elements of quantum physics already at the level of the fourth year of Italian high school (17-18 years old students) using Feynman's sum over paths approach. More precisely, the educational sequence is based on a continual dialectic juxtaposition between the wave and the Feynman's sum over paths models of light, and constitutes an attempt to provide a unifying perspective on different theories of light encountered by students in high school, and often perceived as disconnected: the ray model, the wave model, the quantum model. A focus of the work is on gradually introducing innovative elements in the traditional high school approach. The analysis of the experimentation data shows very rich and complex patterns, allowing to identify activities which may be more productive for students and to uncover weak points and student's difficulties.

Keywords: Light, sum over paths, optics

INTRODUCTION AND THEORETICAL FRAMEWORK

The teaching of light in the secondary school physics course can present itself to students as the progressive introduction of different theories (ray optics, wave optics, electromagnetic optics, the photon model) where very little time is devoted to explaining their relationship. Looking at the Italian textbooks, ray optics and wave optics are presented in very different parts of the course, corresponding to very different student ages: geometrical optics at grade 10, and wave optics at grade 12. Then, electromagnetic waves and a very basic (mainly phenomenological) photon model are introduced in grade 13, the last one in Italian high school. With the possible exception of the connection between wave optics and Maxwell's equation, very little or no space is devoted in textbooks to their compatibility or respective domains of validity. Such approach could possibly exacerbate student difficulties and confusions between the wave and ray model, which have been observed even at University level (Wosilait et al., 1999). Also, as more than a hundred years have elapsed from the initial formulations of the idea of a light quantum, many researchers and teachers have felt the need of going beyond the quasi-historical (Whitaker, 1979) approach offered by a majority of textbooks, and proposing to students a deeper conceptual reconstruction of quantum physics, emphasizing its structure as "a rational theory, with its own rules, its own language and first of all, its own facts" (Fabri, & Wheeler, 1996). Thus, the value of the theory as a breaking point with the classical conceptions should not (or not only) be simply stated within a meta-scientific, historical-like narrative, but should become apparent from the internal coherence of the non-classical model and its capability to explain physical facts.

In part in response to these needs, our group has proposed to introduce the photon model using Feynman's sum over paths approach already at the fourth year of secondary school, presenting it as the currently accepted synthesis of the secular debate between the corpuscular and wave models of light (Malgieri, Onorato, & De Ambrosis, 2015). Feynman's model allows to interpret all the traditional wave phenomena (interference, diffraction etc.) in terms of photons, and also provides a clear picture of how Fermat's principle, which is the foundation of ray optics, may arise from the rules of the sum over paths model, in the limit of small wavelengths with respect to relevant length scales of the problem. Thus, following this route, students can be led to juxtapose and compare models, and critically examine the relationship between them. The research question which has inspired the design of our teaching-learning sequence can be summarized as follows: can the sum over paths approach be used to help students acquire, early in their career, an integrated mental model of light, with a conceptual understanding of the connection between the photon model, wave theory, and ray optics?

The teaching-learning sequence (TLS) we developed constitutes a first attempt at transposing such idea in the educational practice. The main focus of the sequence is on the juxtaposition of the wave and photon models of light, and the need for a statistical interpretation of the results of wave optics, explained in terms of Feynman's model. In broad terms, the sequence comprises two main blocks of activities; the initial part is tightly connected to experimental evidence, as the phenomena of interference, diffraction and iridescence (thin film interference) are observed and analyzed in the laboratory, and explained in terms of the wave theory of light; in the second part, following rather closely the track of Feynman's book *QED* (Feynman, 1985), students are presented with novel, inescapable evidence demonstrating the existence of photons as a fundamental constituent of light, and the sum over paths model is introduced as a way of making sense and interpret the phenomena previously observed in terms of photons.

STRUCTURE OF THE TLS

The structure of the TLS is schematically reported in Table 1.

The first three lessons of the TLS consist of laboratory activities. The experimental phenomena observed, all of which involve light interference, starting from the iridescence of soap bubbles, are interpreted and modelized using a wave model which is directly derived from an analogy with sound and mechanical waves, as it is usual in the high school treatment at this level. In the fourth lesson, which is the heaviest in theory content, we pose the problem of the evidence for light quantization, and of the inconsistency of such evidence with both the classical wave and particle models. Feynman's model of the sum over all possible paths in its simplest form is introduced; and in the three final lessons the model allows to explain and re-interpret the experimental evidence of light interference phenomena. In the last lesson, which circularly closes the sequence, students work individually on a guided problem which returns on thin film interference (responsible for bubble iridescence) from the point of view of the Feynman model.

An important element in our sequence is the possibility of visualizing the mathematical model underlying quantum theory, a possibility provided to students mainly through GeoGebra simulations (Malgieri, Onorato, & De Ambrosis, 2014, 2018). The issue of providing a visual representation of quantum objects has long been debated in the research literature, with several authors arguing that such representation may favour the persistence of classical or hybrid quantum-classical conceptions. By design, the simulations we use, or guide students to produce, do not contain any direct visual representation of quantum objects, but only represent elements of the experimental setup (source, detectors, and physical constraint), and elements of the model such as paths and their associated tiny arrows or phasors. Even so, great attention to students' choice of words during their work is necessary to prevent overly concrete interpretations of elements of the model (e.g. the possible paths as alternative trajectories, or phasors representing amplitudes as vectors connected to some physical quantity) which have sometimes been reported for the educational use of Feynman's approach (Malgieri, Onorato, & De Ambrosis, 2017). It is also worth mentioning that in this experimentation we tried to have students take a more active role, involving them not only in the manipulation of existing simulations, but also in the creation of a new one representing the phenomenon, discussed several times within the sequence, of thin film interference.

Activity (location and time)	Experiments	Theory	Methods
1. Iridescence (Physics lab, 1 hour)	Observation of iridescence in soap bubbles	Wave model explanation of iridescence	Group work on the explanation of iridescence.
2. Interference (Physics lab, 1.5 hours)	Experiment on two slit interference	Wave model explanation of two slit interference	Laboratory group work
3. Diffraction (Physics lab, 1.5 hours)	Measurement of the width of a hair	Wave model explanation of light diffraction	Laboratory group work
4. Feynman's model (Classroom, 1.5 hours)		Evidence for the existence of photons and introduction to Feynman's model	Frontal lesson
5. Applications (Classroom, 2 hours)		Explanation of interference, diffraction and refraction using Feynman's model	Work in pairs on interference from multiple slits
6. Visualization of the model (Computer lab, 1 hour)		Explanation of thin film interference using Feynman's model	Group task on the construction of a GeoGebra simulation on thin film interference
7. Working with the model (Classroom, 2 hours)			Individual work on thin film interference using Feynman's model

Table 1. Structure of the TLS

The comparison between the wave and photon models of light runs as a common thread through the whole sequence. The central idea is that wave theory provides, in a statistical sense for a large number of photons, the same results which are given as probabilities for individual quantum objects by Feynman's approach. The connection with ray optics is developed essentially in lesson 5, when the explanation of light refraction using the sum over paths approach offers the possibility to show students how the results of geometrical optics are recovered in the limit of small photon wavelength.

Because of the age of students and the time available for the teaching sequence, only some essential ideas about quantum physics were discussed with students. We concentrated mainly on the way probabilities are computed in quantum physics for events (which in our case were always photon detections) which can happen through different, mutually exclusive routes, which is the cornerstone of Feynman's approach (Feynman, 1948, 1985). Most importantly, we attempted to begin building the language of quantum physics: the concept of a quantum object as a different entity from both a particle and a wave; the source-to-detector philosophy (Dobson, Lawrence, & Britton, 2000)); the general way of approaching a problem by considering all alternatives which lead to the same experimental outcome for the system as a whole.

METHODS AND CONTEXT

Aiming at a high level of students' participation and motivation in the activities, we choose to avoid traditional frontal lessons almost entirely; frontal teaching has been necessary only within the fourth lesson, for the introduction of the "rules of the game" of Feynman's approach. The privileged educational strategy was group or pair work, both in the physics laboratory, in the computer lab and in the classroom, using worksheets for guided inquiry experiments, guided problem solving, and activities involving the use or the construction of simulations. The worksheets filled in by the students allowed to collect a large amount of data with important indications on the critical points in the development of students' conceptual understanding.

The experimentation involved four classes (around 80 students) at grade 12 of science-intensive high school ("Liceo Scientifico") Taramelli in Pavia. The duration was about 10-11 hours in each class, in November and December 2017. The experimentation was conducted by a researcher, which was not the regular physics teacher in the classes. On a qualitative level, student's participation and interest during the experimentation was generally high, and they participated to the proposed activities with interest and positive attitude.

RESULTS AND CONCLUSIONS

Data collected during the teaching learning sequence includes laboratory sheets and reports, worksheets used by the students for exercises and problems, and teacher's notes on students' comments, questions and difficulties. Here we shortly report the main results from the analysis of such data.

1. The sequence was appropriate for the age of students, both in its formal and conceptual content. The analysis of the worksheets in most cases shows a majority of correct and complete answers to each one of the questions proposed in exercises and problems; this is especially true when students are required to work in pairs (for example, problem proposed in lesson 5, see Figure 1). When working individually, students may have difficulties with the details of Feynman rules (e.g. the phase shifts due to reflection) but they appear to master reasonably well the general conceptual meaning of the approach. For the final worksheet on thin film reflection, completed by the students individually in Lesson 7 (see Figure 2), the percentage of answers displaying a general understanding of the model was 73%, while answers completely correct in all details were 49% (sample N = 76 students).
2. Students were in general well disposed towards a probabilistic/statistic reading of natural phenomena, and the new language introduced by Feynman's approach. However, sporadic cases of strong epistemological resistance were observed. For example, a student objected that she did not consider it sufficient to learn how to compute probabilities, but she desired instead a deeper understanding of why Nature

behaves in such a way. Since the epistemological aspects of quantum theory were not a focus of the present work, students were not encouraged to entertain in philosophical debates for long times. Cases of tenacious opposition to the tenets of quantum physics by secondary school students were observed and discussed recently in the physics education community (Malgieri, Onorato, & De Ambrosis, 2017; Ravaioli, & Levrini, 2017).

3. The objective of providing a comprehensive, integrated perspective on the theories of light appears to have been partially met. Students understand and correctly describe the probabilistic-statistic relationship between the wave and photon theories. However, ray optics appears to be too far in the past in their school curriculum (they studied it two years earlier) to recall or apply correctly its rules, and to grasp the connection with Feynman's approach. This is due in part to the fact that in the Italian tradition geometrical optics is very rarely taught as stemming from Fermat's principle but more often as a phenomenological theory. Future experimentation will explore strategies for further reinforcing the student's understanding of the relationship between the sum over paths approach and ray optics.

