The participants of this research are students from the first year of high school (15-16 years old). They were from a public school and attended along four years in a project which their science classes were planned and executed with the assumption of Inquiry Based Learning (Munford & Lima, 2007; Motokane, 2015). For the National Science Education Standards (NSES, 1996), the Inquiry Based Learning has some essential elements in science classes such as engaging students in solving scientific problems, enable them to prioritize evidences to solve this problems, construct explanations with scientific knowledge, and finally, communicate and justify their explanations. According Bybee in the book Scientific Inquiry and Nature of Science, edited by Flick e Lederman (2006), science doing is composed by some fundamental suposings as data collecting, logical reasoning, substantiate explanations with reliable evidences. So, for this author, this didactic approach may promotes a wide comprehension of nature of science and science inquiry. Therefore, as students experience these essential aspects of Inquiry Based Learning, they become even more aware of scientists' practices and ways scientific knowledge is constructed and structured; getting close to scientific culture through creation of an investigative context (Sasseron, 2015).

Besides that, throughout the four years which the students participated in the project, classes were planned and applied in collaboration with the same teacher, who is also a member of our research group.

In this study we characterized 67 written texts produced from the questions: "Who is the scientist?" and "What do the scientists do?". We analyzed the transcriptions of the texts by using the ALCEST software 4,5 (Analyse Lexicale par Contexte d'un Ensemble de Segments de Texte). This tool provides a lexical quantitative analysis regarding word repetition and succession, creating thematic groups (classes). These lexical classes are formed by Units of elementary context (UECs) (Kronberger & Wagner, 2013), which are segments of texts. Thus, each class is composed by different UECs, from classification and distribution of words. It is produced by the frequency and by the $\chi 2$ distribution of the vocabularies.

Besides that, the software produces a plot that illustrates the descending hierarchical classification (DHC), representing the fragmentation of the textual corpus and the relationships between the different classes. Other stages of analysis were done qualitatively with the intention of identifying the meanings presented on the lexical classes in association with the visions about nature of science established in literature. These data constructed by the authors were discussed and validated by experts.

FINDINGS

From qualitative analysis, we named the classes generated by the software considering the content words and context words (UEC's). The following examples represent the classes, with the categorization made by the authors and representatives UECs for each one:

Table1. Categorization made by the authors according to ALCEST data: content words (in bold) and UECs for each class.

Class	Content words	UECs	Category
1	**chemistry, area, science, fact, biology, evolution**	"The scientist **studies theories of science**. There are several **areas** to be **studied** in **science**, **for example, chemistry, biology, historian, humanities**, astrology, among **others**. **Theory** is what **has already been** confirmed into a certain point." " **Physic** and **science** norms that conduct to a **nature** phenomena, how they are susceptible to be represented by experimental observation, and put them in logical schemes"	Areas of scientific studies
2	**discover, thing, machine, medice, laboratory, do, day, experiment the, for**	"The scientist proves **very important things for** our **day** by **day**. Also, scientists **do very interesting things like** studying **their** students **to be** their **future** substitutes, bringing **future to** their country." "Scientist is the one who studies science, he **discovers and invents** things like objects, robotic **machines and experiments**."	Results of scientific studies
3	**criate, hypothese, universe, society, subject, prove**	"**His work** is exercised doing research, studies, collected **information**, analysis of samples, **creation** of theories, etc. to **try to prove** their theories **create hypotheses and proving** their theories take **information to society** " "**His work begins**, **but** his ideas, **research**, and testing **will work out** or not and **they** ask for **help** from other scientists to **improve** their **experiment**"	Methodologies of scientific studies

The data analysis indicated that students' speech about science and scientist is based on three aspects characterized by the categories created: (i) Scientist’s acting areas; (ii) Results of scientific studies and (iii) Methodologies of scientific studies.

It is important to highlight that views presented here are not isolated or independent, it associates and complements each other, setting up a global panoramic of science perception (Fernandéz et. al 2000). Thus, when analyzing representations about scientific doing and associate them to views about nature of science is important to consider that their relations made up a conceptual framework (Driver & Oldham, 1986; Fernandéz et. al 2000).

The assignments made by the students point out a wide comprehension of the scientific community composed by different areas (noted in classes 1 and 2 – see Table 1). This is mainly featured from roots of words as **chemistry, biology, physic, area**; which describe class 1. It is worth to mention the indication of “human sciences” and the “historian” as a scientist, that represent a broad understanding of the scientific culture; relating science to its social and human areas. Also, this perspective reveal a refusal of the unproblematic and ahistorical view.

Besides that, students were able of recognize the limitations of science knowledge and the perspectives that open up to the present society (Fernandéz et al., 2000) as noticed in class 1 ("**Theory** is what **has already been** confirmed into a certain point."- Table 1) and class 3 ("and testing **will work out** or not - Table 1). In these classes students approached the non-linear conception of scientific doing, that is represented by a continuous search for revisions of results (Fernandéz et al., 2000). These beliefs contrast with an "experimentalist reductionism", which corresponds to a simplistic view of scientific work (Fernandéz et al., 2000).

In this sense, by highlighting society as belonging to the process of scientific production ("**and proving** their theories take **information to society"** - Table 1), the student portrayed the social character of the construction of knowledge, distancing itself from a neutral image of science. This conception approached the collective, social and historical understanding of scientific studies and disconnecting itself from the view of the scientist as a genius who holds the absolute truth, living in a "kingdom apart from society" (Bizzo, 2009).

We can see from UECs and content words from class 2 that it represents “Results of scientific studies”. This class has peculiarities as a broader appe of scientific production and applications as noted in "Also, scientists **do very interesting things like** studying **their** students **to be** their **future** substitutes, bringing **future to** their country. (Table 1)" In this UEC, students understood even educational researches as a scientific practice and how it relates to society.

Furthermore, these textual productions presented an apprehending of the construction and dissemination of scientific knowledge, proper to the investigative process of nature of science such as the work with data ("studies, information collected"); the survey of possible solutions to the problem ("hypotheses"); tests ("analysis of samples"); conclusions ("creation of theories") and scientific dissemination (“take information to society”) (Carvalho et al., 2013).

Understanding these moments belonging to the investigative context, their science classes have approximated the student to aspects about scientific doing (Sasseron, 2015). In this sense, the student have not shared a cumulative, linear and rigid visions about the structuring of scientific knowledge.

Getting in touch with such fundamental steps of investigative process by Inquiry Based Learning, students are able to resignify stereotyped views about scientific work. In this way, this didactic approach may be related to distance students from views massively reproduced in media. Thus, this overview comprehension leads students to argumentation and consequently act in their society considering scientific knowledge (Sasseron, 2015).

In this context, it is noticed that these students have contacted and accessed to lexical and epistemological repertoire of scientific knowledge that can be use to make explanations of natural and social phenomena more accurately (Castro, 2017).
Therefore, learning concepts and scientific theories get more significance since concepts and theories are then situated in its own production context (Gil Pérez & Martínez-Torregrosa,1987; Mundord & Lima, 2007).

FINALS CONSIDERATIONS

Results found in this study could be related to the teaching context in which the student were attended, since the Inquiry Based Learning has the purpose of create an investigative context, specific to the science community (Motokane, 2015). By getting in touch with such fundamental situations of the investigative process, they are able to contrast the scientific knowledge with views that are known by society, resignifying stereotyped and naive views about science and scientific work.

Thus, this didactic approach promotes the comprehension regarding science and technology, society and the environment (Sasseron, 2015). Therefore, contributes to student's citizenship education, whereas they may be able to reason and consciously participate in situations that involve decision making and positioning about scientific issues.

So, studies approaching views about nature of science is extremely important to analyze the students' proximity to scientific culture. In this field, these data also lead to possible gaps on the current didactic approaches used in science teaching and how it relates to the teaching-learning process and student's decision- making in their society.

CREATIVITY IN DATA ANALYSIS THROUGH CONFRONTATION WITH ANOMALOUS DATA

Pascal Pollmeier[1], Sabine Fechner[1]
[1]Paderborn University, Paderborn, Germany

Creativity is perceived to be one of the core competences to succeed in the modern world. It is connected to art, music, dancing, etc., but there is just little insight into the role of creativity in science. As data analysis plays a major role in science, creative thinking has to be used to form theories out of observations. This study uses models-of-data to represent the mental model of the students. Within models-of-data different observations and previous knowledge are linked through different types of links, e.g. causal links. The goal of this study was to examine the creative aspect of data evaluation in presence of anomalous data. The students were confronted with two experiments which contradicted each other with regard to the underlying theory. Afterwards the students were asked to decide about their favored theory and reasoning about their choice in their lab reports. The model-of-data, which was reconstructed from the lab reports of the students, was used to extract creative aspects in the mental modelling process.

Furthermore, a pre-post-questionnaire on epistemological beliefs of the students was conducted. Students mostly acquired an unscientific view on epistemology in school. The question was whether the confrontation with anomalous data and the triggering of creative modelling processes have any influence on this.

The results show that most students did not take anomalous data into account in their modelling processes. They did either not recognise or just ignore the data. Just a few students worked on their theory because of the new, contradictory data. The students working on their theory scored higher in the post-questionnaire, so a positive effect of creativity on scientific epistemology can be assumed. Thus, creativity obviously gets a part of science and should be taught in school science in order to make students aware of their own creative potential.

Keywords: epistemology, conceptual change, anomalous data

BACKGROUND AND RATIONALE

Data analysis is a crucial process within science education. Students have to deal with data to construct evidence and enlarge their theory. Even if this process seems to be much straight forward, creativity is needed to do so (Ertl, 2010; Kind & Kind, 2007). Like Kind and Kind (2007) mention, creativity is “the ability to produce novel and appropriate work” (p. 1). In the field of philosophy of science one can find many theories about how knowledge is constructed (Kuhn, 1996; Lakatos, 1978; Popper, 2005). Every theory of knowledge acquisition or the structure/nature of knowledge includes elements of creativity, but often it is not directly referred to. Because of this flawed classification of creativity in the scientific process, students do not perceive their own creativity in a scientific context (Braun, 2011). Even in modern, kind of scholastic versions of knowledge acquisition theories like “conceptual change theory”, creativity is not mentioned directly (diSessa, 2002; Limón, 2001; Posner, Strike, Hewson, &

Gertzog, 1982). This favors the connection of creativity to arts, but more heavily the separation from science. However, theories of NOS (nature-of-science) define creativity as a crucial part of epistemology (Lederman et al., 2002).

Furthermore, the modelling process is full of creative tasks that can be made visible through the generation of models-of-data (Chinn & Brewer, 2001). Models-of-data enable us to see the linking between different knowledge aspects, which differ in their creative level. Besides the creative level of links, model-of-data can give information regarding the epistemology of the students. Creativity and epistemology are directly linked to the question whether creativity is needed to generate knowledge. In the next section I will give an overview of the linking and nature of this to conceptual understanding.

THEORETICAL FRAMEWORK

Creativity has its roots in the 1950s and the presidency of Joy P. Guilford of the American Psychological Association (APA) (Plucker, 2001). After his presidential address, creativity reached more attention and many different researchers worked in this field. Creativity was first assumed to consist of convergent and divergent thinking (Simonton, 2012). Divergent thinking seems to be the "more creative" task, wherein students have to think about a problem in various ways, or from different perspectives. By doing so, they may find more possible solutions. This simple definition of creativity seems to be too narrow, so more research was conducted regarding influencing factors of creativity. Attention was given to environmental influences like socio-cultural influences (Funke, 2000), multiculturalism (Simonton, 2012), social embeddedness (Massoudi, 2003) and much more. A conclusive definition of creativity would include the personality, intelligence and identity of a person (Simonton, 2012) as well as different environmental factors, most importantly freedom, space for thinking and the process itself (Funke, 2000).

As Kind and Kind (2007) assume, creativity has a clear connection to scientific modelling processes. Anomalous data is well known to trigger cognitive conflicts which can be seen as starting points for theory processing. In *conceptual change theory*, there is a long tradition of research focusing on this field (Limón, 2001; Posner et al., 1982). However, most of this research does not include creativity. The integration of anomalous data in the existing mental, theoretical network can be visualized in so-called *model-of-data* (Fig. 1). *Model-of-data* are visual representations of the cognitive system of observations with explanatory approaches in an inquiry setting (Chinn & Brewer, 2001). These models contain observations and previous knowledge, set in relation by different types of links (e.g. causal link, inductive link, etc.). The different links between the aspects reveal different degrees of creativity. As can be seen in Figure 1, some of the links, e.g. 6 → 7 are simple causal links. But there are more creative links too, e.g. the analogical link of aspect 6-9 with aspects 10-13. Causal links sometimes are obvious, but this analogical link must be explored through cognitive processes. Once explored, it is not self-evident, that the link or aspect gets part of the theory. Before integrating the aspect, there will be a plausibility-check for the whole theory (Chinn & Brewer, 2001). With the help of models-of-data the creative modelling process can be examined in a relatively direct way. It is important to reflect the role of epistemology in connection to creativity. It is assumed, that a higher creativity level leads to a more informed epistemological insight.

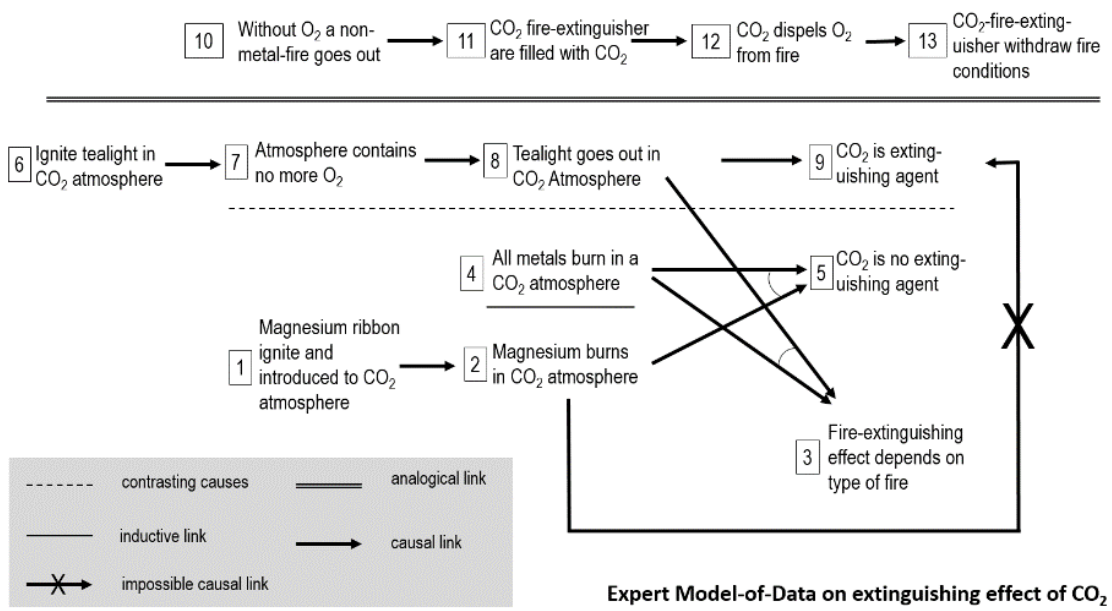

Figure 1. Example model-of-data for burning conditions of selected substances and the extinguishing effect of CO_2.

To create a model-of-data and reflect about epistemology it is necessary to create information which could be processed. Therefore, anomalous data can be used, as they are a crucial component of the conceptual change process (Posner et al., 1982). Chinn and Brewer (1993) postulate seven different ways of reaction to anomalous data. Most ways (5 out of 7) deal with ignoring anomalous data because of different reasons (e.g. "holding anomalous data in abeyance" (Chinn & Brewer, 1993, p. 8)). There are two ways of theory transformation which differ in their degree of change. There can be minor changes in the peripheral region of the theory or major changes on the core beliefs of the students.

RESEARCH AIM

The main aim of this study is to identify creative aspects in the data evaluation task in presence of anomalous data in a lower secondary school science course. In addition, the induction of a conceptual change through anomalous data can be evaluated.

RESEARCH DESIGN AND METHODS

In this study, grade-7 students (N=30) were confronted with anomalous data regarding the extinguishing effect of carbon dioxide. At first the students observed the attempt to extinguish burning fat with water as opposed to carbon dioxide. Before this observation the students were encouraged to form their own hypotheses. In a second experiment the students had to form hypotheses and observe burning magnesium in a carbon dioxide atmosphere. This experiment served as confrontation with anomalous data because the ongoing redox reaction can be observed. Afterwards the students had to decide, if carbon dioxide is an extinguishing agent or not. To force the students to a distinct statement, they had to formulate a mnemonic. In view of epistemology the students were encouraged to ask for further information they need to formulate the mnemonic.

To collect data, the students had to fill up a lab report for the whole intervention. The lab report was structured by the author to keep the students' focus on the experiments and hypotheses instead of creating a lab report. The data generated through this report served for setting up the model-of-data of the students by the author and the categorization into the categorical system of Chinn and Brewer (1993). Additionally, a pre-/post-questionnaire with closed and open items was conducted. The open items generate a qualitative access and were adapted from existing nature-of-science questionnaires (Lederman & O'Malley, 1990; Schwartz, Lederman, & Lederman, 2008). Similarly, the quantitative part of the questionnaire was adapted from established nature-of-science questionnaires (Lederman, Abd-El-Khalick, Bell, & Schwartz, 2002; Meichtry, 1992). Table 1 shows some of the items and the categorical system.

Table 2. Scales, items and sources of the pre- & post-test.

Scale	Number of items	Sources	Example item
Creativity	5	Lederman et al., 2002; Schwartz et al., 2008; Meichtry, 1992	Scientists are creative.
Scientific process	4	Lederman et al., 2002	Does the development of scientific knowledge require experiments?
Data as preliminary source of knowledge	3	Lederman et al., 2002; Schwartz et al., 2008	When you use the word 'prove', what do you mean?

In addition to the items presented above, some items were added by the author which could be rated on a four-point Likert scale. With this self-generated items, it is possible to draw attention on various aspects.

The combination of the qualitative and quantitative approach within the questionnaire and the in-depth information out of the lab reports enables to have a closer look on the creative modelling processes.

RESULTS

At first, a reliability analysis was conducted to evaluate the compiled questionnaire. This analysis resulted in poor values, so a factor analysis was conducted. Table 1 shows the scales after re-categorization through factor analysis. In a previous attempt, the category 'data as preliminary source of knowledge' was divided into the categories 'data' and 'tentativeness of scientific knowledge'. Also some items were sorted in different categories

Table 2. Cronbachs-Alpha values for the recategorized scales.

	Pre-test	Post-test
Creativity	.477	- .067
Scientific process	.688	.289
Data as preliminary source of knowledge	.169	.683

regarding to the new categorization. Table 2 shows the reliability values for the re-categorized scales.

As one can see, the reliability values after the factor analysis are not very well at all, but in case of the few items and a small sample some concessions can be made.

In a pre-post comparison, a significant effect can only be found for the perception of creativity (t=1,976, p=.03, N=23, d=0,40). All other categories do not reach a level of significance (p > .05). With a view on the open items no big differences can be observed. A few answers are a bit more advanced, so the students were more precise e.g. in mentioning important steps of the scientific process. Furthermore, the communicative nature of science got clearer for the students in the post-questionnaire. They mentioned that scientist have to talk about their findings, to generate new evidence.

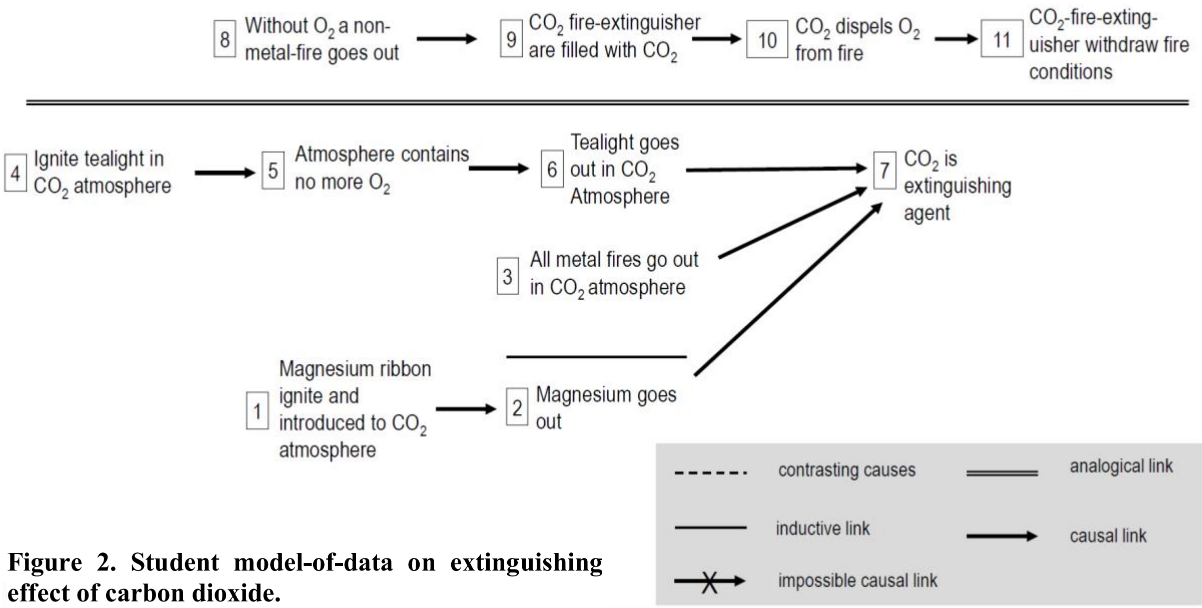

Figure 2. Student model-of-data on extinguishing effect of carbon dioxide.

Furthermore, the students had to compare the work of scientists with their own work and they saw many similarities in that. Especially the process of scientists and students seems to be similar, whereas the state of knowing differs. The students said, that they know what should be the outcome of an experiment, because some scientists conducted the experiment earlier (BA12). When these scientists conducted the experiment, they do not know what would happen, so this is a big difference between students and scientists.

Next to the questionnaire, the lab report can provide information regarding the modelling process. Figure 2 shows the reconstructed model-of-data for the students' view on the extinguishing effect of carbon dioxide. As can be seen, the students used very few different types of links between the events. Causal links are overrepresented, whereas some links do not exist (e.g. contrasting link & impossible causal link). The whole model-of-data is conclusive for the students, there are no contradictions. With regard to the demonstrated experiments, some of the events are incorrect, which leads to a model-of-data which differs from an expert view in Figure 1.

The most important difference of the students' model-of-data and the expert ones can be seen in event 2. While the experts observe the ongoing reaction of magnesium in carbon dioxide, the students observe a fire in the process of being extinguished. The observations differ, which can also be explained by the students' reaction to anomalous data. Figure 3 shows the distribution of responses to the anomalous data of the students: Most students ignore the anomalous data, which means they recognize the contradictory character of their observation, but do not deal with it. This distinction is important because there is a second group which not dealing with the anomalous data, but also not noticing them as contradictory. Furthermore, there is a small group of students which worked on their initial theory. Some changed their core beliefs (theory change), some changed peripheral aspects of their theory (peripheral theory change). Regarding the group "Theory change" it must be stated that the students of this group did not reach the expert theory. Their initial theory was about the missing extinguishing effect of carbon dioxide, so they changed their theory to "carbon dioxide is an extinguishing agent" after they take the observations shown in Figure 2. Students in the group "peripheral theory change" just changed aspects of their theory. For example, some students thought about the amount of carbon dioxide which is needed and the correlation of it to the speed of the extinguishing process. This group processed a change on the "protective belt" (Lakatos, 1978, p. 48) of their theory, without affecting their core beliefs. The students of these two groups who worked on their theory even scored higher in the post-questionnaire.

DISCUSSION AND CONCLUSION

All in all, the study shows that the students use creative mechanisms while modelling, but in a very limited scope. With a look on the student's model-of-data in comparison to the expert one's, two aspects could be emphasized: First, the students use less creative links. Like mentioned above, students mostly use causal links. Causal links belong to less creative links in comparison to the other possible links. While contrasting causes and impossible causal links require divergent thinking, causal argumentation has a more convergent character. By including convergent thinking, a certain level of creativity is reached. A more advanced level needs more types of thinking and a degree of freedom, which can be achieved by divergent thinking. Second, the students use less links at all. While experts build a strong network of their events, the students build up less connections and reach a lower level of interconnectedness. A possible explanation of these big differences between students and experts could be seen in the previous knowledge. Experts have a huge amount of knowledge and profession in their field, while students are novices. Additionally, students are not as experienced in theory construction as experts, so that it is a big challenge for them to construct a theory, even if it is not that complex.

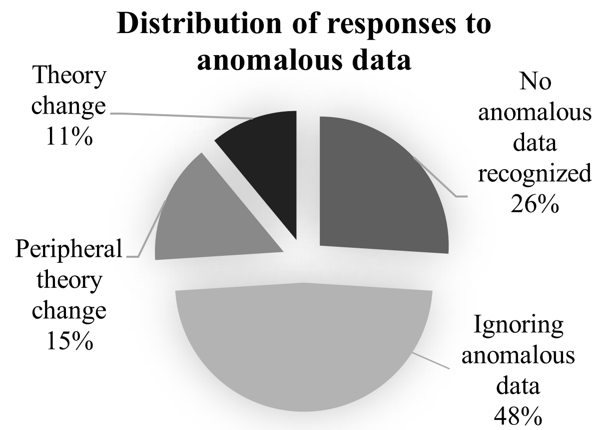

Figure 3. Distribution of responses to anomalous data.

Furthermore, the knowledge in the field of epistemology and overall meta-conceptual awareness can have an influence, which leads directly to the content of the questionnaire. As described earlier a significant effect was just found for the category “creativity”. One can say, the modelling task and confrontation with anomalous data seems to influence the understanding of creativity. The students worked creatively in the lesson and learned on a meta-level, too. The implicit confrontation with creative activities can help to reach a better understanding, but just in a limited amount. The effect size is not large (d=0,40), but it was not expected to be large without an explicit theming of creativity. With a look on the other categories one can see the stability of epistemological beliefs. For example, the average of category “data as preliminary source of knowledge” in pre-post-comparison differs about ΔM=0.2 (M_{pre}=2.93; M_{post}=2.73), for category “scientific process” the mean difference is even smaller with ΔM=0.014. It gets clear that core assumptions about epistemology are such entrenched, that they will not change through a 60-minute intervention. More time and repetitions are needed to consolidate an informed epistemology. However, although this intervention has potential for optimization, the “creativity”-category showed up a positive connection between creativity and epistemology. If there would be more work like this in school, the students can be assumed to expand their epistemological beliefs.

What remains unclear with regard to the model-of-data is the ignorance of many students to the anomalous data. First it is questionable why some students do not recognize the anomalous data. It might be possible, that these students have very entrenched initial theories, so that they sort anomalous data out just because it does not fit their theory. This process then takes place before any observation is documented, therefore no anomalous data can be seen in their lab reports. A possibility to prevent such processes would be to give precise observation tasks. A clear structure might help the students to document every observation and thus a separation of observation from analysis is possible. Second, it must be asked, why such a huge amount of students ignore the anomalous data even though they observed them. Besides the entrenchment of initial theory, what might play a role here too, the reason may lie in the anomalous data itself. Like Posner et al. (1982) state, there are some presuppositions for accommodation what mainly means to build up a new theoretical background for upcoming information. One presupposition is comprehensibility of the new concept. The students have to imagine a new concept to explain the anomalous data. Maybe there is a lack in theory building, respectively previous knowledge, which seems to be crucial for theory construction. When the students cannot imagine a new theory to explain new data, they may stick to their initial theory. This adoption can be underpinned by Kuhn’s (1996) theory of scientific revolutions. If there is no alternative to the existing theory – with which the students are dissatisfied – they will stick to the ‘old’ theory. The expert theory, which is taught in 8-9 grade in Germany, seems to be too complex and ‘out-of-reach’ of the students. Also the quality of the anomalous data can be reanalyzed. The anomalous data must be meaningful, otherwise they might rebound on the protective belt of the initial theory. Quality can be discredited in many ways. Besides the meaningfulness there can be problems with the source of data (Is the source believable?), the methodology of generating the data (How was the data generated?), etc.

In the model-of-data it gets obvious, that students use creative thinking. For example, the inductive and analogical links in Figure 2 show aspects of divergent thinking. Even causal links have a creative portion, which seems to weigh more for the students than the experts. Experts have a huge amount of knowledge, so it might be more easy to draw causal links. Students lack of previous knowledge in most scientific areas, accordingly causal linking is difficult.

To sum up, the intervention is suitable to make students aware of creativity in science. Because of the higher scoring of students who worked on their theory in the post-questionnaire, a connection of creativity and epistemology can be assumed. However, an overall effect on epistemological beliefs cannot be observed. This may due to the fact, that beliefs are very stable and students do not change their whole epistemology or entities just because of an irritation resulting from anomalous data. To reach higher effect sizes, the quality of the anomalous data should be reviewed. The main goal of this study was to influence epistemology through creativity, not to enlighten the thematic focus. This does not mean that the thematic focus is irrelevant, but even if the students do not reach the expert theory, the intervention can be successful. When students work creatively, they have the best opportunities to work like real scientists (Chinn & Malhotra, 2002) and enhance their epistemological beliefs.

TENTATIVENESS AND SOCIOCULTURAL EMBEDDEDNESS – RESISTANT MYTHS ABOUT NATURE OF SCIENCE?

Stefan Müller[1] and Christiane S. Reiners[2]
[1,2]Institute of Chemistry Education, University of Cologne, Cologne, Germany

An adequate understanding of Nature of Science is a necessary condition for social participation. With regard to current controversial public discussions about socio-scientific issues, it seems particular important that students have adequate ideas about the supposed limitations of science. However, recent studies have shown that many preservice science teachers believe in myths regarding the tentativeness and sociocultural embeddedness of scientific knowledge and that their conceptions about both aspects have been resistant to change.

The purpose of our research project is to investigate preservice science teachers´ conceptions about the tentative and sociocultural nature of scientific knowledge, the origins of this conceptions and their resistance to change as well as possibilities of altering them in teacher education. In a first study, forty-one preservice chemistry teachers participated in a curriculum-oriented Nature of Science course, designed in the sense of the Conceptual Change Theory. Data were collected by using questionnaires, interviews, classroom artefacts and participatory observation. Results indicate that while the preservice chemistry teachers mostly held only partially informed or inconsistent views about both aspects at the beginning, the intervention mostly leads to much more informed views regarding the sociocultural embeddedness. However, the intervention also led to a certain degree of uncertainty for some participants with regard to the tentativeness of scientific knowledge. In addition, it turned out that the origins of the preservice teachers´ conceptions are very diverse.

Keywords: Nature of Science, Conceptual Change, Initial Teacher Education (Pre-service)

INTRODUCTION

With regard to current debates on “fake science”, “alternative facts” and controversial public discussions on socio-scientific issues, it seems particularly important that students become empowered to evaluate scientific processes and publications adequately. Therefore, adequate ideas about not only the strengths, but also the limitations of scientific knowledge are necessary (McComas, 1998). Students should be particularly aware of both the tentative nature of scientific knowledge and its social and cultural embeddedness (Osborne et al., 2003). Thus, in cases of public resistance to science “it seems that the main problem is not only the lack of understanding of the relevant science, but also—and perhaps most crucially — the lack of understanding of the uncertainty inherent in science.” (Kampourakis, 2018, p. 830)

The importance of an understanding of the tentativeness and the socio-cultural embeddedness of scientific knowledge is indicated in national science education standards documents (Olson, 2018). Nevertheless, little research in science education has focused on either or both of these two aspects of Nature of Science (NOS) in particular. A necessary condition for a thorough understanding of NOS on the student side is a teachers´ adequate understanding of NOS (Lederman, 1992). However, studies show that many preservice science teachers tend to have naïve views on both aspects (Abd-El-Khalick, 2006). Further, some recent studies indicate that misconceptions to some aspects of NOS are less likely to change then to other aspects, including views about the tentativeness and social cultural embeddedness of science. Both aspects seem to be especially resistant to change (Cofré et al., 2019). Mesci and Schwartz (2017) argue that one reason for this resistance to change is that the tentative nature of scientific knowledge contradicts the worldview of many future teachers. This is in line with Snow (1964), who criticized a large gap between the sciences and the humanities. Accordingly, for our study we derived the hypothesis that preservice science teachers´ conceptions about the tentative and socio-cultural nature of scientific knowledge are inadequate and resistant to change, because both aspects are more likely assigned to the humanities.

While most of the mentioned studies investigate conceptions of science teachers or preservice science teachers in general, there are no studies dealing specifically with views of preservice chemistry teachers about the tentative and sociocultural nature of science. Such an investigation seems necessary, because chemical knowledge plays a crucial role to understand contemporary challenges such as climate change or the expansion of regenerative energy sources. Therefore, adequate ideas of the strengths and limitations of this knowledge are essential for students to participate in public debates. Based on these considerations, the following research questions arise:

- Which conceptions about the tentativeness of scientific knowledge and its socio-cultural embeddedness do preservice chemistry teachers possess?
- Are these conceptions resistant to change?
- What are the origins of these conceptions and their resistance?
- How far are school-related contexts and NOS-activities suited to promote a more adequate and more functional understanding of both aspects among future chemistry teachers?

To answer the research questions different qualitative studies were conducted. Design and main results of an initial study, which mainly aims at answering the first three questions, are presented in the following sections. However, to assess views about NOS aspects, a clarification of the terms “tentativeness” and “sociocultural embeddedness” is necessary, and this dealt with in the following chapter.

THE TENTATIVE NATURE OF SCIENCE

The conducted studies are based on the following definition of tentativeness of scientific knowledge, which is also visualized in a diagram (see Figure 1):

From a philosophy of science perspective, scientific knowledge becomes reliable more and more over time, because it is empirically tested, valid for a long time and therefore very robust to changes (Osborne et al., 2003). Accordingly, scientific knowledge is widely accepted within the scientific community. In addition, most scientific theories have a high explanatory value and are almost free of inconsistencies. In this regard, scientific knowledge is durable (Abd-El-Khalick et al., 2008). However, all categories of scientific knowledge (theories, laws, constants, …) cannot be proven absolutely. Therefore, they are tentative as they are principally all subject to change (Popper, 1959). These changes can be slow and continuously or revolutionary (McComas & Olson, 1998). Scientific knowledge can change when new evidence and knowledge arise by conceptual or technological progress. Changes might also be due to reinterpretation of existing evidence and knowledge in light of new theoretical ideas or to changes in the cultural and social spheres (Lederman et al., 2002). It depends on the scientific community whether scientific knowledge is rejected, changed or partly changed (Kuhn, 1962). The principal tentativeness of scientific knowledge thus does not imply arbitrariness or unreliability of science. Far from it, the ongoing critical review and discussions by scientists, as well as the rejection of obsolete findings underline the durability and reliability of accepted knowledge. In this way, scientists are able to gain reliable knowledge approximately (Bell, 2009).

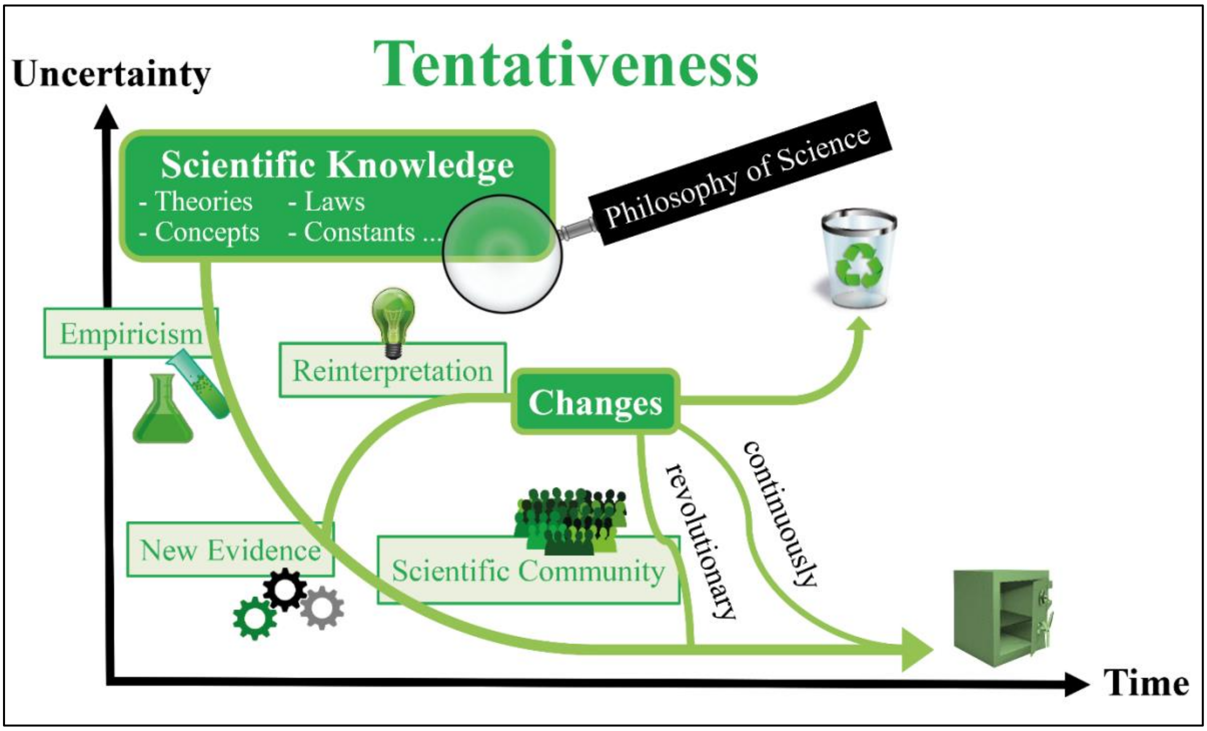

Figure 1. A scheme visualising the tentative nature of scientific knowledge.

The definition above (as well as the following definition of sociocultural embeddedness) is not intended to be passed on to students as declarative knowledge. But, it is rather a proposal and guiding framework for teachers to design competence-oriented learning environments (Allchin, 2013). In this way, learners should be able to participate actively in discussions about the certainty and trustworthiness of scientific knowledge.

THE SOCIAL AND CULTURAL EMBEDDEDNESS OF SCIENCE

Since science is a human enterprise, scientific knowledge is embedded in a wider social and cultural context (see Figure 2): On the one hand, scientific knowledge affects many elements and spheres of society and culture, for instance when new technologies are developed based on new scientific knowledge. On the other hand, scientific research is affected by numerous factors, including social fabric, worldviews, power structures, philosophy, religion as well as political and economic factors. These factors may influence the choice of research subjects, the way research is conducted (e.g. public funding for scientific research) and/or the final acceptance and dissemination of scientific findings by the scientific community or the society (Abd-El-Khalick et al., 2008; Kaya & Erduran, 2016). When analysing the sociocultural embeddedness of scientific knowledge, the historical context and the milieu of the time of the respective knowledge, should also be taken into account (Niaz, 2016).

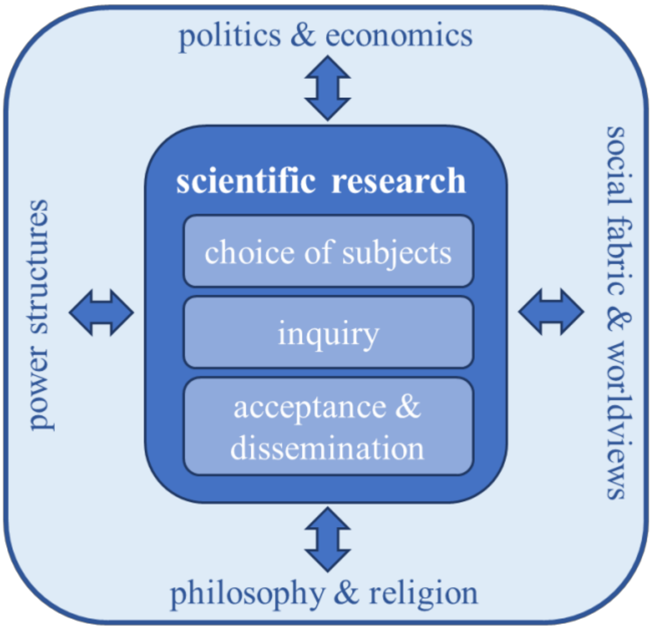

Figure 2. A scheme visualising the sociocultural embeddedness of science.