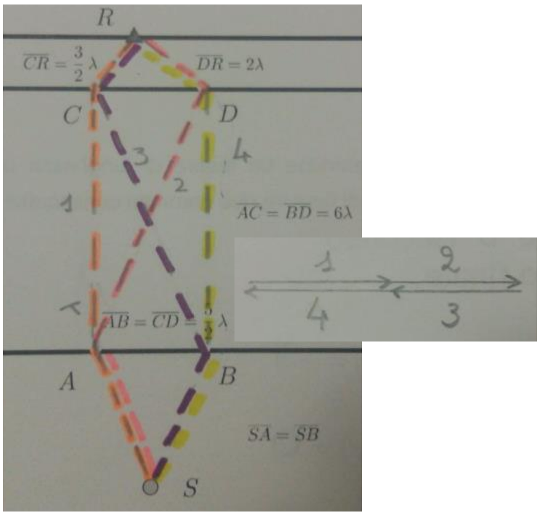

Figure 1. – Pictures produced by a student pair of the possible paths and (in the inset) phasors for computing the detection probability for a problem of photon interference from successive slits.

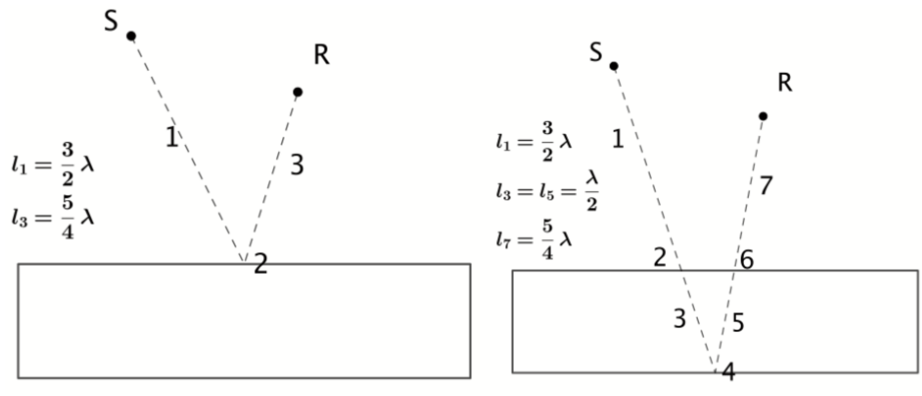

Figure 2. – Part of the worksheet on thin film reflection. Students are required to solve the problem of finding the reflection probability for two different wavelengths of light. The incidence of light is considered as approximately normal to the surface, and multiple internal reflections are ignored (but the issue is discussed with students).

The objective of providing a comprehensive, integrated perspective on the models of light appears to have been partially met. Students understand and correctly describe the probabilistic-statistic relationship between the wave and photon model. However, ray optics appears to be too far in the past in their school curriculum (they studied it two years earlier) to recall and apply correctly its rules, and to grasp the connection with Feynman's approach. This is due in part to the fact that in the Italian high school geometrical optics is very rarely taught as stemming from Fermat's principle, but more often as a phenomenological theory. Future experimentation will explore strategies for further reinforcing students' understanding of the relationship between Feynman's photon model and ray optics.

ACKNOWLEDGEMENT

The authors wish to thank Dr. Dario Codegoni Principal of the "Taramelli-Foscolo" High Scool, and the whole group of Math and Physics teachers of the same school for their collaboration and support to this work.

A TEACHING-LEARNING SEQUENCE TO BRIDGE THE GAP FROM MICRO TO MACRO IN THERMODYNAMICS

Massimiliano Malgieri[1], Claudio Sutrini[1], Monica Di Savino[1], Pasquale Onorato[2], and Anna De Ambrosis[1]
[1]Department of Physics, University of Pavia, Pavia, Italy.
[1]Department of Physics, University of Trento, Povo (TN), Italy.

In this paper we report about our progress in developing and testing a teaching-learning sequence (TLS) meant to lead high school students to an integrated perspective on the subject matter, to give them a taste of the computational side of the discipline, and have them reflect on its foundational aspects. In addition to aiming at traditional disciplinary learning goals, the TLS uses multiple strategies to activate and maintain students' engagement and interest. The sequence starts from a motivating activity on the irreversibility of processes and covers the first and second principle of thermodynamics and the concept of entropy. A central activity on thermal contact involves the use of a playable stochastic dice and coin toy model, which is meant to act as a mediator between the experimental results and theory, as well as to introduce elements of group game, with an expected increase in students' engagement. Another pivotal point in the sequence is an open discussion, stimulated by the reading of passages from Boltzmann, Loschmidt and Zermelo, on the compatibility between the reversible laws of Newton's mechanics and the irreversibility contained in the second principle of thermodynamics. The TLS was tested with a class of 23, grade 11 students of a science-oriented high school

Keywords: Thermodynamics, toy models, simulations

INTRODUCTION

The teaching of thermodynamics has been in past years among the most openly and widely debated areas of physics education. Poor educational results and a high incidence of alternate mental models of thermodynamics concepts have been consistently reported by many authors at the level of introductory college instruction (Loverude, 2015). Based on such data, proposals of curriculum renewal, innovative teaching learning sequences and educational reconstructions have been advanced. In relatively recent years, the idea of a "computational" approach to the teaching of thermodynamics, heavily based on computer simulations, has gained momentum (Moore & Schroeder, 1997). However, these proposals are usually centered on undergraduate education, and difficulties are perceived in promoting computational thinking at the level of secondary school. Also, several authors have argued that the traditional dichotomy between microscopic and macroscopic approaches to the subject matter needs to be downplayed, in favor of a more integrated approach in which the student can be led to think to a given problem under both perspectives (Reif, 1999; Levrini et al., 2010). Our group has been involved in research on the teaching of thermodynamics for a number of years, and has been part of the drive for innovation coming from the computational perspective, especially by proposing strategies for making computer simulations an effective bridge between theoretical models and experiment, and by investigating the outcome of the use of computer simulations in the teaching-learning process (Borghi et al., 2004). In recent times we have started developing an approach to different problems in physics which is based on activities where student groups compare the results of a real low-cost experiment with those of a) a playable dice/coin model and b) a numerical simulation extending the stochastic model to a number of elements not easily achieved by actually performing the game with physical dice or coins. In this perspective the design of simulations still plays a significant role, but such simulations do not take the lead from theoretical considerations but are motivated (and made easier to understand) as extensions of playable games of chance. The success of the toy model and simulation in emulating the behavior of real systems is then, only as a last step of the activity, explained in terms of a more complete microscopic theory. This idea has been tested with problems coming from different areas of physics: radioactivity, luminescence, and thermal contact (Onorato et al., 2017; Malgieri et al, 2018) and in the present work we used it as a central activity for a Teaching-Learning Sequence (TLS) on thermal phenomena, irreversibility and the second principle of thermodynamics for the secondary school. The TLS here presented and tested constituted a substantial revision and re-design of the one we discussed in Malgieri et al., 2016; our aim in particular was to increase the engagement of all students, proposing diverse activities capable of "activating" students with different skills and interests, improving the laboratory and game sessions, expanding the dimension related to the discussion of historical controversies.

THEORETICAL FRAMEWORK

Design of the TLS

The design of the teaching-learning sequence is based on a "three-dimensional approach" (Besson et al., 2010), involving a synergic integration of a critical analysis of the scientific content in view of its reconstruction for teaching, an overview of current teaching materials such as textbooks, and an analysis of educational research on the topic, with a particular focus on the literature on student difficulties. In particular, we considered research on student difficulties on the first principle of thermodynamics (Loverude et al., 2002); on the second principle and the concept of entropy (Loverude, 2015; Christensen et al., 2009; Leinonen et al., 2015); on general concepts of probability and statistics related to the teaching of thermal physics (Loverude, 2009). Fundamental choices, supported by much previous research, were to take a microscopic approach (Moore & Schroeder, 1997; Reif, 1999) and to abandon the order/disorder metaphor for introducing entropy (Leff, 1996; Wei et al., 2014). The analysis of foundational and historical-epistemological issues, with a focus on long standing historical debates (Steckline, 1983) played a significant role both in our initial design and in the following revision.

The construct of engagement

In the process of revision which led to the current version of the TLS, a central role was played by the construct of engagement (Mosher & McGowan, 1985; Fredricks et al., 2004). Engagement has a long history in the science education literature, but recent consensus has formed that it should be regarded as a multi-dimensional construct consisting of three interrelated dimensions: behavioral, emotional, and cognitive (Fredricks et al., 2016).

Behavioral engagement includes characteristics such as participation, effort, attention, positive conduct; emotional engagement primarily highlights positive and cooperative interactions with classmates, and self-identification with the current task or topic; cognitive engagement can be defined as the student's individual psychological investment in learning, which, if high, allows him/her to exert the necessary effort for comprehension of complex ideas. According to Newmann (1992) engagement is improved in learning environments in which the tasks students are confronted with (a) are authentic; (b) give students the opportunity to take responsibility for design, execution, and evaluation; (c) provide opportunities for collaboration; (d) require diverse forms of talents, maybe also those which are not often elicited in school; and (e) provide opportunities for fun. Yonezawa et al. (2009) also highlight the importance of allowing students practice and discuss critical thinking with respect to the accepted norms of the discipline in a favorable, democratic environment. Cavanagh et al. (2009) hypothesize that a necessary element for student's engagement, resides in the balance between their expectations for learning before the activity and their actual capability to learn during the activity. A main objective of the revision and re-design of our TLS was to improve as much as possible student's engagement, while preserving or improving the very good results on disciplinary learning of the sequence, reported in Malgieri et al. (2016), which shared its core disciplinary structure with the one discussed in this article.

Long term research questions concerning the development of our TLS can be described as follows. 1) Can playable toy models contribute to students' engagement and conceptual understanding in the learning of thermodynamics? 2) Is the task of building computer simulations which reproduce and extend the playable toy model bringing it closer to the real experiment meaningful and productive for students' learning? 3) Are 17 year old students mature enough for the debate on the foundations of thermodynamics to have a positive effect on their learning, and contribute to their understanding of the nature of science?

STRUCTURE AND DESCRIPTION OF THE TLS

The TLS has a total duration of about 22 hours and is structured according to the following steps: 1) Motivating activity on reversibility and irreversibility. 2) Microscopic time reversal and macroscopic irreversibility. 3) Kinetic theory of gases and the first principle of thermodynamics, concepts of microstates and macrostates. 4) The approach to thermal equilibrium. 5) Boltzmann's definition of entropy and the second principle of thermodynamics. 6) The historical debate on the second principle of thermodynamics. 7) Entropy and heat exchanges: a justification of Clausius' formula. In Figure 1, the TLS is represented in schematic form; the steps 3, 5 and 7, have a mainly theoretical content and are mostly delivered in the form of frontal lessons; elsewhere, such teaching strategy is kept to a minimum; group tasks, pair tasks, whole class discussions and gaming/coding activities are the prevailing instructional settings as will be discussed more in detail below.