RESEARCH DESIGN AND METHODOLOGY

In two parallel chemistry education courses forty-one preservice chemistry teachers took part in a case study in 2018. To determine the participants´ conceptions about the two aspects "tentativeness" and "socio-cultural embeddedness" as well as their origins, a semi-standardized open-ended questionnaire was used as a pre-test, partly based on the VNOS-C questionnaire (Lederman et al., 2002). Additionally, semi-structured interviews were used for validation and for generation of more profound insights. During the following intervention classroom artefacts, portfolios and participatory observation were collected to validate the participants´ views in the sense of data and methodological triangulation (Flick, 2018). The participants finally completed the same questionnaire as a post-test, to determine conceptual changes.

Accordingly, the intervention itself was designed in the sense of the Conceptual Change Theory by Posner, Strike et al. (1982). Due to the conditions Posner, Strike et al. marked out, it was divided into three stages: During the first stage, the participants were encouraged to reflect on their own preconceptions. Therefore, they investigated characteristics of science. In the second stage, they had the opportunity to rearrange their views or build up new ideas about the social and cultural embeddedness of science and the tentative nature of various types of knowledge. For this purpose, the preservice teachers analysed and reflected historical and current case studies from chemistry, which are also relevant to the curriculum (for example the replacement of phlogiston theory, the discovery of quasicrystals or the current political influences on climate research). In addition, they carried out non-contextualized black-box activities, designed to illustrate both aspects. The last stage of the intervention aimed at applying their new ideas to chemistry teaching. Accordingly, the students analysed classroom situations and textbooks in which the aspects play a major role.

In order to answer the research questions, the pre- and post-test data from each participant were analysed using the qualitative content analysis according to Mayring (2015). Based on comparable studies (Miller et al., 2010; Mesci & Schwartz, 2017) the preservice teachers' views about both NOS aspects were assigned to a continuum of categories from naïve and inconsistent to increasing levels of "informed" (+, + +, + + +). A participant´s view about an aspect was assigned as naïve when it is contrary to the definitions above. For example, one preservice chemistry teacher regards scientific knowledge or at least a category of scientific knowledge as unchangeable:

> "Not scientific laws. They cannot be revoked, because other theories are based on them." [All German quotations in this article were translated by the authors.]

If the participant´s conception partially correspond to the definition, but partially also contradict it, it was encoded as inconsistent. The level of "informed" depends on the way of explanation: it is possible, that the participant argues only with the help of examples (+) or is explaining his/her view using a single argument (+ +) or provides a multidimensional and differentiated explanation (+ + +).

The Inter-Coder Reliability between the two coders is $p_0 = 0.9$ for views about both aspects, while the coefficient κ (Brennan & Prediger, 1981) is 0.83 concerning views about the tentative nature of science and 0.86 related to views of the sociocultural embeddedness.

RESULTS

The results of the assignment are presented in Table 1.

Table 1. Preservice teachers´ views about the sociocultural and tentative nature of scientific knowledge.

	Not classifiable	Naïve	Inconsistent	Informed +	Informed + +	Informed + + +
Views about the embeddedness of scientific knowledge in sociocultural contexts						
Pre-test	4	3	11	16	7	0
Post-test	0	0	4	12	14	11
Views about the tentativeness of scientific knowledge						
Pre-test	1	4	10	13	12	1
Post-test	0	5	5	21	10	0

Views about the sociocultural embeddedness of scientific knowledge

Related to the sociocultural embeddedness the preservice teachers´ views are relatively heterogeneous, but mostly inconsistent or only partially informed prior to the intervention. In fact, there is not a single participant with views on the highest level of "informed" in the pre-test. After the intervention, almost all of the participants possess informed views about sociocultural embeddedness with 11 future teachers having ideas on the highest level, such as:

> "Politics, particularly, influences science, whether by conditions of education and research or by research funding. […] Some research subjects also promise a high reputation, expressed in scientific mainstream. Furthermore, scientists are naturally human beings and as such social beings. […] Consequently, ethics also plays a major role. Finally, the fact that people often hold on to familiar concepts and therefore do not want to accept opinions contrary to their own ideas could affect the dissemination of scientific findings (see Daniel Shechtman and the discovery of quasicrystals)."

Overall, almost two third of the participants are more informed in the post-test.

In order to explain this significant conceptual growth and to identify the origins of their views, the participants were also asked to share experiences that shaped their views of scientific knowledge. Those inductively formed categories (Mayring, 2015) indicate that the embeddedness of science is not a common topic, especially not in school education (see Table 2). Many participants could not even name any experience related to this NOS element. Based on these results, the following conclusion arises: Conceptions about the sociocultural embeddedness are not resistant to change, but they barely exist due to a lack of discussion.

Table 2. Influences named by preservice chemistry teachers shaping their views of NOS aspects.

Views about the tentativeness of scientific knowledge

Tentativeness is discussed more often in science education (see Table 2), both at university and at school level. Therefore, a few more preservice chemistry teachers held informed views before the intervention compared to the sociocultural embeddedness (26 versus 23). For example, many participants mention the development and changes of different atomic models as examples of tentativeness. However, the majority has only partially informed or inconsistent conceptions (see Table 1). For instance, one participant believes that scientific knowledge can change and confirms this statement with an example:

> "Yes, the atomic model has changed again and again."

However, when asked about the differences between the sciences and the humanities, the same person also states:

> "In science, it is possible to prove hypotheses."

A context analysis was used to show that the term "prove" in this statement is not used in the sense of everyday language, but is to be understood as a distinction to the humanities and thus in an absolute sense. Accordingly, the participant was coded as inconsistent.

After the intervention, in total more preservice teachers have informed views than before (31 versus 26). In addition, the examples mentioned by the participants to explain tentativeness indicate that they associate their ideas more often with chemical content. However, the post-test results also show that some preservice teachers remain on the same level of understanding or even have less informed views about the tentative nature of science than in the pre-test. In summary, with regard to tentativeness two problems emerged from the study: First, preservice chemistry teachers are not able to explain their views and therefore mainly remain on the first level of information and second the intervention seems to unsettle some of the participants:

> "Now I think: Everything could be wrong, everything could be right. No one knows."

That means the intervention is suitable to initiate the cognitive conflict necessary for a conceptual change, but it is not suitable to solve it. For this purpose, the movies, TV shows and books, mentioned by the preservice teachers as influences on their conceptions about science (see Table 2) might be useful in further studies, to create cognitive conflicts and initiate further conceptual changes.

Another finding is that before the intervention, the participants´ conceptions about tentativeness are often restricted to models and theories, but less to other types of scientific knowledge (see Table 3). During the intervention, there is an improvement concerning other categories of changeable knowledge. For example, laws, constants or conceptions are mentioned more often as subject to change in the post-test. Nevertheless, theories and models remain the most frequently mentioned examples.

Table 3. Categories of changeable scientific knowledge mentioned by preservice chemistry teachers.

Theories/Models	37	57
Data	6	19
Laws	5	10
Classification systems	4	3
Definitions/Concepts	3	25
Hypotheses	2	1
Universal constants	0	11
No entry	1	0

The two cultures

Some statements of the participants, who made great progress in regard of both aspects, show that after the course they see more similarities between science and humanities. As an example, we look at the participant GK59: He is a male preservice teacher and studies chemistry and biology in the 4th semester at the University of Cologne. His views about tentativeness and sociocultural embeddedness during the pre-test were assigned as inconsistent. When asked, which ways of thinking and working he considers characteristic of science or the humanities, he reveals views that correspond mainly to scientism:

> "In addition, scientific methods are objective and reproducible. [...] In the natural sciences, facts and the research path are what matter. In the humanities, this is not the case."

However, the post-test questionnaire and post-interview reveal that GK59 holds informed (+) views after the intervention. Additionally, he sees more similarities between the sciences and the humanities:

> "I don´t remember what I had written, but I was more of an idealist than a realist. Scientists are not perfect. They are always influenced. A lot of things have changed for me."

Consequently, there seems to be a connection between adequate ideas about science on the one hand and bridging the gap between the two cultures on the other. This connection has to be fostered in the future. At the same time, it should be noted that some perils arise from epistemic relativism (Romero-Maltrana et al., 2019).

CONCLUSIONS AND DISCUSSION

The initial question was: Are conceptions of the two NOS aspects - tentativeness and sociocultural embeddedness - resistant to change? Based on the presented results and related to preservice chemistry teachers, the answer has to be: to some extent. The intervention led to a significant higher level of information about the sociocultural embeddedness of scientific knowledge. Accordingly, views about the embeddedness appear to be not that resistant. It seems that this NOS-tenet is simply neither often reflected nor in detail, neither within science education nor in public. Consequently, it should be taught in a more multidimensional way within science education, addressing the different dimensions of embeddedness (see Figure 2). For example, using different contexts, non-contextualized activities and structural aids turned out to be most helpful for a conceptual growth.

On the other hand, the resistance of misconceptions about tentativeness of scientific knowledge could be confirmed, because the participants are not able to explain their views. Furthermore, those views are often restricted to theories and models and less to other types of scientific knowledge. Last but not least, the intervention unsettles some students.

Consequently, a more differentiated discussion of tentativeness of all types of scientific knowledge is necessary to achieve a more adequate understanding. And to make it less likely that preservice teachers will be unsettled by such a discussion of tentativeness, the focus should also be on the certainty and durability of scientific knowledge. That's underlined by Clough (2007, p.2), who says:

> "Students who claim that science is tentative without acknowledging the durability of well-supported science knowledge can hardly be said to understand the nature of science."

First results of a subsequent study indicate that an approach, which takes into account the above considerations, is potentially suitable to promote a more adequate understanding of tentativeness. Accordingly, it is justified to describe the resistance to change of preservice chemistry teachers´ views about tentativeness as only "partly resistant".

INTEGRATING INQUIRY, HISTORY AND REFLECTIVE LEARNING TO IMPROVE VIEWS OF SCIENCE: DESIGN AND EVALUATION OF AN INTERVENTION

Cristina Cobo Huesa, Ana María Abril Gallego and Marta Romero Ariza
University of Jaén, Jaén, Spain

Scientifically literate citizens require an appropriate knowledge about science in order to acquire a good understanding of how science works and affects their daily life. This knowledge about science, which is known as Nature of Science (NOS), is considered a crucial aim of worldwide science education standards. For this reason, preservice teacher development adopts an essential role in this science educational scene, due to teachers' responsibility for promoting meaningful context to learn about science. Therefore, the purpose of this study consists in evaluating the impact of an intervention intended to improve preservice teachers' understanding of epistemological and sociological aspects of NOS. The intervention was developed using a design based research methodology. It integrates inquiry-based teaching (IBT) and the history of science through an explicit and reflective instruction, embedded in the scientific controversy of the spontaneous generation theory. Pretest-posttest differences between the experimental and the control group scores and the effect size are used to discuss improvements in the understanding of NOS after the intervention. Overall, the results show that the experimental group obtained a moderate progress and scored higher than the control one, with significant scores in three items applied in the evaluation. These results support the potential of combining inquiry and the history of science, along with explicit reflections about NOS, to improve preservice teachers' understanding of both key epistemological and sociological aspects of science.

Keywords: history of science, inquiry-based teaching, nature of science.

INTRODUCTION

An appropriate understanding of the Nature of Science (NOS) is one of the main aims of scientific literacy since it provides citizens a holistic view about how the scientific enterprise works and influences their life, to participate in socio-scientific issues democratically (Hodson, 2014; Next Generation Science Standards, 2013; OECD, 2019).

A consensus view has prevailed in the instructions focused on improving people's beliefs of NOS (Abd-El-Khalick & Lederman, 2000; Akerson, Abd-El- Khalick & Lederman, 2000; Lederman, 2007). This consensus view integrates a list of seven tenets, mainly referred to epistemological aspects of science. Nevertheless, despite of the fact this general view can be useful to start teaching NOS (Kampourakis, 2016), we consider not to reduce science to some simplifying aspects, but give a real image of its multiple relations with our contemporary social system, highly required in preservice and prospective teacher development courses. In that sense, in the last few years, many authors (Acevedo-Díaz & García-Carmona, 2016; Allchin, 2011; Dagher & Erduran, 2016) have reconceptualized NOS in their attempt to stand out the social system of NOS and to take into account multiple aspects of scientific practice, from the experimental to the social dimension, in a higher level of organization.

Regarding this broader sense about science, teaching NOS integrates an understanding about epistemological aspects, such as the nature of scientific knowledge (scientific theories, laws and hypothesis, the tentative nature of scientific knowledge) and the role and nature of scientific practices (observation, inference, modeling, classification, logical reasoning). Moreover, sociological aspects play an important role in this framework, highlighting the complex relationships between science-technology-society and those within the scientific community (personal scientific beliefs, motivations, professional scientific competence, acceptance of new scientific theories) (Manassero, Vázquez & Acevedo, 2001).

Besides the social need of NOS to take part into socio-scientific decision-making in our closest, regional or local, and global environment, the comprehension of NOS also fosters the human side of science, effective teaching-learning processes of scientific ideas and critical thinking (Driver, Learch, Millar & Scott, 1996; McDonald & McRobbie, 2012).

Despite these justified reasons, there are some obstacles in the effective instruction of NOS. On the one side, teachers' beliefs about NOS reveals they have an idealistic, empiric and positivistic view of science, which considers science as an absolute and static body of knowledge (Akerson, Erumit & Kaynak, 2019; García-Carmona, Vázquez-Alonso & Manassero-Mas, 2011; Lederman, 2007). On the other side, some experts sustain NOS is not relevant for real societal life and too demanding for students (Kötter & Hammann, 2017). Actually, the integration of NOS in curriculum increases the potential of instructions in fostering the understanding of science facts, theories and laws, as well as to humanize sciences (Acevedo-Díaz, García-Carmona & Aragón, 2017, McComas, 2011; Nelson, Scharmann, Beard y Flammer, 2019; Yacoubian & BouJaoude, 2010). As consequence, the improvement of preservice teachers' view of NOS is justified by the fact they cannot teach contents they do not know about or they do not find useful, suggesting the need to support them in developing a better understanding of this issue and showing them its utilitarian nature, through contextualized, noteworthy and effective teaching-learning sequences (TLS).

Researchers in the area claim that a higher effort should be placed on the design and evaluation of effective interventions to improve conceptions of NOS (Clough, 2018). In this sense, inquiry-based teaching (IBT) and the history of science provide powerful opportunities to recognize and understand key features of NOS (Abd-El-Khalick, 2013). An IBT approach mainly fosters the understanding of epistemological aspects of scientific knowledge and practices, whereas the history of science shows the social construction and validation of scientific knowledge in its real context. In addition, the integration of both methodologies within the critical analysis of scientific issues in an explicit and reflective way, offers interesting opportunities to address these two dimensions of NOS consistently, to promote the dialogue and to challenge students to change their naïve conceptions of NOS to informed ones (Acevedo-Díaz et al., 2017; McComas, 2011, Yacoubian & BouJaoude, 2010).

Considering the above arguments, this work presents the design and evaluation of an innovative intervention integrating inquiry, history of science and reflective learning to improve pre-service teachers' understanding of NOS.

THE INTERVENTION: INQUIRING ABOUT THE ORIGIN OF LIVING BEINGS

The intervention consisted in the implementation of a TLS, entitled "Inquiring about the origin of living beings", contextualized in the scientific controversy of spontaneous generation theory (Cobo-Huesa, Abril & Ariza, 2019).

This TLS introduces Aristotle's thoughts about the spontaneous generation of life under particular circumstances and engages pre-service teachers in discussions about the origin of mold in rotten oranges, challenging them to design their own experiments to refute Aristotle and to evince the biogenesis theory. At this point, pre-service teachers are not only involved in a hand-on activity based on the IBT, but they have also to reflect about their bias observations and explanations about the appearance of mold guided by their prior experiences and thoughts and about the role of their mistakes in the scientific theory refutation. Afterwards, they are invited to learn about the events in the history of science that fostered the evolution of scientific ideas towards the biogenesis theory. Likewise, they have to discuss, under a critical and a reasoning stance, about epistemological and sociological aspects of NOS through several historical episodes, which show some experiments and explanations made by the most relevant scientists involved in the spontaneous generation theory (Cobo-Huesa et al., 2019). Therefore, this intervention addresses the dialectical processes involved in the development of scientific knowledge, through an explicit reflection about the characteristics and the role of evidences, explanations, motivations of scientists and the standards and values of scientific enterprise. Finally, participants have to value the didactical benefits of IBT and the history of science in science education.

In short, this TLS emphasizes the structure of "construct the knowledge before discover it". That is, participants have to design and conduct their own experiments and struggle in the constructing evidence-based knowledge, before knowing about the huge and creative effort made by scientists to overcome the overwhelming acceptance of spontaneous generation theory. In addition, this intervention becomes useful to provide scenarios where students make connections between their prior knowledge and ancient theories.

METHOD

Research design and samples

A pretest-posttest-control group design was used to evaluate the impact of the intervention on pre-service teachers.

The sample consists of an experimental and a control natural group enrolled in the third course of a university degree to become primary school teachers. The experimental group consists of 51 students (30 female, average age 21), while the control group included 23 students in the pretest sample (13 female, average age 22) and 19 students in the posttest sample (10 female-two missing data, average age 21) due to limitations in the sample collection in this group.

The intervention was developed in the context of Didactics of Natural Science subject practices in the experimental group and it took six hours (three sessions). By contrast, the control group received a traditional instruction of science, instead of the intervention previously described and, as consequence, without an explicit and reflective instruction about NOS. The pretest and posttest were administered in the control and experimental group, a month and a half before and after the intervention, respectively.

Instrument

The assessment tool used to measure the impact of the intervention on preservice teachers' understanding of NOS was the Spanish version of the 'Views on Science-Technology-Society' (VOSTS) questionnaire, which consists in a pool of one hundred empirically developed multiple-choice items about several issues about NOS (Manassero et al., 2001). Each item consists of several statements that show appropriate, plausible or naïve views of the issue addressed in the item, classifying by a panel of expert judges. The participants valued each statements in a Likert type scale rating in 1 to 9. Afterwards, these direct scores were standardized through a quantitative metric rating in a scale [-1 to 1], so scores closest to -1 reveals a naïve view of NOS, while a score closest to 1 reveals an appropriate view of NOS.

For the purpose of this study, we selected 10 items from this questionnaire, dealing with epistemological and sociological dimensions of science. The items used in the pretest and posttest are shown in Table 1.

Table 1. Items of Spanish version of VOSTS used in the pretest and the posttest to evaluate the effectiveness of the TLS.

Dimension	Item	Issue
Epistemology	10113	Science procedure: the general science procedure involves observation, formulate and test a hypothesis.
	90111	Theory-laden: Scientific observations are rarely neutral. Instead, they are guided by scientists' theoretical beliefs, prior knowledge and expectations.
	90411	Tentative: although scientific knowledge (facts, theories, laws) is reliable and durable, it is always subjected to change.
	90651	Mistakes: they are intrinsic to scientific practice and, sometimes, they involve new discoveries or advances.
Sociology	20821	Social embeddedness of science: the social and historical context influences the construction of scientific knowledge.
	60111	Motivation: the main reason to do science depends on scientist's personal background.
	60211	Standards and values: scientist must not be only objectives, open-minded and fair-minded, but also imaginative and creative.
	70211	Disagreements: Disagreements in science are due to scientific (e.g. lack of facts), moral and personal reasons (e.g. personal benefits).
	70221	Decision-making: the logical structure, coherence, as well as scientists' interests and motivations, influence the acceptance of a scientific theory.
	70411	Competition: scientists compete for financial aids that fund their research. This competitive situation can cause conflicts of interests and scientific corruption.

The effectiveness of the intervention was assessed by comparing the pretest and posttest average scores of each item, in the experimental and the control group, and through the effect size statistic. This statistic measures the magnitude of the difference between two scores in standard deviation units (Morris, 2008). A positive value of effect size shows an improvement in the understanding of NOS after the intervention, and an effect size is considered relevant if it is larger than 0.30, although below this value, differences could still be statistically significant ($p < 0.01$) (Vázquez-Alonso, Aponte, Manassero-Mas y Montesano, 2016).

RESULTS

The objective of this study is to assess the improvement in pre-service teachers' views of NOS by comparing the variation in the average scores of the ten items applied in the pretest-posttest assessment, as well as by determining the magnitude of this variation through the effect size statistic. Therefore, the analysis of results is focused on detecting an improvement in key aspects related to epistemological and sociological dimensions of science to reflect about the learning potential of the TLS to provide a proper global view of NOS.

On the one hand, if we attend to the descriptive statistics of the experimental group (which receive the NOS education treatment) in Figure 1, participants' beliefs of NOS before the implementation of the TLS (pretest line) reveal a negative score in one item (60111_Motivation) and an overall homogeneous pattern in the rest of them, with slight positive scores. After the implementation (posttest line), in general, the profile is characterized by an improvement in nine of the ten items evaluated, but in different achievement degrees. If we attend to effect size line, four of that items show relevant scores after the implementation ($d>0.30$): 90651-mistakes ($d=0.66$), 20821-social embeddedness of science ($d=0.41$), 60111-motivation ($d=0.59$), 70211-disagreements ($d=0.31$). Three of these remarkable items address the sociological dimension of NOS (20821, 60111, and 70211) and one of them, the epistemological one (90651). The differences were statistically significant ($p<0.05$) in three of the former items (20821, 60111, 90651) (Wilcoxon signed-rank test). Respect to the remaining items, three of them show a moderate improvement (90411-tentative, 60211-standards and values, 70221-decision-making) and two items show a weak improvement (10113-science procedure, 70411-competition). The item 90111, related to theory-laden nature of observations (epistemological dimension of NOS), practically maintains its initial score after the implementation of the TLS.

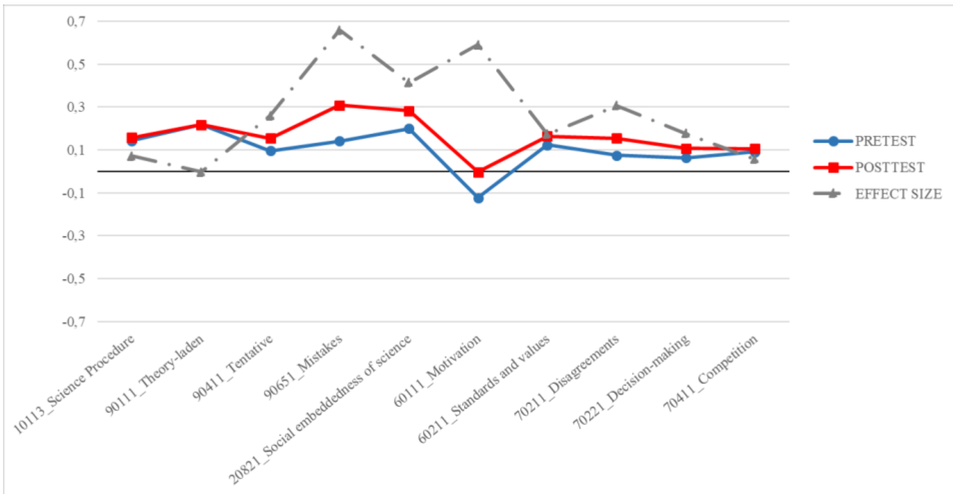

Figure 1. Average scores for the experimental group in the pretest and posttest, and effect size of index differences between two tests.

On the other hand, Figure 2 shows the descriptive statistics of the control group in the items applied. If we attend to pretest scores, they are similar to that obtained in the experimental group (Figure 1), with a negative score in the item 60111 and slight positive scores in the remaining items. However, the overall profile in the posttest is quite different from that in the experimental group. Despite of the fact that three items show a relevant improvement (20821, d=0.32; 60111, d=0.50; 70221, d=0.38), the other scores decline. As we can see, two items (20821 and 60111) improved in both groups in a relevant way, though the effect sizes in the experimental group are higher (0.41 and 0.59, respectively) than those in the control one (0.32 and 0.5, respectively). Finally, the differences are statistically significant in one item (70211) (Mann-Whitney U test), which shows a decline.

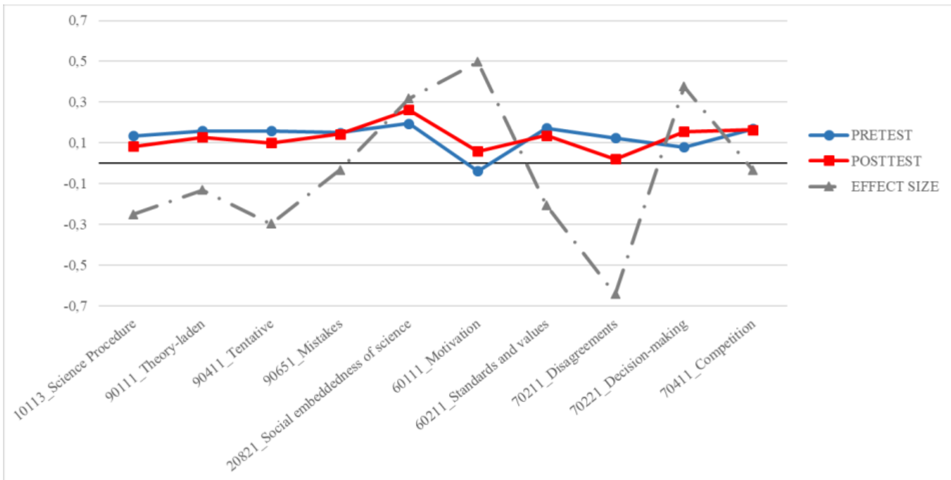

Figure 2. Average scores for the control group in the pretest and posttest, and effect size of index differences between two tests.

DISCUSSION AND CONCLUSIONS

This study presents the evaluation of an innovative intervention integrating different educational approaches (IBT, history of science and explicit reflection about NOS), using a pretest-posttest-control group design.

In this evaluation, the analysis of pretest and posttest scores and the effect size statistic provide useful information to determine the magnitude of the TLS effectiveness in improving pre-service teachers' view of NOS.

First, the experimental and the control groups sustain similar conceptions about NOS, with a remarkable naïve conception about the motivations that lead scientists to conduct their research. Nevertheless, after the intervention, both groups show different patterns. Respect to experimental group, according to effect size, students undergo a positive learning evolution in nine of the ten items evaluated, except for the item related to theory-laden nature of observation, which shows a very slight decline. In the control group, seven items show a negative learning progress.

Second, taking into account the progress of both groups, with regard to the four epistemological issues evaluated, the main strengths of the TLS intervention deal with the tentative nature of scientific knowledge (90411) and the role of mistakes in science (90651). Regarding the six sociological issues, the most remarkable improvements deal with the standards and values of scientists (60211) and the disagreements in the scientific dialogue of new theories acceptance (70211), as well as with the social embeddedness of science (20821) and the motivations of scientist (60111). These two last items are considered as strengths since the effect size scores obtained in the experimental group were considerable higher with respect to those in the control group.

These results can be discussed considering the reinforcing and highly contextualized nature of the TLS implemented (Clough, 2018). This approach deals with key aspects of NOS through a hands-on activity based on IBT and a deep analysis of the history of science, in an explicit and a reflective framework, to promote the conceptual change to a naïve to an adequate view of NOS (Abd-El-Khalick, 2013). As consequence, regarding the most improving epistemological issues after the TLS implementation, the structure of this intervention support the construction of an adequate view of the tentative nature of scientific knowledge and the intrinsic feature of mistakes in science. In fact, the TLS shows the change of mind of several scientists along the history in their attempt to determine the origin of living beings, as well as the fact to consider mistakes as an opportunity to learn and not to consider them as obstacles to solve the spontaneous generation controversy. Respect to the most improving sociological issues, the TLS reveals how scientists' personality and interests determine their experimental designs and arguments, which may have fostered the evolution to an adequate view of the standards and values of scientists and scientific disagreements. Last, motivations of scientists and the social embeddedness of science are issues widely addressed in the intervention. It points out the occupations and aspirations of the scientists involved in the controversy, as well as the highly rooted belief about spontaneous generation in society, that kept off any experimental explanation against it. These two aspects are embedded in our daily life, and that might be the reason of the improving showed in the control group, although it is minor than the improving identifying in the experimental group, probably due to the explicit and reflective instruction received.

Therefore, the assessment of the TLS effectiveness exhibits that the experimental group achieved a significantly better understanding of NOS. This modest increase replies the results of other studies, although with a higher sample (Vázquez-Alonso et al., 2016). Besides, the TLS described involves both dimensions of NOS in a more equitable way than those reported in other researches (Abd-El-Khalick & Lederman, 2000; Akerson et al., 2000; Kartal et al., 2018; Schwartz, Lederman & Crawford, 2004; Williams & Rudge, 2019).

Finally, to better understand the potential of this TLS on improving pre-service teachers' view of NOS, we have to focus on the short duration of this instruction (three sessions of two hours). Besides, naïve conceptions may be highly rooted in pre-service teachers so, despite the explicit and reflective instruction, they may try to dismiss or transform some of the new aspects addressed in the TLS to defend their prior mistaken conceptions (Clough, 2011). This fact reveals the need for meaningful, constructive, appealing and contextualized methodologies which promote an effective teaching of NOS.

In short, this research work offers insights into effective methodologies to achieve significant improvements in key aspects related to the broad nature of scientific knowledge, which is essential to acquire a proper scientific literacy. Likewise, the strengths and weakness identified feature some aspects about NOS that must be reinforced in the TLS and deserve special attention. Science educators must strive to face on diverse challenges in the Didactics of Science to contribute to a better understanding about science and science teaching process.

Supporting this cause, this TLS, evaluated through evidences based on the practice, provides some courses of action to foster preservice science teacher development and to guide future interventions.

EXPLORING PHYSICS TEACHERS' CONCEPTIONS OF THE NATURE OF THE SCIENCES

Dimitrios Schizas[1], Dimitris Psillos[2]
[1]International Hellenic University, Thessaloniki, Greece
[2]School of Primary Education, Aristotle University of Thessaloniki, Thessaloniki, Greece

The present study investigates how Greek in-service physics teachers understand the unique features of school physics and biology. Our theoretical framework focuses on the notion of worldview and important differences that exist between the Newtonian and the neo-Darwinian worldviews, whereas our methodology involves questionnaires and mainly individual interviews. The empirical findings indicate that participants understand the nature of the sciences (NOTSs) from the perspective of how they understand their own science and tend to share homogeneous NOTSs conceptions that mostly stem from how they have assimilated positivistic tenets. As a result, they have serious misunderstandings regarding several NOS items and project upon biology epistemological characteristics that biology does not possess. Remarkably, when participants accept that there are differences among biology and physics they resort to a pre-Darwinian (non-scientific), namely teleological way of thinking.

Keywords: Misconceptions; Nature of sciences; Teacher thinking.

INTRODUCTION

While there is a large number of research studies that have explored what teachers know about Nature Of Science (NOS; e.g., Lederman, 2007; Vázquez-Alonso et al., 2013), there are no studies that have explored teachers' NOS conceptions with a focus on epistemological differences between the natural sciences. This gap in the literature may be attributed to the current consensus NOS view; NOS researchers focus more on a universal view of science and less on specific features of individual natural sciences.

Recently there is certain criticism against this domain-general approach to NOS (for a synopsis, see Kampourakis, 2016) and many science educators argue that research should also focus on the differences between the various natural sciences (Schizas, Psillos & Stamou, 2016). However, the suggestions of these critics have not been employed in empirical research.

The purpose of this study is to conduct such research by employing an alternative domain-specific NOS or Nature Of The Sciences (NOTSs) perspective. In particular, we aim at exploring how in-service physics teachers address the unique features of Newtonian physics and Neo-Darwinian biology by focusing on how they understand the respective worldviews. Thus, the following research questions are considered important: (a) Do physics teachers use homogeneity as a starting point in addressing the unique features of Newtonian (school) physics and Neo-Darwinian biology? (b) Do they share a kind of epistemological idiosyncrasy that results from how they perceive the Newtonian worldview or are their conceptions simply fluid, inconsistent and naive, as current NOS research demonstrates (e.g., Abd-El-Khalick & BouJaoude, 1997; Apostolou & Koulaidis, 2010).

Before embarking on the results of our study, it is necessary to present a brief description of the main differences between the Newtonian and Neo-Darwinian worldviews along with aspects of our methodology.

THEORETICAL FRAMEWORK

Our choice to focus on how in-service physics teachers perceive domain-specific epistemologies by using the notions of Newtonian and Neo-Darwinian worldviews is grounded in (a) epistemological assumptions that consider the notion of worldview as crucial in epistemological studies of sciences and (b) didactic assumptions that concern the nature of school physics and biology (Schizas, Psillos & Stamou, 2016). The Newtonian and Neo-Darwinian worldviews are not only important in the world of natural sciences but also influential in considerable sections of physics curricula (e.g., classical mechanics and geometrical optics) and biology curricula (e.g., molecular, cellular and evolutionary biology), respectively.

The Newtonian worldview embraces all physical scientific fields that constitute the so-called classical physics and complies with positivism (Frodeman, 1995), which flourished in school and academic environments for many years and advanced Newtonian physics to the status of model science and standard for all others.

Newtonian physics is predominantly nomothetic and possesses a mathematical theoretical structure consisting of interconnected universalities (i.e., scientific laws) that are (a) deterministic, (b) causally-closed, i.e., everything that explains a physical system is already contained within the mathematical equations that describe this system, (c) timeless or reversible, i.e., laws are assumed to work the same towards the past or the future, (d) fully known, i.e., Newtonian physics eliminates the presence of unforeseen events and (e) predictable, i.e., Newtonian physics possesses the positivist feature of making certain predictions because of reductionist and essentialist methodological choices. Interestingly, because of these choices the empirical phenomena under study can be experimentally reproduced under laboratory conditions and thus the experimental method has been considered the proper scientific method for a long time (Baltas 1988; 2004).

On the contrary, the Neo-Darwinian worldview draws its assumptions from evolutionary biology and is mostly based on the techniques of hermeneutics and historical sciences (Smocovitis, 1992). Neo-Darwinian biology lacks the kind of mathematical and universal statements that are widely recognized as ‘Newtonian laws’ (Sober 1993) and it is not necessarily underpinned by mathematical structures. Thus, compared to Newtonian physicists, biologists do not grasp empirical phenomena as if they were simply representatives of general phenomena and explore how these phenomena manifest themselves in specific places and times, finding thus regularities that are (a) causally complex, i.e., various causal factors are interrelated and form a causal structure, (b) contingent, i.e., an event does not necessarily occur because the presence of another event as in determinism, but has a tendency to occur in a particular context, (c) causally open, i.e., the action of a causal agent is interrelated with the effects of other causal factors that belong to many different organizational levels, (d) nonreversible, i.e., unexpected and unique events such as mutations and stochastic changes in environmental conditions often create discontinuities in the behavior of biological systems and make this behavior a historical outcome and (e) more or less unpredictable, i.e., historicity does not allow certain predictions, such as the predictions made by Newtonian physics, because predictions are based on the interpretation of historical processes, which leaves substantial variability unexplained (Stamou 2002).

METHODOLOGY

According to Greek legislation, secondary education physics teachers possess the appropriate qualifications to teach not only physics but also biology. Since the present study aims at an in depth analysis of their NOTSs views rather than statistical generalizability, the sample size is not required to be large. Thus, our sample involved fourteen Greek acting physics teachers (8 males, 6 females) who were purposefully selected out of a larger pool of physics teachers willing to participate in our research, and represented a range of individual and educational profiles.

Data were collected through questionnaires and mainly through individual interviews, which seem to be the appropriate research choice for studying learners' NOS views in depth (Lederman, Abd-El-Khalick, Bell, & Schwartz, 2002). Prior to the interview sessions, each teacher was asked to complete a multiple-choice questionnaire whose items focused on differences between classical (Newtonian) physics and Neo-Darwinian biology and were different from the usual ones (VOSTS or VNOS for example; Lederman, Abd-El-Khalick, Bell, & Schwartz, 2002) employed in contemporary studies during which teachers' conceptions of NOS items are examined. These items presented respondents with bipolar agree–disagree statements or positions coupled with several reasoned viewpoints or justifications to choose from. Each couple was classified as either an informed (I) or a non-informed (NI) NOTSs view and each questionnaire item involved only one informed position and justification. The final version of the questionnaire resulted from a developmental procedure that involved several stages and consisted of 6 items concerning the presence or absence of scientific laws in natural sciences, the nature of scientific methods and the nature of scientific predictions and explanations.

Our purpose behind the administration of the questionnaire was to trigger teachers' thinking of NOTSs and create a context in which these views could be discussed. This discussion was carried out during in-depth individual interviews that lasted approximately 60 min. each.

During the interview sessions, all participants were handed their questionnaires and were encouraged to explain their responses, clarify the meanings they ascribed to key epistemological terms, and provide specific examples to illustrate and contextualize their NOTSs views. Follow-up and probing questions were used to clarify vague or obscure statements in the participants' responses, whereas due to digressions we often paraphrased the questionnaire's questions and used many other open-ended questions to further investigate the respondents' lines of thought.

All interviews were recorded verbally and fully transcribed afterwards. Interview transcripts were then content-analysed by the authors and one experienced science teacher. Inter-rater agreement was considered necessary to be established before the analysis of the whole dataset and was accomplished by a two-round analysis of randomly selected data sets.

RESULTS-DISCUSSION

Scientific theories and laws

All participants disregard the presence of non-nomothetic natural sciences and to some degree they comply with positivism in defending the necessity for sciences to possess scientific laws. Moreover, all participants hold the number one NOS myth (McComas and Olson 1998: 54) "...that with increased evidence there is a developmental sequence through which scientific ideas pass on their way to final acceptance as mature laws" when agreeing with that in each natural science, scientists make scientific hypotheses that, if verified, become scientific theories, which in turn, with much more evidence, become higher order generalizations referred to as scientific laws.

The presence of this misconception in participants' mind motivated us to explore how they understand the distinction between the concepts of scientific laws and theories along with how they understand the relation between the concept of law and the empirical world. In both cases there are misunderstandings that indicate more serious misunderstandings about the very nature of Newtonian science. Most participants overlook that scientific laws are primarily ideal constructs resulting from idealistic rather than inductive reasoning, thereby reflecting how things must behave as opposed to merely reflecting how things happen to behave. They also disregard the fact that the concrete empirical phenomena that Newtonian physics grasps and handles through the use of experimental methods are simple representations of the relevant general phenomena and thus, they miss a lot of epistemological qualities behind how Newtonian physics transforms empirical phenomena to physical phenomena. Remarkably, due both to reasonable difficulties they encounter in finding or recalling physical theories independently of physical laws (thus resulting in misleading definitions of the concepts of 'theories' and 'laws') and their strong belief in the nomothetic character of natural sciences, they are triggered to believe that scientific laws are superior to scientific theories.

Scientific methods

Most participants view the scientific method as a lock-step and a universal step-wise procedure) in which experiment is a necessary prerequisite for validating scientific theoretical constructs when agreeing with that in all scientific research, the scientist observes and records natural facts, provides explanations on the basis of those facts, and then tests whether these explanations are true or not through experiments. This positivistic view complies with the ability of Newtonian physics to transform all natural phenomena into experimental phenomena and helps participants to determine the relation between the scientific and natural worlds and define the notion of scientific-ness.