Motivating activity on reversibility and irreversibility

In the initial activity students, divided in groups, are required to produce, videos for physical events which either look realistic also if the video is time-reversed, and videos which don't have such property, using similar equipment in both cases. The activity is not preceded by an explanation of its meaning (which is discussed later) and is meant to provide students with an intuitive understanding of the concept of irreversibility. Another aim was to activate students' engagement on the nontrivial (but within their reach) task of producing videos which look realistic when played backwards. Students worked on several different systems, including the well known cases of marble collisions (one-to-one and one-to-many collisions); cart collisions (elastic and inelastic) and special systems designed to provide a macroscopic analogy to the issue of energy dissipation, in which energy comes to be hidden in the microscopic world. Overall, a disciplinary goal was to provide students with the intuitive idea that irreversibility is connected to energy "spreading and sharing" (Leff, 1996) either in space, or over more degrees of freedom than those it was constrained to initially. However, no connection between the spreading and sharing of energy and the concept of entropy was made at this time.

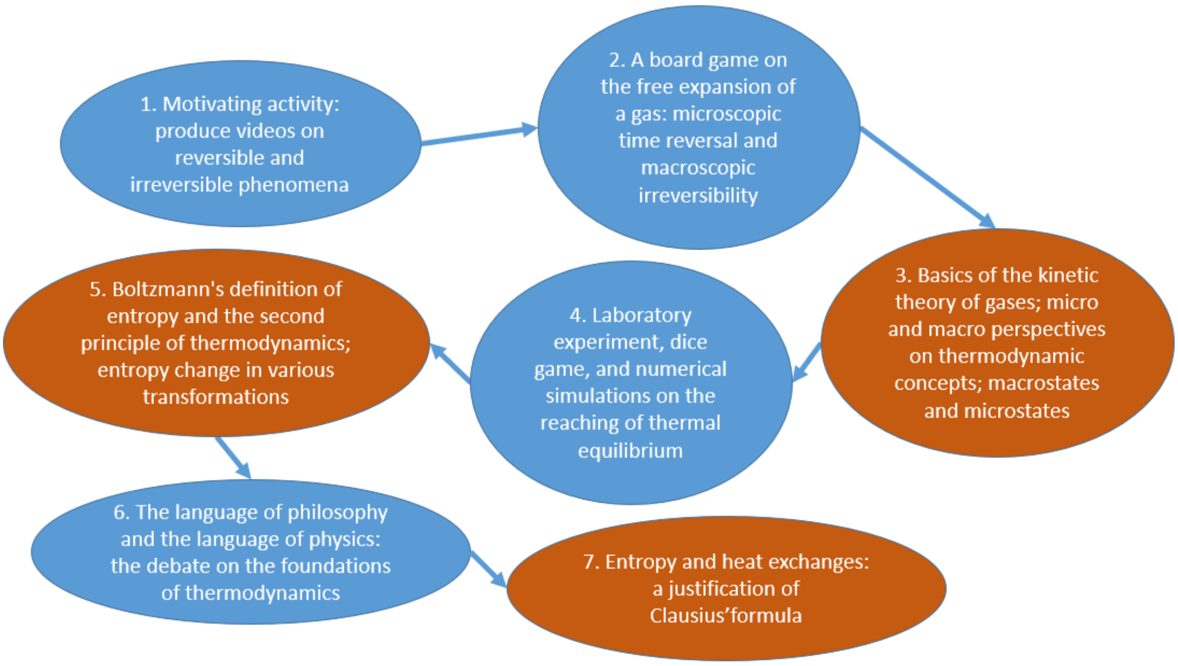

Figure 1. Schematic representation of the TLS. Steps colored in orange have a mainly theoretical content and are delivered mostly in the form of frontal lessons; on the contrary, steps colored in cyan involve significantly or entirely group tasks, laboratories, open discussions and other less conventional activities.

A board game on the free expansion of a gas.

In the context of a worksheet to be completed working in pairs, students play a board game meant to represent, in a stylized way, the free expansion of a gas. Four tokens move on a hexagonal grid cardboard according to deterministic rules (no randomness is involved) as can be seen in Figure 4. The rules are designed in such a way that movement of tokens is symmetric under time reversal in the same sense as Newton's laws. The game starts with all tokens on the left side. Students are led to reflect on the fact that, although the dynamics of the system is symmetric by time reversal, this does not mean that the two cases are equally likely that a) the tokens, starting from half the board, expand into the other half; or that b) being initially spread on the whole board, they spontaneously constrain themselves to half the board in a certain number of moves. In other words, the game stimulates students to reflect on the only apparent contradiction between microscopic laws that are symmetric under time reversal and the macroscopic concept of irreversibility. Proceeding on the worksheet after the game, students are led to reflect on the fact that, if the number of "tokens" approached 10^{23}, events such as the self-constraining of tokens on only one side of the box would become incredibly unlikely. Within students' worksheet, the game is also played using a random rule (with six sided dice) for token movement. In that case, considerations of time reversal symmetry do not hold, but the general probabilistic treatment of the chance of tokens constraining themselves to half the board remains, exactly, the same. The game can be seen as an introduction to the Loschmidt paradox, which will be later discussed with students.

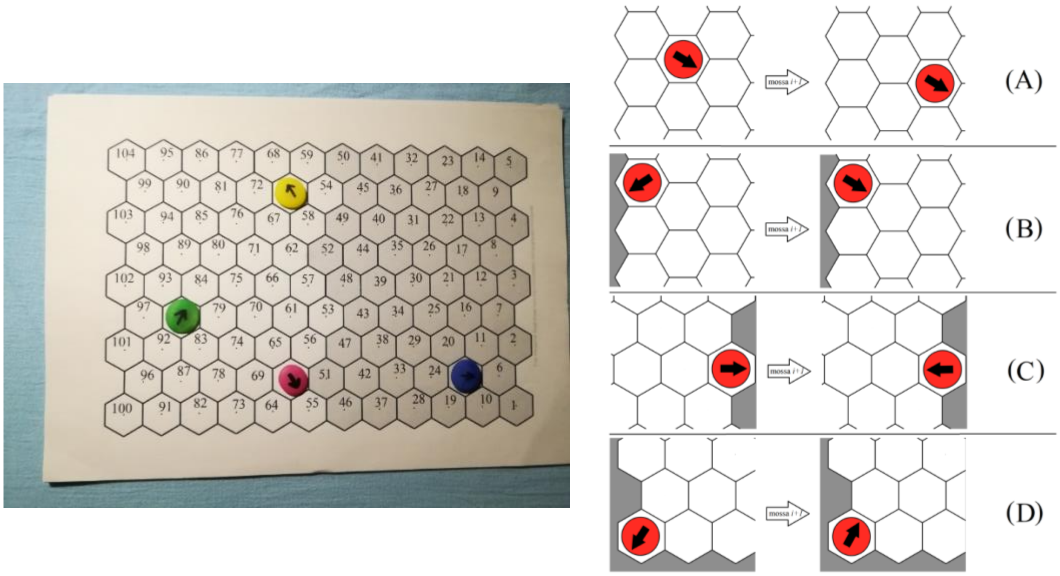

Figure 2 – Board game on the free expansion of a gas. (Left) the board and tokens (Right) the special moves representing wall collisions. Token collisions are not considered in the game.

Laboratory activity on thermal equilibrium

After a theoretical interlude in which, building on the intuitive understanding gained from the initial activities, students are introduced to 1) a microscopic perspective on the ideal gas law, 2) the first principle of thermodynamics, 3) the concepts of macrostates and microstates, a new group activity is performed in the physics laboratory. There, students start with simple experiments on heat transfer, namely between water in a container and the environment, and between two water samples at different temperatures. After the experiment, students are explained a simple toy model representing thermal contact. A cardboard has two rows of squares, with different numbers of squares, which can be either filled with a coin or empty. According to the roll of two dice, coins are exchanged between the rows. The model also allows to define a "toy-temperature" (Onorato et al., 2017) inspired by the kinetic definition of temperature, which is proportional to the ratio between the number of occupied squares of row, and the total number of squares of the same row.

The number of squares on each row corresponds to the number of faces of two dice each group has available (for example, a 12 sided and a 20 sided dice). A certain quantity of coins is initially distributed on the squares of the two rows so that one is almost filled, one almost empty. The experiment proceeds with students throwing the two dice, and moving the coin from one row to the other if the roll of the two dice corresponds to one filled and one empty square. Students repeat the process of throwing dice many times exchanging each time the positions of coins until they declare that the system is essentially “at equilibrium” (30-35 times are typically sufficient).

In the next lesson, students are taken to the computer lab (the activity spans 4 hours in total, of which 2 in the physics lab and 2 in the computer lab) where each of the groups is given the task of writing down the abstract pseudo-code for a computer program simulating the toy model for an arbitrary number of squares on the two rows, and initial coins. Subsequently the teacher helps students to write the actual code in Matlab/Octave (no more than 20 lines of code), and perform simulations with a larger number of rows and coins observing a progressive reduction of fluctuations away from equilibrium. Finally, the teacher analyses the toy model as a game of probability along the lines described in Onorato et al. (2017) drawing an analogy between the board game and the actual process of heat transfer. The most significant result of tihis comparison is the derivation from probabilistic consideration of the exponential behavior of the approach to equilibrium, observed in the real experiment. Thus, the toy model is justified as a simplification of the underlying microscopic dynamics of the real problem of heat transfer. Also, the toy model connects to the game of the free expansion of a gas, in the sense that allows to represent the equilibrium macrostate as the one with the highest multiplicity in microstates. The toy model is also coherent with the intuitive idea of spreading and sharing of energy, in that irreversibility is tied to an increase in the number of energy microstates available to the system (considering first the two objects as isolated, then in thermal contact). The activity in the computer laboratory proved to be quite engaging for students, activating in particular those with an interest in informatics.

Classroom debate on the foundations of thermodynamics

The activity developed in three steps: first (1), in a joint lecture with the philosophy teacher, students are introduced to the language of paradoxes, starting from the paradoxes devised by ancient Greek philosophers. The goal of the lecture is to introduce students to the idea that while the scientific method signs a discontinuity between the language of physics and the one of philosophy, there is also a line of continuity, consisting in the use in physics of elements of language such as paradoxes and mental experiments. Then (2), students are given an individual worksheet containing original texts of physicists of the XIX century, debating Loschmidt’s paradox, the paradox of Maxwell’s demon, and the meaning of the second principle. Finally (3), the texts are openly debated in the classroom.

The discussion was very participated and, according to some of the interviewed students, contributed greatly to increase students’ self-confidence. The activity was an occasion for students to practice critical thinking with respect to the accepted dogmas of the physical discipline, by taking opposite sides in historical debates. As previously discussed, this may be a key element in promoting students' engagement. The effect of activation and increased engagement was particularly evident in the case of students with a personal interest in philosophical questions and issues.

CONTEXT AND DATA COLLECTION

The TLS had a total duration of 26 hours and was tested with a class of 23, grade 11 students (12 male and 11 female) of a science-oriented high school ("Liceo Scientifico"). Lessons and activities were conducted conjunctly by the teacher of the class, who had participated in the process of revision of the TLS, and a researcher of our group.

Data for the experimentation is very rich and includes pre and post-tests, an initial psychometric test (Raven matrices) evaluating each students' potential, individual notebooks, group lab reports, worksheets, the recording of all lessons, final productions of each group in the form of a PowerPoint presentation, a final online anonymous satisfaction questionnaire, and individual interviews to four students who were selected either because, according to the teacher, had displayed highly unusual engagement in the sequence with respect to other physics lessons, or, in one case, because the student had already a pre-existing strong interest in the discipline. In this article we discuss pre- and post-test data, and some general threads which can be detected in students' satisfaction questionnaire and interviews.

DATA ANALYSIS

Pre-test data

The pre-test was composed mainly by standard items from research-validated assessments on thermal phenomena, most of which taken from the literature discussed in the Theoretical Framework section. Students displayed several incorrect ideas well documented in the literature: for example, 18 students out of 23 defined temperature as a "measure of heat", despite having encountered the ideas of heat and temperature previously in the high school curriculum. The confusion between heat and temperatures also caused many students to refer to thermal contact as the "transfer of temperature" between bodies. Students showed difficulty also with probability and combinatorics: only 6 students out of 23 correctly determined how many numbers of 3 digits can be obtained using 4 basic digits. Also, students performed very poorly (17 out of 23 incorrect answers) with an item concerning the magnitude of fluctuations in samples of different dimensions, generally displaying the belief that the probability of a fluctuation from the mean of given magnitude is independent of the size of the sample and confirming a difficulty already noticed in the literature in the context of the teaching of thermodynamics. As reported in Loverude (2009) this kind of question may be very difficult even for advanced undergraduates. The very low result for this item further highlighted the importance of conducting numerical simulations of our model systems with increasing number of elements, in order to observe directly fluctuations fade away with the growing magnitude of the considered sample.

Post-test data

Data from the disciplinary post-test generally provided encouraging indications, as it did in the version of 2016: although both samples were small, the disciplinary results can be considered similar. For questions which can be compared with the literature (microscopic interpretation of the compression of an ideal gas, variation of the number of accessible microstates for two systems in thermal contact, variation of entropy in the same situation) results are comparable with or better than those reported in the literature for University students. A majority of students seemed to have gained a reasonably good understanding of the concept of entropy, and about half the students could analyze in detail, including correct and complete conceptual explanations, the situation in which the entropy of the universe is increased due to irreversible heat exchange between a initially hot body and the environment. Difficulties persisted in the definition of temperature (7/21 students) and heat (4/21). However, to our disappointment, the misconception that the magnitude of fluctuations from the mean is independent from the size of the sample seemed to be quite robust: notwithstanding our efforts, only 6/21 of students provided the correct answer in the post-test, in a question similar, although not identical to the one of the pre-test.

A general thread in the post-test was that for items requiring an explanation, students generally were extremely prolific in writing, producing long and detailed explanations and analyses for the proposed physical situations. According to the teacher, such result was very unusual for the class. Even when those explanations were not, from a disciplinary point of view, completely correct, the willingness of students of elaborating and reporting them can be considered a sign of increased self-confidence and engagement.

The satisfaction questionnaires

Satisfaction questionnaires were given to students at the end of the sequence in anonymous form. The questionnaire was presented as an online survey which students could complete at home. Question concerned the relation with teachers and fellow classmates, the perceived role of group work, pair work, and a general evaluation of their experience with the TLS. Raw approval rates were very high, with 60% of students providing a fully positive evaluation, and 40% stating that the experience was more on the positive side. Group and interdisciplinary activities were particularly appreciated. However, students were not necessarily, and not all, convinced that their understanding had been improved with respect to traditional teaching: while almost all students report of having been more engaged with the TLS than during the usual lessons, and a majority reports an increased interest for the discipline, only about half of them think that the structure of the TLS was overall beneficial for their understanding. Overall, students' results and questionnaire confirm the prevailing view that the reflexes of student's engagement on cognitive outcomes are not trivial or immediate, although the former may well be a factor influencing the quality of students' learning.

Some general results from students' interviews

It is possible to detect in the interviews some recurring themes: A common students' observation concerns the satisfactory experience in building the knowledge of the subject starting first from group work on games or laboratory activities. Students report that in the first stages of the sequence they could not get the general picture of what they were doing and thus concentrated on the activities with greater personal engagement and without prejudices on what the intended results should have been. However, in the end they were able to connect all what they had done in a coherent picture. One student says "[...] *If one had begun with theoretical lessons, probably there would not have been so much attention, or would have felt so much involved, instead in this way, when theory was presented, it connected to things we had seen already in practice, and all became simpler, so for me it was useful*". Another student observes that this approach allows to understand concepts in a deeper, and probably more long-lasting way. He also remarks that working in this way, theory and disciplinary norms appear to come in response to a necessity of explanation and formalization student themselves perceive, while with the usual approach they come from authority, and are somewhat imposed to them.

Students appreciated the effort of establishing a connection between different areas of physics by adopting a microscopic perspective, and often coming back to the picture provided by mechanics. All students seem aware of the nature of physics as a connected and consistent whole, but also remark that, in the usual teaching and in textbooks, subjects and theories often appear disconnected and unrelated one with another.

One of the interviews which was particularly important for us was to a female student who had generally mediocre results in physics, but was extremely active and engaged in the TLS, and had good results in the final test. She reported the satisfaction she experienced in arriving in some case, to an explanation on her own, and highlighted the importance of the debate on historical controversies in increasing her self-confidence to tell what she thought without fearing that it could be wrong. This student reports having had previously a difficult relationship with physics, which she perceived as something which, she says, "*did not correspond to me*" ; but states that this project gave her again confidence in her possibilities, and the desire to re-approach the subject: "*this project has made flourish a passion which was hidden and so… it was very useful, it brought me the desire to try again*".

Some partly critical observations came from the student with a long-standing personal interest in physics. Although he also appreciated the teaching-learning sequence and most of its activities, he reported that at certain times the approach had confused him, because he was well adjusted to the usual method of having a complete and self-consistent formal presentation of the subject, which he could then understand more in depth using the textbook or other sources.

CONCLUSIONS

Students enjoyed the TLS. This is confirmed by worksheets, interviews, and the online approval questionnaire given to students after the experimentation, in which students' approval rates were very high. Part of the success of the TLS may be due to its capability to "activate", through different activities, students with different personal interests (coding, taking and reversing videos, giving a presentation, philosophical discussion…). Disciplinary results were good but, considering the smallness of both samples, they were not significantly better or worse than in the previous version of the sequence.

The effort of expanding the moments of active learning, group work, and multi-dimensional activity had positive effects in the self-confidence of students, their engagement in the sequence, and the general quality of their argumentation. The quality and complexity of the final productions of each student group (PowerPoint presentations) is also an element confirming such tentative conclusion.

The classroom discussion on historical controversies was also very participated and engaging for students. This was not entirely expected, but we can now confirm that 17 year old students can understand, and become interested in, the historical debate between Boltzmann, Loschmidt, Zermelo, on the meaning of the second principle, and other long-standing issues in the foundations of thermodynamics.

AN INTERVENTION STUDY ON STUDENTS' DECISION-MAKING USING TRADE-OFFS TO RESOLVE SOCIO-SCIENTIFIC ISSUES

SAKAMOTO Miki[1], YAMAGUCHI Etsuji[1], YAMAMOTO Tomokazu[2], INAGAKI Shigenori[1], WAKABAYASHI Kazuya[1], TOKURA Sayuri[1]

This study aims to examine the effects of an intervention enhancing students' socio-scientific decision-making. Socio-scientific decision-making necessitates reasoning from multiple perspectives and the use of trade-offs. We developed a socio-scientific issue-based unit for non-science undergraduate students focusing on students' decision-making for resolving conflict around the issue. In this unit, students considered the trade-offs of science and technology and engaged in a decision-making intervention focused on proposing solutions to resolve conflict. The participants were forty-nine non-science undergraduate students. In pre- and post-tests, students were asked to construct arguments on the focal issue. Their arguments were explored mainly in terms of the quality of their decisions. A comparison of pre- and post-tests revealed a general shift to higher-level responses after the intervention. Students' arguments on socio-scientific issues changed from justificatory arguments to proposals for solutions. This demonstrated that the instruction promoted students' socio-scientific decision-making, particularly in generating solutions to resolve issues.

Keywords: socio-scientific issues, decision-making, multiple perspectives

THEORETICAL FRAMEWORK

Socio-scientific issues (SSI) represent complex social dilemmas related to the application of scientific principles and practices. In the last decade, science education researchers and practitioners have made significant advances in the use of SSIs as a context for transforming science learning (Romine, Sadler, & Kinslow, 2017; Sadler & Dawson, 2012). Current literature regarding the effects of SSI interventions reported the beneficial results on interest and motivation, content knowledge, nature of science, and community of practice (e.g., Sadler, 2009). SSI approaches can be an effective means of supporting learning that are aligned with Vision II science literacy, which focuses on the ways in which students conceptualise and use science content and practices through explorations of complex issues (e.g., Zeidler, 2014).

Friedrichsen, Sadler, Graham, and Brown (2016) presented a model for SSI instruction that highlights: (a) a focal issue, (b) the interaction of science ideas and practices, (c) social connections, (d) the use of information and communications technologies (ICT), and (e) a culminating experience that encourages students to synthesise their ideas. In their instructional model, SSI-based instruction should start with the presentation of a compelling issue. Their model posits three interacting elements as the primary substance of students' learning experiences: social connections, science ideas and practices, and ICT. Students ought to substantively apply science ideas and practices as they negotiate the focal issue. They should also have opportunities to consider the social complexities of the focal issue, which often interact with the ways in which the underlying science is interpreted or applied. As they make sense of the focal issue, students should interact with ICT in order to access and analyse new ideas as well as share their ideas with classmates or broader audiences. The culminating experience is designed as an activity for students to synthesise their experiences with the focal issue and apply their learning throughout the unit. In a culminating experience, students return to the focal issue and apply their scientific understandings to grapple with the social aspects of the issue.