This positivistic view is also accompanied by misunderstandings regarding what an experiment is. Because of losing sight of the transformations that are carried out during experimental implementation, participants encounter difficulties in defining the concept of experiment as a technical means of reproducing natural phenomena under laboratory conditions and possess several misunderstandings. For example, some participants confuse experiment with observation and the manipulation/control of experimental variables with their estimation. Irrespective of these misunderstandings, however, all participants consider experiment as any interaction of scientists with the empirical world that involves the comparison of some deduced state of affairs with some observed state of affairs. Thus, participants are prone to deductive reasoning and this is why they reject the presence of qualitative scientific studies that only involve descriptions.

Scientific predictions

Most participants disagree with the positivistic view of predictability as an essential feature of every science and hold that natural sciences do not have the same predictability. However, they fail to recognize this feature as a fundamental difference between biology and physics because they consider time as a neutral background on which timeless laws of nature unfold (Kwa 2010), exactly as positivism and the deductive-nomological model wish. Thus, they fail to associate the behaviour of biological systems with historical events and encounter serious difficulties in relating the notion of predictability with the historical nature of biological science.

There are also participants who assume that problems concerning prediction are common to both biology and physics. For example, there are participants who maintain that predictability problems in biology are analogous to those in weather models where the parameters involved cannot be estimated with mathematical accuracy, whereas other participants hold that certain predictions are impossible because of the non-linearity of natural systems.

Scientific explanations

Most participants hold that in biology there are no generalizations capable of explaining how biological entities will behave in each environment. However, they fail to recognize this feature as a fundamental difference between biology and physics. Either they hold that biology employs teleological explanations in parallel with deductive-nomological explanations, or they state that the use of deductive-nomological explanations in biology encounters serious difficulties, which, rather than resulting from the unique epistemological features of biology, are similar to those that are sometimes encountered by physicists.

All participants have considerable difficulties in capturing how biological evolution makes biological explanations different from physical explanations. The cause of such difficulties is not only their ignorance of significant aspects of evolutionary theory (which is justifiable for physics teachers). Important causes are (a) their strong belief in the nomothetic character of natural sciences, (b) their misconceived views of the concept of "qualitative data", (c) their adherence to the Newtonian notion of time, (d) their belief that teleological explanations are in principle acceptable and may distinguish biology from physics and (e) difficulties concerning how higher organizational levels are related to evolutionary explanations.

CONCLUSIONS

While at the beginning of our research the participating teachers admit their ignorance about biological topics, they do not hesitate to discuss NOTSs questions concerning biology. This is indeed feasible because most of the participants view the nature of Newtonian physics and Neo-Darwinian biology from a perspective that focuses on what a science should be if it is to be called ‘science’, thereby defining beforehand what can be referred to as ‘essence’ of science.

This essentialist and rather universalist perspective calls the participants to search for a priori criteria that may distinguish sciences from non-sciences in the science they know best; namely, Newtonian physics. Thus, while until now, research has shown that science teachers possess heterogeneous, fluid, incoherent and rather eclectic aspects of NOS (Abd-El-Khalick & BouJaoude, 1997; Apostolou & Koulaidis, 2010), our study demonstrates that behind participants’ NOS and NOTSs aspects may be found homogeneous conceptions that stem from how have assimilated epistemological aspects of school physics and of the underlying positivism.

Moreover, although the participating teachers are not rigidly committed to a coherent and consistent positivistic position because of several misconceived views of key epistemological terms, their homogeneous framework provokes troublesome situations in how they understand the nature of physics and biology. For example, they project upon biology epistemological characteristics that biology does not possess and when they accept that there are differences among biology and physics they resort to a pre-Darwinian (non-scientific), namely teleological, way of thinking.

ACKNOWLEDGEMENT

This study is supported by the program «Study of the development aspects of scientific literacy learners informal and informal education conditions using online virtual labs and use of geographical data», funded by the sectoral operational program “Competitiveness, Entrepreneurship and Innovation 2014-2020” under the Partnership and Cooperation Agreement (NSRF) for the period 2014-2020.

ADDRESSING NATURE OF SCIENCE ASPECTS ON A PD-PROGRAM FOR GREEK SCIENCE TEACHERS: DESIGN – IMPLEMENTATION &VALIDATION

Anna Koumara, Katerina Plakitsi
University of Ioannina, Ioannina, Greece

A Science Teachers' Professional Development (PD) Program on Nature of Scientific Knowledge (NOSK) aspects is designed, implemented and evaluated, based on the cycle of expansive learning. A needs analysis showed that NOSK is not explicitly included in Greek Science classes and its integration might be a solution to students' indifference towards them (questioning phase). A relevant literature review highlights three approaches to teach NOSK: through History of Science (HOS), Scientific Inquiry (SI) and Socio-scientific Issues (SSI). The PD-program includes all three, in that order, to provide the 49 participant-teachers alternative paths to embed NOSK in more school science units, designed according to the community of trainees' Cultural-Historical characteristics and the Principles of Adult Education (analysis and modelling phases). Teachers examine and test the new model (4th phase) through a voluntary assignment to design and present a lesson plan to the plenary. The implementation phase consists of classroom observations and a 5th meeting, finishing with a 6th meeting (reflecting phase). Arisen contradictions are dealt to evolve the whole activity system. Tasks for evaluation are included in all phases. Results to that point show that the PD-program is successful.

Keywords: Nature of Science, Continuing Professional Development, Secondary School

INTRODUCTION

The importance to include Nature of Science (NOS) aspects in Science teaching is acknowledged among all researchers. The arguments for this are: a) better understanding of the limitations of science, b) increase interest in classroom, c) achieve better understanding of scientific knowledge and d) achieve scientific literacy (related to citizen education) (Matthews, 1997; Lederman, 2019). Especially the one about scientific literacy is widely adopted worldwide in science curricula (Allchin, 2014, Lederman et al, 2014). However, even though researchers and curricula designers agree that NOS needs to be taught – and specifically in an explicit way (Lederman et al, 2014, Lederman 2019), there is no consensus on a common list of NOS aspects (Lederman, 2019; McComas, 2017; Clough, 2007; Allchin, 2011; Matthews, 2012; Erduran & Dagher, 2014; Van Dijk, 2011).

As for Greece, even though there is academic work in the field (Piliouras & Plakitsi, 2015, Piliouras et al, 2017, Stefanidou & Skordoulis, 2017, Kampourakis, 2016), a survey (Koumara & Plakitsi 2017, 2019) showed that NOS is not included in the Greek secondary education and graduates have naïve views on it.

In the present work, the design, implementation, works for evaluation and initial results of a Professional Development (PD) program on teaching NOS aspects to 49 science teachers are presented in brief. We prefer to use the term "Nature of Scientific Knowledge" (NOSK), to communicate more accurately what is meant by NOS (Lederman 2019), to refer to the characteristics of scientific knowledge that are inherently derived from the manner in which it is produced (Scientific Inquiry) and are suitable for K-12 students to learn about.

We adopt Cultural Historical Activity Theory (CHAT) (Engeström 2001, Engeström & Sannino 2010) as a guiding framework for the design and analysis of the PD-program, something that is in agreement with Roth & Lee's view (2007): *"adopting CHAT as a guiding framework allows for a questioning of the structural determinations of current educational practices"* and also it has been used by many other researchers in the field of Curricula design and teacher training, in Science and other fields (Kolokouri et al, 2012; Kornelaki, 2018, p.20; Rodrigues et al, 2011; Jóhannsdóttir, 2014; DeWitt & Osbourne, 2007).
Education is a complex, multi-parametric activity system, that interacts in network relations with other systems, via the conceptual tools it has developed (Engeström, 2001), where they merge as *"a constellation of two or more activity systems that have a partially shared object"* (Engeström & Sannino, 2010). CHAT was selected so that we can be able to deal with the complexity of education's activity system. For example, the analysis of what the trainer is doing, using tools (educational means) to teach his/her trainees (a common ternary relation) is not an analysis of the activity system of education. The framework of Activity Theory suggests the excess of the directly visible dual and ternary relations among the nodes of the system, to define the way in which the other nodes are present and influence the examined condition (Kornelaki 2018, p.20).

NOSK ASPECTS

According to Lederman et al (2014) those characteristics are: (a1) Scientific knowledge is empirical, (a2) Scientific knowledge is inferential, observations and inferences are different, (a3) Scientific knowledge is durable but changes in the light of new evidence, (a4) Scientists' creativity and imagination are needed in all parts of a scientific research, (a5) Even though objectivity is the goal, subjectivity within scientists is inevitable, derived from scientists' personal beliefs, background knowledge, training, expectations, etc. (a6) Scientific knowledge is culturally embedded and (a7) Scientific Laws and Theories are different kind of knowledge.

CULTURAL-HISTORICAL ACTIVITY THEORY (CHAT)

CHAT is a "cross-disciplinary framework to study how humans purposefully transform natural and social reality, including themselves, as an ongoing culturally and historically situated process" (Roth et al, 2012). The first generation of CHAT was introduced by Vygotsky and the second by Leontiev (1978) with his perception on a collective system of human activity. Engeström (1987) illustrated Leontiev's views, introducing the triangle for human activity systems, see Figure 1 (Barma, 2011, Plakitsi et al, 2018, p. 50-52).

The relations between the Subject (usually people, lately they are also corporations that move towards a desired goal) and the Object (the goals of the activity) are mediating through tools, community, rules and division of labor (Igira & Gregory 2009). Tools/artefacts are culturally produced means that subjects use to perform the activity. They may be material, or mental, like language. Community refers to all the participants who share the same object, shape and direct individual actions to the collective activity. Division of labor refers to the way subjects –

members of the community divide their responsibilities during an activity. The triangle of the activity system refers both to the horizontal actions and interrelations between the members of the community and the vertical distribution of power, resources and relative societal/professional status (Plakitsi et al, 2018, p.53). The nodes of an activity system are not static and isolated to each other, but they are dynamically connected; the system is regarded as a unity (Hasan & Kazlauskas, 2014).

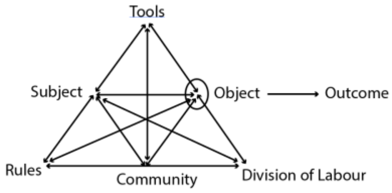

Figure 1: The structure of a human activity system

The third generation of CHAT (Engeström, 2001), moved beyond the barriers of one activity system, including minimally two activity systems that interrelate, promoting multiple perspectives, dialectics and networks for collaboration. Contradictions and tensions that might appear would play a crucial role as the most important motive for development of human actions, transforming both the activity and the outcome (Plakitsi et al, 2018, p.55). The 3rd generation of CHAT could be summarized in the following five principles: an activity system a) is the unit of analysis, b) is multi-voiced, c) its problems and potentials can be understood against their own history, d) Contradictions are the driving force of change and e) through the cycle of expansive learning it is possible to study the transformations of the activity system, while it is reconceptualized to embrace a radically wider horizon of possibilities than in the previous mode of the activity (Engeström 2001).

Engeström & Sannino (2010) give an ideal-typical sequence of actions in an expansive cycle, which is presented in detail, because the whole PD-program was designed and implemented based on the cycle of expansive learning:

- The first action is that of questioning. Participants in an activity system are criticizing or rejecting some aspects of the accepted practice and existing knowledge. Primary contradictions appear, within each and any of the nodes of the activity system.
- The second action is an analysis of the situation to identify systemic tensions or contradictions within and between activity systems. Secondary contradictions appear between two or more nodes, eg. a new object and an old tool.
- The third action is that of modeling, to construct an explicit, simplified model of the new idea that explains and offers a solution to the problematic situation.
- The fourth action is about examining and testing of the model to establish its potential and limitations
- The fifth action is that of implementing the model by means of practical applications, enrichments, and conceptual extensions. Tertiary contradictions appear, between a newly established mode of activity and remnants of the previous mode.
- The sixth and seventh actions are those of reflecting on and evaluating the process and consolidating its outcomes into a new stable form of practice. Quaternary contradictions appear, between the newly recognized activity and its neighboring activity systems.

The above are illustrated in Figure 2 (Engeström & Sannino, 2010)

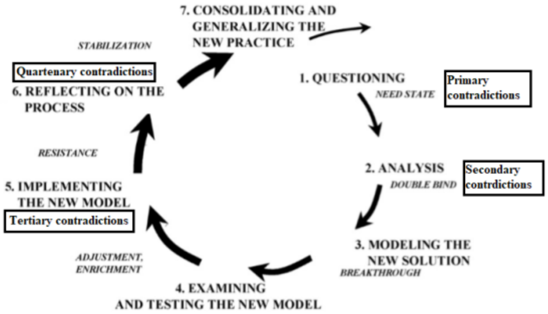

Figure 2. Actions and corresponding contradictions in the cycle of expansive learning (Engeström & Sannino 2010, Engeström 2001).

The process of expansive learning should be understood as construction and resolution of successively evolving contradictions. It is worth mentioning that all strategic actions presented in Fig. 2 are an indicative series of steps and not a “universal formula” that follow each other automatically; any step might be missed (Plakitsi et al., 2018, p. 81).

DESIGN & IMPLEMENTATION OF THE PD-PROGRAM

The PD-program was co-organized with the 4 Lab Centers (EKFE) of Thessaloniki. 49 science teachers participated voluntarily; their average age was 50 years old and they worked in education for 10-30 years. It took place in twilight courses and during mornings teachers followed their regular program at school: that was deterring for a long-last program. It was decided to contain four 3-hour meetings, one per fortnight. The first one took place on April 2018. At the end of the 4th meeting, teachers asked for a 5th meeting, that took place on December 2018 and lead to another one, on May 2019. The first writer, after the required permission, observed 9 of the above teachers in their classrooms during the school year 2018-19. All the PD-program was designed, implemented and took its final form and presented as a cycle of expansive learning (see Fig.2).

Before the first meeting between teachers – research group there were two separate activity systems, one of the Greek educational system and one of the research group. Through the interaction between those two systems, we target on expansive learning: both teachers and researchers participate in the design and implementation of a radically new, wider and processed object for their activity.

Each one of those systems are presented below in brief and then the shared system of teachers & researchers through the cycle of expansive learning.

1. **Activity system of a Greek science teacher**

Earlier surveys (Koumara & Plakitsi 2017 & 2019) pointed out that the Greek Science Curriculum does not include teaching of NOSK aspects, textbooks prompt – in a small degree – to discuss about only some of them, teachers haven’t learned them during their studies, so they intuitively refer to some of them, without assessment, and finally students have naïve views on NOSK aspects. Success in the National exams to enter university is a major value among the Greek families, so students’ preparation for the exams begin many years before. As a result, parents are an integrant part of the community, who press teachers and students for good grades and success in tests. Teachers end up focusing on the body of knowledge (definitions, laws, equations) and solving mathematical problems, which is what is examined in the National exams. Teachers have primary contradictions with the above, because students don't participate actively in classes, claiming that school is far from their interests.

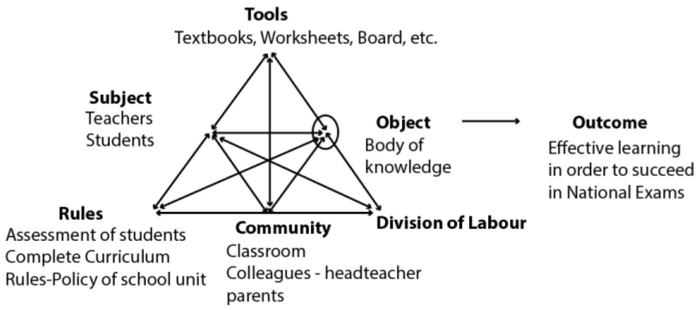

Figure 3: Activity system of the Greek science teacher

2. Activity system of the research group

Researchers in their own activity system have recorded three approaches to teach NOSK aspects, through a) History of Science (HOS), b) Scientific Inquiry (SI) and c) Socio-Scientific Issues (Lederman, 2009; McComas, 2017). For each approach, there are advantages (i.e. Matthews, 2015; Abd-El-Khalick & Lederman, 2000; Schwartz, 2006; Akerson, 2007; Eastwood et al, 2012; Zeidler & Sadler, 2011) and disadvantages (Lederman 2009; Bell et al, 2013; Allchin et al, 2014). From the above, it is concluded that none of the three approaches alone is enough. Furthermore, according to Allchin (2011), all teachers don't regard each approach to be as important as another, which was also a conclusion from our interviews with teachers (Koumara & Plakitsi, 2017). In our opinion, it is justified from their different cultural characteristics.

Taking that into consideration, it was decided to include all three approaches in the PD-program. As for the order of presentation: teachers' interviews showed that most of them don't regard NOSK to be as important as the body of knowledge. This can be explained from their cultural characteristics: they were trained in Science Departments, without any pedagogical instruction, and the activity system they lived in – both as students and teachers – was that of the National exams, the solution of advanced mathematical problems, without tasks that include or assess NOSK aspects.

In order to change their attitude, it was regarded to be important to start the PD-program with HOS, to recognize NOSK aspects throughout the evolution of scientific knowledge, and to realize that NOSK is part of science. The SI approach follows, which is within the desired culture of Greek Science Education. Finally, the PD-program closes with SSI, that our previous survey showed that is the most contradictory among the three.

Apart from that, the research group included in the design of the PD-program the basic principles of Adult Education: a) Adults learn more effectively when they participate in the learning process, when the content is focused on their needs and their previous knowledge and experience are used and b) Adults prefer to learn in their personal manner, according to their special cultural characteristics and abilities (Jarvis, 2010, p.106-110).

3. Cycle of expansive learning

3.1. Questioning

At the beginning of the PD-program, teachers were asked why they attended the program. Their answer was a description of the classroom activity system, similar to the one described on paragraph 1. The primary contradiction to the accepted practice was that their students don't participate actively, which makes their job tiring. They attended the program, because they were already critical towards the existing system and they seek for anything that could inspire their students to be more energized.

3.2 Analysis

Teachers knew the schedule of the program from its announcement. When the lecturer informed them that the goal was to a) learn NOSK aspects and b) be able to teach them themselves, secondary contradictions arose: a) in order to teach a new object they had to design new resources (tool), since there are none in the textbooks and b) there might be opposition, mainly from parents, if teaching is completely different from the regular.

Discussion lead to their suggestions, some of which were based on the inclusion of all three approaches of NOSK teaching: for example, teachers who already used HOS in their teaching, could add NOSK aspects to that content. Respectively, teachers who use SI and SSI could add NOSK aspects to what they already do, based on extracts vaguely derived from the textbooks. So, on the one hand teachers could design lesson plans easier and on the other students would not attend completely different classes than the ones they were used to. Also, it was decided not to do any intervention in the 12th Grade, the exams year.

3.3 Modelling the new solution

Each one of the first three meetings was dedicated to a NOSK teaching approach (HOS/SI/SSI). Their content was both original tasks and adjustments from the literature. The PD-program began with an induction to NOSK aspects.

1st meeting: HOS approach. The evolution of the concept "pressure" from 1638 to 1662 was presented. The choice was made firstly because the same phenomena are interpreted through different inferences: a) the partial abhorrence to a vacuum (Galileo), b) the weight of the air (Torricelli and Pascal), the infamous experiment on Puy-de-Dome being a crucial experiment and c) the "springs of air" (Boyle) developing the air-pump for the crucial experiment (Koumara, 2019) and secondly because of the intense effect of the new philosophical stream (Mechanical Philosophy). Before the presentation, teachers were asked to recognize and note down NOSK aspects. By the end of the lesson, these aspects were summarized in a table.

2nd meeting: SI approach. Teachers participated in a Black Box activity (Koumara & Plakitsi, 2018) and recognized NOSK aspects during its solution. Black boxes' computer applications and other classification tasks were also included (Bell, 2008). The meeting ended with a task where different inferences came from the same observations[1].

[1] https://scienceonline.tki.org.nz/Nature-of-science/Nature-of-Science-Teaching-Activities/Conflicting-theories-for-the-origin-of-the-Moon

3rd meeting: SSI approach. The topics were a) different inferences from interpreting the same diagram for the reasons of climate change (IPCC, 2001), and 2) advantages and disadvantages of using nuclear energy vs. coal for electricity (Sadler et al, 2007).

3.4 Examining and Testing the new solution

Teachers knew from the announcement of the program that they had to present a lesson plan as a final assignment, based on any school unit they wished, using NOSK aspects explicitly. Also, the assignment was not mandatory, so that teachers with increased responsibilities were not discouraged to participate in the program.

Even though the assignment was voluntary and occurred on the end of May, a season with increased responsibilities for teachers, 30/49 teachers delivered 29 lesson plans (2 teachers cooperated). 21 of them were successful. On the other 8, there was either incomplete application of the new model of activity or the old model remained. 7 of them were presented in the 4th meeting. Discussion followed each presentation between teachers and researchers. Questions, claims, different opinions and suggestions were heard. The program ended with teachers ask for a 5th meeting by next winter, after they would teach NOSK in their classes.

3.5 Implementing the new solution

Throughout school year 2018-19, the first of the writers observed 9 of 49 teachers in the classroom, in order to study how they embedded NOSK in their teaching. It was found that, in some occasions, there was disharmony between the suggested tasks for NOSK teaching and the daily school practice (tertiary contradiction). That was the theme of the 5th meeting (December 2018), where two videotaped lessons on NOSK teaching – of different character – were shown, analyzed and discussed. Through them and teachers' experience in NOSK teaching, contradictions appeared for some teachers between the object of the activity and its motive, which lead to upgrades of the activity.

3.6 Reflecting on the Process

The final 6th meeting took place on May 2019, where teachers whose lessons the first author observed, presented their experience to the plenary. Discussion followed. Quaternary contradictions arose, directly connected to other network activity systems, like the request to make changes in the curriculum and the textbooks. Teachers – having a first-hand experience themselves – have affected their schools and prepare for change.

3.7 Consolidating and Generalizing the new practice

We would reach that stage when the Curriculum changes and NOSK aspects are included.

EVALUATION OF THE PROGRAM – RESULTS

In order to evaluate the program, participant teachers were given the following tasks: a) before the 1st meeting they completed the VNOS-D+ questionnaire (pre-test) and 10 of them gave semi-constructed interviews, b) in the 4th meeting they: i) delivered their designed lesson plan on NOSK teaching, ii) completed a post-training evaluation form and iii) completed the post-test VNOS-D+ questionnaire, c) throughout school year 2018-19 classroom observations took place on how NOSK is integrated in the Greek school reality, using a protocol (and taken field notes) d) in the 5th meeting they completed a questionnaire on the usability of the three approaches in NOSK teaching and e) in the 6th meeting they wrote a report on their activities through the whole year, any difficulty they came through, what helped them to overcome it and how they regard their results.

All the above are analyzed. Initial results show that the PD-program improved their knowledge on NOSK, created a positive view towards its integration in the classroom, trained them to design their own lesson plan and teach NOSK. It is also positive that they asked for more interactive meetings, in order to exchange their views after their teaching experience.

Regarding the three approaches, they mention that a) students want variety in the tasks they are occupied with and b) more chances are given to teachers to embed NOSK aspects. Most of them mention that HOS is useful for teachers' training on NOSK, SI for students to perform tasks and SSI is for the desirable teaching.

STEREOCHEMISTRY IN HIGH SCHOOL: HISTORICITY IN BRAZILIAN TEXTBOOKS OF ORGANIC CHEMISTRY

Daniele Trajano Raupp[1], Tania Renata Prochnow[2] and José Cláudio Del Pino[1]
[1] Federal University of Rio Grande do Sul, Porto Alegre, Brazil,
[2] Lutheran University of Brazil, Canoas, Brazil

In this paper, we intend to present a brief analysis of how historical aspects related to stereochemistry are being addressed in Brazilian high school's textbooks. The reason for this research focuses on two points. Firstly, in Brazil, the textbook as a guide to classroom work is a reality, especially since the Federal Government established the National Textbook Program, which consists of free distribution of textbooks for public school students across the country. Second, stereochemistry comprehension is challenging because, in addition to requiring of visuospatial skills, it is sometimes introduced arduously to students who fail to relate this knowledge to their previous experiences, once their teaching is focuses on formulas and nomenclatures, without proper contextualization. This could be one reason that explains why some students show resistance to learn Chemistry. We believe that an approach of using the historical context can awaken a lost motivation on the students, since stereochemistry has many interesting aspects when taught within this perspective. Moreover, motivation can be considered as a requirement for learning. To achieve the proposed goal we analyzed five chemical textbooks approved by the National High School Textbook Program. Applying a methodology to analyze the historical content of science textbooks, we decided to focus on type and organization of historical information, since it provide guidelines for a comprehensive analysis and it is a dimension commonly used in books that seek the application of a story-related approach. The analyzes reveal a deficiency in the historical approach, and the reason may be due to the lack of formal education that most writers (themselves chemistry teachers) have about the history of science. This associated with the fact that teachers rely heavily on textbooks to select historical content to include in their science classes, contribute to a poor understanding of historicity by chemistry students in Brazil.

Keywords: *Secondary school, History of science, motivation.*

INTRODUCTION

The problems related to the formation of scientific concepts of stereochemistry have been widely discussed in the literature. Some researchers pointed out that the main difficulty in solving those problems resides in understanding the three-dimensional level. Difficulty occurs since the ability to visualize three-dimensional aspects of molecules and their relations with other molecules is a considerable challenge (Wu & Shah, 2004; Kozma, Chin, Russel, & Marx, 2000). The complexity of problem solving at this level (Baker, George, Harding, 1998) justifies the fact that for some students learning stereochemistry can be difficult and sometimes traumatic (Kurbanoglu, Taskesenligil, Sozbilir, 2006). Others researchers, however, argue that the learning problem is related to the fact that the topics in organic chemistry are introduced in a way so arid for students who cannot relate this 'school science' with his previous daily experiences. This reflects the thinking of Lima, Pina, Barbosa, & Jófoli (2000) who claim that "Teaching chemistry often has summarized the mathematical calculations and memorization of formulas and nomenclature of compounds". Correia, Donner Jr, & Infante-Malachias comment on the specific case of Organic Chemistry claim that it "is introduced so barren for students who cannot relate this school knowledge with previous experience" (2008, p.489). As a result, the weeks spent studying stereochemistry are somehow viewed as frustrating for students (Evans, 1963). In addition to the students' difficulty in transposing 2D structures in 3D to solve problems in the area, there is this another barrier to be transposed in the classroom: the student's motivation for learning (Cardoso, Colinvaux, 2000). According to Pozo (2002), motivation can be considered as a requirement, a precondition for learning. When the student has an interest in a certain area, that interest impels him to go deeper into it and to overcome the obstacles that may arise during the learning process (Fita, 1999).

Therefore teaching stereochemistry is also a challenge for teachers, as well as to develop strategies that facilitate the understanding of scientific concepts, as one must address the lack of motivation to study chemistry. The complexity of the issue becomes even clearer when we study the early history of stereochemistry. The concept of chemical space (one of the original names of stereochemistry) for some scientists was considered a reverie, being violently criticized, is now considered a key concept, without which modern chemistry would be almost inconceivable (Ramberg, 2000). The idea that there was a spatial arrangement of atoms in the molecule was a scandal in the early nineteenth century, for the prevailing idea was that molecules had no dimensions (Spek, 2006). The history of how the foundations of stereochemistry were constructed reveals a real scientific battle between influential chemists and young scientists. Disagreements did not prevent young researchers from trying to convince their opponents using experimental evidence. The concept of stereochemistry has made it possible to understand how a small number of chemical elements can form millions of compounds and the relationships between structure and properties. Without this key concept, used extensively not only in the field of Organic Chemistry, modern chemistry would be almost inconceivable. So much so that over the last few decades, most of the discoveries in chemistry are related to structural aspects, with several of them being awarded the Nobel Prize in Chemistry.

Thus, we consider that an approach using historical contextualization can increase students' motivation and to contribute to the motivation for learning and the consequent development of competences and desirable skills such as understanding global stereochemistry. So, our research question is: *How are historical aspects related to stereochemistry being addressed in Brazilian high school textbooks?* That´s because in Brazil, the textbook as a guide to classroom work is a reality, especially since 1985, when the Federal Government established the National Textbook Program, which consists of free distribution of textbooks for public school students across the country. So, the purpose of this paper is to present a brief analysis of how historical aspects related to stereochemistry are being addressed in Brazilian high school's textbooks.

TEXTBOOKS AND HISTORICAL CONTENT OF SCIENCE

In the last decades, textbooks have sparkled interest on the part of researchers, due to its importance in the teaching and learning process. As learning resources, textbooks are universal and available to both students and teachers. (García, Izquierdo, Fiedler-Ferrara, & Mattos, 2002; Upahi & Ramnarain, 2019). Some studies point that textbook writers do not seem to pay sufficient attention to historical research on science (Brush, 2000) as a result, there is inadequately addressed in textbooks (Niaz, 2000). This seems to occur not because space limitation, but because of a lack of knowledge of the history and philosophy of science.

According to Leite (2002), the historically organized presentation of science content would be the correct way to give students an adequate idea about the nature of science, how it develops, and how scientists work, some of the concepts or principles; so that students could acquire a sense of how science evolves under the influence of internal and external factors. In addition, the textbook may hold the potential to help students comprehend the relevance of science to their everyday lives, and recognize the scientific process as closer to the real work of scientists (Pellegrino, Peters-Burto, & Gallagher, 2018).

It is necessary to demystify the image of chemistry as a dogma to avoid the idea of a science basically done by geniuses or that is far from done (de Quadros Loguercio & Del Pino, 2007). For this, not only the type of historical material used but also the way it is used are determinants for the type of image of science, scientists and scientific practice given to students (Leite, 1986). There is evidence that, not only in Brazil, teachers rely heavily on books to select the historical content they include in their science classes (Leite, 1986), so the quality of the information presented becomes a crucial point in the teaching of chemistry.

METHODOLOGY

The sample consisted five chemical textbooks (A, B, C, D, E) used in High School, approved for the National High School Textbook Program (Figure 1). When found, the chapters referring to stereochemistry were analyzed based on the dimension considered most relevant by Leite (2002) in her methodology to analyze the historical content of science textbooks: Type and organization of historical information.

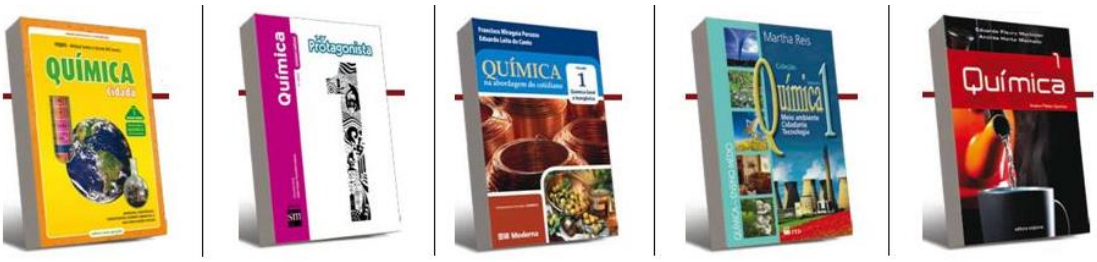

Figure 3. Books analyzed

This dimension provides guidelines for a comprehensive analysis and was chosen because it is a dimension commonly used in books that seek the application of a story-related approach. From these dimensions we selected the following subdimensions (Leite,2002, p.344):

a) Scientists' life

• biographic data (at least name, and date of birth and death)

• personal characteristics (feelings, character, mood, etc.)

• episodes/anecdotes (married to...,decapitated by ...)

b) Type of evolution of science

• mention to a science discovery (a discovery or historical idea is mentioned)

• description of a science discovery (the happening of a certain discovery is described)

• mention to discreet periods (two or more periods/discoveries are mentioned but not related)

• linear and straightforward (one period is related to the following, keeping the direction)
• real evolution (movement 'back and forth' between opinions, including controversies, etc.)

In addition, the names of the scientists mentioned, and the episodes covered in the analyzed books were pointed out.

RESULTS AND DISCUSSION

In general, in the books analyzed, the topic is approached more broadly with the title "Isomeria". It was found that Book C does not address the topic at any time. Books A, B and D, on the other hand, present the content with the aforementioned title and use a classification that contains in addition to the flat isomer the terms and geometric isomer and optical isomer. It has been found that Book C does not address the topic and Book D presents only scientific concepts on content without any mention to scientists or the history of stereochemistry.

It should be noted that both terms are obsolete, and their use is strongly discouraged by the guidelines of IUPAC (2014). According to Gouveia-Matos (1997, p.20) these terms "are known to any high school student of today when studying what is still, unduly, called optical isomerism, and not enantiomers". This improper classification occurs precisely because current books continue to use obsolete terms. Only book E, that is, only one of the five analyzed books names the chapter referring to the content as "Stereoisomerism" and classifies the stereoisomers correctly, (according to IUPAC's recommendation) into two main groups: diastereomers and enantiomers.

Table 1 presents the summary of the analysis.

Table 1.Type and organization of historical information in the Brazilian textbook.

	Scientists		Evolution of science	
Book	Scientists mentioned	Scientists' life (number of citations)	Description of a scientific discovery	Mention of a scientific discovery
A	Friedrich Wöhler Louis Pasteur Jacobus van't Hoff Joseph Le Bel William Knowles Barry Sharpless Ryoji Noyori	Biographical Information (0) Personal characteristics (0) Episodes (3)	Separation of enantiomers (Nobel Prize 2001)	Finding the isomerism
B	William Knowles Barry Sharpless Ryoji Noyori	Biographical Information (3) Personal characteristics (0) Episodes (1)	-	Separation of enantiomers (Nobel Prize 2001)
C	-	-	-	-
D	-	-	-	-
E	Melvin Spencer Newman Jacobus van't Hoff Joseph Le Bel Adolph Kolbe	Biographical Information (3) Personal characteristics (0) Episodes (1)	-	Discovery of Chirality (Nobel Prize 1901)

In Book A, the episode of the urea synthesis, a historical fact of the finding of isomerism by the chemist Friedrich Wöhler, is quoted, it can be seen that in the description there is no biographical information (not even nationality). Described as the work of an isolated scientist, when in fact a group of scientists was responsible for it. The pattern is followed for Louis Pasteur, van't Hoff and Le Bel. Louis Pasteur is quoted in the episode "Discovery of Optical Isomerism" by his study of polarized light which is continued by van't Hoff and Le Bel. Classified as a description of a scientific discovery, because it explains with some level of detail the experiment performed with polarized light. The asymmetric synthesis research conducted by Knowles, Sharpless and Noyori points out that they were awarded the Nobel Prize in Chemistry in 2001 for being responsible for developing methods to obtain enantiomerically pure compounds on an industrial scale. There is no information about the method or how the work was developed and so classified as mention.

The award is also cited in Book B, the only mention being made to scientists throughout the chapter, presented in a table "Chiral Drugs: Asymmetric Catalysis gives Nobel Prize." The authors, in this case, inform the nationality of the scientists. In Book E, the first scientist mentioned is Newman in the passage that presents the concept of conformational isomers, only a mention to explain the origin of the name of the representation, without bringing any data from the scientist. In the "Curiosity" box titled "The Asymmetric Carbon Controversy" he deals in detail by citing the scientists involved (van't Hoff, Joseph Le Bel and Kolbe) as well as acceptance in the scientific community. The text presents biographical information as well as the dates in which the facts occurred, from the beginning of the researches in 1874, as well as the harsh criticisms that the discovery provoked in the scientific community until its acceptance the consecration of van't Hoff, like the first chemical to receive the Nobel Prize in 1901. Thus this episode is classified as a description of a scientific discovery containing detailed information that allows the understanding of the episode as a fact that contributed to the evolution of the field.

It is clear that only the categories mention and description of a scientific discovery are identified in the analyzed materials. This shows the reduction of the historical content to biographies and superficial discussion about the way that the science is built. That is considered one of the problems that may arise when history of science is included in science teaching; Leite (2002) argues that, naturally, there is nothing wrong in using them, since ‘It is as valuable to know something of the lives of great scientists, but the point is that, perhaps unconsciously, sometimes history of science is reduced to names and dates’.

ACKNOWLEDGEMENT

PROPESQ - Dean of Research - Federal University of Rio Grande Do Sul

FINAL CONSIDERATIONS

In general, answering the research question, the books analyzed do not privilege the understanding of the historical evolution of stereochemistry. Books A, B, and E cite some scientists who are part of the construction of this field as well as historical facts. Nevertheless, some author's concern to present information related to daily life is noticed, even if most of it is done superficially. Thus, the presentation of the historical content in the analyzed High School textbooks seems to us unsatisfactory, since the understanding of the concepts must be done in a socio-historical perspective so that students can attribute meaning to the field of study, noting the evolution of the area and its importance in everyday life. If the story or even the everyday-related examples are treated as mere additional information or a "curiosity", students can get the message that names and formulas are the focus of study and that the understanding of other aspects are unnecessary or irrelevant. Even more when we consider the fact that students may not understand phenomena that are not related to their daily life. Finally, a motivational approach to science teaching must be with a context-based to promote the relevance of learning in the students' view (Gabel, 1993; Holbrook & Rannikmae, 2017) mainly on stereochemistry, once comprehension is challenging, and without proper contextualization it becomes even more difficult for students. The great advantage is that stereochemistry has many interesting aspects and an interesting and rich history to be learned within an historical perspective.

PART 7: STRAND 7

Discourse and Argumentation in Science Education

Co-editors: *Maria Andrée & Kalypso Iordanou*

CONTENTS

STRAND 7: INTRODUCTION

DISCOURSE AND ARGUMENTATION IN SCIENCE EDUCATION

Strand 7 Discourse and argumentation in science education includes research on the understanding, supporting and promoting use of evidence and argumentation discourse in science education. The strand also includes research on scientific practices related to knowledge evaluation and communication, supporting the development of critical thinking, discourse analysis, meaning making in science classrooms and talking and writing science in the classroom. Although there has been substantial interest in discourse and argumentation in the field of science education research for the past decades, the developments of what is called the 'post-truth era' or the 'post-truth society' has emphasised the urgency of attending to matters of critical examination and argumentation in science education. To science teachers these societal developments poses challenges regarding how to teach appreciation of scientific evidence and argument while, at the same time, establishing inclusive science teaching practices where students' personal experiences, views and emotions are acknowledged and welcomed. This E-proceeding includes nine contributions; all contributing to advancing the understanding of potential roles of argumentation and critical thinking in science education from primary school practices to undergraduate studies.

Taking the post-truth era as a starting-point, Yann Shiou Ong and Richard Duschl argue that engaging students in problematizing data and evidence in scientific inquiry is an essential part of what activities are required in science education for supporting the development of students' critical stance. Ong and Duschl contribute to the proceedings with a study of students' problematizing data and measurement issues during an extended group discussion. Their findings provide suggestions with regards to the instructional design and moves that might be useful for sustaining students' problematisation of data and validity of claims. The proceedings include additional contributions pointing to the importance of focussing on qualities of scientific argumentation.

Maria-Antonia Manassero-Mas and Ángel Vázquez–Alonso point to the importance of problematising the concepts for discussing argumentation. More specifically they discuss the importance of the different geneologies of critical thinking and scientific thinking. Manassero-Mas and Vázquez–Alonso argue that critical thinking is a construct created stemming from cognitive psychology and developed in philosophy, whereas the notion of scientific thinking has emerged from scientific practice in science education from the studies of history, philosophy, sociology, nature and processes of science (among many others).

The remaining contributions to the E-proceedings focus on the scrutiny of argumentation and discourse in science education classroom practices in different parts of the educational system.

- Argumentation in primary science education: Jennifer Krupinski, Sarah Rau-Patschke and Stefan Rumann have studied of how primary school students explain scientific phenomena orally and how their explanations change from 1st to 4th grade. The results are intended to be used for developing evaluations of oral explanations in primary school and future interventions.
- Argumentation in secondary science education: Gonzalo Bermudez, María Ottogalli, and Lía García examined the application of a learning sequence they developed on using Toulmin's Argument Pattern (TAP) to make decisions on biodiversity issues. Examining students' and teachers' discourse, results revealed several obstacles

including students' difficulty with terminology of TAP, little motivation to engage in group discussions and evaluation of knowledge claims, as well as limitations in students' epistemic judgments. Teachers contribution was found to be limited to knowledge activation and management of the activity.