Wu and Tsai (2007, 2011) proposed an integrated analytical framework for learners' informal reasoning on SSIs, using three indicators: decision-making modes, reasoning modes, and reasoning level or quality. Decision-making is intuitive when it is spontaneous and immediate, and it is evidence-based when it takes into account information of a factual nature. Reasoning modes are characterized by their social, ecologic, economical, or scientific/technological orientations. The total number of reasoning modes would also be obtained as quantitative measures. The greater the total number of reasoning modes an individual learner utilises, the more he/she is orientated to reasoning from multiple perspectives. Reasoning quality describes the learner's ability to generate arguments using three components: supportive argument, counterargument, and rebuttal.

SSI cannot be solved on the basis of 'simple cause and effect reasoning'. Because of the multidimensionality of SSIs, socio-scientific decision-making necessitates reasoning from multiple perspectives, including scientific, environmental, and social (Lee & Grace, 2012). To examine students' reasoning from multiple perspectives, Lee and Grace (2012) categorised the justifications students provided in support of their decisions into six types, each representing a distinct perspective, and counted the number of perspectives invoked by each student. Some research (Liu, Lin, & Tsai, 2011; Wu & Tsai, 2007) generated the total number of reasoning modes, which was an equivalent indicator to Lee and Grace's (2012) perspectives.

In socio-scientific decision-making, students first need to understand and describe SSIs in its complexity; second, they need to be able to generate solutions that account for multiple perspectives on the issue, and third they have to be able to critically evaluate solutions (Eggert, Ostermeyer, Hasselhorn, & Bögeholz, 2013). Several studies developed various instructional interventions to improve students' socioscientific decision-making performance. Some studies provided a decision-making framework, or provided decision-making strategy training, or provided prompts to reflect on the choice of decision-making strategy (Fang, Hsu, & Lin, 2018). One such structured decision-making framework is as follows: define the problem, options, criteria, information, survey, choice, and review (Sutter et al., 2018). As for an appropriate decision-making strategy, Eggert and Bögeholz (2010) identified the ability to use trade-offs as one crucial aspect of socio-scientific decision-making, and described the use of tradeoffs as a *compensatory decision-making strategy*. In contrast, a non-compensatory strategy means the use of a cut-off. Various instructional interventions have been developed to support students' use of appropriate decision-making strategies, such as introducing the optimization strategy (e.g. Papadouris, 2012), and using additional meta-cognitive approaches (Eggert et al, 2013; Gresch & Bögeholz, 2013; Gresch, Hasselhorn, & Bögeholz, 2013).

These intervention studies focused mainly on choosing the best option or selecting among possible solutions rather than developing new, alternative solutions. Although Eggert et al.'s (2013) socio-scientific decision-making questionnaire consisted of items that represented the development of sustainable solutions to SSIs, they dealt with the summed score of the scale on ‘developing and evaluating solutions’. Kim, Ko, and Lee (2019) designed and implemented the community-based socioscientific issues program (SSI-COMM). This program included the phase of action-taking, where students look for and implement the best solutions to the issue. However, Kim et al. (2019) did not analyze the students' solutions. Furthering these studies, therefore, this study examines students’ socio-scientific decision-making focusing on the ability to generate solutions that account for multiple perspectives, while also considering trade-offs or conflicts around the issue.

AIM AND RESEARCH QUESTIONS

We designed a socio-scientific issues-based curriculum unit for non-science undergraduate students focusing on students’ decision-making for resolving conflict around SSIs. The study used a pre - post intervention approach to investigate the quality of students’ decisions and was guided by two research questions:

1. When students engage in a decision-making intervention and consider the trade-offs of science and technology, is their socio-scientific decision-making orientated towards evidence-based decision-making and reasoning from multiple perspectives?

2. How do the students’ arguments around SSIs change during the intervention? Do their arguments progress from being one-sided to two-sided, and do they transform into proposed solutions to the issue, while accounting for multiple perspectives and considering trade-offs?

METHODS

Participants

Forty-nine non-science undergraduate students (13 male, 36 female).

Curriculum Unit

The goal of the curriculum unit was for the students to generate compromise-based solutions to resolve the conflicts around SSIs, rather than choosing the best option. The theoretical framework of the design of the unit was a model of SSI instruction presented in Friedrichsen et al. (2016). The development of a genetically modified organism, that is, Japanese cedar pollinosis alleviation rice was selected as the focal issue. First students learn the scientific background of the process and treatments of allergies and GMOs [scientific ideas]. In collaborative sessions, students then explored opinions favouring or opposing the focal issue, examining the benefits and drawbacks of the genetic modification technology [social connections]. Collaboratively, they clarified the complex relationships among the opinions and identified six competing perspectives, or trade-offs: financial gain, medical expenses, treatment, side effects, development of genetic modification technology, and environmental impact [scientific practice]. Finally, they constructed a compensatory solution to resolve the conflicts of some of the trade-offs [culminating experience]. Table 1 shows an overview of the instructional unit.

Task

Students were asked to construct arguments as if they were making a public decision on the development of transgenic rice as medicine for pollen allergies. We conducted the pre-test with the whole class at the beginning of the unit. The post-test was implemented as individual homework after the unit.

Analysis

For the first research question, we analysed students' justifications in supportive arguments or counterarguments in terms of the perspectives used, following the methods of Lee and Grace (2012). Six categories were defined to classify perspectives, which were identified during instruction.

This study explored students' decision-making mainly in terms of the level or quality of the decision, focusing on dealing with trade-offs (for the second research question). The quality of students' decisions was analysed utilising three components: supportive arguments, counterarguments, and proposal of solutions. The evaluative rubric is displayed in Table 2. The rubric was composed of six levels, the lowest of which included only an unsubstantiated claim. Successive levels progressed to include justifications, counterarguments, and proposals. Following the rubric of Eggert et al. (2013), students' solution proposals were categorised as 'higher-level' if they were detailed and intended to resolve the conflicts of multiple trade-offs. We regarded such proposals as the result of reasoning from multiple perspectives.

Table 1. Overview of the curriculum unit.

Lesson	Learning activity
1	Introduction of Socio-scientific issues
2	Science ideas: Learn about the scientific aspects of allergies and genetic modification
3	Social connections: Explore opinions of multiple stakeholders.
4	Socio-scientific decision-making task: Pre-test
5	Science practices: Clarify the relationships among the opinions and identify competing perspectives.
6	Generate solutions to resolve conflicts.
Homework	Socio-scientific decision-making task: Post-test

Table 2. Rubric for assessing the quality of the students' decisions and examples from this survey.

Level	Description	Examples
0	Made only simple claims, without justification.	I agree.
1	Made claims justified by supportive arguments, but no counter-arguments (justificatory arguments: One-sided).	I would like to formulate an opinion from the standpoint of opposing the development of Japanese cedar pollinosis alleviation rice. (skip) I do so because according to the opinion of an opposing doctor, drugs currently in use are highly effective and their side effects are known *[supportive arguments]*.
2	Generated supportive arguments and counter-arguments (justificatory arguments: Two-sided).	I would like to formulate an opinion in favour of the development of Japanese cedar pollinosis alleviation rice. (skip) Opponents are concerned about unknown allergies and side effects that the consumption of genetically modified crops may bring *[counter-arguments]*, but all drugs of any sort inevitably come with side effects.
3	Generated two-sided arguments and suggested a need for the proposal to resolve conflict on one trade-offs.	I would like to formulate an opinion in favour of the development of Japanese cedar pollinosis alleviation rice. (skip) Certainly some farmers are opposed to this considering the risk of cross-contamination of ordinary rice *[counter-arguments]*. (skip) Also, when it comes to the stage of actually cultivating the rice in question, it would be vital to prevent the opposing farmers' worry of rice contamination from becoming reality. It will be essential to provide farmers wishing for the development of alleviation rice with a thorough explanation of all such an endeavour would entail,

		and to rigorously manage and cultivate the fields with alleviation rice *[suggest a need for solutions]* .
4	Generated two-sided arguments and constructed a proposal to resolve conflict on one trade-off.	I would like to formulate an opinion in favour of the development of Japanese cedar pollinosis alleviation rice. One reason to oppose it is the dangers associated with it. Unknown side effects are one such danger. (skip) Naturally, with unknown side effects, it is not immediately clear how to deal with them, and thus the number of hospital visits may actually increase rather than decrease *[counter-arguments]*. To prevent such outcomes, long-term experimentation is necessary, but the budget for such is limited. What if we invited individuals, well-informed about the dangers involved, to participate in clinical experimentation and provided them with alleviation rice free of charge or at low cost? *[solutions to resolve conflicts]*. This would reduce the need for developers to spend large amounts of money on long-term experimentation, as well as provide those agreeing to clinical testing of pollinosis alleviation rice with extremely low-cost treatment. After all, it is essential to prove its safety in order for it to be fully accepted by society *[conflicts of side effects]*.
5	Generated two-sided arguments and constructed a proposal to resolve conflict on multiple trade-offs.	I would like to formulate an opinion from the standpoint of opposing the development of Japanese cedar pollinosis alleviation rice. (skip) Advances in genetic modification technology will contribute to the future development of various other types of functional rice and will also benefit developing countries and rural areas *[counter-arguments]*. If we could just reliably eliminate side effects and other risks to health as well as the environmental destruction caused by the spread of modified genes, the value this advancement could provide seems very much worthy. For example, what if at first only a small number of farms were to cooperate with development companies in genetic modifications, in a limited area, isolated from other farms, with rice grown only indoors, as well as distribution limited to take place directly between development companies and farms? *[first solution to resolve conflicts: Environment]* This would prevent contact with other plants and contamination of conventional rice, and thus prevent spread. Furthermore, by delaying practical use of alleviation rice treatment until its safety has been confirmed by repeated clinical experiments, and allowing it only in cases where conventional treatments have failed and the person in question applies for and consents to its use, I believe a minimum level of safety can be guaranteed. *[second solution to resolve conflicts: Side effects]*

RESULTS

First, the students' justifications in supportive arguments or counterarguments were analysed in terms of the perspectives used. Figure 1 displays the frequency data of each perspective used in pre- and post-test. The perspective of treatment was used most; eighty percent or more of the participants used this aspect of information or evidence to make their arguments. Figure 2 illustrates the average number of perspectives the students used. The number of perspectives embedded in the supportive arguments remained the same, while the number of perspectives in the counterarguments increased significantly after intervention ($t(48)=1.359$, *n.s.*; $t(48)=5.322$, $p<.001$). At the post-test, students cited on average two categories of counterargument. Therefore, students became more capable of reasoning from multiple perspectives on the SSIs.

Next, the quality of the students' decisions was rated. Figure 3 presents the distributions of these levels in the pre- and post-tests. More than 80% of the arguments generated in the pre-test were justificatory arguments without proposals to resolve the conflict, and about half of their arguments were one-sided. Most students were able to make evidence-based decisions before the intervention, however inadequately. About 10% of the arguments were rated level 3, as they did not provide a detailed solution themselves. In the post-test, more than half of the students were able to propose a solution for one or more of the trade-offs. The students' decision levels increased significantly from pre-test to post-test (*T=841.50, p<.001*), with a notable increase in the number of arguments at levels 4 and 5. That means students' arguments transformed into proposals of solutions to resolve the conflicts of the one or more trade-offs. Table 3 shows the utilisation rate of each trade-off in solutions students proposed in the post test. Trade-offs of financial gains, environmental impact, and side effects were treated most in students' solutions.

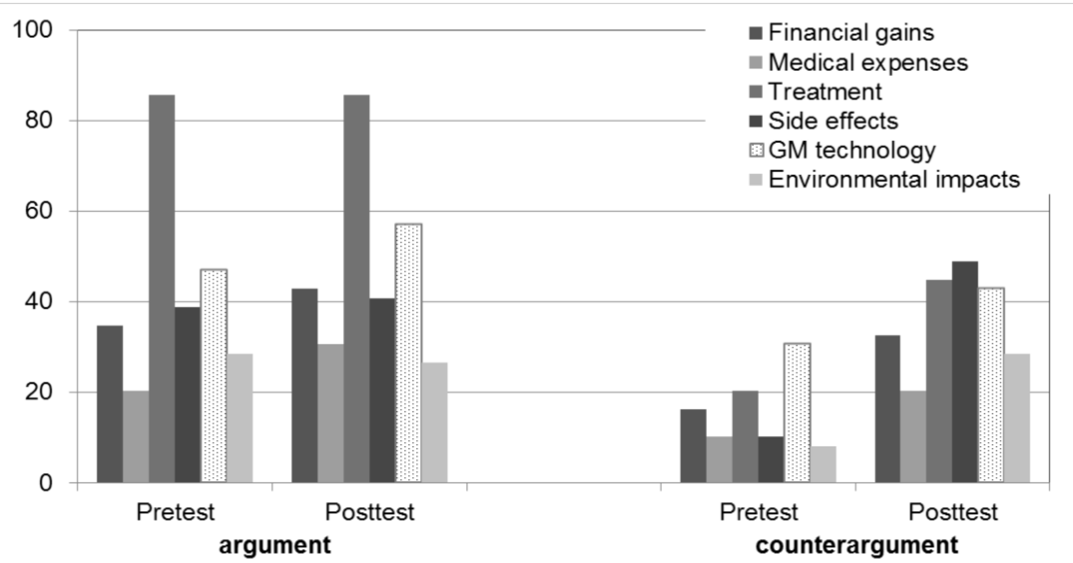

Figure 1. Utilisation rate of each perspectives in students' justification in pre- and post-test (%).

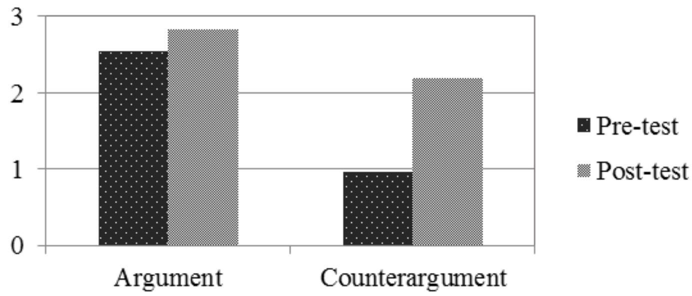

Figure 2. Average number of perspectives invoked among students' justification in the pre- and post-test.

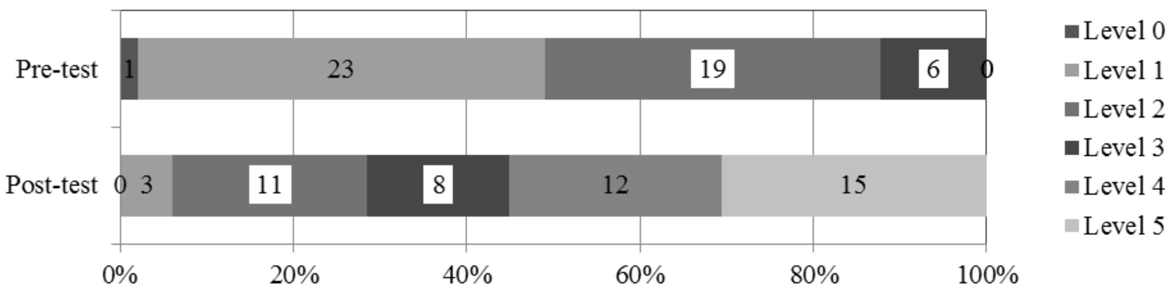

Figure 3. Distribution of the quality of the students' decisions in the pre- and post-test.

Table 3. Utilisation rate of each trade-off in students' solutions.

Tradeoff	Financial gains	Environmental impacts	Side effects	GM technology	Treatments	Medical expenses
(%)	51.85	51.85	44.44	22.22	14.81	7.41

DISCUSSION

We developed a socio-scientific issue-based curriculum unit for non-science undergraduate students focusing on students' decision-making for resolving conflict around the issues. In our SSI-based unit of instruction, the students considered the trade-offs of a specific scientific technology (the development of transgenic rice as a hay fever remedy) and engaged in a decision-making intervention focused on proposing solutions to resolve conflicts. A significant increase of perspectives embedded in students' counterarguments in the post-test demonstrated that students became more capable of multi-perspective reasoning on the SSIs. A comparison of the pre- and post-test scores revealed a general shift to higher-level responses after the intervention; the students' arguments on the SSIs changed from justificatory arguments into proposals for solutions. In the post-test, one-sided arguments diminished, and the number of perspectives embedded in their counterarguments increased. Moreover, solutions on multiple perspectives of the issue as well as those on one perspective were developed. Our hypothesis is supported by the transition of students' written arguments.

These findings demonstrated that our instruction promoted the students' socio-scientific decision-making, both in reasoning from multiple perspectives and in their compensatory decision-making dealing with trade-offs. However, we should pay attention to the fact that some of trade-offs were less-utilised in proposing solutions. Providing the framework for students to analyse and develop solutions on such trade-offs would may bring more proposals to resolve conflict on multiple trade-offs, that is, level 5 decisions. Based on these results, we should improve the details of our instruction in order to further improve students' decision-making.

This work is the result of an ongoing research whose objective is to verify the efficiency, in terms of learning and comprehension, of an inquiry approach script applied to students in classes of Physics laboratory in relation to the traditional scripts. To this end, we have applied each kind of script for an inclined plane experiment to two first year classes of public high school and to one class of Physics course in a public university, which was divided in two small groups. Both schools are in the state of Minas Gerais, Brazil. From the comparison of the results from the three classes it was possible to perceive that the inquiry approach script was not only more efficient, but also provided greater involvement of the students in developing the activity. Also, there was a clear change in the posture of the students in terms of the autonomy required for each group work. To evaluate the students' learning, in addition to participation during class, each group produced a report with a discussion of the results and the respective conclusions.

Keywords: inquiry learning, Physics laboratory, inclined plane experiment.

INTRODUCTION

Experimental activity is a significant didactic resource for Science Education, allowing, from choices, different approaches. According to Andrade-Neto and Leyva-Cruz (2015), theoretically, experimental activities usually performed within the laboratory stimulate an active participation of students, as well as generate reflective situations about phenomena and physical concepts. However, we have perceived that the "filling tables" model, usually applied in several schools, has not provided an effective learning, nor developed the student's thinking. For this to be possible, it would be necessary a changing in the experimental classes and a reformulation of the curriculum of higher education courses, which would not only prioritize the conceptual content, but also the procedural and attitudinal contents of the student. One possibility would be to modify the teaching methodology, using the investigative model. According to Goya (2014), despite its simplicity, the inclined plane experiment has enormous didactic potential. Due to Galileo Galilei's discoveries using it and its importance to the History of Science, the inclined plane experiment appears in the list of the ten most beautiful experiments of all time, according to the journal Physics World in 2002. The inclined plane experiment can be consisted of a very simple apparatus which can easily be found in physics labs. Also, it is concept is easily found in mechanical physics textbooks. Despite the apparent simplicity, errors considered basic, related to conceptual failures and data collection, happen very often in the classes. Ueno-

Guimaraes and Muramatsu (2017) observed in their studies on laboratory classes of a university that students were having difficulties in basic and fundamental concepts often used in a laboratory, such as order of magnitude, units of physical magnitude and standard deviation. This observation led Ueno-Guimaraes and Simões (2015) to question the validity of maintaining didactic laboratory of Physics in the curriculum, without a reformulation of its methodological strategies. Our proposal idea for the inclined plan experiment is to induce the students to determine the static friction coefficient of a body by considering two practical approaches. The first is the traditional approach, where students should follow a pre-established script. This practical model does not provide any moment of reflection for the students on what is being done and does not require much preparation for its realization. The second approach is the investigative experimentation model, which stems from a problem initially proposed by the teacher or the students themselves. This model has the characteristic of allowing greater autonomy of the students in the decision of the procedures to be performed in the laboratory. Autonomy enables students to take an active position in knowledge building and provides a greater understanding of what is being done in the experiment. The general objective of this work is to discuss on how investigative scripts can be implement in classes of physics didactic laboratories, aiming to enable changes in the experiments and generate improvements in the consolidation of knowledge related to it. We are proposing a specific objective of measuring the effectiveness of this experimental model in the learning of physics contents, in comparison to the traditional model.

THEORETICAL FRAMEWORK

The activities called "investigative" are seen as starting point, where the student can develop the understanding of scientific concepts, leaving a passive posture and acting on the object of study. According to Azevedo (2012), the process and the attitudes to which the student is submitted, within the investigative process, are as important as the final results and the learning of the concepts itself. Azevedo (2012) indicates that for an activity to be considered investigative, the student must go beyond the field of superficial manipulation and observation of the experiment in the class. The method requires reflection, discussion and explanation about the phenomena under study. As this model gains prominence, it should be emphasized, according to Munford and Lima (2007) and Azevedo (2012), that an investigative activity does not necessarily need to occur within or even be an activity of a laboratory. Actually, for an activity to be considered "investigative" it should have five moments: a question or the introduction of a problem situation; a moment of investigation, where the students will discuss the problem and devising a way to solve it; a moment when the hypothesis will be constructed; moment of discussion involving the group members and, finally, a moment of reflection, where different views on the problem from the several groups are debated in the class. An important feature of investigative activity is its versatility. Wellington (2000) denotes it as degrees of openness and orientation, which can vary according to the objectives and the structure of investigative activity. Some activities, because of these degrees of openness, may be seeing as ordinary to students, or sometimes, the opposite, and it may be a whole new situation, where a more active participation of the students will be necessary. Considering the notion of degrees of freedom and the idea of moments necessary for an activity to be qualified as investigative, Ueno-Guimaraes and Muramatsu (2017) introduced in their work a table based on the original idea of Pella (1969), described in the works of Carvalho (2010). In the original table there was five degree of freedom, where higher degree corresponds to a higher level of participation of the student in the experiment. Ueno-Guimaraes and Muramatsu (2017) added in their work another degree of freedom named degree zero. This results in a restructuration of the degree of freedom chart, shown in the Table below, where the symbol T represents the teacher participation and S represents the participation of the student.