- Argumentation in higher education: Maria José Cano Inglesias, Antonio Joaquín Franco- Mariscal and Ángel Blanco-López compared the capacity of second-year engineering undergraduate students with pre-service science teachers to identify evidence in argumentation. The results show that both groups of students were able to provide arguments with evidence using a wide range of evidence, however the pre-service science teachers provided arguments of better quality of evidence. Based on the results, Inglesias and her colleagues argue there is a need for recognizing argumentation as a capacity that needs to be trained in education. Bruno Kestutis de Alvarenga Sipavicius, Jo Rodrigo Santos Silva and Daniel Manzonide-Almeida examined the production of arguments and graphic inscriptions in an inquiry-based learning activity. Results showed that students who were are not previously exposed to graphic and schematic literary inscriptions in basic biology classes before the application of the activity produced more arguments and drawings (graphic design, schematic design or free artistic design) compared to a group of students who first engaged in analysis of graphs and images and then pursued the inquiry-based activity. Welington Francisco, Lôany Gonçalves da Silva and Wilmo Ernesto Francisco Junior analysed the dialogues of six undergraduate Chemistry Course students, using a model which establishes relationships between the verbal actions performed in the pragmatic, argumentative and epistemic plans with the enunciative strategies. The results showed that the initiations of metaprocess - demanding a construction of ideas and major reflection - and process type - demanding an opinion or interpretation of who is answering - favored the argumentation because they demanded a higher level of students' reflection and engagement that triggered epistemic operations of low and higher cognition such as definition, classification, explanation and generalization.
- The role of teachers in promoting practices of argumentation. Based on an episode from chemistry teaching in a Brazilian public school, Gabriel Saraiva Gomes and Marcelo Giordan problematize the role of argumentation related to socio-scientific issues (SSI). They illustrate and discuss how the controversial character related to SSI need to be conceptualized as a discursive construction performed by teacher and students in the classroom. Ana Elisa Montebelli Motta and Marcelo Tadeu Motokane conducted a study of discursive moves of a pre-service biology teacher that are related to students' work with evidence. Their results suggest a relationship between discursive moves of the pre-service teacher and the students' construction of evidence and point to a lack of metacognitive moves. They argue the results reflect a lack of metacognition related to argumentation in teacher education.

CLUSTER SIZE MEASUREMENT: A STUDY OF SECONDARY STUDENTS PROBLEMATISING DATA

Yann Shiou Ong[1] *and Richard A. Duschl*[2]
[1]Nanyang Technological University, National Institute of Education, Singapore
[2]Southern Methodist University, Texas, USA

Taking a critical stance toward public information in the post-truth era is essential for citizens' decision making. Such a critical stance stems from problematising the evidence—consideration of what might be uncertain and thus problematic about a claim. This paper contributes to existing research on problematising by reporting on a discourse analysis of students' problematising data and measurement issues during an extended group discussion. Through moment-by-moment analysis of group discourse, problematising instances that sustained the discussion were identified. Findings suggest instructional design and moves useful for sustaining students' data problematisation and scaffolding their epistemic cognition around claim validity.

Keywords: Decision making, Instructional Strategies, Investigative Learning

INTRODUCTION

In the post-truth era, taking a critical stance toward public information tainted with misinformation, "alternative facts", and "fake news" is essential when making decisions with personal, social, community, and global impact. Such a critical stance stems from problematising the evidence when consumers of public information consider what might be uncertain and thus problematic about a claim. Problematising is a central activity across the sciences (Phillips, Watkins, & Hammer, 2018) as scientists constantly struggle with making epistemic decisions around what and how to measure/observe, what data to keep or discard, how to represent and interpret data and patterns, and what is the most scientifically sound explanation for the observed patterns as evidence (Grandy & Duschl, 2007). Thus, engaging students in problematising data and evidence in scientific inquiry is an essential part of scientific activity supporting students' critical stance development.

According to Engle and Conant (2002), problematising refers to opening up issues via students' questions, proposals, challenges, etc. Problems could be presented to students by their teachers or emerge during student activity. Focusing on what motivates problematising, Phillips and colleagues (2018) interpret problematising as students' intellectual efforts in conveying their feelings of uncertainty as a question. Through analysing episodes of class discussions around phenomena, demonstrations, and homework problems, Watkins and colleagues claimed students' demonstration of uncertainty by positioning themselves as not understanding, confused, or uncertain led to their scientific engagement (Watkins, Hammer, Radoff, Jaber, & Phillips, 2018). However, similar to many scientific argumentation interventions in K-12 classrooms, such discussions problematise what counts as evidence in support of claims but miss out on opportunities for students to problematise data. That is, students do not get to grapple with empirical uncertainties associated with making measurements and data representation/interpretation, all of which are essential to the work of scientists (Manz, 2018).

Motivated by the identified gap in existing literature, this paper contributes to research on epistemic cognition/practices by reporting on a study examining how problematisation of data was sustained among a group of ninth graders in a Singapore school, resulting in extended discussions examining data measurement issues. The paper seeks to answer the research question (RQ): How was problematisation of data sustained among students in a group (a) without and (b) with teacher involvement? Based on study findings, the paper highlights useful instructional designs and potential discourse and mediation moves for sustaining such discourse.

METHOD

The discourse data comes from a larger research study of four student groups' critique and construction of claims over a three-semester inquiry course in a Singapore secondary school (Ong, 2018). Each group worked on an open-ended inquiry project of their choice. In semester one, two groups (A1 and A2) experienced student-centred critique instruction designed using the Productive Disciplinary Engagement guiding principles (Engle & Conant, 2002) to foster students' engagement in scientific critique. Scientific reports and posters were *problematised* as research products to be critiqued, scientific soundness criteria (broadly aligned with the constructs of validity and reliability) were introduced as *critique resources*, students and teacher *shared epistemic authority* to critique, and ideas were held *accountable* to the scientific discipline via the scientific soundness criteria. A2, the group studied in this paper, comprises three students—Victoria (V), Jane (J), and Kang (K) (pseudonyms). A2 investigated the effects of vibration frequency on size of clusters formed by soap water droplets, which was inspired by a problem in the 2016 International Young Physicist Tournament ("ultrahydrophobic water" problem) ("IYPT Problems," n.d.). The group dropped soap water droplets using a dropper from a height above a water-filled petri dish placed above a sound amplifier, which functioned as a vertically vibrating source. At certain frequencies, the soap water droplets form clusters which remained for a while on the water surface. The group investigated how the vibration frequency of the source affected the size of droplet clusters formed on the surface of the water.

A2's discourse is selected for analysis as it represents a unique dynamic segment where students engaged in eight minutes of talk interrogating data and measurement issues around *how to measure cluster size of droplets from recorded videos*. The discourse segment is twice as long as other groups' longest singular topic segment (two to four minutes) about data collected during investigations. Following A2's group talk, the first author—also the inquiry course co-teacher—joined in A2's discussion for a further 13 minutes. All 21 minutes of the "cluster size" discourse segments were transcribed and analysed. Problematising instances were analysed first by examining questions (i.e. discourse moves to clarify a previously mentioned idea or to seek new ideas) and second by identifying challenges raised (i.e. discourses that identify problems with an idea) from the transcript. Talk turns around questions and challenges were interpreted to characterise how data was being problematised. Questions and challenges that shifted what was problematised yet sustained the cluster size measurement problem were coded as problematising instances.

FINDINGS

The "measuring cluster size" discourse segment started with A2 students reviewing videos they took of droplet clusters forming on the surface of a water-filled petri dish. Table 1 summarises the 8-minute group talk around how cluster size should be measured based on the problematising instances, what was problematised, and the students' proposed solutions. Students' pseudonyms are abbreviated as V, J, and K for Victoria, Jane, and Kang respectively.

Table 1. Summary of the "measuring cluster size" discourse segment

Problematising Instance #x = line no. (( )) = actions/inferred idea	**What's Problematised**	**Proposed Solution(s)** #x = line no. (( )) = actions/inferred idea
#1 V: When we look at the video, how will we know ((the diameter))?	How to measure cluster diameter?	#2 K: Find the longest point Note: A2's initial proposal was to measure cluster diameter
#14 V: If we have two frames that are very close, if the cluster width is about the same, do we have to measure every one?	What if clusters in two frames have similar widths?	#53 K: Focus on one area. #54 J's counter: Clusters move on their own.
#58 V: If we have a few clusters, what do we do?	Which cluster to measure if there are multiple clusters?	#59-61 K & J: Find biggest cluster size because that's the research question – how frequency affects cluster size.
#65 V: How do you know if this cluster is bigger, or this is bigger, or this is bigger? ((referring to image on laptop))	How to determine biggest cluster of droplets?	#67 J: Count the droplets. #70 V: Measure diameter of cluster in every frame #74 K: Take three or four frames that look the biggest then measure the diameter. #75 V's counter: Clusters all look about the same. #84 K: Measure diameter of cluster with most droplets.
#87 J: If we're measuring diameter, coz the droplets can move, what if it moves from like that ((gestures ⬯)) coz this is the maximum…into like that ((gestures ⬭))?	What happens if a cluster changes its shape?	#88-89 K & V: Measure the up-down ((cluster height)). #90 J's counter: It could be become a circle or an oval. #91 K: Find the bigger diameter. #94 J: Cluster has same amount of water droplets. #96-110 A2 decided to use two factors: (a) how many droplets and (b) diameter to find biggest cluster.
#113 V: What happens if we have two results: 1. the diameter is larger but there are less droplets. 2, the diameter is not so large but there are more droplets?	What happens if we have results with conflicting measures based on the two factors?	#116, 118 J: Compare the entire thing, the shape. #119 K: Take priority – diameter or number of droplets. #120 J: Number of droplets is priority. #121 V: But number can be ((incomplete sentence)) #122 J's counter: But the droplets are around the same size.
#123 V: Some droplets are small, some are big ((based on video)).	Are droplets of similar size?	#124 J: Droplets are quite around the same size. #124-127 J & K: There's definitely inconsistences in the droplets for every experiment.

#128 V: If we are finding number of droplets, why are we even finding the diameter?	Why do we need factor (b) diameter?	#130 K: Our main thing is to find cluster size. #131, 137 J: Cluster moves so its diameter changes ((c.f. #87)). You have to compare the entire size.
#144 V: Is there any way we can find the average of both?	Can we average factors (a) and (b)?	#145, 147 K: No way. One is length, one is amount. If such as situation happens, we find the priority. #148-151 V: That means in our experiment, we have to assume that all the droplets are the same size. K & J agrees.

In summary, the "measuring cluster size" segment saw A2 deliberating over two possible measures: number of droplets in a cluster or cluster diameter. The segment ended with the group concluding they had to assume all droplets are of the same size in order to use number of droplets as cluster size measurement. Note that the group's decision to use number of droplets differs from their initial plan to use cluster diameter as cluster size measurement, as stated in their investigation proposal (completed prior to the analysed discourse segments).

After A2 reached the conclusion, Kang sought confirmation with the co-teacher on their decision to use number of droplets as cluster size measurement and their proposed assumption. This led to the "validating assumption" discourse segment between the students (V, J, and K) and the teacher (T). Table 2 summarises the 13-minute group talk around how A2's proposed assumption could be validated.

Table 2. Summary of the "validating assumption" discourse segment

Problematising Instance #x = line no. (( )) = actions/inferred idea	**What's Problematised**	**Proposed Solution(s)** #x = line no. (( )) = actions/inferred idea
#158 K: Can we make an assumption that the droplets are all the same size?	Can we assume all droplets are of the same size?	#159-167 A2 justifies their change in cluster size measurement by highlighting problem with cluster diameter (c.f. Table 1, #87 for problem).
#168 T: Which one will be more scientifically sound? Let's say you try to present this to your peers or other scientists, what do you think they will say is the problem with your approach?	Which measurement, number of droplets or cluster diameter, is more scientifically sound?	#178 K: We should ditch diameter, cos if people are going to copy our experiment, they're going to work…make even more then they'll get at the exact same thing. Or, they'll just use amount like one drop, two drops, three drops, but assuming that it's all the same… ((K's idea seems to suggest using number of droplets would ensure reproducibility of their results by others carrying out the same investigation, or that others would make the same assumption about droplet size))
#190 T: How can you strengthen your argument? How can you make your case stronger?	How to strengthen argument for using number of droplets as cluster size measurement?	#191 J: I can make a diagram on the board. #194, 196 K: I think the idea we got is quite okay. It shows why we shouldn't use diameter. Over cluster size. ((referring to highlighted problem with diameter in #159-167))
#208, 210 T: So, is there some way you can provide us with more evidence…that your assumption is valid or sound?	What evidence supports validity of assumption (droplets are of same sizes)?	#213-216 V: ((From videos)), it's not that much difference with size.

#217 T: Am I supposed to visually see that they are not much different?	How to observe (lack of) difference in droplet size from videos?	#218 K: Use a ruler to measure. #228-239 A2 and T discussed the group could determine range of droplet sizes with a frame, and repeat it for a few video frames. #245-256 A2 and T discussed idea of finding average ((instead of range)) size of droplets over several frames. The idea was dropped because it would take too much time.
#260 T: How many frames do you need?	How many frames to sample?	#261 K: I think, five? #262 V: Three? #266, 268 J's counter: Three is too little…five? Five to ten. #269 K's counter: Ten is too much. #289, 293 J's counter: …it depends on how many…frames per second we are doing. Like 60 frames per second, we're doing like five frames? That's too little.
#270 T: How do you pick the frames?	How to sample the frames? Note: At this point, students and the teacher do not have common understanding of what they should measure in sampled frames: cluster size or droplet size	#270-274 K: Pick the five frames that are the biggest cluster. J agrees with K #275 T: Why the biggest cluster? #276-277 K & J: Because that's what we're finding…which is the biggest cluster size. #282 K: Among this entire video ((i.e. within the same video)), we find five frames that is the biggest cluster size.
No questions or challenges posed to cause shift in what was problematised.	How to measure "size"? Note: At this point, students and the teacher do not have common understanding of what they are measuring: cluster size or droplet size	#294 K: We can use a ruler and put it on the computer. #295 V's counter: Don't use a ruler. #295 K: Then we use…a scale. So if it's 12 cm on the computer, it is 8 cm in real life. #301 J's counter: But the Tracker ((a motion sensing software)) can already do it. #302-309: K & V do not want to use the Tracker as they find it weird and do not understand it. #312 T: Just print it ((image of cluster)) out and measure it ((droplet sizes)). #315 K's counter: If it expand and expand, then it will become a bit blurry.
#324 T: What's your ((referring to V)) concern if we sample based on one video? ((#283 V: You want to do it within the same video?))	Should sampled frames come from one or multiple videos? Note: At this point, students and the teacher do not have common understanding of what they are measuring: cluster size or droplet size	Previous proposed solution is to use one video, c.f. #282. #326, 329 J: Because it's just one video? One video takes a lot of effort…one second in each video is 60 fames. #328 V's counter: Take a few frames from each video. Because if you just take one video, then one person drop ((the droplets) then it's ((incomplete sentence)) #335, 341 J &K: It is possible that in one video, one frame has a lot of droplets but in the next frame, it collapses so there are no droplets. #346 V's counter: Don't choose the frame where it collapses. #347 K: Our five frames must be the biggest amount. #350 V's counter: Choose any five frames within the whole ((video)) #351, 353, 355 K: No, five frames in that ((incomplete sentence)). It's better than five seconds in that video which is different. It's not going to be fair because ((referring to video with J dropping the droplets)) if you're going to use five seconds in different positions ((points to different positions

		in video timeline)), it is not going to be very fair. ((K seems to equate one frame to one five second)). #361, 363 V's counter: It's more fair if we do from different things. Then you can show that even though there are differences in other variables…the droplet size still doesn't change. #364 J: No, now we're only changing one variable. We can't change another variable for this.
#365 T: What are we trying to do with this sampling anyway? What are we trying to find out?	What is the purpose of sampling video frames?	#366 J: The cluster size? #367 V: Show that there is not much difference in the droplet size. J realises her misunderstanding; K agrees with V.
No problematising instant as the discourse re-joins previous discourse based on what was problematised.	Should sampled frames come from one or multiple videos?	#373 J: What if one big droplet just dies in one frame and then in another frame there's tiny droplets? #374 V's counter: That's not our fault coz we're trying to find the difference in droplet size. If the droplet collapses, then so be it. Just take another frame with a lot of droplets. #380, 382 K's counter: Actually, I'm thinking about it, five frames per second there's not much difference…Because in five frames per second, in that five frames in one go, how many droplets will J actually drop? Not much. #384-387: V & K: Doing five frames of the same thing won't make much difference. Say, you're doing five droplets of the same duration when the result is almost the same, then what's the point of doing it? #390 K: So I think V was right. We should pick five frames in different times.
No problematising instant as the discourse re-joins previous discourse based on what was problematised.	How many frames to sample?	#390 K: So one video is 15 seconds right? #391, 395 V's counter: It's more like a full minute…or more. #394, 396, 398 K: Then we take the five best… at different intervals. Coz you can't pick the best five in like a five second interval.
#400 J: How do you pick the best?	How to decide "best" frames to sample?	#402-403: V & K: The most number of droplets in the video. #404 T: Why? #405 J: Because, more variation. #407 K: So if the other teacher asks, oh that variation is too…big. Then we can say that this is the biggest variation ((inaudible)) a frame. #408 V: So this is the most number. If even within the most number, there is not much difference, that means ((incomplete sentence)). #412 T: Is it logical, or not? Will you be convinced if someone said that to you? #413 K: Yeah #428 K: Because in the end, what we're doing for this thing is just to find, is just to put our assumption in a test in saying that, is it ((the droplets)) the same size, and then vary it. ((Unsure what K means by the second "it". Could refer to number of droplets or cluster size)).

To summarise, in the "validating assumption" segment, the first author (co-teacher) initially problematised the scientific soundness of A2's decision, asking A2 what their peers or other scientists might find problematic with their approach. She then requested A2 to provide evidence to support their assumption as valid or sound, which led to discussion of how A2 could determine droplet size range from video frames and how to sample the frames/clusters. The discourse segment also saw the first author clarifying with the students what they were trying to determine with the sampling (#365), as the lack of common understanding on the purpose of sampling became apparent from the students' persistent disagreements over whether the video frames/clusters should be sampled from within one video or across multiple video recordings (c.f. Table 2, #351, #353, #355 versus #361, #363). After the students reached a common understanding, they agreed on sampling frames from multiple videos, the number of frames to sample, and the criterion for selecting the fames to sample.

DISCUSSION

During the "measuring cluster size" segment (Table 1), students initially sustained the cluster size measurement problem by highlighting inadequacies of proposed solutions in relation to observed cluster behaviour in videos (instances at lines #14, #58, #65). That is, students tested the solutions on empirical data. Students then came up with hypothetical scenarios of cluster movement and data measurements (#87 and #113) to test the limits of proposed solutions. The group incorporated two factors for measuring cluster size and prioritised one factor, in order for the measurement to encompass the hypothetical scenarios. Next, Victoria challenged the necessity of the cluster diameter factor as a measure of cluster size if they were to prioritize the factor of number of droplets (#128). To keep both factors, Victoria wondered if they could "find the average of both" factors (#144), which Kang rejected as the factors measured different physical quantities (length versus amount) (#145, 147). Consequently, A2's discussion of the cluster size measurement problem led them to identify an assumption they had to make in their investigations: all the droplets were the same size (#148-151).

The group brought up the issue of their assumption to the first author (also the co-teacher), possibly to seek endorsement from the teacher. While the first author could have resolved A2's measurement problem by approving their assumption, she sustained the problem and upped the ante by problematising the scientific soundness of the group's measurement decision and the validity of their assumption (Table 2, lines #168, #208, #210). With the researcher's support, including redirecting students to the purpose of sampling video frames (#365) when a lack of common understanding of the purpose was noticed, A2 rose to the challenge. The group concluded they would measure variation in droplet sizes (using frames from multiple video recordings, with justification for why this is a better approach than using frames from a single recording) to justify their assumption that droplets have similar size.

CONCLUSION

The "cluster size" analysis presented in this paper suggests some useful instructional designs and moves for sustaining data problematisation. Inquiry instruction was designed to have students plan and carry out investigations and work with empirical data they collected, with limited teacher intervention until students have had opportunities to grapple with their data. Working with messy, real data meant students' initial proposed measurement might not always work, which was what A2 realized as do many scientists. Instructional moves within students' grasp for sustaining data problematisation include: testing (measurement) solutions using hypothetical scenarios, identifying the solution core by questioning necessity of all solution parts and considering synthesis of solutions, and identifying assumptions in solution. More challenging instructional moves that may require instructor's scaffolding include: problematising scientific soundness (e.g. validity and reliability) of (measurement) solutions and validity of assumptions, as well as redirecting students when lack of common understanding is detected (e.g. when disagreements persist). While these instructional design and moves are non-exhaustive, they suggest what students are capable of when given the opportunity to problematise data.

ACKNOWLEDGEMENT

We would like to thank the students and their teacher mentor for participating in the research study.

SCIENCE EDUCATION AS THINKING: THE BEAUTY OF SCIENTIFIC THINKING AND CRITICAL THINKING

Maria-Antonia Manassero-Mas[1] *and Ángel Vázquez–Alonso*[1]
[1]University of the Balearic Islands, Palma, Spain

This communication studies two key cognitive competences in 21st-century education, namely, critical thinking and scientific thinking, which have different origins and traditions. Critical thinking is a construct created within the framework of cognitive psychology and has been cultivated especially in philosophy since the old times, whereas scientific thinking emerged from scientific practice in science education, mainly from the studies of history, philosophy, sociology, nature and processes of science (among many others). Due to their different research traditions, both concepts are expressed in specialized literature with different formulations, terminologies and dialectics. This communication explores the relationships between critical thinking and scientific thinking in order to elaborate a synthesis, connect both research programs and show their resemblance in order facilitate their understanding and implementation by science teachers who are not specialists in these issues. Finally, the applications and the implications of the resemblance for science education are discussed.

Keywords: Scientific competences, scientific thinking, critical thinking.

INTRODUCTION

Currently, several educational organizations and experts agree about the great value of thinking for 21st-century general education. Thus, critical thinking (hereafter CT) has become a centre of attention in mainstream education, as it is broadly considered important and functional for personal, social and work life (National Research Council, 2012). The European Union (2014) proposed seven key competences and some transversal skills to achieve key competencies: critical thinking, creativity, initiative, problem solving, risk assessment, decision making, communication and constructive management of emotions. The OECD's (2009) PISA skills and competencies for the 21st century involve three dimensions, which include skills such as research, problem solving, creativity, decision making, critical thinking responsibility and the ability to think independently. Furthermore, many prestigious educational experts suggest keys for deep learning that include critical thinking as a common issue; for instance, Fullan's 6 C competencies for deep learning include critical thinking, creativity, communication, collaboration, citizenship and character (Fullan & Scott, 2014).

On the other hand, scientific thinking (or scientific reasoning, as it is also labelled) emerged in science education. An extensive literature on history, philosophy, sociology and nature of science, socio-scientific issues, argumentation, meta-cognition, reflection, and some papers on processes of science often mention a set of cognitive, epistemic, procedural and value skills that are put into play in scientific practice. Further, some prefer the label scientific reasoning to refer to scientists' habits of mind (Kind 2013), yet this label may convey some reductionism of scientific thinking to logical thinking.

As CT consists of challenging beliefs from reflective analysis to clarify and distinguish mere opinions from propositions based on information and evidence, it directly connects with the very essence of scientific knowledge, often understood as the coordination of facts and theories to validate knowledge (Kuhn, 2002).

This study elaborates the concepts of CT and scientific thinking to unveil their resemblance; as a consequence, the claim that CT may be considered a cross-cutting concept for science education is discussed. Further, the lack of consensual conceptualisations for the two concepts leads to different formulations, terminologies and dialectics, which is especially misleading for teachers to achieve 21st-century educational competences. Hence, another aim seeks to contribute some clarification for the two concepts that provides clearer understanding for teachers and science teachers who are not specialists in these issues in order to teach them with quality. Moreover, a claim is made to consider CT a cross-cutting concept for both general and science education and, as a consequence, to discuss the contributions and implications of their role in science education.

Critical thinking

CT is the key tool of philosophy since its birth, yet its conceptual framework has been mainly developed within cognitive psychology along the 20th century, involving the so-called higher order thinking skills. The CT literature provides multiple definitions, each contributing to highlight some important aspects of critical thinking, yet this multiplicity suggests that scholars disagree about a consensus definition. Norris and Ennis' (1989) short definition is one of the most celebrated: "... reasonable thinking that is focused on deciding what to believe or do".

Beyond the lack of consensus on the definition, scholars agree that CT is composed of multiple skills, so that some scholars choose to define CT through the complex and diverse set of higher order skills that are put into play when thinking. For example, Fisher's (2009) extensive definition proposes the following skills for CT: identifying the key elements; identifying and evaluating assumptions and implicit values; clarifying and interpreting expressions and ideas; judging the acceptability and credibility of affirmations; evaluating different types of arguments; testing your own conclusions; producing arguments; appreciating and interpreting data and evidence; recognizing logical relationships between propositions; understanding and using language with clarity, precision and discrimination. Further, some controversies about the differential relevance of skills are still hotly debated, yet some scholars agree to distinguish between basic, process and dispositional (values) skills (Costa, 2001).

Several educational programs have been established and applied for teaching CT for decades (Costa, 2001). Most programs still remain empirically untested in terms of determining their actual impact and thinking achievements (Saiz, 2017). Indeed, efforts have been made over the years to assess the effects of such complex and elusive learning, and some assessment tools have come to light, but they are not without controversies (Norris & Ennis, 1989).

Scientific thinking

Kind (2013) traced back the history of scientific reasoning to conclude that it involves three types of knowledge (content, procedural and epistemic knowledge). Further, Kind and Osborne (2016) considered the lack of consensus about the meaning of scientific reasoning a failure and proposed a taxonomy that involves six styles of scientific reasoning: mathematical deduction, experimental exploration, hypothetical modelling, categorization and classification, probabilistic and statistical thinking and evolutionary accounts.

On the other hand, some scholars prefer the term scientific thinking to label the kind of thinking skills involved in scientific practice. This trend underlines scientific thinking as the intentional coordination of theory and evidence to seek, understand, interpret, represent and explain knowledge (Faye, 2014; Kuhn, 2002).

Further, an extensive science education literature on history, philosophy, sociology (socio-scientific issues), and nature of science, argumentation, meta-cognition, reflection, and some papers on the processes of science have contributed to the development of the skills and values involved in scientific practices to validate scientific knowledge, yet just a few explicitly use the concept of scientific thinking (hereafter SCFT) to refer to that wide multiform mind-set of scientists' skills and values involved in scientific practice. For instance, the Next Generation Science Standards (NGSS, 2013) propose for scientific practice the following skills, which constitute a kind of basic universal SCFT:

- asking questions and defining problems
- developing and using models
- planning and carrying out investigations
- analysing and interpreting data
- using mathematics and computational thinking
- constructing explanations and designing solutions
- engaging in argument from evidence
- obtaining, evaluating and communicating information

Erduran and Dagher's (2014) reconceptualization of the nature of science (NOS) presents a broader SCFT inventory when developing the two interactive NOS dimensions (cognitive-epistemic and social-institutional). The first one includes scientific practices, aims and values, scientific knowledge and methods and methodological rules, and the second one contains professional activities, scientific ethos, social certification, social values, and organisational, political, and financial aspects of science. In turn, each of them includes specific science skills and values (classification, observation, experimentation, epistemological tenets, institution networks, critical examination, theory choice, anomalies, peer evaluation, creativity, contributions from different persons, etc.). Similarly, Manassero-Mas and Vázquez-Alonso (2019) also proposed a broader collection of SCFT skills for scientific practice.

Some science education literature identifies the students' difficulties in learning nature of science and socio-scientific issues, and highlights some of the students' basic thinking errors, such as ignoring data and justifications, introducing personal opinions, making inadequate inferences and reinterpretations, jumping to conclusions as self-evident, not admitting evidence contrary to their ideas, inability to evaluate counter arguments and lack of basic epistemic knowledge, such as confusing facts and interpretations (García-Mila & Andersen, 2008; McDonald & McRobbie, 2012).

RESULTS

Scientific thinking

The literature on SCFT is summarized in a taxonomy that has been elaborated previously and involves ten broad aspects of SCFT (Vázquez-Alonso & Manassero-Mas, 2018). Seven SCFT aspects of the taxonomy have a predominantly epistemic orientation:

1. Observation
2. Categorization
3. Pattern recognition
4. Creation and verification of hypotheses
5. Control of variables
6. Models, metaphors and analogies
7. Coordination of explanations and evidence

The remaining three aspects of SCFT show a predominantly social orientation:

8. Elaboration of materials
9. Information and communication
10. Attitudes and values

The former ten aspects of SCFT are so broad that their epistemic or social dominant orientation is primary in each aspect, yet this dominance should not be interpreted as pure or exclusive in any of them. Furthermore, each aspect of SCFT can be broadly developed in a list of exemplary skills that contribute to characterize the aspects and help to provide much specific connection to science education curricula. The list highlights some significant skills associated with each aspect, though in any case, the list must not be taken as exhaustive or closed, as it still is open to scrutiny for enlarging or completing the depiction of each SCFT aspect.

The first aspect, observation, is likely the simplest aspect of SCFT, which involves all kinds of watching, collecting data, gathering information, describing, chronicling, etc. on the entities under observation.

The aspect categorization knowledgeably involves scrutiny skills such as defining, sorting, organizing, ordering, analysing, comparing, contrasting, etc. assumptions, concepts and problems concerning the entities under research.

Similarly, the categorization skills involve grouping similar data, quantifying measurements, discovering regularities, synthesizing and generalizing the empirical data.

The aspect about creation and verification of hypotheses embraces skills such as asking questions, identifying problems and assumptions, formulating hypotheses, planning and developing investigations, applying statistical analysis, using technology appropriately and applying mathematical and computational thinking.

The control of variables is likely the most representative aspect of the experimental character of many procedural scientific practices that involve highlighting surprising or contradictory data, posing practical problems, using logic, controlling the effects of multiple variables and attributing causality to events.

The coordination of explanations and evidence includes central skills: using tests, arguing and identifying evidence data, deducting, inferring, and abducting conclusions, issuing critical judgments, accepting and rejecting theories, validating knowledge, suggesting solutions or comparisons, and constructing coherent, valid and reliable explanations and theories.

The aspect models, metaphors and analogies involves creating models, analogies and theories, solving problems, making decisions, searching bases for knowledge, replicating theories, models and knowledge and simulating models and data.

The information and communication aspect is revealed in skills such as communicating and sharing knowledge, publishing discoveries, working cooperatively as a team, participating in congresses, discussing theories and solutions with colleagues, evaluating one's own and others' communications and assuming personal and social responsibilities.

The elaboration of materials aspect involves all kinds of skills that contribute to elaborating the tools needed to inform the scientific practice, such as exploring the literature and hypotheses, constructing tables, figures, diagrams and graphs, creating and imagining investigations and experiments, developing technologies, tackling scientific and social needs and problems and informing scientific policies.

The scientific attitudes and values involves acting ethically and legally, whilst cooperating and competing and being sensitive to relationships with society; further, thinking with correctness, integrity and impartiality, maintaining a sceptical and curious attitude, showing openness of mind, challenging knowledge with alternatives, evaluating assumptions, predicting consequences, and searching for new ideas and knowledge with creativity and imagination.

The former list of associated skills to SCFT develops each aspect of SCFT, yet their complexity does not allow claiming that any skill belongs exclusively to the assigned aspect. Thus, the list does not intend a correspondence between skills and aspects of SCFT to be univocal; instead, a skill may overlap in several aspects of SCFT. In spite of this overlapping, it is expected that the development of skills may contribute to orientate teaching and to relate SCFT to CT.

Critical thinking

A taxonomy of CT has been empirically elaborated from the skills included in 17 CT assessment tools (ranging from 1 to 88 skills), which are much less ambiguous than authors' definitions. The limited extension of this paper does not allow detailing the procedures, which consisted of identifying the assessment skills declared in each tool and quantifying the frequencies of the different CT skills to empirically synthesize the main components of the taxonomy. In order to overcome the difficulties of this analysis (different terminologies, unbalanced number and some grouping of skills presented in questionnaires), an interpretive analysis was applied to state the degree of equivalence between the different specification and wording of skills (categorical reasoning, deduction, drawing conclusions, etc.), to balance the contributions of the different instruments and to prioritize the grouped dimensions and categories (Vázquez-Alonso & Manassero-Mas, 2019).

The analysis produced the following list of categories in decreasing order of frequencies: communication, problem solving, reasoning, creativity, argumentation, decision making, clarification and precision of ideas, fallacies and errors, identification of assumptions, and evaluation. Taking into account the relations of similarity, overlapping or inclusion between some of these categories taken from the literature on CT, the suggested taxonomy for CT is formed by the following main four dimensions (Table 1):

• The dimension of creativity encompasses the set of cognitive actions and operations aimed at generating questions, ideas, conclusions, models, analysis and synthesis.

• The dimension of reasoning and argumentation encompasses the mental and cognitive operations aimed at justifying the validity of a conclusion.

• The dimension of complex processes (problem solving and decision making), encompasses the set of skills applied to find a solution for a problem or make the most appropriate decision.

• The evaluation and judgment dimension refers to the operations aimed at judging the quality and fairness of any element of one's own or others' thinking (information, assumptions, conclusions or consequences) or any thinking process or skill (justification, validity or reliability).

Table 1. A taxonomy of critical thinking, developing its main dimensions and categories.

CREATIVITY (generating ideas, conclusions)		
	Asking good questions	
	Observation (compare, classify)	
	Analysis and synthesis (parts-whole, analogies, models)	
REASONING AND ARGUMENTATION (justifying predictions, implications, conclusions)		
	Logical (deductive)	
	Empirical (explain with data, information, evidence)	
		Inductive (generalizations)
		Argumentation (abductive)
		Statistical (probabilistic)
	Fallacies and Errors	
COMPLEX PROCESSES		
	Decision making	
	Problem solving	
EVALUATION AND JUDGMENT (assessment of the thinking quality)		
	Intellectual standards (clarity, accuracy, relevance, ...)	
	Reasoning (quality assessment of reasons and arguments)	
	Actions (judging solutions, decisions, consequences, ...)	
	Credibility of sources	
	Identifying assumptions	
	Communication (clarification of meanings)	
	Meta-cognition (evaluating one's own thinking)	
		Self-regulation and self-reflection
		Attitudes and affects (dispositions)

Each dimension develops as sub-dimensions and categories to accommodate the multiple CT skills arising from the analysis. For example, the development of the dimension of reasoning and argumentation includes all the mental operations involved in the justification of conclusions, which encompass logical-deductive thinking, empirical thinking (which justifies conclusions with facts and evidence), statistical-probabilistic reasoning, and a special section for the errors of thinking, that is, the well-known fallacies of reasoning.

A key implicit idea in this theoretical framework states that CT is the foundational construct, thus, it has the highest hierarchical level in the framework; consequently, this construct must be reserved for labelling the global construct. Moreover, the subsequent levels of the taxonomy depict the set of lower level categories of thinking skills thus included in CT. Broadly speaking, creativity skills might be considered the lowest level category of the taxonomy, whilst evaluating and judging might be considered the highest one.

Indeed, the taxonomy does not advocate that the different categories are totally disjointed or different from each other; on the contrary, as they all are kinds of human thinking, the different categories may share some elements and be related to each other. Of course, the more complex the category, the more elements it encompasses of other categories; for instance, the category "thinking standards" is normative and applicable to any thinking skill, and the complex "problem solving" may certainly include elements of creativity and reasoning.

A synthesis: the relationship between critical and scientific thinking

It is common sense that CT is a human competence, which, in the case of its application to scientific practice, becomes an essential part of SCFT, although described under the nomenclature of scientific practice. To justify this claim, the comparison between the CT taxonomy and the aspects and skills of SCFT was elaborated, and its results are presented herein (Table 2). The aspects of SCFT and the dimensions of CT have been qualitatively compared, seeking to identify mutual correspondences between the categories of the two constructs, through the best fit among their contents. The results of this comparison of contents show each category of CT and its corresponding aspects of SCFT in the same row.

Table 2. Relationships between critical thinking and scientific thinking operationalized through the correspondence between critical thinking dimensions and categories and the aspects of scientific thinking.

Critical Thinking (DIMENSIONS / Categories)	**Scientific Thinking** (Aspects)
CREATIVITY	
Asking good questions	4 Creation and verification of hypotheses 10 Attitudes and values
Observation	1 Observation
Analysis and synthesis	2 Categorization 3 Recognition of patterns 5 Control of variables 8 Models, metaphors and analogies
REASONING AND ARGUMENTATION	
Logical	5 Control of variables 7 Coordination of explanations and evidence
Empirical • Inductive • Argumentation • Statistics	 4 Creation and verification of hypotheses 5 Control of variables 7 Coordination of explanations and evidence
Fallacies and Errors	5 Control of variables
COMPLEX PROCESSES	
Decision making	6 Models, metaphors and analogies
Problem solving	7 Coordination of explanations and evidence 8 Elaboration of materials
EVALUATION AND JUDGMENT	
Reasoning	7 Coordination of explanations and evidence

	9 Information and communication
Actions	9 Information and communication
Credibility of sources	8 Elaboration of materials
Identifying assumptions	10 Attitudes and values
Standards	10 Attitudes and values
Communication	8 Elaboration of materials
	9 Information and communication
Meta-cognition	
• Self-regulation and self-reflection	9 Information and communication
	10 Attitudes and values
• Attitudes and affects	10 Attitudes and values

Some aspects of SCFT are assigned to several different categories of CT, and conversely, some categories of CT share several aspects of SCFT. This means that the correspondences between SCFT and CT are not isomorphic, as the best-fit-content does not imply that all the skills of the SCFT aspect accurately fit all the skills within the corresponding category of CT (and conversely). It just means that most of both CT and SCFT contents correspond with each other.

The SCFT aspect #7, coordination of explanations and evidence, is the most repeated aspect over the categories of CT, as seven categories share common contents with it. The SCFT aspects, #9, information and communication, and #10, attitudes and values, also spread across many CT categories, especially across the categories of evaluation and judgment. Conversely, the categories of CT that unite many aspects of SCFT are decision making, problem solving and analysis and synthesis.

DISCUSSION AND CONCLUSIONS

This paper focus on empirically unveiling the skills and dispositions common to CT and SCFT to make them understandable for science education, to overcome their pursuit in separate research fields and their meta-knowledge nature that makes them different from any other school curriculum contents. SCFT and its relationships to the higher order skills have been claimed necessary to achieve learning of epistemic issues taught in science education (such as socio-scientific issues). The literature results also show that there are additional, important and surprisingly coincidental similarities between the two constructs, such as the approaches to teaching methodology and assessment instruments. These new potential similarities deserve future analysis, which may contribute to strengthen the resemblance and the foundational nature of thinking for science education (Swartz, Costa, Beyer, Reagan & Kallick, 2008).

The results of the comparison elaborated herein show an extraordinary resemblance of SCFT-CT that allows closing the theoretical gap between two apparently different research traditions and bringing closer thinking-based teaching and science learning. It is likely that the similarity between CT and SCFT lies in their common qualities of being human thinking and the common meta-knowledge feature that they both share.

Additional differences also stem from the analysis, though most are not in conflict as they differ on qualitative emphasis. For instance, credibility of sources or fallacies are quite important for CT, yet scarcely relevant to SCFT due to the scientists' social accreditation; conversely, the control of variables is an extremely important skill in science and hardly practised in CT.