Table 1. Degrees of freedom in investigative activity and the corresponding participation of teachers and students.

	Degree 0	Degree I	Degree II	Degree III	Degree IV	Degree V
Problem	-	T	T	T	T	S
Hypotheses	-	T	T/S	T/S	T/S	S
Work plan	T	T	T/S	S/T	S	S
Data	S	S	S/T	S	S	S
Conclusion	T	T	S/T/class	S/T/class	S/T/class	S/T/society

The degree zero means the student has zero degree of freedom in terms of acting on their own or thinking about what is going on in the experiment. The effective participation of the student is almost none. The theory of the experiment is present and the students have to achieve the objective by filling table and perform some pre-established calculations. Sometimes, the final objective is to prove a known scientific concept or get a specific known physical quantity. Adding the fact that the script is also very restrict, the student knows what should be the final result and, sometimes, they manipulate the data to get it. At degree one, students have some freedom to choose how to perform the data collection. The students still have to follow a script which resembles a kind of “cake recipe”. The script of the experiment is established from the proposal of the problem to the conclusion of the experiment, and only activity left for the students is to fill the tables. At degree two it is given to the students the opportunity to formulate their own conclusions from the collected data, but these should be presented and discussed with the teacher and the rest of the class. In this level of participation some new problems may appears during the execution of the experiment. At degree three the students should develop their own script or working plan to solve the problem presented by the teacher. Also, they should discuss among them how the data will be collected. The conclusions are discussed in group and with the classroom, with teacher guidance. At degree four the students are responsible for all the steps of the development of the experiment and on how to get the results from a proposed problem by the teacher. Finally, at degree five, the students should be able to propose and solve the problem. This degree of freedom is usual in more advanced academic levels, such as Masters and Doctorates.

METHODOLOGICAL PROCEDURES

The research being present here is basically of qualitative nature. However, some data were taken and they consisted of descriptions of the situations experienced by the authors in the laboratory classroom and part of the text from reports produced by their students. The physical structure of school's city was taken into consideration in the activities carried out in the classroom. Both high school and the university, where the activities were applied, are public school of a historic city of Ouro Preto. This city is a mining area of central part of Brazil and it was grown from the colonial times without any major plan. It was possible to use it as a contextualization of the activity since it has several streets consisted of steep slopes. The present work was carried out with two classes of the first year of public high school in the state of Minas Gerais, named A and B, and with a group of students in the undergraduate physics course of a Federal University of the same state. In both high school classes, the Newton's Laws would still be worked out, giving for a fair comparison between them on the performance and results obtained in the inclined plane experiment. An introductory text and pictures of the cities was used to contextualize the problem and generate a discussion. The discussion was mostly guided by the questions raised by the students. It was expected that the important characteristics of the problem would be identified in the situation contextualized such as when a car could not go up in a steep slope street due to a lack of friction between a car tire and the ground. It was important that the students could make the correlation of this situation with the experimentation to be performed. The necessary trigonometric formulas and correlations were presented for the development of discussion and activity as demand arose. Groups of four or five students were formed at the end of the discussion, so that the structuring of experimentation would be performed by them as a group, offering the possibility of autonomy in their decisions and allowing an improvement in argumentative capability, in defense of the proposed model. Doubts have appeared during the discussion and they were accentuated during the execution of the practice. Working with trigonometric properties, students could not relate concepts to application in the experiment. Some of them could identify the opposite and adjacent side of the right-angled triangle in the drawings on the board, during the explanation, but could not identify them in the experimental apparatus they had assembled. As an evaluative method, both in the traditional and investigative approach, it was necessary that the students had a discussion about the results obtained and that they wrote a short report about the procedures performed in the laboratory, as well as about the obtained results. The classes of the first years A and B from high school were composed of 19 students and 12 students, respectively. These students had several serious conceptual flaws. Many of them had even not seen several subjects, which were included in the school curriculum but not addressing to them. This generated some difficulties during the classes preventing the activities to be, satisfactorily, performed. The third class consisted of freshman of Physics course. They had already worked on the fundamental concepts, during their high school, necessary for the realization of the activity. The assumption was that these students would perform the laboratory activities much better as compared to high school students who were still addressing these fundamental concepts.

PRESENTATION AND ANALYSIS OF RESULTS

The data were taken in the following way: for high school class A we used only the traditional script and for class B only the investigative scripts. For the freshman of the university we applied the traditional script for half of the class and investigative script for the other half. In terms of participation level of the students the traditional script can be classified as degree one while the investigative script can be classified as level three. The traditional script was applied to the high school class A, which its students are considered as exemplary by the school, since they used to have “good conduct” in the classroom and have grades considered reasonable by the school. The class B is the opposite and it is considered “lost cases” by the school. Thus, we would expect in an overall terms that students from class A would perform better compared to students class B. Based on this assumption, we decided to apply only the traditional script for class A, which in theory would not need as much help as class B, and only the investigative script to class B. The proposal of the script was to find the value of the static friction coefficient of two surfaces, glass and wood. It was required in the script a comparison between values obtained for the static coefficients from the angle obtained from the opposite and adjacent side (Table 3 of the script) of the slope and from force equations which requires the measurements of the angle (Table 5 of the script). In principle, the students should find equal values or close values for the coefficients. In addition, it was necessary, at the time of the assessment, to answer whether these values coincided and to explain these results. The results found by the students using the traditional scrips are arranged in the tables, as it was required in the script. Below we present only the tables with the results of for the frictional coefficients using the traditional script applied to class A. All groups in class A were able to perform the experiment satisfactorily, at the predetermined time but with the help of the teacher.

Group 1

Table 3

Surface	Wood	Glass
μ_s	0,375	0,5

Surface	Wood	Glass
μ_s	0,05	0,45

Table 5

Check: Do the data obtained for the static friction coefficients calculated in table 5 match the values of the last row of table 3? Yes (   ) No (x)

Answer: *The value of the wood was similar.*

Group 2

Table 3

Surface	Wood	Glass
μ_s	0,46	0,46

Table 5

Surface	Wood	Glass
μ_s	0,03	0,6

Check: Do the data obtained for the static friction coefficients calculated in table 5 match the values of the last row of table 3? Yes ( ) No (x)

Group 3

Table 3

μ_s	0,35	0,452

Table 5

Surface	Wood	Glass

Surface	Wood	Glass
μ_s	1,663	0,012

Check: Do the data obtained for the static friction coefficients calculated in table 5 match the values of the last row of table 3? Yes ( ) No (x)

Answer: No answer.

Group 4

Table 3

Surface	Wood	Glass
μ_s	0,427	0,432

Table 5

Surface	Wood	Glass
μ_s	0,570	0,565

Check: Do the data obtained for the static friction coefficients calculated in table 5 match the values of the last row of table 3? Yes ( ) No (x)

Answer: *The values were different because there was some wrong data.*

By observing the calculated values for the static friction coefficient of tables 3 and 5 of each group and comparing them, it is possible to draw some conclusions. In some cases, students were able to find very small values, up to about ten times lower than expected, as seen in table 5 of groups 1, 2, and 3. When looking for the source of errors, we came across parallax in obtained the angle and unit conversion. Similar errors were also found in the reports of the students in the work of Ueno-Guimaraes and Muramatsu (2017). Group 3, besides the previous errors, they also found a value for the static friction coefficient greater than one, which is physically impossible. Looking for the source of the error, once again, we come across unit conversion errors. For instance, the hypotenuse value found by them was in km. Only group 4 was able to reach similar values in both methods. Even so, we had the use of generic phrases, denying this proximity in explaining the comparison of values. Make us wonder if they understood what they actually did. The freshman of the university presented a better performance, managing to follow the pre-established script without major procedural and interpretation problems. Problems arose largely from data collection and data processing. Below we present the tables with the results obtained by the groups from the university Physics course, using the traditional script.

Group 1

Table 3

Surface	Wood	Glass

μ_s	0,38/0,42	0,42/0,47

Table 5

Surface	Wood	Glass
μ_s	0,26	0,34

Check: Do the data obtained for the static friction coefficients calculated in table 5 match the values of the last row of table 3? Yes (   )   No (x)

Answer: *The differences between the calculated coefficients in the two tables may have been caused by measurement errors.*

Group 2

Table 3

Surface	Wood	Glass
μ_s	0,36	0,26

Table 5

Surface	Wood	Glass
μ_s	0,29	0,26

Check: Do the data obtained for the static friction coefficients calculated in table 5 match the values of the last row of table 3? Yes (   )   No (x)

Answer: *The values attributed in the predicted measures agglutinated a series of numerical failures that resulted in divergent results.*

Group 3

Table 3

Surface	Wood	Glass
μ_s	0,398	0,349

Table 5

Surface	Wood	Glass
μ_s	25	27,7

Check: Do the data obtained for the static friction coefficients calculated in table 5 match the values of the last row of table 3? Yes (   )   No (x)

Answer: *There were errors in weight convertion*.