Within this approach, thinking may be deemed a more appropriate label to designate SCFT than reasoning, as its skills exceed the six reasoning styles suggested by Kind and Osborne (2016); in fact, according to the taxonomy, the six reasoning styles relate partially to the aspects of SCFT 2, 3, 4, 5, 7 and 8. Thus, reasoning styles are just a subset of CT that relates to the dimension of reasoning and argumentation, and the CT-SCFT model accounts for the six reasoning styles as a particular case of the model, and extends it with additional SCFT skills.

The interpretation of the relationships among CT and SCFT skills can contribute to improve both science education and general education through their coordinated, explicit and reflective teaching. The findings may contribute to realize the potential of science education to improve students' thinking skills, and vice-versa, the students' thinking skills may contribute to improve deep learning in science. The latter is plainly advocated by some science education literature suggesting that mastering higher order skills (CT in our terms) is a key condition to successfully develop the activities (debating, choosing, deciding, etc.) leading to deep learning in science (i.e., epistemic learning of socio-scientific issues, Simonneaux 2014). The former may be exemplified by Kuhn's (1993) proposal, demanding an enlargement of specific argumentation issues to involve broader CT skills (as reflected in the CT taxonomy).

Lastly, the point here is not about choosing critical or scientific labels for teaching thinking skills, but the clear understanding that most of them are conceptually equivalent. The clarification of the similarity between critical and scientific thinking through their corresponding taxonomies and relationships benefits both general and science teaching by making both constructs understandable for teachers. It benefits general teaching because learning of thinking skills is not only improved from the thinking-based programs, but also from science education teaching scientific skills. Conversely, CT skills, usually advocated by general education, also benefits and improves science education, as they too are SCFT skills.

HOW PRIMARY SCHOOL STUDENTS EXPLAIN SCIENTIFIC PHENOMENA

Jennifer Krupinski[1], Sarah Rau-Patschke[1] and Stefan Rumann[1]
[1]University of Duisburg-Essen, Germany

Teachers have the task of supporting and evaluating their students in developing their explanatory skills. Although children are asked to construct explanations from the first grade. Nevertheless, there is no hint of a description of the requirements they have to fulfill in order to explain or a general definition of what a student´s explanation should look like. If we want to evaluate students' skills, we need a basis that allows us to asses theses skills. This kind of basis is missing in early science education. The following qualitative quasi-longitudinale interview study attempts to understand how primary school students explain scientific phenomena orally and how their explanations change from 1st to 4th grade. Using a sample of 126 students, oral student explanations at the selected phenomenon state of aggregation of water are videotaped and prepared for a qualitative content analysis using a deductive derived category system. The validation study led to a further survey to examine the influence of a hand puppet as an addressee on the quality of the explanation. The results of the two preliminary studies are presented in the following article.

Keywords: Explanation Construction, Primary School, Language of Science

INTRODUCTION

‚Why is the snowman melting?' ‚What happens to the water in the puddle?' The fascination of scientific phenomena accompanies us from our childhood. This does not change the fact that understanding and explaining phenomena is a complex challenge. A challenge we have to face at school from the very first grade. Students´explanations are firmly anchored in the curriculum of early science education. For example, students' textbooks require a high variety of explanations. This reflects the anchoring of explanatory skills as a component of one of the central aims of early science education. The children are expected to develop scientific literacy and in doing so, learn to construct and discuss their explanations about scientific phenomena (Möller et al., 2014). Thereby, explaining is understood as a discursive practice for knowledge construction (Prediger et al., 2016). When clarifying and structuring one's own knowledge to construct an explanation, possible gaps in knowledge and problems of understanding can be uncovered and become the starting point for a new learning process (Webb, 1989). This shows the substantial importance of explaining not only for school learning but also for lifelong learning. Under consideration that the students are asked for explanations from first grade on, when the development of their writing skills just started and the classroom interaction bases on oral communication mostly, it is clear that we should focus on oral explanation skills for a first look. If we want to support the further development of the students' explanatory skills specifically, we must assess the current state of their abilities first. But in order to evaluate student explanations or assess their quality, a basis is needed, that tells us what a good student

explanation should look like. The problem is that this basis does not yet exist, especially not for primary science education. Neither there is a generally accepted definition of explaining nor a description of criteria or requirements which must be fulfilled by the students to build an adequate explanation. Filling this gap is one of the purposes of our study.

THEORETICAL BACKGROUND

First of all, the missing consensus of a definition of explaining makes it necessary to clarify our understanding of a student‘s explanation which is bases on often-used definitions in language and science educational research (Klein, 2016; Osborn & Patterson, 2011; Morek, Heller, & Quasthoff, 2017).

> *An explanation is the product of an interactive process of knowledge transfer between two or more actors, using descriptions and combining different parts of knowledge to generate new knowledge. In this process, it is possible to use argumentative elements too.*

Additionally, the variety of explanations by using the *explanation typology* of Klein (2016) is taken into account. Within the framework of this typology, the facts to be explained (explanandum) are devided into *Explaining-What*, *Explaining-How*, and *Explaining-Why*. *Explaining-What* is represented by questions for words, terms or meanings of representations or a theoretical concept like *"What are the states of aggregation?"*. In order to explain *'What'* the explainer uses declarative knowledge resources to support the recipient in understanding the explanandum or to enable him to construct a mental model of the terms, representations or theoretical concepts to be explained.

In contrast, *Explaining-How* focusses on procedural knowledge. The explainer wants to enable the recipient to do certain actions independently or to use scientific methods. This kind of explanatory process is initiated by questions such as *"How can you change the states of aggregation of water?"*. An essential feature of this explanation type is the sequencing and adherence into a logical order.

Explaining-Why shows the greatest similarity with the common understanding of a scientific explanation to clarify the occurrence of a scientific phenomenon. Thereby a necessary clarification of the available knowledge and the targeted selection and linking these components of knowledge or arguments is needed. This reorganizing thinking process of selecting suitable facts can be understood as a part of conditional knowledge. This type of explanation is represented by questions like *"Why can you see your breath in winter?"*. (Klein, 2016; 2017)

The three types of explanations show an increasing level of abstraction from *Explaining-How* to *Explaining-Why*. At the same time, they refer to further important requirements in student‘s explanation like the kind of interpretation the students show in explaining the phenomenon.

This leads us to the category *'scientific understanding'*. This category describes more then the decision if the explanation is right or wrong. It makes statements about the knowledge source the students use to explain. The teacher or evaluator also gets an impression of how the student interprets the phenomenon. For example, from a scientific point of view, it is wrong if the students explain that the ice cubes disappear when they melt, but if we consider that the students are referring to their direct observations, it is a quite correct statement. That's not yet an interpretation of the phenomenon. In addition to the scientifically-conclusive interpretation that ice melts under the influence of heat and pressure, the young students use different forms of analogies to interpret the phenomenon. Some kinds of interpretation attribute characteristics such as a will and emotions of the inanimate influence factor heat. This leads to explanations such as "If the heat goes up on the ice, then the heat and the cold do not like each other and the ice cubes go away." Hagstedt and Spreckelsen (1986) call this kind of understanding a logogenic or animistic interpretation.

Under the consideration that explaining is a discursive practice for knowledge construction (Prediger et al., 2016) we must bear in mind that oral expressions are usually fleeting and tend to use everyday language. For this reason, it is useful to look at the linguistic quality (*language*) of the explanations in terms of the completeness, length, structure**,** and activ or passiv construction of the statements.
At the same time, discursivity refers to a possible influence of the addressee on the quality and scope of the explanation. The confirmation of the importance of orientation and consideration of the recipient of the explanatory process is supported by the research work of Kulgemeyer and Peters (2016). In Webbs research (2015) also points out, that the initiation of explanatory processes is triggered and influenced by the recipient's questions significantly. It can, therefore, be assumed that *recipient orientation or interaction* is another important facet of the analysis of explanations.
Using the example of game instructions, which is a part of explaining-how, Röhner (2009) was able to record in her longitudinal study that the logical *structure* of the explanation and its *completeness* increases from the first to the fourth grade. At the same time, it is one of the few studies which focus on early explanatory skills. Most other studies on student explanations focus on secondary school like the study of Sandoval (2005). Her research underlines the importance of structure for the quality of high school student explanations and argumentations (Sandoval, 2005). This overview of research supports the impression that the research on students' explanations and explanatory skills of primary school students is low. Therefore, the following study strives to answer the questions:

1. How do primary school students explain scientific phenomena orally?
2. What is the difference between oral explanatory skills from 1st to 4th grade?

METHOD

A quasi longitudinale qualitative interview study trys to answer these questions. The study is videotaped and in order to take into account the discursive character of the explanatory process and to get an overview of the improvement of the explanatory skills from the first grade on, the focus is on the oral explanations. In order to ensure the comparability of the content of the explanations, the phenomenon of the states of aggregation of water has been selected because this topic is anchored in the curriculum of early science education and can be presented in various complexities so we can use the examples in all four grades. The setting includes three selected examples of this scientific phenomenon (see fig.1-3):

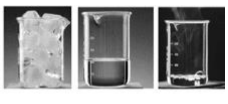

Figure 1 State of Aggregation of Water

Figure 3 Function of a Steamboat

Figure 2 Evaporation of Water on a Black Board

These phenomena were represented to the students in short video sequences. The following oral explanation process of the primary school students between one student and a recipient was videotaped in an interview situation. The recorded explanations with a duration of three to five minutes then were transcribed and prepared for qualitative content analysis according to Mayring (2014). In the center of the qualitative content analysis is the category system, which is deductively derived in a first step and includes the six main categories as shown in fig 4.This category system is tested in a pilot study with a sample of 57 primary school students' explanations distributed over the four grades.

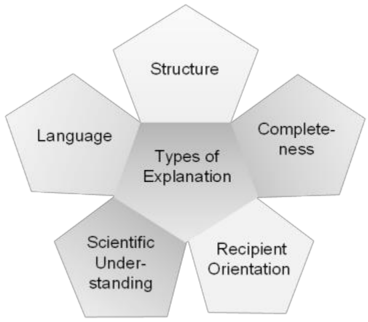

Figure 4 Deductive Category System

The following results relate to the pilot study (validation of the category system) and its impact on the process and the evaluation of the main study. The results of the pilot study will also demonstrate the necessity of a further survey to check the influence of a change of addressee between real person and hand puppet on the explanatory quality. These results will also be part of the following report.

RESULTS

The purpose of the pilot study was to prove the validation and reliability of the deductive derived category system and the feasibility of the main study. The use of the category system to analyse the piloting data has shown that the selected main categories can be covered in the explanations. However, the first intercoder reliability of $\kappa = 0.43$ showed the necessity of a further differentiation of the definitions and feature descriptions. The revision of the category system resulted in an intercoder reliability of $\kappa = 0.85$. The analysis also provided initial insights into the characteristics of the main categories or the individual facets of the students' explanatory skills. For the purposes of clarity, we decided to divide the sample into two parts. The part *Explaining in School Entrance Phase* includes the explanations of the first and second graders and the group *Explaining in School Exit Phase* covers the third and fourth-grade students.

The analysis has shown that the students from the school entrance phase prefers the type Explaining-What as a first try to clarify the understanding of the phenomenon to be explained. In doing so they mainly use declarative knowledge and also show a strong influence by their direct observations. Looking at the external or structural construction of the explanation, students´statements tend to have no or medium coherence. Therefore, they are only partially able to link and relate their statements to each other. This is also reflected in the fact that simple sentences are used usually in the formulation of their explanations.
In contrast, the students from the school exit phase often use the type Explaining-Why to answer the question *"Can you explain this to me?"*. Their explanations refer to nomological interpretation and the use of conditional knowledge. The predominant use of related sentences is reflected in the high coherence up to complete coherence of their statements.
At first look, the comparison of the two sub-samples reveals a development in the individual facets of the students' skills to explain. However, this development is not reflected in the main category completeness of an explanation. No student in the sample has been able to explain the

presented phenomenon state of aggregation of water (solid, liquid, gaseous) completly. Most of them omitted the gaseous phase of the water, regardless of the grade.

However, a particularly important aspect turned out to be the recipient orientation. First of all, only a few hints of recipient orientation has been detected in the analysis. These few moments, however, had a decisive influence on the explanatory process. It turned out that the interaction between the explainer and the addressee partly led to the termination of the explanatory process. Due to the authority gap between the young student and the adult interviewer, the students partly stopped the explanatory process under the assumption that the recipient has no knowledge deficit and already knows the answer. The necessity of making an explanation is questioned by the student. In order to solve the problem and to enable the student to continue the explanatory process to be able to show the whole spectrum of his explanatory skills, a hand puppet instead of the adult interviewer as a direct interaction partner was used in a second pilot-study. A communicative-supporting effect of the hand puppet is assumed for interviews with children (Vogl, 2015). The interaction with the hand puppet should lead to a reduction of the authority gap and thus to a more relaxed atmosphere of conversation, which stimulates the verbal and cognitive abilities of the children (Vogl, 2015). In contrast, the hand puppet can also tempt to play and have a distracting effect on the young student. Older children might also feel that they are not taken seriously in the interview situation (Vogl, 2015). In order to clarify these uncertainties, we conducted another survey with 24 students from the school entrance and exit phase. The survey procedure in itself was unchanged - only the addressee was replaced. The results show, that the students of all grades accept the hand puppet as an interaction partner. There were no longer cases of early termination or interruption of the explanation process due to the difference in authority between student and interviewer. On the direct question of how they felt about the conversation with the hand puppet, the older children gavepositive feedback also. None of the participants found the interaction strange or even silly. Overall, the children were able to get into the explanation process quicker by using the hand puppet and that fewer impulses and questions from the interviewer were necessary.

IMPLICATIONS AND OUTLOOK

The presented results led to the decision to use the hand puppet also in the main survey as the interaction partner. The main study was done in the summer of 2019. Oral explanations of the three selected phenomenon examples were collected from a total of 126 primary school students over the four grades. This sample is made up of at least 30 students of each grade from at least 2 different schools and 3 different classes. The data is currently being evaluated. First impressions point to the existence of different explanatory profiles, some of which are independent of the age of the students. Further analysis will show whether this impression can be confirmed. Ultimately, the results can be used not only as a basis for establishing an evaluation for oral explanations by students in primary school but equally as a basis for developing interventions. In addition, the findings can be used to further develop differentiated textbook tasks by making the requirements of the explanations transparent.

SOCIOSCIENTIFIC ARGUMENTATION: TOULMIN'S ARGUMENT PATTERN FOR TEACHING AND LEARNING OF BIODIVERSITY AND ITS CONSERVATION

Gonzalo M.A. Bermudez[1,2], María E. Ottogalli,[1,3] and Lía P. García[1,3]

Argumentation and discourse have become central elements of science education. In this framework, biodiversity turns out to be a complex concept, with its conservation being recognised as a socio-scientific issue (SSI) that helps to develop students' scientific and environmental literacy. To explore teacher's and students' argumentative discourse, we developed a SSI-based teaching and learning sequence about the use of Toulmin's Argument Pattern (TAP) to make decisions on context-based biodiversity issues. This research, of a sociocultural nature, uses educational discourse analysis with qualitative (conversational analysis) and mixed methods (sociocultural discourse analysis). After having dialogued with our research registers, we report on students' appropriation of scientific argumentative practices, incorporating TAP to everyday reasoning and school science. We have identified several obstacles in teaching and learning of TAP, mainly in relation to terminology (meanings and usage of "rebuttals" and "warrants"), students' habituation to stereotyped strategies of school culture (showing apathy towards group discussions, evaluation of knowledge claims and the recognition of the need to look for rebuttals), and students' reliance on their own epistemic abilities (as sufficient per se *to evaluate facts and justify claims). Related to this, teacher's most frequent dialogical support moves were 'theoretical knowledge activation', 'activity regulation' and 'knowledge legitimation'. Implications arise on the articulation of ecological knowledge and epistemic thinking, and how to support and orchestrate their articulation in the context of SSI-based science teaching.*

Keywords: Classroom Discourse, Socioscientific Issues, Context-based learning

INTRODUCTION

The evaluation of knowledge through the use of scientific evidence (argumentation) is a significant scientific practice, together with inquiry and the construction of explanations and models (Crujeiras Pérez & Jiménez Aleixandre, 2015). Arguments concerning the appropriateness of experimental design, the interpretation of evidence, and the validity of knowledge claims are central to the everyday discourse of scientists (Erduran, Simon, & Osborne, 2004). Over the past few decades numerous studies have focused on the analysis of argumentation, which have highlighted the importance of discourse in the acquisition of scientific knowledge and students' conceptual understanding (Erduran et al., 2004). In most definitions, argumentation is understood as a social rationally-guided activity, which is primarily comprised of utterances (speech acts). This is why, from a sociocultural perspective, discourse and argumentation have a central role in science education.

Science education scholars of the argumentation strand have typically worked on the basis of a conceptual distinction between argumentation as a process and arguments as the products that can be identified from the process. For decades, Toulmin's Argument Pattern (TAP) (Toulmin, 1958, cited in Evagorou & Osborne, 2013) has been a central analytical framework, which refers to argument as the set of claims, data, warrants, and backings that contribute to the content of an argument. However, Toulmin's model does not properly help to distinguish an analyst between the elements (claim, warrant and so on), especially in dialogic argumentative sequences, since discursive aspects become lost when translating them to TAP elements (Nielsen, 2013). Also, many researchers have relied on other frameworks of argumentation theory such as Pragmadialetics and Linguistics (Franco & Munford, 2018). However, TAP still is a main theoretical structure in arranging arguments for decision-making issues and inquiry-based teaching and learning (Bernat, Ferrandis, & Gómez, 2019; Crujeiras Pérez & Jiménez Aleixandre, 2015; Ratz & Motokane, 2016). Further, it has not been addressed how secondary-school students use TAP for the construction of arguments and the evaluation of biodiversity-related claims when TAP is part of the content that is taught. In agreement with Evagorou and Osborne (2013), although we used Toulmin's model in our study, we also view argumentation as the social construction of knowledge in which the learners are expected to share ideas, question assumptions and restructure their existing knowledge schemata based on the interactions in their groups.

Biological diversity plays an important role in ecosystem functioning, providing essential benefits to people and their well-being. Despite the utmost importance of biodiversity for sustainable development, it is declining at unprecedented rates. Biodiversity has thus been recognized as educational priority at all educational levels, and it has been proposed that people should be empowered to act in ways that protect and conserve biodiversity (Bermudez & Lindemann-Matthies, in press). For this to happen, Biology teaching should consider biodiversity protection to be a socioscientific issue (SSI) because of its intricate links to individual and societal decisions (Lee, Grace, Rietdijk, & Lui, 2019). Decision-making teaching about SSIs often include group discussion and cooperative learning, strategic training in decision-making strategies, transactional argumentation and the discussion of strategies for widening discussion perspectives (Lee et al., 2019).

Current research on children's reasoning about biodiversity generally focuses on the acquisition of scientific definitions, plants and animals names, or on students' conceptual understanding in different learning environments (e.g., Almeida, García Fernández, & Strecht-Ribeiro, in press; Bermudez, Díaz, & De Longhi, 2018; Kontkanen, Kärkkäinen, Dillon, Hartikainen-Ahia, & Åhlberg, 2016; Lee et al., 2019; Pérez Mesa, 2019). Related to this, Yli-Panula, Jeronen, Lemmetty and Pauna (2018) have recently surveyed current instructional methods in biology that promote biodiversity teaching and learning, and revealed that the most used teaching methods were hands-on instruction, experiential learning and teacher presentations, with role plays, debates and study trips being the least used ones. In spite of this, decision-making about SSIs is an important means to develop and deepen students' understanding of ecological knowledge through data analysis and construction of evidence-based arguments (Lee et al., 2019).

We use this framework as a way of explore teacher's and students' argumentative discourse in a SSI-based teaching and learning sequence about biodiversity conservation issues.

METHODS

A teaching-learning sequence (TLS) was designed and implemented in the 5th course (32 students aged 16-17) of a state secondary school in a small town in the Province of Córdoba, Argentina. All students came from families of medium to low socioeconomic status. The underlying goal of the TLS was to facilitate students' meaning and decision-making in an argumentative context about current SSIs. The design and execution were carried out jointly by the first and third author. The latest is the regular teacher of the group of students for the subject "Ecology", and has 15 years of experience in secondary schools. The first author was the research team's primary liaison with the teacher and class, designing lessons and coteaching. The second author helped with field notes and with the analysis of classroom discourse transcripts.

The TLS tackled argumentation practices in biodiversity-related SSIs, which were contextualised to current environmental tensions in the Province of Córdoba, in 5 out of 9 lessons (80 min/lesson). In the first session, biodiversity alternate frameworks were identified by the teacher by showing slides with images of plants, animals and other biodiversity expressions at different organisational levels. In lesson 2 students read a short document that narrated the evolution of the conceptualisation of biodiversity and presented its current political and scientific definitions. Our school reference scientific model of biodiversity was an adaptation of the conceptualisation put forward by the Intergovernmental Platform on Biodiversity and Ecosystem Services (IPBES, *www.ipbes.net*). This Panel has further specified the meaning of biodiversity as occurring on three organizational levels -genetic, species, and ecosystems (Convention on Biological Diversity, *https://www.cbd.int/*)- to include more components, such as species evenness, species composition, functional composition, and landscape units. A fieldwork to an urban natural park was undertaken in lesson 3, where native plants and animals were perceived and identified with the help of a dichotomous key. In return to the classroom (lesson 4), students discussed about a newspaper article about the conflicts arising on the use of exotic species for native forest reforestation and worked in groups in order to propose a solution to a decision-making task. Afterwards, students re-described their understanding when they had to recognise the species and explain the components of biodiversity, in terms of our reference model, as the slide presentation of lesson 1 was shown again. Lessons 5 to 9 addressed scientific argumentation using TAP framework. First, transposed context-based scientific evidence of biological diversity was used for discussing about its protection (native forests shortage, invasive alien species threat and the implicated ecosystem processes). Then, students in small groups had to identify and use scientific evidences provided by the teaching team in order to take a position over and make a decision about biodiversity conservation in Córdoba. With the purpose of deepening biodiversity understanding and making arguments more complex, new scientific evidence -contextualized to agricultural expansion- were offered to the students after their thoughts and everyday experiences were retrieved. After students had elaborated progressively more complex TAPs, they had to write a letter to the governor and the local media to express their concerns and recommendations about the recent approval of a law and another draft law on native forest protection and countryside forestation. Lessons 5 to 9 are the analytical units of the current paper.

Our research has a sociocultural nature and focuses on argumentative practices in terms of TAP elements. We use educational discourse analysis with qualitative (conversational analysis – CA-) and mixed methods (sociocultural discourse analysis -SDA), according to Mercer (2010). Recursive analytical categories were identified by CA and their reports are illustrated by commented selected extracts of transcribed talk. After SDA, we coded teacher's utterances (questions and statements) during the teaching of TAP following an interpretative perspective, whereby categories of teacher's purpose discursive moves were developed and refined, using a bottom-up approach, through an iterative process (Bansal, 2018).

RESULTS AND DISCUSSION

TAP for evaluating knowledge claims and elaborating arguments

TAP elements are often used by researchers to categorize students' arguments (Evagorou & Osborne, 2013; Nielsen, 2013) but they are less frequently taught to students with the purpose of discussing and making decisions about biological conservation. In the sequence of next dialogue (extracted from lesson 5), it is shown how students used TAP knowledge to produce an argument sequence about experiences relevant to their own contexts. This was considered to be an indicator of students' understanding in terms of the appropriation of community practices that sustain scientific discourse. References: T = teacher, S = Student (Arabic numbers are used to differentiate them, e.g. S1), numbers before S and T indicate the talk turn within the same lesson.

197 T: This form of argumentation helps us not to say something unfounded. Generally, we reach a conclusion without thinking about the backing that supports it, then we are opposing conclusions that are not related to any evidence, no warrants. Am I clear?

198 S1: No.

199 S2: I can come to the conclusion from data, let's give an example, I say that Melisa stole my cell phone, but I do not have any evidence that she actually stole it… [I can't make such claim]. That's what it means.

200 T: Perfect! What it would be an evidence or the warrants to support that claim?

201 S2: For example, that Melisa had done the same thing in the past and someone had seen her.

202 T: The data would be 'my cell phone was stolen', the warrants would be 'since Melisa has previously stole my phone…" Then I can search for backings to support my claim that she had stolen it. For example, something that has to do with human behaviour that indicates that in general people who already stole once tend to do it more than once, since there is a pattern of repeated behaviours. I mean, not because I invented it but as a scientific evidence supports my claim.

203 S1: Oh! Right, I get it.

204 T: Unless…, a rebuttal is an exception. Unless…

205 S2: Unless I had lost it.

206 S3: Unless Melisa hadn't come that day.

207 T: Great! Now we can write down what we have said.

Obstacles to and scepticism toward argumentation practices

We have identified several obstacles in teaching and learning of TAP for biological conservation. In some situations, it seems that difficulties in task completion arise from the ways in which students use words with very different meanings from those assigned in the scientific community (Reigosa & Jiménez Aleixandre, 2007). For instance, the term "reserve" in Spanish is valid for both "rebuttal" and "a protected area for wildlife" meanings, with the latter being more significant for the students in the context of our activity. Because of this, after the following dialogue, that took place on lesson 5, the teacher started using synonyms of "reserve", such as "counter-argument", "exceptions" and "refutation".

172 T: What does "rebuttal" ["*reserva*" in Spanish] mean?
173 S1: Something that is taken care of, that is maintained.
174 S2: Something that retains…
175 S2: A water reserve, for instance.
176 T: But in this context... [5 seconds, no answer]
177 T: We are talking about argumentation, what is argumentation, then?
178 S1: Something that is talked about?
179 S4: Rebuttals ["*reservas*" in Spanish] are exceptions.
180 S5: Is it something that is being discussed? [...]
185 T: We seek to conclude on something, and based on that, take decisions. I asked you what we can do in the fields there are constantly flooded... Thus, using theory we will seek to reach a conclusion, but based on scientifically validated evidence. that's why we have been talking about what researchers have found in their study of water infiltration, to develop our backing. Then, what would be to argue for us? Coming to conclusions using scientific evidence, that implies discussing what justifications and theoretical framework we will use to come to an agreement. For example, which are your warrants and backings in order to say whether you're going to log or not? One can take different positions according to the theoretical framework and thus reach different conclusions.

Another issue was identified when addressing "warrants", which are the statements that relate evidence and conclusions. When justifying, students should use rules or principles to link available data to the conclusion and make use of laws or a set of scientific knowledge to support their reasoning (Toulmin, 1958). However, in our study, students replicated data or redescribed backings instead of justifying their claims. This is in agreement with Sanmartí (2008), who points out that when justifying a phenomenon, students usually write a tautology, or refer to little relevant reasons. Terminology also imposed obstacles to assignment completion since a literal translation of "warrants" into Spanish is "*garantías*", which have a strong legal connotation associated with rental agreements. Moreover, at school, justifying is usually used as a synonym to the fact of arguing (Custodio, Márquez, & Sanmartí, 2015), and then, some students had difficulty in perceiving when we were talking about the whole argument pattern (TAP) or about the warrants.

Third, students' habituation to stereotyped strategies of school culture was an obstacle to the teaching and learning of argumentation as a scientific practice. According to Reigosa & Jiménez Aleixandre (2007), in stereotyped images about teaching and learning, roles are clearly defined and characterized by the teacher giving instructions and the students following them. This was evident in our study as a generalized apathy towards group discussions and the evaluation of knowledge claims, which posed difficulties in evidence selection to support a conclusion, an expansion of the zone of proximal development (ZPD) in student-student interaction, and in the recognition of the need to look for rebuttals. Therefore, most students did not spontaneously participate in whole-class discussions, remain sceptical about knowledge construction and waited for the teacher to "provide legitimate school knowledge". Moreover, only some students in the social interaction within small groups benefited from a given intervention of the teacher, then limiting their collaborative and active knowledge-construction (Reigosa & Jiménez Aleixandre, 2007). As a consequence, the teacher spent significant time in whole-class discussions in lessons 6 and 7 in order to re-contextualise prior small-group interactions.

Fourth, the fact that people tend to rely recklessly on assessments that are based on everyday experiences or common-sense reasoning may be an obstacle to expanding their initial views. This obstacle may influence learning when students are likely to believe that their own epistemic abilities are sufficient *per se* to evaluate facts, the truthfulness of statements and justify claims (Scharrer, Bromme, Britt, & Stadtler, 2012). We found examples of this obstacle when students clung to ideas or observations, without questioning them from a broader framework, in the context of discussing with the teacher and their counterparts (e.g., *"I always saw it that way"*, *"in the country there are cows, always"*, etc.). We consider the third and fourth obstacles to be related to *epistemic thinking* and traditional school science, which emphasises the need for students to shift towards a *multiplist* perspective according to which the source of knowledge is in the self and knowledge is multiple, subjective, uncertain, and justified by personal preferences and judgments (Barzilai & Eshet-Alkalai, 2015). Epistemic thinking is a multi-faceted construct that includes cognitive-level epistemic processes and strategies as well as metacognitive knowledge, skills, and experiences related to the nature of knowledge and to knowing strategies and processes.

Decision-making based SSI argumentation: the conservation of biological diversity

Epistemic practices were linked to TAP when students had to evaluate scientific evidences in order to make decisions about biodiversity conservation. After small-group discussions, through which students had to answer open-ended questions regarding SSIs, students produced argument patterns as the one shown in Figure 1. Initially, students faced difficulties in interpreting scientific evidences and identifying TAP elements, but eventually managed to elaborate complex arguments, which was supported by teacher's epistemic moves (Ratz & Motokane, 2016). This is in agreement with Lee et al. (2019), who provided evidence to the impact of cultural exchange on students' own and others' views on broadening their perspectives (ZPDs, Reigosa & Jiménez Aleixandre, 2007) and stimulating their critical reasoning. Also, students had to write letters to the governor and the local media as a homework assignment in order to express their concerns and recommendations about two draft laws on native forest status and countryside reforestation (see Methods). Some students, even who previously had had little class participation, got involved with the task and produced proper arguments by incorporating scientific knowledge, as the one shown in Figure 2. Therefore, as stated by Lee et al. (2019), we found that issues that lead students to informed decision-making could be used as a context, with more background scientific information provided, to deepen students' understanding of ecological knowledge through data analysis and construction of evidence-based arguments.

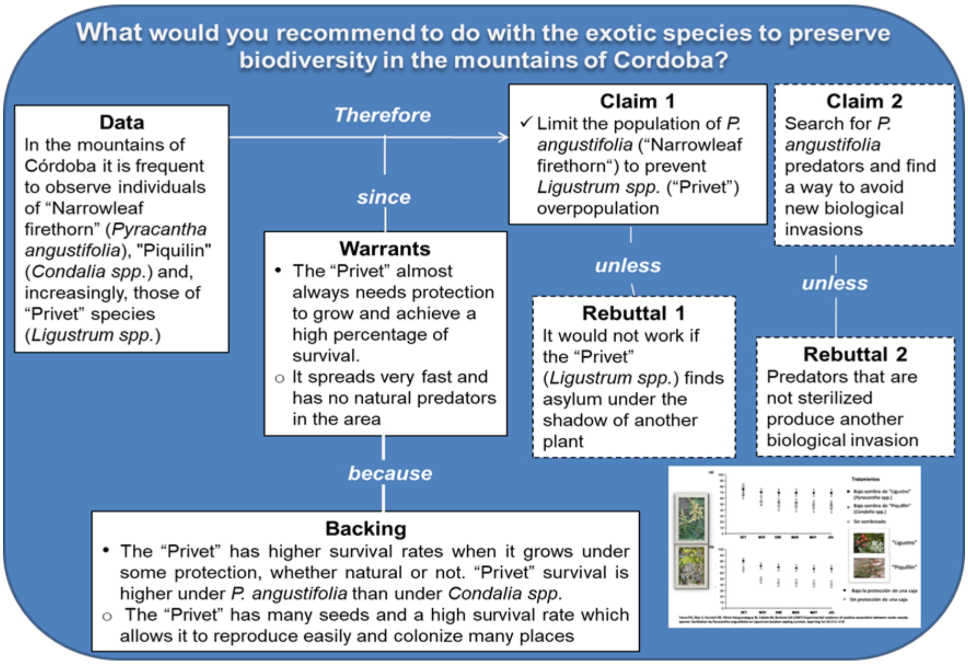

Figure 1. Students' Toulmin's Argument Pattern elaborated for decision making about SSIs after evaluating scientific evidences. References: Closed circle = based on given scientific evidence. Open circle = based on other evidence. Solid and dotted line: argument elements requested and not requested in the assignment, respectively.

Dear Editor,

We are writing to inform you about environmental issues that affect the native forests of Cordoba. Through our investigations we have discovered that the rate of forest loss has been 19,354ha/year between 1979 and 2010, due to an increase in cultural vegetation, mainly monocultures, that has caused the loss of soil and its fertility. Also, wild fires and overgrazing has led to the clogging of water bodies, the solvation of river basins and flooding, since deforestation impedes water absorption.

The loss will continue to increase since, according to agroforestry law, only 2% of the area of the farmlands must be reforested. Also, the agricultural frontier is going to expand due to changes in the native forest areas subject to agricultural activities (draft law).

Therefore, the solution we propose is to modify the agroforestry law by increasing the forested area and favouring native species with seeds or that agricultural activities are avoided in areas with native forests.

We hope this letter reaches the public and becomes aware of the importance of our native forest.

Students of 5th course

Figure 2. A letter written by a group of students in order to express their concerns regarding decision-making about biodiversity issues.

Teacher's discursive moves to support the teaching of TAP

The findings corresponding to the teacher's support provided to guide students during TAP teaching and learning are presented in Table 1 (lesson 6 and 7), where the types of strategies identified are summarized, expressed in percentages of teacher's talk turns and illustrated with examples. Supports by the teacher has the function of scaffolding, that helps learners to carry out tasks that they would not be able to achieve alone, and to enable the development of a higher level of autonomous competence (Reigosa & Jiménez-Aleixandre, 2007). In the current study, we found that the most prominent categories of teacher's support were 'theoretical knowledge activation', 'activity regulation' and 'knowledge legitimation' (Table 1). These supports could be related to the development of an open-ended activity (Crujeiras Pérez & Jiménez Aleixandre, 2015), and to the above-mentioned obstacles in teaching and learning of TAP, and suggests that students do not participate in science-classroom discourse themselves. Rather, in the current study, the teacher provided specific opportunities for students' engagement, which is in accordance with Bansal's (2018) findings. Related to this, we agree with Scott, Mortimer and Aguiar (2006) regarding school scientific dialogue that entails the teacher to act as a thinking thread by opening up conversational space to diverse views, and hence, leading to dialogic interactions. Although the 'reflection on the validity of an argument' and the teacher's request for students' reflection were less represented in teacher's discursive moves (2% and 4%, respectively), these categories could better characterise dialogic argumentation in general, and the evaluation of knowledge claims in particular. Future teachers' dialogic orchestration of classroom interaction, as well as science education research on this topic, should provide insight into dialogic and epistemic discursive moves on other classroom settings, with better school argumentative backgrounds (Bansal, 2018; Lehesvuori et al., 2019; Ratz & Motokane, 2016).

Categories of teacher's scaffolding strategies (frequencies, %)		**Examples**
Theoretical knowledge (29)	Activation (24)	What would pigmentation be? Is it chlorophyll? Why do you think it is important for chlorophyll to break down?
	Contribution (5)	By shrubland we understand a configuration called "Romerillal"; they are bushes that one can find in the "Altas Cumbres" mountains
Reflection on the validity of an argument (2)	Universality (1)	We could say exotic species in general
	Singularity (1)	A rebuttal may also be, for example, that what we have found only applies for the studied species, not for all of them. I can't generalize that it works for all exotic species. Each one has its own leaf feature
Request for reflection on… (4)	the validity of an argument (1)	How would one be able to prove if the following year those hectares were lost or not?
	the validity of the theoretical knowledge used (2)	Why is important to know if the plant is perennial or deciduous for land fertilization?
	the elements of the argument (TAP) (2)	The warrant... if I'm using the theoretical framework that we just said, the warrant has to provide a link between the data and the claim, and are strengthened by the backings
Activity regulation (46)	Regulation of the interpretation of an assignment (19)	What was the problem in the assignment?
	Contribution of the interpretation of non-textual data (11)	This is a satellite photo, what we see is how a closed forest and a cultivated area look like… and thus, it's possible to model this feature and see how it changes
	Request for interpretation of non-textual data (14)	What does the y axis say?
	Request for reflection on an assignment completion (1)	What have you done to answer this question?
	Contribution of process for assignment completion (2)	That is the process to be done, to analyse how big are the bars and what do they represent

Knowledge legitimation (18)	Validation (16)	Good, it's a rebuttal of the conclusion
	Correction (2)	The "espinillo" is not typical of the Chaco-Serrano forests, but it's commonly found in the region called "Espinal"
Clues (1)	Clues that suggest a specific response (1)	Are you sure that that is the problem?

Table 1. Dialogic supports provided by the teacher to guide students during TAP teaching and learning.

In order to make some concluding remarks, we would like to highlight that argumentation and socio-scientific issues, such as biodiversity conservation, is a plausible strategy to promote relational and contextualized scientific practices, even in unprivileged environments. We acknowledge that the case study of a single teacher and TLS has limitations in terms of generalisation. However, we showed how students were able to use TAP in order to evaluate the acceptance of claims, integrate scientific evidence and make decisions about biodiversity conservation. Argument-based instruction research should explore the articulation of knowledge and epistemic thinking, and how to support and articulate them in the context of argumentative-based science teaching. Last, SSI-based instruction has helped students to challenge commonly held assumptions about biodiversity and ecosystem functioning, and to overcome mental obstacles in a way to empower their decision-making.

IDENTIFICATION OF EVIDENCE BY ENGINEERING UNDERGRADUATES AND PRE-SERVICE SCIENCE TEACHERS IN AN ARGUMENTATION ACTIVITY

María-José Cano-Iglesias[1], Antonio Joaquín Franco-Mariscal[2] and Ángel Blanco-López[2]

[1]Department of Civil Engineering, Materials and Manufacturing. University of Malaga, Malaga, Spain

[2]Department of Science Education. University of Malaga, Malaga, Spain

Scientific argumentation is considered as one of the general competencies that engineering students must achieve. This paper analyses the capacity to identify evidence in an argumentation activity on characteristics of materials, developed with 46 engineering undergraduates of the second year of the Degree in Industrial Technologies Engineering and 81 pre-service science teachers of the University of Malaga (Malaga, Spain). These pre-service science teachers studied a Master's Degree in Secondary Education and were classified for this study in two groups depending on whether or not their previous degree was related to the knowledge necessary to solve the activity. The activity proposes to argue the choice of a bicycle according to the material of manufacture (steel or aluminium), focusing this paper on the analysis of the evidence shown in their arguments. A number of evidence, their type, their quality in terms of the level of adequacy and precision, and the inclusion or not of personal ideas, were considered as dimensions. The results show that engineering undergraduates are capable of providing arguments with more evidence and of different types (economic, physical-chemical and mechanical) as opposed to pre-service science teachers. On the contrary, pre-service teachers offer arguments with a better quality of evidence than undergraduates. Pre-service science teachers from degrees unrelated to the activity used a significant number of personal ideas when arguing. These results highlight the need to continue training both undergraduates and pre-service teachers so that they can argue in their profession in the best possible way.

Keywords: Initial Teacher Education (Pre-service), evidence-based approaches, decision making.

INTRODUCTION

The promotion of reasoning and argumentation skills constitutes an important role in the competencies that undergraduates must acquire (Andrews et al., 2006; Mercier & Sperber, 2011). Hence, university education has an inescapable responsibility in promoting these skills (Mouraz et al., 2014).

In the field of engineering, argumentative skills are of great importance not only because they allow them to support in a reasoned way an idea in the resolution of a problem, but also since they allow engineers to justify which is the best of their proposals according to the requirements of the client and the current regulations (De Castro, Torres & Candelo, 2015).

Thus, learning to argue is essential to persuade the interlocutor about the engineer's position on a problem or about the solution to that problem (Jonassen, & Kim, 2010). Also, the development of the argumentation in engineers is considered as one of the general competencies that every undergraduate of the Degree in Industrial Technologies Engineering must achieve (Ministry of Education and Science, 2007).

However, Holvikivi (2007) established that one of the problems that engineers face is not the mathematical reasoning for the resolution of problems in their discipline, but the adequate use and ability of language structures to express formal reasoning about the solution of a disciplinary problem. Several studies support this difficulty (Escudeiro, Barata, & Lobo, 2011; Marco-Galindo, Macau-Nadal, Nussbaum & Schraw, 2007; & Pastor-Collado, 2010) and have detected essential mistakes in the communication skills of engineering students.

Argumentation is one of the relevant scientific practices in science education and consists of being able to evaluate statements based on evidence. It implies recognizing that scientific conclusions and statements must be justified, that is, supported by evidence (Jiménez-Aleixandre, 2010).

The argumentation can be raised in the teaching-learning process concerning any problem, either exclusively scientific/technological or socio-scientific. In order to design and evaluate argumentation activities, it is important to have an adequate model understanding the argumentation. In this effort, the Toulmin model (2003) and the Jiménez-Aleixandre simplification (2010) stand out to facilitate the understanding of the essential elements of a good argument: evidence, justifications, and conclusions. This study aims to analyse the capacity to identify evidence in an argumentation activity proposed to engineering undergraduates and pre-service science teachers.

In short, from initial training, it is, therefore, necessary to place greater emphasis on preparing students in scientific argumentation in order to achieve an important impact on the outcome of their learning in the sciences (Yalvac, Smith, Troy & Hirsch, 2007).

METHOD

A total of 127 students from the University of Malaga (Malaga, Spain) participated in this study during the academic year 2018/19, divided into three groups:

- Undergraduates (UG) of the second year of the Degree in Industrial Technologies Engineering (N = 46, 37 men and 9 women),
- Pre-service science teachers from similar degrees (SD) with the necessary knowledge to solve the activity (engineering and chemical sciences) (N = 37, 24 men and 13 women), and,
- Pre-service science teachers from other scientific degrees not related to the knowledge (NSD) (N = 44, 21 men and 23 women).

SD and NSD were studying a Master's Degree in Secondary Education Teaching at the University of Malaga.

The participants answered an argumentation activity included in a broader questionnaire, as a previous step for the design of an argumentation training programme with students from the Industrial Engineering School of the University of Malaga. The statement of the activity was:

"You are going to buy a bicycle, and you have to choose the material for its frame. If the options are between a steel or aluminium frame (Figure 1), indicate which one you would choose and reasonably justify why you choose that frame concerning the other".

Figure 1. Steel (option A) and aluminium (option B) frame bicycle

The responses of the participants were analysed according to the three elements of an argument (evidence, justification, and conclusions), focusing this paper on the identification of evidence. Three dimensions were considered in the analysis:

(1) Evidence number.

(2) Type of evidence provided: economic, physical-chemical (density, interaction with the environment, etc.) and mechanical (tenacity, elasticity, production/repair properties, etc.).

(3) Its quality in terms of the level of adequacy and precision to scientific-technological knowledge.

The inclusion or not of personal ideas was also considered as another dimension.

A rubric (Table 1) was used for the analysis (Table 2), which was established by consensus among the researchers (authors of the paper), adding the necessary levels to address the range of responses offered by the participants adequately.

The following are some responses given by participants in order to illustrate how the analysis was carried out:

***"Option A, since even if the bicycle weighs more it is more resistant"* (NSD03).**

The response of this pre-service science teacher presents two pieces of evidence (weight and mechanical resistance of the bicycle) (level L2 for evidence number), which correspond to two types of evidence (physical-chemical and mechanical) (level L4 for

evidence type). According to the evidence quality, these pieces of evidence are appropriately, but one of them (resistant) is an imprecise evidence (level L2 for evidence quality). This response does not present any personal ideas.

Table 1. Rubric generated for the analysis of the evidence identified by students

<table>
<tr><td colspan="6">Evidence Number</td></tr>
<tr><td>L0: No evidence</td><td>L1: One piece of evidence</td><td>L2: Two pieces of evidence</td><td>L3: Three pieces of evidence</td><td>L4: Four pieces of evidence</td><td>L5: Five pieces of evidence</td></tr>
<tr><td colspan="6">Evidence Type</td></tr>
<tr><td>L0: No evidence</td><td>L1: Economic</td><td>L2: Physical-chemical</td><td>L3: Mechanical</td><td>L4: Two different types</td><td>L5: Three different types</td></tr>
<tr><td colspan="6">Evidence Quality</td></tr>
<tr><td>L0: Inappropriate</td><td>L1: Some inappropriate</td><td>L2: Appropriate but imprecise</td><td colspan="2">L3: All appropriate and some imprecise</td><td>L4: All appropriate and precise</td></tr>
<tr><td colspan="6">Personal Ideas (qualities, use, appearance, preference, personal budget)</td></tr>
<tr><td colspan="3">No</td><td colspan="3">Yes</td></tr>
</table>

"Option B, because this bicycle is lighter, does not rust and is cheaper than the other bicycle" **(UG21).**

The response of this undergraduate presents three pieces of evidence (weight, corrosion resistance and price of the bicycle) (level L3 for evidence number), which correspond to two different types of evidence (economic and physical-chemical) (L4 for evidence type). However, the quality of the evidence was categorized in the level L1 since the property price was indicated inappropriately (a bicycle with a steel frame is cheaper than one with an aluminium frame). This response does not present any personal ideas.

"Option B. Bicycle with aluminium frame. I would choose the aluminium frame since it is a tougher and lighter bicycle. It is also nicer to the touch and the eye. Moreover, it does not rust easily although it is a little more expensive to repair the frame" **(SD31).**

The response of this pre-service science teacher presents five pieces of evidence (weight, mechanical resistance, corrosion resistance, price and mechanical aspects) (level L5 for evidence number) that correspond to three different types of evidence (economic, physical-chemical and mechanical) (L5 for evidence type). These pieces of evidence are appropriate, but some are not precise (the participant mentions that it is a robust bicycle but any specifications are given) (L3 for evidence quality). He emphasizes its touch and showiness as a personal idea.

The Kruskal-Wallis test was used to study possible statistically significant differences between the groups, using the Mann-Whitney U test to detect the group that produces the differences in each case and the possible differences between sexes.

RESULTS

The percentages of responses in each group and dimension are shown in Tables 2 and 3. Responses at level 0 of the rubric were not found in none of the dimensions.

Table 2. Percentage of responses of each group for the dimensions evidence number and evidence type.

	Evidence Number					Evidence Type				
	L1	L2	L3	L4	L5	L1	L2	L3	L4	L5
UG	39.1	30.4	23.9	4.3	2.2	4.3	39.1	8.7	32.6	15.2
SD	67.6	18.9	13.5	0.0	0.0	2.7	70.3	0.0	24.3	2.7
NSD	75.0	22.7	2.3	0.0	0.0	2.3	77.3	0.0	20.5	0.0

Table 3. Percentage of responses of each group for the dimensions evidence quality and personal ideas.

	Evidence Quality				Personal Ideas	
	L1	L2	L3	L4	No	Yes
UG	17.4	8.7	28.3	45.7	67.4	32.6
SD	5.4	2.7	13.5	78.4	70.3	29.7
NSD	0.0	6.8	6.8	86.4	54.5	45.5

It can be seen that UG offers a higher number of pieces of evidence (mean value 2.00) compared to pre-service science teachers (mean SD: 1.46; mean NSD: 1.27).

Likewise, UG was the group with the best results regarding the type of evidence, on the one hand since it was the only group that identified the three types of evidence (SD and NSD did not use mechanical evidence), and on the other hand, because they argued with a greater number of different types.

However, the best results in the quality of evidence were offered by SD (mean value: 3.65) and NSD (mean: 3.80) versus UG (mean: 3.02).

NSD was the group that used the most personal ideas when arguing.

The Kruskal-Wallis test showed that there were significant differences in at least two groups for the number, type and quality of evidence, but not for personal ideas.

The Mann-Whitney U test indicated statistically significant differences between UG and SD for the variables number of evidence ($Z = -2.638$; $p = 0.008$), type ($Z = -2.399$; $p = 0.016$) and quality ($Z = -3.019$; $p = 0.003$), but not for personal ideas ($Z = -0.279$; $p = 0.780$). For UG and NSD the same significant differences were found (evidence number: $Z = -3.866$, $p = 0.000$; type: $Z = -3.215$, $p = 0.001$; quality: $Z = -4.043$, $p = 0.000$; personal ideas: $Z = -1.234$; $p = 0.214$). The Mann-Whitney U test indicated that there were no significant differences between the SD and NSD groups.

No significant gender differences were found in the UG and SD groups, although there were within NSD, regarding evidence quality ($Z = -2.720$; $p = 0.007$) and personal ideas ($Z = -2.125$; $p = 0.034$), in both cases in favour of women.

CONCLUSIONS

The results show that knowledge may influence some aspects of the capacity to use evidence, in this study in terms of the quantity and types of evidence used, but not the evidence quality. The absence of such knowledge may be related to the use of personal ideas rather than evidence in the arguments offered.

On the other hand, the results obtained show the need to train both undergraduates and pre-service science teachers on scientific argumentation. In this second case, bearing in mind that they will be the future technology/science secondary teachers, who will, in turn, have to train their students in argumentation.

THE PRODUCTION OF LITERARY INSCRIPTIONS BY STUDENTS OF HIGHER EDUCATION IN THE HEALTH AREA WHEN CONDUCTING AN IMMUNOLOGY INQUIRY-BASED LEARNING ACTIVITY

Bruno Kestutis de Alvarenga Sipavicius[1], João Rodrigo Santos Silva[1] and Daniel Manzoni-de-Almeida[2]

[1] Universidade Federal do ABC, UFABC, Santo André, Brazil

[2]Grupo de Estudos e Pesquisa em Ensino & Ciências (GEPEC), Centro Universitário das Faculdades Metropolitanas Unidas, FMU-FIAM FAAM, São Paulo, Brazil

The aim was to analyze the production of literary inscriptions in the form of drawings and argumentative writings by groups of students of higher education when they carried out an inquiry-based learning activity with the subject of immunology. The analyzes showed that the students produce literary inscriptions in the form of drawings and arguments in the proposed inquiry-based learning activity, however, there is more production of graphic inscriptions and arguments referring to the drawings when the groups of students were not previously exposed to other graphic and schematic literary inscriptions in basic biology classes before the application of the activity.

Keywords: Inquiry-based learning in Biology, inquiry-based learning in Immunology, literary inscriptions in science education

INTRODUCTION

In one of the objectives of science education, proposed by Hodson (2014), "students learn to do science" and inquiry-based learning activity is an important active learning methodology that makes it possible to reach this learning objective. By executing this methodology students can collect data and interpret them using the logic of science and thus producing the meanings of reality by means of the so-called, primarily by Latour & Woolgar, 1979, literary inscriptions. Literary inscriptions can be defined as the material resources that can be used by scientists to materialize, learn the object or phenomenon studied from a given reality, for example, writings, annotations, arguments, photographs, explanations, diverse designs. The study of the production of literary inscriptions is of interest in the science education and it is up to the teacher the mediation of the construction of knowledge in class using inscriptions.

Inquiry-based learning activity is an active learning methodology [MAA] are possible to be developed by teachers through problematizing objectives that encourage students to develop in a critical and autonomous way about given content, ultimately stimulating their curiosity. (Borges, Alencar 2014; Oliveira, 2014; Moreno 2016,) For Gewhr et al. (2016) MAAs need to be organized based on appropriate pedagogical strategies: concept maps, peer instruction and the verbalization and observation strategy. However, Berbel (2011) shows that for such results to be effective, it is necessary to understand, choose and interest students in face of new learning.

Active Learning Methodologies are the representation of the activity of scientists, in which the production of evidence occurs in two different ways. In the first, through “hands on” activities, which are carried out experimental laboratory practices in the construction of primary data, to solve important problems for the group of students, as in Silva (2011). In the second, they are “hands off” activities in which secondary data related to a problem situation are offered, which are solved only through arguments with other literary inscriptions. In this way, the process of scientific enculturation takes place, appropriating scientific cultural tools, their criteria for the production, communication and evaluation of scientific knowledge (Deboer, 2006; Munford e Lima, 2007; Bybee, 2006; Driver et al, 1999; Kuhn, 1993; Duschl, Osborne, 2002).

The argument only exists when there is a case for direct affirmative. For this, three minimum elements related to Toulmin's (2006) argumentative pattern are necessary: the data show it, the conclusion, has its merit established through the guarantee, which justifies and links the data to the conclusion. It is necessary to understand the dynamism of this model, as the conclusion is provisional, given its relationship with other more convincing elements, which are supported by direct evidence, specialized literature, together with the qualifiers of each dependent field. Only from the points above is it possible to classify, evaluate and criticize an argument.

The development of scientific reasoning occurs in two ways. The first of the primary data, which students build through experimentation and the collection of evidence of reality. The second of the secondary data is collected by others and presented in different ways- graphs, tables, schemes. The former are important for students to understand the source of the data, while the latter are understood as authoritarian, as they are possible to be manipulated in order to identify patterns. In this way, the second is able to generate a greater number of arguments than the first, but which are of worse quality, as they are more distant from the scientific knowledge established by the literature (Kelly, Druker, Chen, 1998; Hug, McNeill, 2008).

The quality of the arguments depends on an appropriate set of scientific knowledge present in the data and its justifications. In order for these to have these characteristics, it is necessary to apply scientific theories relevant to each of these specific problems. The construction of this theory takes place by reasoning during the process of building evidence and models. These are especially important on the molecular scale as in the astronomical macroscopic, because they are strongly abstract in nature, due to their evidences, they are not perceptible to the average daily vision. However, the more distant this is from a theme, the lesser the student's participation, being necessary for the teacher to be a mediator between the spheres of everyday life and the scientific knowledge of abstract models, through socio-scientific activities and contents (Hogan, Maglienti, 2001; Sandoval, 2005; Osborne, 2007; Erduran, Duschl, 2004; Berland, Reiser, 2009; Bottcher, Meisert, 2010; Jiménez-Aleixandre, Puig Mauriz, 2010; Chiaro and Leitão, 2005).One of the literary inscriptions present in the sciences is drawing, both in articles and in teaching, in the form of graphs constructed using a table of collected data, diagrams from microscopic photos and in an isometric representational form of agents and phenomena and phylogenetic trees. The use of drawing in teaching serves for students to deepen their knowledge, communicate it and be able to be evaluated by the teacher. With drawing it is possible to overcome the limitations of teaching centered only on passive listening and writing, stimulating investigative teaching and student curiosity (Quillin, Thomas, 2015; Ainsworth, Prain and Tytler; 2011). For Vygotsky (1989) the drawings represent a preliminary stage of writing, not representing what is seen, but what is known. Therefore, the aforementioned author suggests that the drawing has the same origin as the written language, and, with the development of writing, the drawing is configured as other ways of representing what is written, such as, for example, a graphic description.

Here, our proposal of investigative activity, went in two directions to analyse the work with the literary inscriptions, drawings and writings, by the groups of students of heath area course during an immunology inquiry-based learning activity. In a first, the literary inscriptions as graphic designs and schemes were presented and analysed with the students; and in the second moment, the literary inscriptions of the same nature were produced by the students themselves. And also, the production of literary inscriptions in the form of arguments in both situations. The “inquiry work movement” by student groups with these literary inscriptions in classes sequence was our focus of analysis. How did the students move in the two ways situations proposed that mobilized the construction of students' knowledge in biology classes?

METHODOLOGY

The immunology inquiry-based learning activity*:* the inquiry-based learning activity is used with adaptations from the proposal described in Manzoni-de-Almeida et al., (2016). Briefly, the inquiry-based activity consists in the creation of the narrative that begins with problem situation and a question in which a researcher, interested in accomplishing a treatment of a chronic illness with stem-cells, studies to treat a mouse with chronic disease with these stem-cells. However, before performing the treatment it is necessary to identify in which of the samples of bone marrow cells collected from a healthy mouse there is only the presence of stem cells and not other types of already differentiated cells. To solve this question, and to find out which of the samples are undifferentiated cells, the groups of high education students receive raw results from experiments performed by the laboratory techniques Polymerase Chain Reaction (PCR), Northern blot and flow cytometry. In all these spaces the students can write and draw about the immunology case in the inquiry-based activity.

Data collection: the data were collected in the classes of bases of biological cell, taught in the first year of undergraduate courses in the health area. For the purpose of this study, the application of the activity was structured in two forms: “Situation 1” and “Situation 2”. In 1 the groups of students performed in the first class the analysis of graphs and images.

The images consisted of 13 simplified diagrams of B lymphocyte maturation; there were also 2-column plots illustrating the gene expression of the RAG and Actin gene. Each group of students received the same 13 diagrams of cell differentiation of B lymphocytes, but their 2-column graphs changed, some received graphs illustrating the gene activation of RAG and Actin from stem cells, others from pre-B cells and others from mature B; later in the second class they carried out the inquiry-based learning activity with theme of Immunology, described above.

In 2 the groups of students first, carried out the inquiry-based learning activity, later in the second class, carried out graphs and images analyses. In both situations, students were divided into groups to carry out activities (17 students divided into 3 groups in 1; and 13 students divided into 3 groups in 2; Total 6 hours/class for each class; held twice). The students read and signed the Free Consent Term (TLC) (Protocol CEP: 0985/2015).

Data analysis: literary inscriptions produced was the analysis of: 1) the presence of drawings produced and classified in graphic design, schematic design or free artistic design (adapted from Quillin & Thomas, 2015); and 2) was the analysis of production of arguments in the Toulmin standard (2006).

RESULTS, DISCUSSION AND CONCLUSION

The analyzes of the selected data set showed that the student groups produced literary inscriptions in the form of writings and drawings by carrying out the inquiry-based learning activity only in Situation 2 (Figure 1, example). In Situation 1 the groups of students produced only written literary inscriptions of arguments. The analysis of the material produced by the groups of students showed the development of drawings classified as diagram and graph, with 9 drawings in graphical format (5 graphic designs in each application of didactic activity) and 1 schematic drawing in Situation 2. However, in the analysis of the material of Situation 1, the presence of drawings classified as schema and graphs was not detected.

Most of the graphics produced were in accordance with the raw data, with the RAG and actin gene expression bars. However, instead of making just one column for each one, using the raw data experiments, they made one for each one. Which led some students to create the time graph? Both cases were not appropriate with the literature. Such results are consistent with Fernandes and Morais (2011), as there is a lack of mathematical literacy in the construction of graphs, as well as reading and understanding of them.

The analysis of the writings produced by the student groups in the reports showed that in both situations there were written arguments produced according to the Toulmin standard. The analysis of these writings showed a total of 49 arguments in Situation 1, divided in the detection of 28 and 21 arguments in each application of the didactic activity. In the analysis of Situation 2 the presence of 29 arguments was detected, being the detection of 16 and 13 arguments in each application of the activity. The texts produced in Situation 1 are short arguments and little related to the empirical data of the inquiry-based learning activity investigative activity, but linked to argue, “schematize” the design, the phenomenon exposed. However, the arguments related to Situation 2 are directly derived and referenced from the graphic designs constructed by the students themselves.

In both situations the arguments were short and with little theoretical depth in the reported area of the activity. We believe that this occurrence is due to little familiarity with the theoretical subject, since the studied classes are located in the first semester of the health course, which corroborates with Hug, McNeill (2008), as well as Chiaro and Leitão (2005), because secondary data were offered which can be manipulated and trends can be seen. However, without prior knowledge of immunology, a topic unfamiliar to students, there was a misunderstanding in the graphic data of gene expression, considering those of 1.5 RAG as mature B lymphocyte, which was from the trunk. The arguments written in both situations were slightly longer and close to the literature when describing the maturation of B lymphocyte.

Table 1: **Written and image expression of the construction of knowledge by the groups of students performing the inquiry-based learning activity in the classes with basic biology knowledge in the courses of the health area**

		Situation 1		**Situation 2**	
		1	2	1	2
Number of drawings produced	Graphics	0	0	5	5
	Schemes	0	0	0	1
Number of arguments produced		28	21	16	13

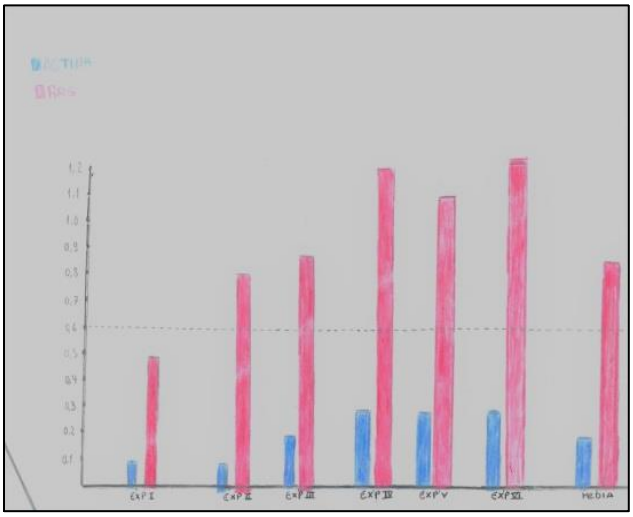

Figura 1 Exemple Graph Situation 2

This suggests that student groups in this Situation 1 did not contextualize the graphical format of literary inscription as a social practice linked to the construction of meaning to understand the proposed biological phenomenon. As the phenomenon is already given, deciphered in graphs and diagrams, the movement of student groups was only to "explain" it by the written verbal language, the arguments, which present the greatest total number in this sequence. The option of presenting the drawings in schematic and graphic form in Situation 1 suggests that the design in science teaching as a way of representing reality and as a communication strategy as proposed by Ainsworth, Prain & Tytler (2011) reinforces the role of the drawing as an active learning tool because the student explores, coordinates and justifies his understanding in science. Bowen et al., (1999), noticed that the construction and better use of students with the graphic design is more positive from the construction of the graphs by the students themselves when developing the situation research since the meaning of the graphic drawings passes knowledge and experiences with social practices, also social practices of science, which are directly associated with the composition of the inscriptions. However, the inverse phenomenon, the work with the ready literary inscriptions can bring difficulties of interpretation by the students, since, the students first have to realize an effort of understanding of the biological phenomenon from the drawing and later to realize the work of deconstruction of the understanding transmitted by the literary inscription for the construction of the biological meaning proposed by the data (Bowen & Roth, 2002; Roth, 2013). This discussion also suggests that the phenomenon of the absence of the production of inscriptions in the format of drawings in Situation 1 also by the non-"appropriation" of social practices and scientific in the construction of analyzes of literary inscriptions.

In conclusion, the work of the teacher in the classroom with the most diverse nature of literary inscriptions in inquiry-based learning activity can provide several creative aspects of scientific expression for students; and immunological inquiry-based learning activities, such as the one studied, can provide the production and interpretation of a diversity of important literary inscriptions related to the objectives of scientific literacy in the training of science teachers, biology (in particular Immunology) and the insertion of students undergraduate programs in the areas of biological sciences and health in scientific culture for the development and training of researchers in the natural sciences.

THE CONTROVERSIAL ASPECT OF THE SOCIOSCIENTIFIC ISSUE AS A DISCURSIVE CONSTRUCTION OF THE TEACHER

Gabriel Saraiva Gomes[1], Marcelo Giordan[1]
[1]School of Education, University of São Paulo, São Paulo, Brazil

The Socioscientific Issues (SSI) movement is a contemporary part of the Science-Technology-Society-Environment (STSE) approach in Science Education which aims to study controversial issues of scientific and social interest widely disseminated by the media in order to promote students' development. We aim to illustrate and discuss how the controversial character related to an SSI is the result of a discursive construction performed by teacher and students in the classroom. An episode extracted from a didactic sequence applied by a Chemistry teacher in a Brazilian public school is presented and analysed. In the episode, conflicting points of view about the pollution of a stream are explored in order to transform this issue into a controversy. The structure of the interaction was described in terms of triadic Initiation-Response-Feedback patterns and the discursive move performed in the classroom was characterized as a displacement of mental context shared between the teacher and the students.

Keywords: Socio-scientific issues, classroom discourse, context-based learning.

INTRODUCTION AND THEORETICAL BACKGROUND

Promoting citizens' scientific education goes beyond understanding the scientific concepts that explain the phenomena observed in nature, since the main purpose of studying Science in school is not only to deal with its conceptual contents, but also the methods used by researchers, aspects of the nature of this knowledge and its implications in other spheres such as Society, Politics, Economy and Environment.

In this sense, for nearly five decades or so, the STSE (Science-Technology-Society-Environment) approach has been configured as a strategy for promoting the relationship between scientific knowledge and different areas in which it is involved. As dictated by Pedretti and Nazir (2011), there is no single possible approach when thinking about developing STSE proposals in education, however, all of them converge to the fact that it is necessary to raise awareness of the studies regarding the articulation between scientific production and technological and social demands.

The authors (*idem*) suggest a classification of STSE teaching proposals into different variations according to teaching resources and emphasized purposes, and, more specifically, the study of socioscientific issues (SSI) aiming at the development of values in students, the understanding of the nature of Science (NOS) and the awakening of conscience about socio-political-environmental action. Pérez and Lozano (2013) signal that since the beginning of the 21st century, the STSE movement has undergone a reconfiguration towards the study of SSI and has become a way of effecting the STSE relationship in the classroom. Therefore, an Academia's concern is studying and understanding the nature of these issues and ways of integrating them as didactical proposals in the classroom.

Socioscientific issues in Science Education

SSI can be considered as controversial issues about scientific knowledge that present implications for different areas, such as society, economy, politics and environment. The controversial aspect of an SSI often leads to wide media coverage, which presents the issue for the population and influences divisions of opinion because most of them are involved in studies that are still under development (Ratcliffe & Grace, 2003; Pérez and Lozano, 2013). Examples of SSI are climate change and global warming, nuclear threats, genetically modified organisms planting and consumption, marijuana decriminalization, and animal experimentation.

Since these questions are related to the population's experience and lead to a division of opinions and consequent discussion, working with SSI in the classroom can promote benefits for the development of students in the cognitive sense, by learning scientific concepts, and also in the moral sense, by the acquisition of values and value judgments, fostering of critical thinking and promotion of argumentation (Zeidler, Sadler, Simmon & Howes, 2005; Zeidler & Nichols, 2009).

Considering these characteristics, Pérez (2014) indicates that teacher's planning capacity is essential when bringing SSI in the classroom, once dealing with a controversy creates a necessity for the teacher to articulate knowledge of different areas, mediate discussions and expression from different points of view brought by students, and structure teaching sequences in order to create a learning context (Zeidler & Lewis, 2003) faithful to the commitment of cognitive and moral development of students. Thus, it becomes target of research how the teacher creates and sustains this SSI-influenced context in the classroom.

Socioscientific issues as teaching contexts

Before exploring how SSI can generate a teaching context, it is important to keep in mind a clear understanding of what "context" means. For this definition, we rely on the notion proposed by Edwards and Mercer (1987), who argue that in a learning environment there are three kinds of shared contexts by teacher and students and act as elements of meaning making. They are the situational context, relative to the material environment of the actions; the linguistic context, related to the progress and content of the classroom discourse, and the mental context, related to the ideas evoked and shared in the social plan of the classroom. Giordan (2013) points out that the engine of meaning processes in the classroom is the displacement of contexts over time, what Edwards and Mercer (1987) call "continuity", which means that a previously experienced situational or linguistic context later becomes a mental one that is reclaimed in the classroom by the teacher or the students to proceed with the development of their ideas.

Combining this definition with the SSI approach, we argue that it functions as structuring issue of classroom teaching proposals, which acts as a mental context that is constantly recovered by the teacher and, therefore, reconfigures itself over time, anchoring scientific concepts and subsidizing the formation of opinions by the students. In other words, in order to become an effective teaching resource, the teacher needs to pose a question at the beginning of a teaching sequence, which is constantly revisited for its solution or discussion. This means that, to recover a lived context, the teacher uses the discourse, mainly mediated by the speech, to effect the contextual displacement. Thus, the proposition of the triggering question that serves as guide to the classroom activities, that is, the construction of the context, is a discursive phenomenon and, therefore, keeps in itself the characteristics of the SSI used for the creation of the teaching proposal.

In this sense, since there is a controversy involved in an SSI, we aim to study the discursive characteristics, in terms of structure, function and content of the utterances related to the construction of the controversial aspect of an SSI in the classroom by a Chemistry teacher. More specifically, we aim to demonstrate how she and two students involved in a discursive interaction mobilize the displacement of contexts to understand a controversy related to the pollution of an aquatic environment.

RESEARCH SCENARIO AND METHODOLOGY

The data presented in the next section is taken from the development phase of a didactic sequence (DS) entitled “Do you know what is in the water of the Pirajussara stream?”, developed and applied by a Chemistry teacher to high school students in a public high school in the city of Embu das Artes (Brazil). The main goals of this DS were to determine the quality parameters of a water sample (such as color, turbidity, pH and salinity) of the Pirajussara stream, a water source located in São Paulo (Brazil), and to discuss the origins and possible solutions for the pollution suffered by this stream since the 1960s.

Data were collected through audio-visual record of the lessons, using two digital cameras positioned in the background and in front of the recording environments, and four digital recorders to capture the voices of the teacher and students. After recording, the multilevel mapping of the lesson was performed for data selection. This methodology (Silva-Neto, 2016) is based on the segmentation, at different levels, of the DS lessons taking as reference the teaching activities as structuring units of each lesson. Thus, the first level of analysis corresponds to each of the lessons; the second level, to the teaching episodes, which are defined as moments of the lessons in which the teacher presents specific purposes with the class, and the third level, to the discursive sequences, that is, the discourse units that make up each episode.

An episode whose discursive sequences corresponded to the construction of the controversial aspect related to Pirajussara’s water pollution was selected for analysis, as will be explained later. For the analysis, we used the frameworks developed by Mehan (1979) and Mortimer and Scott (2003) for the characterization of classroom discourse. The first author points out that there is a triadic pattern in teacher-student interactions consisting of an Initiation (I), usually posed by the teacher, followed by a student's Response (R), which is subjected to an Evaluation (E) by the teacher. The other ones add that the third turn of interaction does not necessarily work as an evaluation, thus, sometimes it fulfills the role of providing a Feedback (F) to the students’ responses, when the teacher elicits more information from them. Another type of utterance that can be observed in the interaction patterns of classroom discourse is characterized by Silva and Mortimer (2010) as a Synthesis (S) of the interaction. It is usually seen after an evaluation turn, and is used by the teacher either to summarize the ideas that have been discussed or to close the interaction. With these considerations in hand, it is then possible to present the found results.

RESULTS AND DISCUSSION

The selected episode occurred in the last lesson of the DS, in which after gathering the results of the analysis of the quality parameters collected over the other six lessons that made up the sequence, the teacher and the students discussed and solved the initially proposed question, in this case, the water potability of the Pirajussara stream.

After the evaluation of the parameters and the conclusion that the water could not be consumed due to the results obtained, a discussion started about the possibility of cleaning the stream, as can be observed in the transcript below:

Table 1. Transcription of the episode of controversy construction related to the SSI. St = Speech turn; Sp = Speaker (T = Teacher, Sn = Student n); IP = Interaction Pattern (I = Initiation, R = Response, F = Feedback, S = Synthesis of the interaction).

St	Sp	Transcription	IP
1	S1	- Teacher, is there any place where people enter to clean it?	I
2	S2	- No! This is why it is so dirty; nobody goes there to clean it.	R
3	T	- Oh! However, whoever goes there to clean it, whoever does the maintenance, they go equipped, and they wear overalls, gloves, and security glasses. They are ready to do it; they won't enter there, isn't it?	R
4	S2	- But, teacher, if there was anyone to clean it, the river wouldn't be like that, would it?	F
5	T	- But why do we need to clean it?	I
6	S2	- Because it is very dirty! It is mixing sewage with the river spring water.	R
7	T	- But should the sewage be there?	F
8	S1	- No!	R
9	S2	- What?	R
10	T	- The sewage… Is it in the right place, then, if it is mixed with the river spring water?	F
11	S2	- No!	R
12	T	- So if it were in the right place, do you agree with me that we wouldn't need to clean it?	F
13	S2	- Yes.	R
14	T	- If everything were in its own place...	S

In turn 1, student S1 initiates the interaction with a movement of subversion of the interaction pattern, providing an initiation to the teacher about the places where the stream water was cleaned by professionals. In 2, she is answered by student S2, who denies the existence of such places claiming that it was the fact that there were no people to clean the stream that implied the current situation of the polluted environment.

S2 was referring to people in general in her answer, however, we can infer that S1 was asking about the existence of professionals to perform the cleaning of the stream. Thus these people come into direct contact with the water, a fact that was understood by the teacher. S1 was answered in turn 3, when the teacher states that professionals enter the stream properly equipped, hence not having direct contact with the polluted water. Then, in turn 4, student S2 evaluates the teacher's response, putting her disagreement on the fact that if the stream were cleaned by professionals, it would not be polluted.

In order to regain the discourse authority, the teacher directs student S2 an initiation in 5, asking her why the stream water should be cleaned, and receiving the answer that it was dirty because the spring water of the stream was mixing with the sewage discharged by the residences. Again, the teacher asks if the presence of sewage in the water is appropriate and S1 responds negatively, whereas S2 asks the teacher to repeat her initiation. After the teacher does it, S2 responds negatively. In turn 12, the teacher once again puts her authority by asking S2 rhetorically about the need to clean the water if the sewage was not contaminating it, receiving a student's agreement response and concluding the interaction in 14 with a synthesis in the form of the expression "If everything were in its own place ...".

We can infer from the description of the utterances that made up the episode above that the structure of the interaction developed by the teacher and students S1 and S2 occurred in three phases. Between turns 1 and 4 we observed a subversion of the interaction, since the initiation turn was performed by S1, who received answers from both the teacher and student S2, and the teacher's response was submitted to an evaluation by the second student. Between turns 5 and 12 we saw an extended I-R-F-R-F-R-F sequence, in which the teacher regains her classroom authority to guide the students to a single point of view. Finally, in turns 13 and 14, we have the completion of the interaction with a synthesis from the teacher, which pointed to the desired conclusion.

It is in terms of the contents that circulated in the utterances that we identified the creation of a controversy in the classroom. First, we must be clear about what a controversy means. Usually, when we think of an SSI-related controversy we refer to a polemical issue. Nevertheless, Pirajussara's pollution itself does not present a polemical side that causes a sharp division of opinion among people. We argue that the controversy dealt with in this interaction fragment is due to the difference of points of view presented by student S1 and student S2 regarding the solution for the problem of stream pollution, and by the teacher and student S2 regarding the origin of such a problem.

When student S1 brings to the classroom her doubt about the existence of professionals who clean the already polluted stream, she states a possibility of solution for the problem, once she points the need to clean a dirty environment. However, student S2 brings another demand, in this case, that if there were people to clean the stream it would not be in such a situation. To work with such divergence, the teacher chooses not to deal with the solution demand proposed by S1 by simply explaining to her that the professionals who clean the stream enter such an environment appropriately equipped.

However, due to S2's opposition to the teacher's explanation, the teacher takes a different path in which she chooses to deal with the source of the problem. The demand brought by student S2 is that the stream is polluted because the water from its spring is being mixed with the sewage content from the residences. Thus, the teacher conducts the second part of the interaction in order to convince the students that even before thinking about the possibility of cleaning the stream, one must think about the source of its pollution, that is, the lack of access to sanitation system. This information is implicit in the teacher's synthesis utterance, where “If everything were in its place ...”, can actually be interpreted as: if the population living around the stream were assisted with basic sanitation policies, the sewage produced would be destined for the correct location rather than the stream.

CONCLUSIONS

We could identify that the controversial aspect related to the SSI that underpinned the DS was the opposition between demands related to the pollution of the Pirajussara stream: on the one hand, the need to clean an already polluted environment, and on the other one, the need to stop the sewage discharge into the water. The teacher discursively explored this opposition in order to convince the students that even before thinking about the solution for the problem, one must think of its real source. To do so, from a subversion of interaction promoted by S1, the teacher regains her authority and develops a series of I-R-F triads to reach the desired point of view.

Returning to the idea of contextual creation based on an SSI, the construction of the controversy observed in the described episode was made possible by a series of contextual displacements (Edwards & Mercer, 1987) performed by the teacher and the students. S1, by bringing its doubt about the professionals, brings to the classroom an external context to the one that was already being studied, that is, the results of the analyses performed in the previous six lessons. To oppose the idea brought by S1, S2 makes another displacement when she brings to the classroom the memory of the dirty stream image, visualized by the class when they visited the stream mouth to collect a water sample. Finally, to convince the students to reflect on the origin of the pollution, also the teacher makes a contextual displacement by bringing to the classroom the discussion about the need for basic sanitation policies, an aspect that had been worked with the class in the first lesson of the DS, in the synthesis utterance.

This result makes ground for one last consideration. As stated earlier, SSI function as a context in which the teacher develops a narrative in the classroom, which, even linear, does not necessarily need to be fully presented at the beginning of a sequence of lessons. The fact that the controversy was revealed only in the last lesson does not indicate that this aspect was missing in the first class. On the contrary, it highlights the potentiality of using SSI as structuring elements of teaching proposals, given the teacher and students’ ability to recover the context that was initially proposed to develop the scientific knowledge in the classroom.

To summarize, we state as a contribution the existence of problematization movement, which occurs using an SSI as the basis for the construction of a DS, and occurs in a discursive way by the recovery of contexts over time. We also propose as further research the study of the discursive characteristics of the problematization movement throughout the lessons of a DS. In doing so it will be possible to identify not only the structure and function of the utterances related to the issue construction, but also the dynamics of contextual displacements that make an SSI an instrument of meaning making in the classroom.

ACKNOWLEDGEMENT

We acknowledge the Coodernação de Aperfeiçoamento de Pessoal de Ensino Superior (CAPES, Brazil) and the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq, Brazil) for funding the research, and the Chemistry teacher who participated in the development of the DS.

ARGUMENTATION IN THE CHEMISTRY TEACHING: ANALYSIS OF DISCURSIVE INTERACTIONS AND VERBAL ACTIONS

Welington Francisco[1], Lôany Gonçalves da Silva[2] and Wilmo Ernesto Francisco Junior[3]

The central role of argumentation in science is producing the debate among people because the argument is directly connected with the learning process to provide the appropriation of scientific discourse, and in order to be a window onto the epistemic work of science. Therefore, the problem question in this study is to *identify which are the verbal actions used by students that favor the formation of scientific arguments in an activity with controversial issues? Thus, argumentation in dialogical model was used to identify verbal actions of six undergraduate students of the Chemistry Course. Data was collected by recording the debate between the two groups of students (a lawyer and two witnesses) and it was analyzed with a model which establishes relationships between the verbal actions performed in the pragmatic, argumentative and epistemic plans with the enunciative strategies. The results show that the initiations of metaprocess and process type favor the argumentation because they demand a higher level of students' reflection and engagement that trigger epistemic operations of low and higher cognition such as definition, classification, explanation and generalization.*

Keywords: Argumentation, verbal actions, enunciative strategies.

INTRODUCTION

The argumentation studies came to be established when a distinction was made between two aspects: (1) the study of logic, which was taken to be the disembedded rules for producing correct inferences from given premises and (2) the study of how people in specific situations actually reason from premises to conclusions (Driver, Newton & Osborne, 2000). Thus, the central role of argumentation in science is producing the debate among people, because the argument is directly connected with the learning process to provide the appropriation of scientific discourse, and in order to be a window onto the epistemic work of science (Erduran, 2006; Kelly & Takao, 2002; Zohar & Nemet, 2002).