The students were able to perform the experiment with very little intervention of the teacher. They managed to complete the experiment in a shorter time than the reserved time, 1h30min. They could even perform the experiment independently. However, they did some mistakes in the collecting data. Group 1 collected obtained wrong values from the opposite and adjacent side of the inclined plane necessary to calculate the tangent of the angle. This let them with different values of the static friction coefficient from table 3 and 5. Another group found identical values for the opposite and adjacent side, even though there was a significant variation of angles. Some parallax problems were also recurring. Non-integer values were noted and used throughout the experiment, but the protractor which the smallest measure was one degree, makes this type of reading incorrect. All students were requested to write a short sentence about the practice performed and all answers were too generic. In 60% of the cases, there were divergences in the values found in tables 3 and 5. Their justifications vary between collection and propagation of erroneous data, even in groups that reached values close to each other. For the students in class B we applied the investigative script. It was took to students a longer time to perform the proposed activities, as compared to the time taken by the high school class A. The investigative script applied can be classified as degree three, and, it is reasonable that a longer time was needed. The need for such autonomy by the students ended up hindering the development of the activity. The discussions took place superficially, requiring many interventions by the teacher, until some consensus and understanding of the objectives and procedures could be achieved. The absence of a didactic laboratory in the Elementary and / or high School created some extra difficulties since the students could not identify the equipment being mentioned and did not know how to use the apparatus. Another difference between class B compared to class A was level of disorganization of the obtained data for the class B to a point of making analysis difficult. The lack of tables to be filled (as in the traditional script) was a decisive factor for this disorganization. During the experiment, students wrote down the collected values in the margins and footers of the pages, and used the back of the sheet, even though they were handed with a blank craft sheet with a template function. The data collected by the students were not organized according to any logic and there were few data with their proper units. As the students were lost in their own data, neither group could reach the objective of calculating the value of the static friction coefficient in both cases, and only one group could correlate the angle of the plane with the value of the force in the block. As shown in the group's next answer: "The force we put on the straight plane is stronger than on the inclined plane because of its angle." As mentioned, the class of freshman of the university Physics course, was divided in two and half of them developed the investigative script. The half of the class was further divided in groups. The first group decided to try to solve the principles of kinematics by calculating the block's descent time and the acceleration to which it was subjected but failed to develop the experiment in this way. After a few minutes of discussion among them and mediated by the teacher, they approached the concept of friction and by recalling the formula that enunciates the phenomenon, they were able to calculate it and come up with some results for the value of static friction coefficient between the studied surfaces. The second group tried to develop by force diagram correctly but the obtained values for the friction coefficients were in the order of 10^{-2}. This was because students did not make the correct conversion of unit, indicating that students have some difficult with units. After the group discussions, they could understand the experiment even thou they got wrong values for the friction coefficient. Similar problem was also observed for the freshmen of laboratory of Engineering courses, presented in the work of Ueno-Guimaraes and Simões (2015). In addition, the second group did not write the text of the evaluation, giving only one sheet, where they performed the calculations. The third group was able to carry out the experiment without major difficulties, because among the members, there was a senior student, who had already performed the experiment in a didactic laboratory, while attending the first period of the previous course. The experiment was performed by them correctly and quickly, not having to use the time 1h30min to practice. The reports written as a form of evaluation by students of investigative experimentation were more descriptive than the reports from the students of the traditional script. The report of the third group, there are deductions and free-body diagrams in an attempt to argue about the validity of the obtained results. In one of the reports, the students pointed out their mistake and how they managed to solve it, showing attention in what was being done by them in the laboratory and corroborating with Borges (2002), when he says that the student takes a new position, from passive to active, allowing a reflection on what was developed and accomplished by him.

FINAL CONSIDERATION

The idea of investigative teaching has been reported in the Literature, but, in practice, it has not been largely applied by the teachers. We still reproduce the teaching model of the last century, in which the teacher is the active agent and the students are passive. By applying the investigative methodology, the improvement and effectiveness of the student's learning is clear. In the degree I of the experiments, all groups were able to reach the proposed objective, which was to calculate the value of the static friction coefficient on two surfaces. When comparing the data obtained by them, we see that only high school group 4 and freshman group 2 were able to obtain values close to each other. This equates to 25% and 33% success, respectively, using the traditional script. In addition to the small number of groups that have managed to come up with expected results, other problems can be considered serious. In all the reports analyzed, there were problems of unit conversion and text interpretation. Students, especially from the early years, did not understand what the script required, concepts such as mass and weight were still not clear to them and they did not know some trigonometric properties. The same mistakes were present in the reports of the investigative script, however, the hit rate was higher, still with some help from the teacher. Anyway, all groups in the investigative managed to reach the objective of the experiment, which the final results were closer to the expected values. The fact that freshman of the university came out with three different approaches shows that there was not only one correct way to conduct the experiment, and allows for further development with respect to student autonomy in the face of a challenge. Unfortunately, students from high school B were unable to deal with the degree of freedom of the investigative script used, possibly due to the fact they were still to immerse in a model of traditional teaching where they are not protagonists. We believe that these results could still be enhanced if there were more meetings such as these, or even if it was possible to apply an Investigative Teaching Sequence in several experiments. There is also the possibility of achieving a gradual opening of degrees of freedom, starting with scripts of degree one and advancing as far as possible. Such procedures will still be put into practice in future research. Another interesting and relevant aspect on this subject, which could be applied in laboratory classes, was addressed by the idea of SCALE-UP (Beichner, 2007). This methodology is strongly related to peer instruction. The idea is to foster a corporate learning environment that would encourage students to collaborate with their peers, questioning and teaching each other. The activity of teachers in this case would be to encourage and assist students to reach their own answers and conclusions about certain problems of physics and let them present their conclusions to the other students. The learning would take place when opposing ideas and having a discussion with the answers and works presented by all the groups. We can conclude by saying that there is an urge for change and an alternative teaching practices which have to be developed and applied. However, as the initial and continued formation of science teachers does not yet favor this kind of approach (Galiazzi, 2011), the use of new methodologies is not widely spread either in theoretical or experimental classes.

PART 6: STRAND 6

Nature of Science: History, Philosophy and Sociology of Science

Co-editors: *Ebru Kaya & Veli-Matti Vesterinen*

CONTENTS

STRAND 6: INTRODUCTION

NATURE OF SCIENCE: HISTORY, PHILOSOPHY AND SOCIOLOGY OF SCIENCE

Understanding of nature of science (NOS) is now seen as an integral part of scientific literacy. In a world struggling with global crises, such as the climate change and the COVID-19 pandemic, understanding of central scientific concepts is usually not enough for engaging with these socio-scientific issues. Discussing and taking action towards a more sustainable world demands scientific competence for citizenship, which includes understanding of uncertainty and tentative nature of scientific knowledge as well as the ethical aspects of science. Thus, maybe now more than ever, there is a need to discuss how history, philosophy and sociology of science could and should inform science education.

Altogether 7 of the studies presented in Strand 6 (Nature of science: history, philosophy and sociology of science) were accepted to be published in the ESERA 2019 conference proceedings. Most of them focus on charting or developing students or teachers understanding of NOS.

Two of the papers focus on secondary school level. The first is written by Anne Caroline de Freitas, Michele d. Facioli Medeiros and Marcelo Tadeu Motokane. The study describes how students experiences during an inquiry-based learning project informed the way they perceive scientists and what scientists do. The second one by Pascal Pollmeier and Sabine Fechner focuses on scientific creativity in the context of data analysis. In this study, the students were confronted with two experiments which contradicted each other with regard to the underlying theory. The authors found that most students did not take anomalous data into account in their modelling processes and the students working on their theory scored higher in the post-questionnaire. In conclusions they propose that creativity should be taught in school science in order to make students aware of their own creative potential.

Two papers focused on pre-service teacher education. Stefan Müller and Christiane S. Reiners present a study examining pre-service science teachers´ conceptions about the tentative and sociocultural nature of scientific knowledge. As public discussions about socio-scientific issues requires understanding of limitations of science, these two aspects of NOS are an important component of scientific competence for citizenship. The results of the study show that the conceptions about these aspects of NOS are also rather resistant to change. The paper by Cristina Cobo Huesa, Ana María Abril Gallego and Marta Romero Ariza reports a study on evaluating the impact of an intervention intended to improve pre-service teachers' understanding of epistemological and sociological aspects of NOS. This design-based study integrates inquiry-based teaching and the history of science through an explicit and reflective instruction, embedded in the scientific controversy of the spontaneous generation theory. The authors conclude that the combination of inquiry and the history of science, along with explicit reflections about NOS, can improve pre-service teachers' understanding of epistemological and sociological aspects of science.

Two of studies carried out in Greece focused on in-service teachers. Dimitrios Schizas and Dimitris Psillos investigated how in-service physics teachers understand the unique features of school physics and biology. They used a theoretical framework on the notion of worldview and important differences that exist between the Newtonian and the neo-Darwinian worldviews. In the other study, Anna Koumara and Katerina Plakitsi designed a development program for science teachers. Using the cultural historical activity theory as a guiding framework, the program combined history of science, scientific inquiry and socio-scientific issues to meet the needs of the teachers and their students.

The last paper by Daniele Trajano Raupp, Tania Renata Prochnow and José Cláudio Del Pino presents a brief analysis of how historical aspects related to stereochemistry are addressed in Brazilian high school textbooks. The results indicate that there is a deficiency in the historical approach, possibly due to the textbook authors' lack of formal education in the history of science. They also point out that chemistry teachers' heavy reliance on textbooks when selecting the historical content to be included in their classes, can contribute to a poor understanding of historicity by their students.

STUDENTS VIEWS ABOUT SCIENCE AND SCIENTIST

Anne Caroline de Freitas[1], Michele d. Facioli Medeiros[2] and Marcelo Tadeu Motokane[3]

[1, 2, 3] University of São Paulo, Ribeirão Preto, Brasil

Science education should enable students to use instruments of science, to comprehend ways of producing, to legitimate and to disseminate knowledge. However, science teaching has been historically characterized by valorization, reproduction and memorization of contents. Consequently, science is pointed out as unquestionable, neutral and dissociated from socio-political aspects. Thus, this study aims to analyze students' views about science and scientists. The students who participated in this study, attended in a project along four years which their science classes were planned and executed considering the Inquiry Based Learning. In this study were evaluated textual productions from the questioning: "Who is the scientist?" and "What do the scientists do?". A lexical analysis by ALCEST software was done. The four lexical classes made by this software were later analyzed qualitatively in association with the visions about nature of science established in literature. Our data show that the students identified science as: composed of different areas; its relationship to society and the usage of different tools and procedures that involve various inquiry methodological steps. As discussed here, these results could be associated with the students' teaching context.

Keywords: Nature of science; Inquiry-based Teaching; Quantitative methods

INTRODUCTION

Science is characterized as a knowledge corpus composed of its own particular norms, values and principles that lead actions and procedures involved in the construction and dissemination of scientific productions (Sasseron, 2015). It involves the development of technical skills such as using specifics equipments; researching skills as: raising hypotheses, making predictions, organizing information, planning experiments, creating models; and also communication skills (Driver, Newton & Osborne, 2000; Carvalho et al., 2013; Dushl, 2016).

Considering this, scientific education should allow students to associate different ways of knowledge construction and how scientists do their studies (Abd-El-Khalic, Bell, & Lederman, 1997; Lederman et al., 2019). However, science teaching has historically been characterized by contents valorization, reproduction and memorization. Consequently, science has been pointed out as unquestionable, neutral and dissociated from socio-political aspects (Fernández, Gil, Carrascosa, Cachapuz & Praia, 2000). Thus, the school context often reproduces stereotypes published in media, reproducing a naive view of scientific production (Morais & Andrade, 2009). These naive views may distance students from scientific culture; interfere on understanding specific issues about nature of science; create a barrier in learning (leading to demotivation in science classes) and consequently this student will face barriers to participate in decision making in their social surroundings (Cachapuz et al., 2011; Kominsky & Giordan, 2002; Fernandéz et al., 2001).

Considering this, is important to identify students conceptions about nature of science in order to elucidate their proximity to scientific culture. So, studies in this perspective contribute to reasoning about current didactics approaches in science teaching and how its reflects on teaching-learning process.

Despite studies highlighted the relevance of analyzing students conceptions about science and scientist, there is a lack of studies which investigate relations between didactic approaches and students views.

In this perspective, this study aims to analyze students' views about science and scientists.