Therefore it is important to develop argumentative activities in science classroom because they can be highly beneficial for students to advance scientific knowledge, learn how to identify and evaluate scientific arguments, as well as to learn how to craft them. Hence, in this study, the following problem question is guided: what are the verbal actions used by students favor the formation of scientific arguments in an activity with controversial issues?

Theoretical background: the dialogical model of argumentation

The argumentation in dialogical model is defined as a linguistic activity that propitiates debatable or controversial ideas, being the enunciation placed in the background of the dialogue. For Plantin (2005, p. 63-4), dialogical argumentation "is triggered when a point of view is questioned in answer to the same question" or some fact or conjuncture to be analyzed. Thus, it is this statement that puts itself in doubt in the argumentation in dialogical model, establishing a triple situation divided into Proponent, Opponent and Third Party (Plantin, 2005).

It is understood as Proponent the one who manifests an opinion contrary to an initial statement, and this opinion is dominant. The Opponent is the one who opposes the proposer, and finally, the Third Party is the speaker who does not identify with either of the two discourses, opposing the proponent and the opponent, transforming this opposition into a question (Plantin, 2005).

Summing up, the discourse construction in this model can be considered as follows: the question generates the argument and the argument generates the conclusion, that is, the answer to the question. Thus, "argumentation can be seen as a way of constructing answers to questions that organizes a discursive conflict" (Plantin, 2005, p. 70). Besides that:

> In such a situation, all semiotic elements articulated around this question have argumentative value. In particular, the justifications can be accompanied by a series of concrete actions, co-oriented by the speeches and aiming to make the positions defended sensitive (Plantin, 2005, p. 65).

Based on these ideas it is possible to identify verbal actions that favor and construct the argumentation through three distinct planes: the pragmatic, the argumentative and the epistemic.

The pragmatic plan is based on discursive actions that create the necessary conditions for the argumentation to effectively establish itself. Verbal actions, in this plan, derive from a plausible topic of discussion, making the argument appear in the eyes of students as an appropriate method for managing these differences (Leitão, 2011). The same author also highlights actions that can be seen as an invitation to argument such as challenging others to formulate their points of view, asking for justification for points of view, placing the student in the position of opponent, presenting arguments to negotiate, resolve different points of view and encourage the student to respond to con arguments. Dialoguing with the ideas of Plantin (2005), it is the moment of the Proponent and Opponent to opine against or in favor of the presented statement (the debatable subject).

In the argumentative plan the verbal action aims to generate and sustain the argumentation by defining operations as definition/justification of points of view and negotiation of divergences. Here, it focuses on how participants practice or encourage others to implement defining operations (Chiaro & Leitão, 2005). The actions included in this category are described by Leitão (2011) as formulation and evaluation of arguments, doubts, objections, con arguments and answers to the objections considered. It is the moment that the arguments of the Proponent and Opponent become conflicting and aim to analyze the initial statement. Here the Third Party has the role of fostering arguability from new questions or statements.

The epistemic plan is related to verbal actions that directly mobilize knowledge, that is, they bring to the discussion information such as relevant concepts and definitions to the domain of knowledge (Leitão, 2011; Chiaro & Leitão, 2005). This epistemic dimension is related to the possibility created in the argumentation of construction and transformation of concepts and development of common reasoning of the domain of knowledge to which such concepts refer. Some examples of actions for this category are: the presentation of contents as concepts and definitions on the subject, demonstration of some procedure, ways of reasoning and observations based on documentary sources or by experimentation and verification of students' points of view (Leitão, 2011). Broadly speaking, they are the answers to the initial questions (or statements).

That is the reason why the argumentation is discussed as a "social and discursive activity that is carried out by the justification of opposing points of view and considerations" (Chiaro & Leitão, 2005, p. 350) in order to promote changes in conceptions/representations of the participants on the topic discussed. Interest in the relationship between argumentation and knowledge-building processes has generated studies that seek to understand the characteristic role that argumentation plays in educational processes and how it can be productively implemented in teaching-learning situations (Leitão, 2011).

RESEARCH PATH AND ANALYTICAL FRAMEWORK

This work is a qualitative research where six undergraduate Chemistry Course students participated. An activity based in investigative case about a discursive conflict was elaborated through a simulated jury on nucleophilic substitution and elimination reactions. The case technique was intimate debate that is known "as structured debate or constructive debate. It is a powerful method for dealing with case topics that involve controversy" (Herreid & DeRei, 2007, p.10).

The activity was developed in 9 (nine) consecutive classes of 50 (fifty) minutes, totaling 9 classroom meetings. In the first class, the case was delivered to the students and read aloud by the teacher, who then opened for clarification on the case and the activity.

The case served as a problematization for the classroom discussion about nucleophilic substitution and elimination reactions, discussing the properties of each one, the advantages and limitations, as well as the laboratory conditions that favor each reaction. This discussion was conducted until the eighth meeting and in the last meeting the simulated jury was performed.

Data collection was done by recording the debate between the two groups of students (a lawyer and two witnesses), which was later transcribed in its entirety. A model of analysis was created (Table 1) which establishes relationships between the verbal actions performed in the pragmatic, argumentative and epistemic plans with the enunciative strategies (Silva & Mortimer, 2010) to identify the argumentative structures that benefited the argumentativeness about the theme and, therefore, which favored the students' arguments.

Table 1. Model of the data analysis.

Model of analysis	
Plans	**Related Enunciative Strategies**
Pragmatic	*Types of Initiations* - Choice: requesting a yes or no type answer. - Product: requiring a name or a fact. - Process: demanding an opinion or interpretation of who is answering. - Metaprocess: demanding a construction of ideas and major reflection.

Argumentative	*Intentions* - Creating a problem: mobilize the student's intellectual and emotional form in the initial development of the scientific story. - Exploring the student's visions: identify and explore the students visions about specific ideas and phenomenon related to the theme. - Keeping the narrative: provide comments about the scientific story to help develop the theme and its relationship. - Introducing and developing the scientific story: make available the scientific ideas in social plan in the classroom.
Epistemic	*Epistemic Operations* There are a set of categories related to the cognitive activities of knowledge construction that are classified as: description, explanation, generalization, classification, comparison etc.

The interactions and verbal actions allow the analysis of the interventions through activities related to the investigative cases, especially when the method is the intimate debate, because it allows the discussion among the students establishing relationships between the students' points of view in scientific terms and the reasons that justify them.

RESULTS AND DISCUSSION

Table 2 presents the main strategies of verbal actions used by the lawyer and witnesses during one of the episode of the debate:

Table 2. Main verbal actions and enunciative strategies presented in the debate.

Episode 2 – Lawyer Questions of the group 1 to the witnesses of the group 2	
Pragmatic plan/initiations	Identified from the type of questions made by the lawyer during the debate. Some examples are: - Challenging the students to formulate viewpoints (*Initiation of metaprocess*) - Requesting justifications (*Initiation of process*) - Requiring the opponents to reexamine their points of view (*Initiation of metaprocess*) - Examining the point of view of who is asking (*Initiation of metaprocess*) - Demanding students' answer to con arguments (*Initiation of process*)
Argumentative plan/intentions	Identified from the enunciations that sustain the argumentation among the students as: - Searching the students' opinion (*Intention of exploring the student's visions*) - Doing juxtapositions of ideas (*Intention keeping the narrative*) - Presenting points of view (*Intention of keeping the narrative*) - Formulating an alternative points of view (*Intention of introducing and developing the scientific story*) - Realizing objections (*Intention of creating a problem*)
Epistemic plan/epistemic operation	Identified from the type of speech content used by the students during the debate. The main epistemic operation is: explanation, classification, description and comparison.

Below, one part of this debate is exhibited among the students about the inversion of configuration in unimolecular nucleophilic substitution reactions:

> *Lawyer:* So the substitution reactions I think according to the literature says that all and (pause) undergo inversion, right teacher?
> *Teacher:* Yes.

Lawyer: I even wondered if it was all Sn2 reactions undergo inversion.
Teacher: Inversion in configuration.
Lawyer: That, inversion in configuration.
Teacher: Inversion can happen, it happens. But that does not mean it will generate your enantiomer.
Lawyer: That's it! I wanted to "like". Because in Sn2 reactions because in the book I think it speaks.
Witnesses 1: Always speak.
Lawyer: That's all, I even thought that inversion of configuration occurs.

In this interaction, the student-lawyer questions the teacher for a process initiation in a content discourse regarding the inversion in configuration that occurs in bimolecular nucleophilic substitution reactions. This action presents itself as a pragmatic plan, because the question invites the teacher to examine the conceptual domain on the subject of the questioner, and thus creates the possibility of disagreement or not about the subject (Chiaro & Leitão, 2005).

Through the interaction, the teacher introduces and develops the scientific story, providing the scientific ideas about the inversion of configuration in this type of reaction, contributing to the student's formulation of the question. Mendes and Santos (2013) present in their results that a positive evaluation and request for clarification from the teacher are strategies for the discourse direction, which is similar in this first round in an argumentative plan.

Then the "lawyer" makes a question from the metaprocess initiation which requires knowledge, reflection and justification of the witnesses about the inversion of the configuration content, keeping the verbal action on a pragmatic plan:

Lawyer: Why does the inversion of configuration occur?
Witnesses 2: Because of the conformation of the intermediate state. And how it will attack here to form the desired product it...
Witnesses 1: And to form the desired product, then it needs the inversion.
Witnesses 2: This group will cause a... a probability in this group in the case this hydrogen and in this brome and then it will reverse to another side, it will pass everything here, and this will be the conformation.
Witnesses 1: It must occur in order to obtain the desired product.

Both witnesses answer presenting justifications and reasons based in the product formation with the goal of keeping the narrative. In the epistemic plan, the students try to explain the inversion of the configuration by supporting the desired product, but this strategy only allows describing one of the causes of inversion. Thus, the epistemic operation observed to approach the description still requires a conceptual evolution to the total domain of the addressed scientific content (Vargas, 2010).

SOME CONSIDERATIONS

The role of the lawyer was an important factor of argumentation because as a proponent, it always began with a question to the witnesses. In addition, the initiations of metaprocess and process type favor the argumentation because they demand a higher level of students' reflection and engagement.

Regarding the argumentative plan, different types of verbal actions stood out. In this episode there were statements involving juxtapositions of ideas, presentation of points of view, search for the opinion of colleagues, formulation of an alternative point of view, objections and others. Throughout this episode, the intention is to maintain the narrative with the purpose of helping colleagues to follow the conceptual development.

In relation to the epistemic plan, the description and classification were the categories more used, but the explanation and generalization categories were also used, and that triggers epistemic operations of low and higher cognition. However, the planned activity required from the student's specific speeches about the content that required the previous study and from this the construction of the scientific knowledge through its arguments.

Therefore, the differential of this work was to apply the analysis model developed for discursive analysis to identify what kind of enunciative interactions/strategies and verbal actions in argumentative situations favored learning. The identification and analysis of these statements contribute to present how the scientific chemical knowledge is appropriated by the students during argumentation activities, allowing the evaluation of the learning process in the course of the construction of their arguments.

PRE-SERVICE TEACHER'S DISCURSIVE MOVES GUIDING WORK WITH EVIDENCE

Ana Elisa Montebelli Motta[1] *and Marcelo Tadeu Motokane*[2]
[1]Postgradute Program in Science Teaching, University of São Paulo, São Paulo, Brazil.
[2]Faculty of Philosophy, Sciences and Letters of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil.

The use of scientific evidence in argumentation is not a trivial pursuit and teachers should have an important role in promoting this practice. Framed in researches about biology classroom argumentation, the purpose of this study is to identify and characterize the discursive moves of a pre-service biology teacher that are related to students' work with evidence. For this, we analysed transcriptions of teacher-students' interactions during inquiry classes into an ecological problem. The data analysis led to identification of the following moves: requires evidence identification, requires clarification, requires claim defence, requires evidence reconsideration, and requires explanation. The results suggest a relationship between the discursive moves identified and the students' construction of more specific evidences, reconsideration of excluded evidence and use of evidence in the defence of an explanation. No metacognitive moves were identified.

Keywords: evidence, argumentation, science education.

INTRODUCTION

Evidence-based argumentation is a type of scientific discourse and a powerful tool in classroom contexts, especially when considering enhancing scientific literacy an important component of science education (Driver, Newton, & Osborne, 2000). Jiménez-Aleixandre (2010) propose that evidence-based argumentation may support students in the development of critical thinking, scientific practices and also ways of learn how to learn.

However, the use of evidence in argumentation is not a trivial pursuit. Several studies have pointed out that students often face difficulties that includes, for example: (a) interpreting evidence, identifying which are relevant to the problem (McNeill & Krajcik, 2007); (b) use sufficient evidence and (c) explain why the selected data can be used as evidence to support their claims (Sandoval & Millwood, 2005). Bravo, Puig, and Jiménez-Aleixandre (2009) described that the use of evidence involves competences on two dimensions: practical, including the use of evidence in different contexts and the operations associated within this performance and metacognitive, that is, the understanding about the nature of evidence, its function and criteria for evaluating.

In addition, teachers have faced different challenges in supporting this scientific practice. One of them refers to the need of moving away from an instruction centered on the transmission of knowledge to an instruction based on student construction of knowledge, understanding the importance of providing opportunities and support for students to raise and test hypotheses, position for and against and also use evidence in constructing explanations (Driver et al., 2000).

Thus, this study aims to identify and characterise a pre-service teacher's discursive moves that are related to high school students' work with evidence. In other words, we seek to comprehend the types of teacher' moves that may help students work with evidence during an inquiry activity.

METHODS

Participants

The participants are a pre-service teacher and five high school students (all girls, from 14 to 15 years old). These students share a low socioeconomic background and attend the same public-school classroom in a small city in the State of São Paulo, Brazil. At the time of the data collection, the pre-service teacher was attending the last period of Biology Teaching course at the University of São Paulo.

Data collection and analysis procedures

Data were collected during inquiry classes designed by the researches under the 'predict-observe-explain' framework (see Erduran, 2006), which provides a context for students' engagement in argumentation. In these classes, students were supposed to think and solve a problem around why the abundance of two plant species was different in two forests with similar abiotic conditions. To do this, they tested predation and competition hypotheses while examining provided data. In order to explain the phenomenon, students should be able to integrate predation and competition concepts into a single causal explanation, understanding that high predation rates of strong competitors can allow other species to establish. Table 1 summarises the inquiry activity proposed to the students, highlighting the evidence available in the instructional material.

Table 1. Summary of the inquiry activity.

Step	Tasks	Evidence Available
Predict	1. Identifying the differences between two forests and hypothesising several causes of these differences.	Map showing abundance and distribution of two plant species in each forest. Table showing these abundances.
	2. Establishing the seed predation as causal account.	Theoretical data - Text describing the life cycle of insect seed predators and the damage they cause to seeds.
Observe-Explain	3. Evaluating whether the predation hypothesis is able to explain the problem.	Field data - Table showing predation rates of the two plant species in each forest.

Predict	4. Establishing the plant competition as causal account.	Theoretical data - Text describing ecological conditions usually associated with plant competition and its negative effects on plant development.
Observe-Explain	5. Evaluating whether the competition hypothesis is able to explain the problem.	Laboratory data - Table showing seedings growth of the two species cultivated under different experimental conditions.

Framed in qualitative methods, this paper reports a case study (Yin, 2003). The classes, comprising 3 hours of video-audio recording, were transcribed and the participants' turns of speeches were labelled as PT for pre-service teacher and S1 up to S5 for students, in order to preserve anonymity. All turns with evidence mentions were selected. Although only the pre-service teacher's turns of speeches have been coded in this study, the analysis took into account the discursive interactions to understand each evidence work developed before and after teacher's interventions. The codification was done by both authors independently and all incongruences were then discussed and resolved. Categories' validity was established by comparing, discussing and refining interpretations in groups of experts.

FINDINGS

The transcriptions analysis allowed the identification of five typical discursive moves: (i) requiring evidence identification, (ii) requiring clarification, (iii) requiring claim defence, (iv) requiring evidence reconsideration and (v) requiring explanation.

When asking for evidence identification, the pre-service teacher gave direction to the students' data analysis, allowing them to select relevant data in solving the problem (Table 1).

Table 1. Excerpt illustrating the discursive move of requiring data identification.

Turn	Speaker	Talk and action	Discursive Move
853	PT	What is happening in forest B?	Requiring evidence identification
854	S2	It is being predated	

When asking for clarification of what had been said, the pre-service teacher commonly allowed students to discriminate better what they wanted to refer to, making data reference more specific. For example, in the excerpt bellow, a student stated that the seeds were being predated. After pre-service teacher's intervention, the student could specify the species she was talking about (species 1), as well as made explicit the comparison between data (the predation rate in forest A and B) (Table 2).

Table 2. Excerpt illustrating the discursive move of requiring clarification.

Turn	Speaker	Talk and action	Discursive Move
854	S2	It is being predated	
855	PT	Which one?	Requiring clarification
856	S2	The seeds of species 1 are being more predated in forest B than in A	

The pre-service teacher promoted the use of evidence by requiring claims defence. In the excerpt, the students present evidence to support their claims after pre-service teacher's intervention, who questions how the students can affirm that the predation is the answer to the problem at that moment (Table 3).

Table 3. Excerpt illustrating the discursive move of requiring data use.

Turn	Speaker	Talk and action	Discursive Move
551	S1	Predation can explain species 1	
552	PT	But what do you have to claim that the predation explains the abundance of the species 1?	Requiring claim defence
553	S2	It is because the species 1 are being more predated in forest B than in A	
554	S1	And that is why they are in a low abundance in forest B	

The pre-service teacher helped students to review their claims by requiring evidence reconsideration. In the excerpt bellow, a student presented a possible explanation for the phenomenon by discounting relevant evidence that could contradict her proposal. This student considers an insignificant difference between predation rates of different species in the same forest and disregards the comparison of predation rates between forests. In the next turn, the teacher highlighted the evidence discounted.

This discursive move was important to promote a step forward conceptual understanding. After this intervention, in turn 675, for the first time, a student suggested an explanation integrating predation and competition concepts (Table 4).

Table 4. Excerpt illustrating the discursive move of requiring evidence reconsideration.

Turn	Speaker	Talk and action	Discursive Move
673	S1	The species 1 is less abundant in forest B because it is more predated in this forest than in	

		the forest A. In forest B, the species 2 is less predated than the species 1, so the species 2 should be in a higher abundance than species 1, but both species have the same abundance because they compete	
674	PT	But if species 2 is more predated in forest B than in A, why does it have a high abundance in forest B?	Requiring evidence reconsideration
675	S2	In forest B, if the species 1 is being more predated than in forest A, it is not so strong anymore, is it?	

Additionally, the pre-service teacher conducted students to use evidence from theoretical bases, and also lead to the construction of an evidence-based explanation by requiring explanation. In the excerpt bellow, when questioning the relationship established between data (*i.e*, high predation rates leads to low abundance of plants) the pre-service teacher allows the student to make explicit her reasoning by appealing to the theoretical data available in the instructional material (*i.e.*, the beetle life cycle) (Table 5).

Table 5. Excerpt illustrating the discursive move of requiring explanation that allowed the use of theoretical data.

Turn	Speaker	Talk and action	Discursive Move
770	S3	In forest B, if there was more predation it would have less abundance of plants	
771	PT	Why? What happens when a plant is predated?	Requiring explanation
772	S3	Because the beetle larva eats the embryo and the seed does not germinate	

In the next excerpt, questioning the students, the pre-service teacher guides the construction of a final explanation supported by evidence. In turn 855, the pre-service teacher asks the students what causes the plants abundance observed. Then, one student identifies the predation of species 1 as the cause of the phenomenon. In the next turn, the teacher asks the students to explain what the predation causes in species interactions and, in turn 859, enable the students to explain the relationship between predation and competition ecological interactions, which makes explicit the cause and effect relationship between data (Table 6).

Table 6. Excerpt illustrating teacher's leading the construction of an explanation to phenomenon by requiring explanation.

Turn	Speaker	Talk and action	Discursive Move
855	PT	We know there are factors acting differently in each forest. What is happening in forest B that results in the pattern observed?	Requiring explanation
856	S2	It is the fact that the species 1 is more predated in forest B than in A	
857	PT	That is right. So, what happens to the interaction between the species 1 and 2?	Requiring explanation
858	S2	Because species 1 is being more predated, species 2 can have an advantage to increase its number	
859	PT	Even the species 1 being the strongest one?	Requiring explanation
860	S1	Yes. The strongest one is being more predated in forest B, so the species 2, which is the weakest, has its number increased	

CONCLUSION AND IMPLICATIONS

Each discursive move identified is showed to be related with students' comprehension, selection, and use of specific evidence to defend and review claims. The pre-service teacher's approach, such as guiding evidence identification or providing hints about what to include in reasoning are similar to the ones discussed by Gotwals, Songer, & Bullard (2012) in a scaffolded writing task.

All moves of the pre-service teacher could be classified as promoting a 'practice of use' dimension of evidence. We did not identify any discursive move related to the promotion of a 'metacognitive' dimension, such as encouraging students to think about the nature of evidence, also considered important to students' critical thinking development (Bravo et al., 2009). These results may be a reflection of the teachers' training itself, since discussions of a metacognitive nature are rarely proposed.

We emphasise the importance of studies that investigate how science teachers can support evidence-based argumentation. Studies that focus on pre-service teachers can provide insights into the relationship between current teacher education and classroom performance for the promotion of this facet of scientific discourse and give us directions to improve it.

PART 8: STRAND 8

Scientific Literacy and Socio-scientific Issues

Co-editors: *Antti Laherto & Eliza Rybska*

CONTENTS

STRAND 8: INTRODUCTION

SCIENTIFIC LITERACY AND SOCIO-SCIENTIFIC ISSUES

The "post-truth" era and the growing realization of the global sustainability crises are both refocusing research and practice in science education worldwide. Abilities for scientific argumentation and contributing to value-based change have been emphasized more and more as important aims of school science. These developments underline and give new considerations to the ESERA Strand 8: Scientific Literacy and Socio-scientific Issues.

Socio-scientific issues (SSI's) have already gained ground in science curricula worldwide and proven successful in rendering science education more relevant for tackling the emerging sustainability issues. According to the research in the field, SSI's can make science learning relevant to students, promote critical thinking and value-laden dialogue, and elaborate the nature of science and the complex connections between science, technology, society and environment. New interpretations of scientific literacy (SL) have also emerged: 'Vision III' stresses that science education should prepare students not only to understand the role of science and informed decision-making in the society but also to question the societal choices and values on the basis of ethical consideration and take action to bring about desirable change. Both domains of the strand, SSI and SL, seem to provide crucial and desirable aspects for creating a responsible and reflective society. At the same time, both domains concern a wide spectrum of human life – from everyday situations to difficulties in making important decisions (that for some may resemble the Trolley problem). SSI's and SL call for an interdisciplinary approach from researchers due to the fact that they deal with moral and ethical questions and values.

The eleven papers from Strand 8 in this proceedings capture the diversity of topics and research approaches within the field of SSI's and SL. Both new and already established orientations to SSI's and SL are manifested in the following papers.

The first two papers focus on informal and nonformal science learning venues, which provide crucially important settings for fostering scientific literacy and sustainability education. Annika Roskam, Kai Bliesmer and Michael Komorek analyse the educational offerings for climate change education provided by out-of-school learning venues. Research on citizen science projects, providing adults with opportunities to work with scientists and vice versa, have remained under-theorised and therefore Till Bruckermann and colleagues propose a heuristic model for designing and evaluating citizen science projects.

The strand 8 contribution includes three papers focusing on SSI-related matters in pre-service primary school teacher education. Athanasia Kokolaki and Dimitris Stavrou employed SSI and Nature of Science approaches in primary school teacher training to negotiate aspects of the EU concept of Responsible Research and Innovation. The paper by Lida Desikou, Athina Koutsianou and Anastassios Emvalotis focuses on how teacher students' epistemic cognition influences how they deal with a SSI. Thirdly, Southern European pre-service teachers' opinions about circus with animals were investigated by António Almeida, Beatriz García Fernández and Penelope Papadopoulou.

School-industry collaboration and the development working-life skills are, also, increasingly important issues for SSI-based education. Prospective teachers' perceptions of the various benefits of collaboration between schools and industry were mapped in Špela Hrast's and Vesna Ferk Savec's questionnaire study. The paper by Luisa López-Banet, Cristina Ruiz González and Enrique Ayuso Fernández surveyed the biotechnology knowledge of Spanish students at the end of their secondary education. Tomotaka Kuroda addressed educational needs posed by working life by conducting a comparative study in Japan and the Republic of Malawi on higher education students' views of the abilities associated with STEM communities.

Finally, three papers investigated students' SSI-related views. To lay the groundwork for SSI-based instruction, Sayuri Tokura and colleagues investigated Japanese primary school students' abilities to recognise and consider other people's diverse cognitive and emotional viewpoints. In the research project reported by Laurence Schmitz and Christiane S. Reiners, an educational tool called "decision diary" was evaluated in supporting students' abilities to identify situations for everyday decision-making. Finally, Bruna Herculano da Silva Bezerra and Edenia Maria Ribeiro do Amaral present a study on how students apply their common sense and scientific knowledge when discussing SSI's in various contexts.

CLIMATE CHANGE AND THE PHYSICAL DYNAMICS OF COAST, WADDEN SEA AND OCEAN AS TOPICS FOR EXTRACURRICULAR LEARNING

Annika Roskam[1], Kai Bliesmer[1], Michael Komorek[1]
[1]Carl von Ossietzky University, Oldenburg, Germany

To illustrate the effects of climate change on coastal areas for learners of every age, a large number of out-of-school learning venues in Germany have emerged in recent years. However, empirical studies have shown that their educational offerings focus on biological content. Because physics is mostly absent, the operators of the out-of-school learning venues fail to demonstrate the intertwining of the dynamics of inanimate and animate nature. Thus, they are unable to address the effects of climate change consistently. Here the present research and development project comes in, which uses the Model of Educational Reconstruction (Duit, Gropengießer, Kattmann, Komorek & Parchmann, 2012) as a theoretical framework. In collaboration with cooperation partners whose out-of-school learning venues attract millions of people each year, new exhibits, guided tours, and learning materials on physical dynamics in the context of coastal areas are being developed (development share). The resulting learning formats are integrated into their existing educational offerings after an empirical examination of their effectiveness (research share). Research and development efforts are thus closely interlinked in this project, which is funded by the German Federal Environmental Foundation DBU.

Keywords: Non-formal Learning, Conceptual Understanding, Qualitative Methods

INTRODUCTION

Coastal areas are characterised by extremely high dynamics and are particularly sensitive to the effects of climate change. However, many learners are unaware of this and usually think in terms of linear cause-and-effect relationships and are generally of the opinion that a cause generates a locally and temporally immediate effect. But the coast and the climate are complex systems whose nonlinear behaviour is often difficult to intuitively understand (Jacobeit, 2007). To illustrate the peculiarities of the complex coastal system and its interaction with climatic changes, a high double-digit number of educational institutions have emerged on the coast of Germany, which use exhibitions, student laboratories, and guided tours as learning formats. They benefit from the large tourist crowds in the coastal regions of Germany, attracting millions of visitors each year.

EMPIRICAL EXAMINATION OF EDUCATIONAL OFFERINGS

Due to many people visiting these out-of-school learning venues, an empirical study was conducted with the operators there. The Model of Educational Reconstruction (Duit et al., 2012) serves as the theoretical framework of the empirical investigation. Two areas are of interest: On the one hand, it is examined how the operators create their educational offerings and who is involved in their development. On the other hand, it is investigated to what extent physical contents are addressed in the context of inanimate coastal dynamics. The following two research questions had to be answered:

(i) How do the out-of-school learning venues create educational offerings, and who is involved in the development?

(ii) To what extent are physical aspects addressed in their educational offerings?

Methods

To answer the research questions, structured guideline interviews with those responsible for the respective educational offerings were conducted. Overall, operators from 11 different learning venues were surveyed. All interviews were evaluated using qualitative content analysis (Mayring, 2014). The interview guide was comprised of questions that already based on a deductively generated system of main categories. The utterances of the interviewees were condensed, assigned to the system of main categories and then subcategories were created inductively. The generated system of main and sub-categories was finally interpreted to answer the research questions.

Results

(i) In only a few cases, science education researchers are involved in the development of educational offerings. The operators of the out-of-school learning venues usually design the educational offerings and ultimately implement it themselves. Most of the operators are without any pedagogical background. Often, they are scientists in the fields of biology or environmental sciences. In the development of exhibitions, the operators only cooperate with advertising agencies to effectively stage their planned exhibits.

(ii) The operators strongly emphasise the importance of physical aspects in understanding climate change and its impact on coastal regions. However, since the operators doubt that physical content could produce a similar level of fascination and interest, the physical view in the offerings is not as strongly emphasised as the biological one. Only as much physics as necessary and as little as possible is integrated into the offerings. In a non-representative analysis (Piplak & Ostendorf, 2018), ten national park houses were examined to what extent physical exhibits can be found there and on which topics. It was also investigated to what extent these exhibits permit interactions by the visitors and whether the information provided is needed for a further understanding of the exhibits. Fig. 1 summarizes the central results. In addition to the lower potential for fascination, many of the interviewees regard the physical content as very complicated since they believe it is oriented primarily to mathematics. Also, in some institutions, there is the idea that addressing physical content means a high expenditure on equipment and a heavy financial burden. For details, see Fig. 2, Fig. 3.

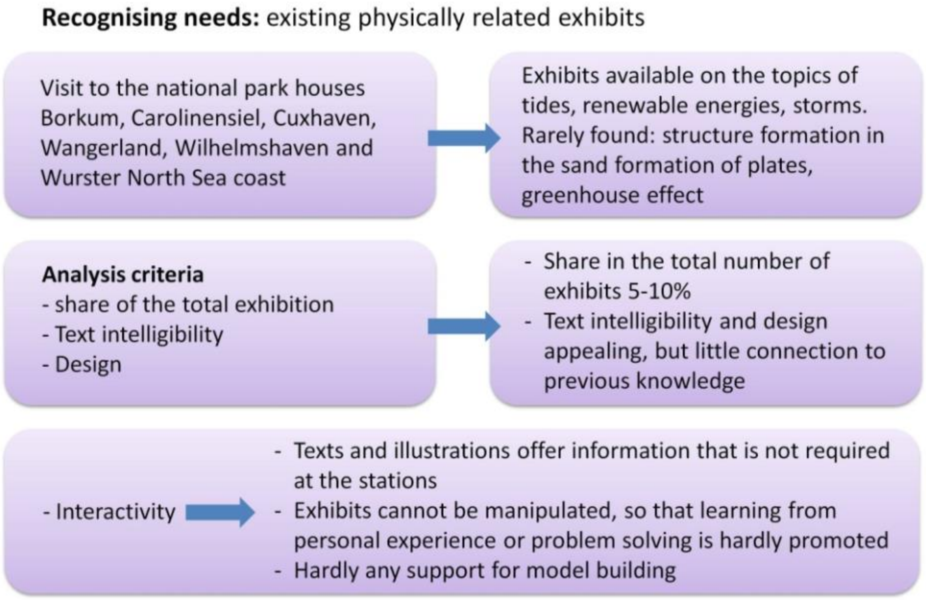

Figure 1. Analysis of national park houses for proportions and type of their physical exhibits

Discussion

The results of the empirical study show that the out-of-school learning venues on the coast represent a very suitable research and development field for science education researchers. Since the support of science education researchers rarely occurs, there is an opportunity to bring together skills from many different areas and to exploit synergies. The operators of the institutions, in their role as scientists, work together with advertising agencies and science education researchers to develop new exhibits and other learning opportunities, thereby eliminating the one-sided focus on biological content in existing educational offerings. Especially science education researchers with a specialisation on the field of physics are in demand for further development of the educational offerings because the operators of the institutions are usually neither physicists nor science education researchers. Besides, the study shows that some "misconceptions" prevail among operators as they feel that the integration of physical content is expensive, complicated, and overwhelms the visitors. Discussions with the operators of the facilities showed that they are very interested in cooperation with science education researchers. Therefore, some of them have become cooperation partners, which is particularly pleasing, as their institutions record a total number of more than one million visitors every year.

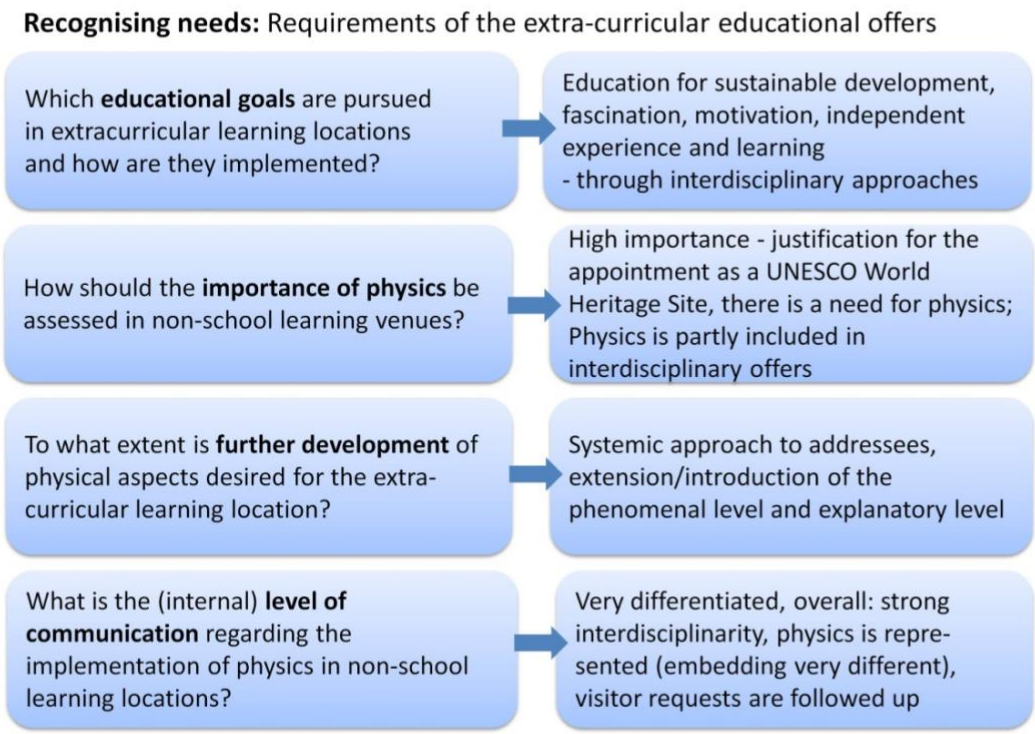

Figure 3. Expressed needs of those responsible for educational institutions on the coast

RESEARCH AND DEVELOPMENT EFFORTS

To further develop the educational offerings together with the operators of the out-of-school learning venues, the project pursues two lines; each is dedicated to one dissertation.

Development of exhibitions in the Design-Based Research cycle

As part of the project, a prototype exhibition was developed. It consists of six different exhibits that illustrate aspects of physical dynamics on the coast. These include ocean currents, tsunamis, formations of structures in granular matter, and tides. All exhibits were tested in the field with real visitors and in a laboratory study. Interviews and observation methods were used. The collected data was evaluated using qualitative content analysis (Mayring, 2014). The results were used in a design-based research cycle (Design-Based Research Collective, 2003) for the improvement and further development of the exhibits (Fig. 4). Also, research results were generalised to provide insights into the learning processes of visitors in exhibitions in general.

Formulation of educational guidelines using the Model of Educational Reconstruction

Through document analysis, scientific literature in the fields of continuum mechanics, thermodynamics, and the theory of complex systems (Bar-Yam, 2003; Demirel, 2014) was analysed to elucidate basic scientific ideas and general laws of coastal physics. It was shown that currents and structure formation mostly represent the physics of the coast. The analysis indicated that currents could be viewed as processes of equalisation, and structure formations can be explained based on positive and negative feedback mechanisms. Besides, empirical studies were conducted on learners' conceptions of physical dynamics on the coast. The empirical data were evaluated with qualitative content analysis (Mayring, 2014) and finally compared with the results of the document analysis. Based on the Model of Educational Reconstruction (Duit et al., 2012), educational guidelines are currently being formulated. These are comprised of both basic scientific ideas and information about the conceptions of learners in the relevant subject area. The educational guidelines address the operators of the out-of-school learning venues to help them integrate aspects of coastal physics into their educational offerings.

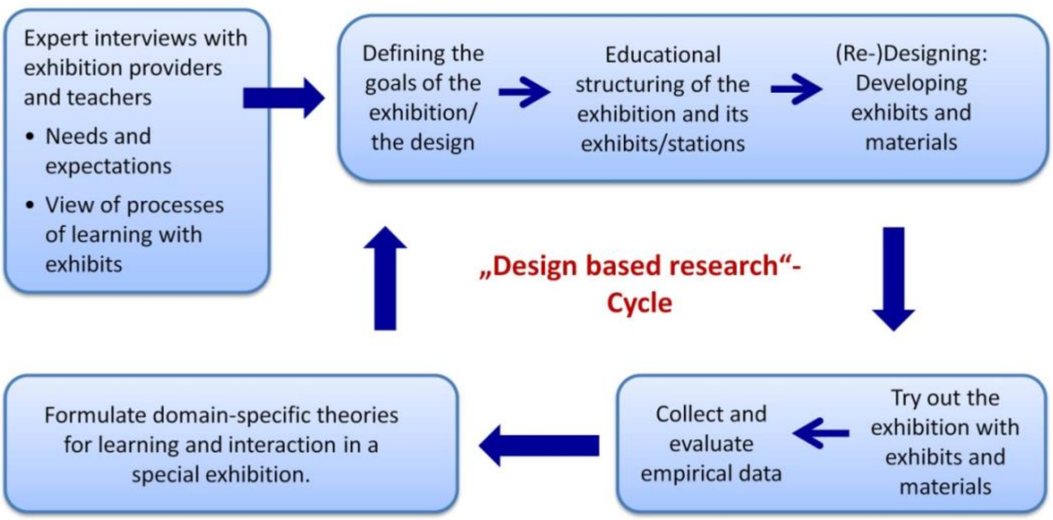

Figure 4. Design-based research cycle in an exhibition on natural structures and formations

Summary and Outlook

Many cooperation partners have well received the project. Cooperation is intensifying. Because the interest has grown significantly, a conference was held dealing with the integration of physical content in exhibitions. A manual and information materials of the produced and empirically evaluated exhibits will be published after the research and development work has been completed. In addition, a brochure will be released, which provides the operators of educational institutions with both the basic scientific ideas of coastal physics and the associated learners' conceptions.

In the meantime, further requirements of the operators and the Wadden Sea guides have become clear. The phenomenon of the tides and the associated forces between earth, moon, and sun represent a major physical and educational challenge. The explanations of the tides are usually misrepresented, both on written explanatory boards and from Wadden Sea guides while guiding in the mudflats. It is often said that the moon-facing tidal bulge is created by the attraction of the moon, while the other tidal bulge, facing away from the moon, is generated by the centrifugal force in the earth-moon system. This explanation is characterised by a separation explanation element and seems, therefore, intelligible, but it is physically incorrect. The two tidal bulges are created solely by differential gravitation in an inhomogeneous gravitational field, as created by the earth and the moon. The centrifugal force is not responsible for the tidal bulges, but it ensures that the earth and moon move around each other stably. These relationships are not easy to understand, neither for visitors on the coast nor for the Wadden Sea guides and the operators of the out-of-school learning venues. The project presented here now has the task not only to educationally prepare physical knowledge in the context of the coastal area but also to train the multipliers in an educational manner.

Growing numbers of Citizen Science (CS) projects focus on learning about science through the collaboration of professional scientists and citizen scientists. However, resources for the design and evaluation of CS projects in terms of learning about science are scarce. Therefore, this chapter aims to provide a model for the heuristic analysis of the supply and use of learning opportunities in CS and apply it to different CS projects. We hope that the design of future CS projects considers the MODEL-CS as an approach to enable as many participants with different prerequisites as possible to take advantage of the learning opportunities provided.

Keywords: Environment, Research cooperation frameworks, Non-formal Learning

1 A MODEL FOR DESIGN AND EVALUATION OF LEARNING IN CS

This chapter aims to provide evidence for promoting science learning in Citizen Science (CS) projects which focus on education. In CS projects, citizens engage with professional scientists in scientific inquiries not only to push forward scientific endeavours but also to learn about science (Wals, Brody, Dillon, & Stevenson, 2014). Therefore, CS projects provide opportunities to learn in informal settings (National Academies of Sciences, Engineering, and Medicine [NASEM], 2018). However, research on learning in CS remains under-theorised (Crain, Cooper, & Dickinson, 2014), mainly for three reasons:

First, initiators of CS projects often lack capacities for designing learning opportunities and evaluating individual learning outcomes (Bonney, Phillips, Ballard, & Enck, 2016). Although CS projects provide informal settings for citizens to learn about science, only 7% of CS projects explicitly focus on education and those mainly on formal settings (Follett & Strezov, 2015). Hence, what citizens learn while participating is rarely the focus of most CS projects. Considering educational outcomes as one of the projects' goals, when planning a CS project, has the potential to improve the intentional design of learning opportunities (NASEM, 2018).

Second, the degree of participation in CS ranges from contribution (i.e. citizens contribute only to data collection) to co-creation (i.e. citizens participate in setting up the research; Shirk et al., 2012). Different degrees of opportunities to participate in scientific activities may impact the available learning opportunities. For example, project designers should ask themselves, if scientific reasoning skills of participants increase by just processing data in contributory CS projects (Jordan, Crall, Gray, Phillips, & Mellor, 2015). Furthermore, project designers need to consider how participants use these opportunities based on their assumed role, motivation, etc. and how it affects what they learn from participation (Phillips et al., 2019).

Third, the constructs to be addressed by learning in CS are not clearly defined, and corresponding assessment tools are scarce (Bonney et al., 2016). Designing opportunities for learning requires to define the constructs addressed (i.e. intentional design). Collaborations of scientists and other initiators of CS projects with science educators might help to address the challenges of intentional design for learning in CS projects.

In our collaborative attempt of natural scientists, science educators and psychologists to evaluate knowledge transfer in CS (WTimpact project), we developed a model to inform deliberate design and evaluation of learning in CS. The Model for the Design and Evaluation of Learning in CS projects (MODEL-CS; Figure 1) follows the framework for public participation in scientific research (Shirk et al., 2012) and integrates a supply-use model on the conditions of learning (Brühwiler & Blatchford, 2011). According to the MODEL-CS, prerequisites of professional and citizen scientists must be accounted for the supply and use of learning opportunities in CS projects. Furthermore, the supply of learning opportunities (e.g. inquiry activities) results in differing use (e.g. participation levels), which can be observed and measured. The resulting data output and the way how it is accessed by citizen and professional scientists influence the scientific as well as individual learning outcomes (e.g. in terms of knowledge development). In a feedback loop, the outcomes also affect citizen and professional scientists in that they result in changes at the individual, project or community level (Shirk et al., 2012).

This model now serves as a heuristic tool for the presentation and analysis of different CS projects. In the following, we illustrate how the MODEL-CS tackles the challenges mentioned above of designing and evaluating CS projects for learning about science. We will show how the model covers the design of learning opportunities and their use during participation as well as learning outcomes after participation. We will present three research projects about learning in CS and how they can be situated within the MODEL-CS.

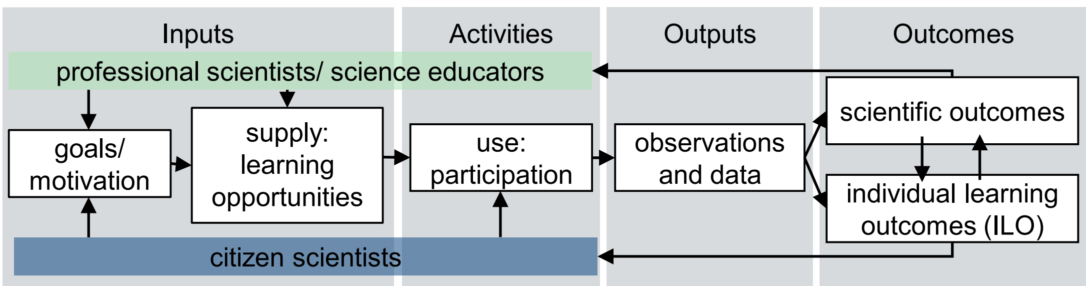

Figure 1. Model for Design and Evaluation of Learning in Citizen Science (MODEL-CS; Logic Model of PPSR; Shirk et al., 2012; Supply-Use Model; Brühwiler & Blatchford, 2011).

2 Youth participation in museum-led Citizen Science programmes

Natural history museum (NHM)-led CS provides a useful context in which to study learning outcomes and project design because both NHMs and CS share the dual goals of scientific research and science education (Ballard et al., 2017). NHM-led CS projects also provide the opportunity to systematically examine the specific nature of the learning settings (supply of learning opportunities) and the activities young people engage in (use of learning opportunities) when participating. The LEARN CitSci project, therefore, studies these two aspects of projects involving youth led by three NHMs (two in California; one in London) across two field-based settings (short-term BioBlitz events and ongoing monitoring projects focused on seaweed, backyard wildlife, or insects) and two online CS platforms (iNaturalist and Zooniverse).

2.1 Methods and Participants

To explore and characterise young people's participation and learning settings, we draw on Cultural Historical Activity Theory (CHAT; Engeström, 2001) and use Environmental Science Agency (ESA) as our research and analytical framework (Ballard, Dixon, & Harris, 2017).

2.1.1 Field-based settings

We relied upon ethnographic field observations to capture data about the participation of over 120 young people (5–19 years), in one ongoing field-based CS project (young people attending at least three sessions) and 3–5 short-term events (BioBlitzes) for each NHM. We developed observation protocols to focus on the features of each setting. Influenced by CHAT, we documented setting features in categories, e.g. tools, rules, division of labour, community setting, object (goals) and interactions with people. An iterative process of analysing field notes, including memo writing and qualitative data analysis using structural and thematic coding aimed to (a) identify types of participation and match them to ESA components, (b) identify and categorise setting features that open up or shut down ESA learning opportunities.

2.1.2 Online/ technology-enhanced programmes

To capture participation of young people in online CS programmes and identify the supply of learning opportunities, we analysed the technological affordances of tools on the Zooniverse and iNaturalist platforms and extracted log files from both platforms for 104 Zooniverse and 115 iNaturalist users. The participants were recruited through existing museum contacts, project activities run by the museums, and advertisement via Zooniverse.

2.2 Findings

2.2.1 Field-based settings

In about 80% of the observations, we saw evidence of young people engaging in scientific practices and opportunities to develop ESA. However, among those episodes in which participation in CS seemed to open up learning opportunities for ESA, we found important patterns in the ways that the CS contexts supplied opportunities for young people to develop and identify their own expertise in a scientific practice, as well as opportunities for constructive interactions around science with facilitators; specifically in short-term events (BioBlitz). We also saw a large proportion of episodes in which a setting feature had the potential to open up learning opportunities for ESA, but had to be characterised as "missed opportunities". These often centred around the design or framing of a programme that did not focus on, or sometimes did not even mention, the contribution to authentic scientific research of the CS activity.

2.2.2 Online/ technology-enhanced programmes

It could be argued that the two platforms afford a range of learning opportunities (e.g. observing, identifying and classifying wildlife or museum specimens), yet they differ substantially. iNaturalist acts as a social network site. Users' contributions and profiles are open to the public. The online community and machine learning techniques scaffold the process of identification. In Zooniverse, however, only scientists set up projects and have access to users' contributions. Observations (data that have been collected) are provided only by scientists, as are tutorials about how to participate (Herodotou, Aristeidou, Miller, Ballard, & Robinson, 2020). Our analysis showed differences in participation profiles (Table 1) and participation itself (use of learning opportunities). Most iNaturalist participants make observations only (taking/uploading pictures), while only 19 (out of the 115) young people also identified observed species. The average number of contributions per user was 22. Yet, 11 participants had between 170 to 17,169 contributions.

Table 1: Participation profiles, based on activity ratio, relative activity duration, variation in periodicity, daily devoted time.

Profiles	Zooniverse (*N* = 104)	%	iNaturalist (iNat; *N* = 115)	%
Systematic	Users are active, visit the platform regularly	5	Linked to iNat for a long period, systematic visits but relatively low activity	29
Casual	Users have inconstant visits, not very active	8	N/A	—
Moderate	Users have constant visits, not linked to the platform for long, not very active	15	Not linked to iNat for a long period, relatively systematic visits, relatively low activity	8
Visiting	Users contributed to projects one or two days only, very active during these days	33	Users only active for 1–2 days	51
Lasting	Linked to Zooniverse the longest, but do not visit regularly, only a few active days	39	Linked to iNat for a long period, very few active days, no systematic participation	12

2.3 Discussion and Implications

Given the wide variety of settings and ways that young people participate in CS, our analysis of how participation and setting features may open up and shut down learning opportunities points to key design features that can inform the design of environmental CS programmes. Specifically, we found that the ways that facilitators framed the activities and positioned young people at CS events like BioBlitzes greatly influenced whether and how young people took on roles in CS practices. For online settings, our findings reveal that the affordances of each platform allow for different forms of participation, as evidenced in the different forms of user contributions. Furthermore, the participation profiles based on cluster analysis provide a starting point for understanding and scaffolding young people's engagement in informal science learning via online CS. While some types of participation we observed are unique to a specific setting, for some types we found equivalents across field-based and online settings, pointing out opportunities for joint efforts in developing design modifications across CS settings to improve the supply and use of learning opportunities.

3 The Design for Participation Affects Pupils' Engagement with Learning Opportunities

From 2007–2017, the Austrian Ministry of Research has run a funding scheme called "Sparkling Science" to promote research cooperation between scientists, pupils and their teachers (Austrian Agency for International Cooperation in Education and Research, n. D.). Sparkling Science projects are quite similar to CS projects. Equally, Sparkling Science projects asked pupils to participate in reasonable research tasks. Bonney and colleagues (2016) suggest that CS projects should rely less on the personal experience of participating scientists and teachers, but should include more objective evaluation methods. Within ten years, we have observed five Sparkling Science projects, which offer different scientific research goals and participants activities (Table 2). All projects included accompanying evaluation research to learn about pupils' learning outcomes. Now we analysed and compared our findings again to find out whether there are common patterns observable among all five projects. The goal is to inform future project designers which activities are more likely to foster pupils' engagement with the learning opportunities offered in CS projects.

3.1 Setting, Participants and Methods

All five Sparkling Science projects (Table 2) followed a predefined set of requirements for integrating pupils and their teachers in a given research process and offered opportunities for pupils to participate in various research phases such as reflecting on hypothesis, collecting data and publishing results. It was expected that pupils develop an understanding of the scientific background of the project as well as how science works, e.g. what counts as high-quality data. Thus, emphasis was put on offering pupils a range of learning opportunities. As all projects conducted field research, pupils were able to work outdoors with scientists and accomplish research tasks independently, such as collecting, analysing and interpreting data. In addition, pupils participated in workshops at the university or their school and/or visited social events. All in all 267 pupils and more than 12 teachers participated in these five Sparkling Science projects. Earlier projects (Table 2) took theories on interest and motivation (e.g. Deci & Ryan, 1985) as a starting point to observe changes in pupil's interest and motivation to participate in these projects (e.g. Wilde, Brätz, Kovaleva, & Urhahne, 2009). Later projects added another focus and tried to observe the pupil's development in understanding the Nature of Science (Urhahne, Kremer, & Mayer, 2007). All projects included a content knowledge test on pupils' understanding of the scientific background. In addition, pupils participated in interviews during or at the end of the project (Table 2). In this study, we conducted a qualitative, comparative case study analysis (Flick, 2007) based on the evaluation reports published for each project.

3.2 Findings and Recommendation

The comparison of the projects' evaluation findings, especially those based on interviews with participating pupils (Table 2), reveals common patterns. All projects show a certain degree of incompatibility of research and everyday school life. Due to changing weather conditions, field research requires flexible planning whereas teachers need long term planning. Primary school teachers are more likely to adapt, whereas secondary and high school teachers may be more restricted. Students' situational enthusiasm does not always fit scientists' approach of persistent work, which follows a standard procedure. In terms of practical science activities, all pupils develop a better understanding of how scientific data is collected and that data quality is related to its accuracy and reliability. However, many pupils have difficulties in understanding the scientific background of the project and engaging in cognitive activities, such as reading and writing scientific protocols. These difficulties persist throughout the project duration. When working with younger children (age 6–15 years), it appears to be helpful to bridge the gap between pupils' needs and their role as researchers in the projects. In general, young pupils enjoy doing practical work or work outdoors. Teenagers are more likely to find research activities rather tedious. Educators who are experienced to work with a particular age group in out-of-school settings are more likely to meet children's needs (e.g. to make fun) than scientists or formal teachers. All pupils want to feel appreciated, valued and trusted for the work they contribute. Pupils expect researchers to be able to answer the research question at the end of the project and are disappointed if they do not learn about the results. The setting and/or expected research outcome should offer a direct link to pupils' personal life, e.g. to their local environment, or answer questions they value important for their own life. The duration of the project and the research activities should not last too long and should avoid repetitive tasks.

4 Learning outcomes in a CS biodiversity project

This CS project links biology education and environmental education in formal education. Research sites were private gardens, schoolyards and parks. Selected aims of the CS project were: (a) to record biodiversity through target species groups with school students (occurrence of selected garden birds; selected butterflies' presence and activities); (b) and aspects of acquired knowledge. Educational goals were defined to increase students' knowledge of the selected species groups and habitat-species relationships, as well as raising awareness towards the importance of green spaces and gardens for biodiversity conservation. Following the supply-use logic model, we inquired learning outcomes for students. Within MODEL-CS, we looked at the effects on individual learning outcomes. In a previous study, we focussed on the perspective of student citizen scientists and concentrated on educational goals and learning outcomes focusing on the following four individual learning outcomes (ILO) categories: (1) Interest in Science and the Environment, (2) Self-Efficacy, (3) Motivation, (4) Knowledge of the Nature of Science (Phillips et al., 2018, p. 7). These four were applied in evaluation via questionnaires, partly pre and post, some ILOs only after the project (Kelemen-Finan, Scheuch, & Winter, 2018). Additionally, a new ILO was introduced to measure attitudes, which were important for the evaluation of the environmental educational aims. Exemplary results show a significant pre-post-rise in the scale 'nature garden' (pre: $N = 317$, Mdn = 10 [3–12]; post: $N = 256$, Mdn = 11 [3–12]; $p < .001$) with a medium to large effect size of 0.52 (Cohen's *d)*. For the 'biodiversity' scale, the analysis also showed an increase, but with only small to medium effect size (Cohen's $d = 0.33$; Kelemen-Finan et al., 2018). In this study, the focus was the skills of students' species identification skills.

4.1 Methods and Participants

Over two years, 428 students from 27 school groups, supervised by 21 teachers, participated in this CS project. In total, 337 garden owners were interviewed with a standardised questionnaire, thereof, the students investigated 80 gardens and parks. Students used survey methods to monitor a set of common and easy-to-determine butterfly and bird species.

In addition to the questionnaires on the ILOs (see above), we tested the improvement of the students' species knowledge as a means to compare the students' perceived learning (i.e. scale 'self-efficacy') with the assessment of species identification rate as learning outcomes. In a quiz, students had to identify seven selected common bird species (four by picture; three by sound) and four common butterflies (pictures) at the closing event of the project. Overall, 186 students participated in this quiz. We compared the species knowledge of students who recorded target species (intervention group) to students who did not (comparison group). Birds were recorded by $n = 122$ students compared to $n = 64$ who did not, for butterfly activities the respective numbers were $n = 99$ for those who did record butterflies and $n = 87$ who did not.

4.2 Findings

Overall, the project improved students' knowledge of target species, and it raised attitudes towards the importance of man-made habitats such as gardens and parks for biodiversity conservation. With respect to species knowledge, the quiz showed that the correct species identification of the students who observed the respective species group were 10–25% higher compared to the group that did not work with the respective species group. For an overlook, see table 3, with visual identification being generally higher than auditive identification.

Table 3: Correct identification rates of the two groups.

Identification rate %	Recorded target species	Did not record target species
Bird Quiz Pic	81%	63%
Bird Quiz Sound	50%	35%
Butterfly Quiz	75%	60%
Overall	**70%**	**55%**

Overall, the recognition rate was highest for the Blue Tit (*Cyanistes caeruleus*, visually: 98% in both groups) and lowest for the Great Tit (*Parus major*, audio; both groups only about 10%). In general, bird song recognition was less successful (50% of students who recorded and 35% of students who did not record birds) than visual recognition (81% of students who recorded and 63% of students who did not record birds).

In the butterfly quiz, most students (95% for students who recorded vs. 69% for students who did not record butterflies) recognized the Swallowtail (*Papilio machaon*) correctly. Common but similar species within some families, such as Pieride (Common Brimstone, *Gonepteryx rhamni* vs. Small White, *Pieris rapae*) or Nymphalidae (Red Admiral, *Vanessa atalanta*, vs. various others) were commonly misidentified, but lesser so by students who had recorded them outdoors. Students who recorded and students who did not record butterflies differed by 4% more correct identifications for the Red Admiral and 26% for the Swallowtail.

4.3 Discussion and Implications

We could show with the birds' quiz that bird identification was satisfying in this CS project and therefore the results of the students reliable; this was not the case in some butterfly species. This aspect is crucial in CS projects to link the learning of the participants with ensuring data quality. Within the project, the science educators of the team did supply an activity with photos of birds and butterflies in a workshop for the students to help them learn the identification. The photos were selected to show the natural range of "good and bad" views on the target species (e.g. difference in illumination to show birds in full light and within treetops in green light). The selection can be an example of a purposefully designed learning opportunity, to support citizen scientists as well as enhancing data quality. The identification workshop did work for visual bird identification but not so well in some butterflies' cases, auditive identification training did not take place.

Therefore, models like the combined and logic model (Brühwiler & Blatchford, 2011; Shirk et al., 2012), or the checklist with ILOs of Philipps and colleagues (2018) are very helpful to link CS projects with educational aims and learning activities. Taking the MODEL-CS as a heuristic framework to think about motivation and goals of citizen scientists (Figure 1), we learned that students and teachers have different expectations and this has to be considered and to be negotiated with those of the scientists, even in contributory CS projects. This project can serve as an example that efforts to undertake evaluation on different individual learning outcomes with a focus on the students and the teachers (e.g. Scheuch et al., 2018) help to further develop CS as a meaningful way of learning in science and environmental education (Wals et al. 2014).

5 Summary Discussion and Conclusions

In this chapter, we provided MODEL-CS as a heuristic tool for connecting the analysis of learning in different CS projects to the logic of CS project design (Shirk et al., 2012). We extended it by accounting for participants' prerequisites and differentiating between the supply and the use of learning opportunities (Brühwiler & Blatchford, 2011). From the analysis of different CS projects in this chapter, the following components seem essential: (a) prerequisites (i.e. goals, interests, motivation, previous knowledge and skills), (b) supply of learning opportunities (i.e. design features), (c) use of learning opportunities (i.e. differences in participation) and (d) individual learning outcomes (i.e. aligned with goals, embedded in activities). Furthermore, the heuristic analysis with MODEL-CS facilitated the identification of interactions between prerequisites and the supply as well as the use of learning opportunities.

When designing and evaluating CS projects for learning, it has to be kept in mind that the interactions between the different goals, the supply and actual use of learning opportunities affect both, the scientific and individual learning outcomes. For the studies reported here, it was especially important to (1) coordinate prerequisites of citizen scientists and professional scientists for the design of learning opportunities, (2) to consider how different activities afford learning opportunities and (3) to embed the assessment of ILOs into the project activities. For example, the professional scientists' goal of acquiring a standardised data collection did not fit to students' situational enthusiasm and hence, resulted in the use of learning opportunities that differed from the standard procedure. This mismatch illustrates how coordinating professional scientists' goals and citizen scientists' prerequisites could inform and improve the design of learning opportunities, a demand for science educators as facilitators in CS projects.

The purpose of MODEL-CS is to provide a model that facilitates new insight into the design and evaluation of CS projects for learning. More specifically, applying MODEL-CS as a heuristic tool to different CS projects with a focus on education could highlight the interactions of participants' prerequisites with the supply and the use of learning opportunities. We hope that MODEL-CS can support the future design of CS projects by considering participants' prerequisites to improve the learning opportunities provided and increase their use.

PRE-SERVICE PRIMARY TEACHER TRAINING ON RESPONSIBLE RESEARCH AND INNOVATION FRAMEWORK

Athanasia Kokolaki and Dimitris Stavrou
University of Crete, Rethymno, Greece

An approach in science education that recognizes science as a collective human endeavor and highlights its relationship both with society and technology, is the negotiation of socioscientific issues (SSI) in science lessons. Responsible Research and Innovation (RRI) framework seems to function as a scaffolding for teachers' implementation of socioscientific approaches in science courses. The aspects of the nature of scientific knowledge seem also to influence teachers' focus on the social aspects of science. The aim of the present study is to investigate the impact of the negotiation of Nature of Science aspects on the development of interactive artifacts about RRI issues by pre-service primary teachers. The results give insights into the balance pre-service primary teachers keep among the scientific content, the social aspects and the epistemological features of science while negotiating RRI issues.

Keywords: Socioscientific Issues, Nature of Science, Pre - service Teacher Education

INTRODUCTION

In recent years, the relationship of the Responsible Research and Innovation (RRI) framework with other established approaches of science education such as Socioscientific Issues (SSI) and Nature of Science (NoS), has been studied (Laherto et al., 2018; Blonder et al., 2016). The RRI framework consists of six aspects – *(1) Engagement of all societal actors, (2) Gender equality, (3) Science education, (4) Open access, (5) Ethics, (6) Governance* – (European Union, 2012). Blonder et al. (2016) notes that RRI aspects seem to function as a scaffolding for the implementation of socioscientific approaches in science courses. However, recent studies reveal that RRI is a difficult concept for students to understand and a difficult concept for teachers to manage during the educational process (de Vocht et al., 2017). Teachers' restriction to 'established' knowledge and their inadequate understanding of the tentative and subjective nature of scientific knowledge reinforce this challenge (e.g. Khishfe, 2017; Karisan & Zeidler, 2017). The correlation between the social aspects of science, that are negotiated via RRI, and the nature of scientific knowledge is highlighted through the Family Resemblance Approach (FRA) (Erduran & Dagher, 2014) which provides an insight of science by presenting it as a unified system of cognitive, epistemological and social aspects. FRA suggests that a deeper and a more realistic understanding of science requires equal emphasis on both scientific concepts and social aspects of science as well as on the nature of scientific knowledge (Erduran & Dagher, 2014). Hence, the connection of RRI with the Nature of Science (NoS) is one step that needs to be done in order to incorporate efficiently RRI in educational practice. Based on the above, our study investigates the extent that NoS aspects influence the negotiation of RRI issues via the development of interactive artifacts on contemporary scientific subjects by pre-service primary teachers. Particularly, the research question of the study is the following:

What is the effect of the negotiation of NoS aspects on the development of artifacts for science teaching focused on RRI issues by pre-service primary teachers?

THEORETICAL FRAMEWORK

The rapid development of science and technology in contemporary society has given rise to a variety of global concerns such as environmental pollution, global warming, manufacturing via nanotechnologies etc. It is widely accepted that students, as future citizens, need to develop argumentation and informed decision – making skills in order to deal with complex, real-world problems related to science and technology advances (Roberts, 2007). These skills can be promoted in science lessons through the negotiation of Socioscientific Issues (SSI), which are social dilemmas rooted in science and which are by definition complex, open-ended, with no definitive answers (Sadler & Zeidler, 2005). SSI are by nature controversial given the uncertain, changing and complex context of a controversy as well as given the lack of their epistemological and ethical structure. Controversies are not usually settled just by evidence due to the emotional and ethical issues that are integrated and due to the involvement of different people and groups that give conflicting explanations and solutions based on their diverse key beliefs and premises (Levinson, 2006).

Moreover, researchers have suggested a close bidirectional relationship between SSIs and NoS. On the one hand, NoS represent the characteristics of scientific enterprise and the epistemology of science and it is argued to be a prerequisite for the engagement in SSIs (Simonneaux, 2008). This means that teachers' and students' informed views of NoS support their understanding of the provisional nature of scientific knowledge and their argumentation based on evidence and the alternative viewpoints. On the other hand, SSIs provide an ideal context for discussing understandings of the NoS as these issues expose people to the limitations, possibilities of science as well as to the role of consensus in science (Khishfe, 2012). The recent conception of NoS by Erduran and Dagher (2014) in the Family Resemblance Approach (FRA), which considers science both as a cognitive-epistemic system and as a social institution, aligns with Responsible Research and Innovation (RRI) framework in shifting the perception of science from a body of knowledge to a complex process involving multiple perspectives, interests, values and uncertainties (Laherto et al., 2018).

RRI is a European Union policy that represents a contemporary view of the connection between science and society, which tries to build public's and other stakeholders' trust and confidence in research and innovation (Sutcliffe, 2011). Particularly, the European Commission (2012) has defined six key areas of RRI which highlight the strong connection between scientific research and societal needs: (1) *Engagement of all societal actors* - researchers, industry, policymakers and civil society - and their participation in the research and innovation process. In such a framework, all challenges are based on common principles and ethical concerns and all work together in order to find common solutions and avoid potential dangers of future innovations. (2) *Gender Equality*. Engagement means that all actors – women and men – are on board. The limited representation of women should be dealt with and especially research centers should be modernized as far as human resources is concerned. (3) *Science Education*. The current educational process should be updated in order to give to future researches and societal actors the necessary knowledge and tools for their participation in research and innovation. At the same time, it is needed to reinforce students' interest and motivation for science as they will participate in social debates about science and they will be future researchers. (4) *Open access.* Research and innovation should be transparent and accessible and that is why people should have free online access to the research results. In this way more and more people will use these results and innovation will be promoted. (5) *Ethics.* Our society is based on common values and principles. Research and innovation should follow and respect these values as only in this way the acceptability and the quality of the results of research will be increased and (6) *Governance.* Policymakers also have the responsibility to prevent harmful or unethical developments in research and innovation.

Despite RRI is mainly conceived as a European policy that aims at the optimization of scientific and technological processes and results, recent research in the field of science education reveal its educational potential (e.g. Blonder et al., 2017; Blonder et al., 2016; Ratinen et al., 2018; de Vocht & Laherto, 2017; de Vocht et al., 2017). RRI could be an appropriate tool that would equip all students, as future citizens, to acquire and use scientific knowledge in order to evaluate the consequences of the outcomes of innovations taking into account limitations of scientific research, societal needs and moral values (Blonder et al., 2016). RRI framework, like SSI-approaches, deals with dilemmas and equivocal situations that arise from the uncertain nature of contemporary scientific subjects. Dealing with such issues, makes it necessary for students to evaluate their scientific knowledge as well as to take into consideration knowledge from other disciplines such as politics, economics, environment etc. in order to form their argumentation and make their decisions about scientific products and innovations (Hofstein et al., 2011). Due to the emergent influence and the novelty of RRI as an educational framework, research about the use of RRI in school reality is really limited. Most studies are connected with the implementation of EU projects in which RRI had a crucial and central role (e.g. IRRESISTIBLE, ENGAGE, PARRISE, RRI-tools etc.). The results of these studies reveal that RRI is a difficult concept for students to understand (Ratinen et al., 2018) and a difficult concept for teachers to manage during the educational process (de Vocht & Laherto, 2017; de Vocht et al., 2017).

Based on the aforementioned, RRI framework reflects the relationship among science, technology and society. This relationship is captured in science education via the negotiation of SSI. However, both SSI approach and RRI framework requires the understanding of the nature of the scientific knowledge in order to handle the uncertainties that are inherent in research and innovation processes.

METHOD

Research Design

The study was conducted in two phases. Particularly:

Phase 1. The first phase of the study took place during the fall semester of 2016-2017. Twelve pre-service primary teachers took part in the investigation. They were divided into six groups of two. Phase 1 was organized in twelve weekly three-hour meetings. Initially, during the first six meetings pre-service primary teachers got familiar with RRI aspects and the scientific content of the contemporary scientific subject they chose to focus on. Firstly, pre- service teachers got familiar with the scientific content. Afterwards, an explicit teaching of the RRI concept took place and pre-service teachers got familiar with RRI aspects through the analysis of newspaper articles. The other six meetings were devoted to the development of their artifact (see table 1).

Phase 2. Due to the results that arose from the data analysis of the first phase, we proceeded to the second phase of the study, which was focused on the investigation of NoS aspects' role in the negotiation of RRI issues by pre-service primary teachers. The second phase took place during the fall semester of 2018-2019. Twelve pre-service primary teachers, who were divided into four groups of three, participated in the investigation. Phase 2 was also structured into twelve weekly three- hour meetings. During the first six meetings, pre – service primary teachers focused not only on the scientific content (focused on micro plastics' potential risks) and the corresponding RRI aspects but also on aspects of the nature of scientific knowledge. Particularly, we focused on three aspects of NoS: i. the tentative (scientific knowledge is subject to change), ii. the subjective (scientist' background, experiences and biases influence scientific knowledge) and iii. the empirical (scientific knowledge is based on observations of the natural world), which are believed to be closely related to socioscientific issues (Khishfe, 2017). Initially, pre – service teachers got familiar with core scientific ideas of micro plastics via inquiry based activities developed in the context of the European Union project "IRRESISTIBLE" (http://www.irresistible-project.eu/). Subsequently, they got familiar with the RRI framework and explore the societal implications of micro plastics via the analysis of newspaper articles. Finally, they discussed about the uncertainties of contemporary scientific topics and the tentativeness of scientific knowledge in general through their engagement in a "mystery box" activity (Lederman & Abd-El-Khalick, 1998). The other six meetings were devoted to the development of their artifact (see table 1).

Table 1. The phases of the study

Phase of the Study	Meetings	Description
Phase 1	Meetings 1 - 6	Pre service teachers' familiarization with: • the scientific content • the RRI aspects
	Meeting 7 -12	Development of the artifact
Phase 2	Meetings 1 - 6	Pre service teachers' familiarization with: • the scientific content • the RRI aspects • aspects of NoS
	Meetings 7 – 12	Development of the artifact

Data collection and analysis

In both phases, data was collected using: (a) audiotapes of every meeting, (b) the final artifact and (c) a final interview of each working group. Due to the exploratory nature of the investigation and the small number of final artifacts, qualitative methods of content analysis were used (Mayring, 2015). The data was analyzed in two axes: (1) the RRI focus of the artifact and (2) the nature of knowledge in RRI activities.

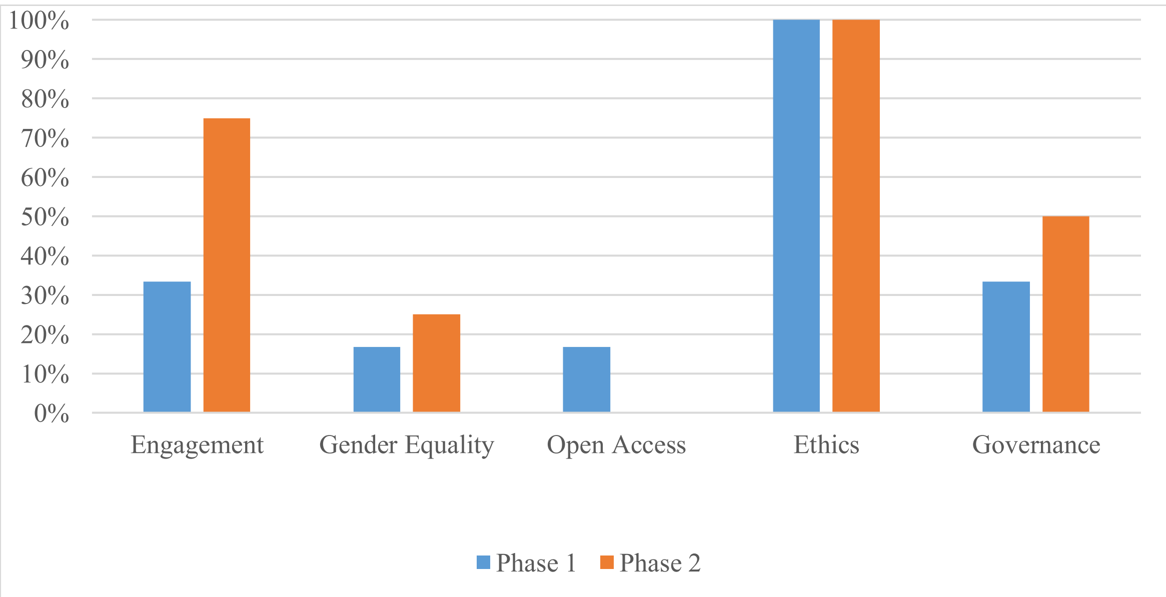
The category systems were developed on the basis of the relevant literature and were differentiated based on the new empirical data. So 'the constant comparative method' was followed, in which new empirical data is compared with data that was collected in previous studies (Strauss & Corbin, 1990). Specifically, concerning the RRI dimension of the artifacts, five out of the six RRI aspects constitute the five categories for the analysis. Relating to the nature of scientific knowledge incorporated into the RRI activities two main categories were developed (controversial – no controversial) based on whether or not the activities reflect the tentative, subjective and empirical nature of science.

RESULTS

Concerning the results of the investigation, in phase 1 pre-service teachers developed in total six artifacts focused on: (i) nanotechnology, (ii) mobile phones, (iii) vaping, (iv) breastfeeding, (v) reproduction -inheritance and (vi) genetically- modified food. In phase 2, pre-service teachers developed four artifacts, which referred to micro plastics with a special focus on: (i) human health, (ii) marine life, (iii) biodegradable bags and (iv) micro plastics in everyday life. The artifacts included both scientific information connected with the corresponding scientific subject and questions on RRI issues.

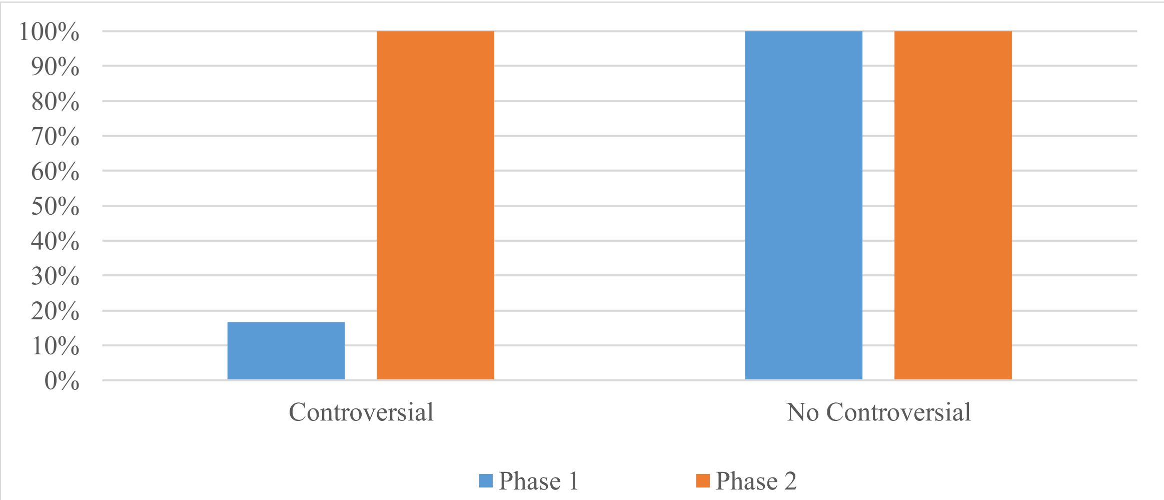
Regarding the RRI focus of the artifacts (see table 2), pre-service primary teachers mainly incorporated activities about ethics but also about engagement and governance. Thus, we notice that in both phases, the same RRI aspects prevail in the artifacts. The difference in the incorporation of the aspect of engagement in phase 2 can be attributed to pre-service teachers' familiarization with NoS given the fact that the activities about engagement were mainly role games that integrated conflicting information and asked students to take a role, to deal with uncertain statements and to form their own perspective.

Table 2. The RRI focus of the artifacts



Concerning the nature of the knowledge in the RRI activities (see table 3), in phase 1 just one artifact out of the six incorporated controversial information while in phase 2 all artifacts contained at least one RRI activity with controversial information. Particularly, in phase 1, pre-service primary teachers tried to communicate via the artifact mainly 'established' knowledge something that prevented them from emphasizing on the debatable nature of contemporary scientific subjects. Therefore, they included general questions concerning RRI aspect which do not require the use of scientific information in order to be answered. For instance, in the nanotechnology artifact, they included initially some general information about nanoscale without any reference to the pros and cons of nanotechnology applications and afterwards they asked some general RRI questions such as *"Should companies display that their products contain nanoparticles? Yes or No?"*. Similarly, in the artifact about vaping pre- service teachers ended up to provide information about conventional smoking due to the conflicting information they encountered during their research about vaping.

Table 3. The nature of knowledge in the activities.



In phase 2, the artifacts included debatable information and asked students to make decisions based on this information. For example, in the artifact of biodegradable bags pre-service teachers presented different perspectives about their value and asked students to reflect on the scientific information provided through the artifact in order to decide if it is worthy to use them in our daily life or whether government should take measures for their limitation. RRI activities in phase 2 gave the opportunity for deeper engagement with the scientific content and the diversity of the perspectives given the fact that the artifacts included empirical studies' results and conflicting information that students were asked to comment on. Moreover, pre-service teachers integrated in the artifacts evidence about new scientific findings for the gradual replacement of plastic as well as activities about the financial and political system's impact on research and innovation processes. All these practices reflected the empirical, tentative and subjective nature of scientific knowledge and provided students with the opportunity to negotiate contemporary controversies about micro plastics.

DISCUSSION AND CONLUSIONS

RRI is a novel framework proposed and developed by the EU in order to promote and foster the cooperation among all the stakeholders involved in research and innovation processes as well as in order to reinforce public's trust and confidence concerning scientific and technological innovations (Sutcliffe, 2011). Despite, RRI is a European policy, recently it has been investigated as an educational tool which enables teachers and students to negotiate societal implications of innovative scientific and technological products (Blonder et al., 2016). It seems that RRI aspects provide a useful scaffolding that equip teachers with specific axes to negotiate the societal implications of scientific and technological innovations. Using RRI aspects as guidelines pre-service teachers managed to approach contemporary scientific topics more globally, examining them not just from the scientific point of view but also from ethical, political and societal perspectives. In addition, when pre-service teachers aim to focus on the societal dimensions of contemporary scientific subjects, they tend to focus on ethics. This fact can be interpreted by the findings of related research which underline that ethical concerns are the most important factors that influence individual decision-making (Zeidler et al., 2002; Sadler et al., 2006).

Finally, pre-service teachers, in the initial phase of the study, wanted to present in their artifacts 'established' knowledge, although the element of uncertainty is inherent in contemporary scientific subjects at the cutting edge of research. This fact could be confirmed in the literature as it is noted that science teachers want to follow a value-free approach during their lessons by teaching just facts and phenomena (e.g. Forbes & Davis, 2008). However, this seems to be overcome via the engagement of pre –service primary teachers with aspects of the nature of scientific knowledge during the phase 2 of the study. Pre – service teachers' familiarization with the empirical, tentative and subjective nature of scientific knowledge seemed to restrict their difficulties of integrating different scientific views and scientific controversies in their artifacts. Thus, generally we could conclude that the inclusion of cognitive – epistemic – social aspects of science during pre - service teachers training seem to help them incorporate more efficiently the nature of RRI concept in their artifacts.

EXPLORING ASPECTS OF PRE-SERVICE PRIMARY TEACHERS' EPISTEMIC COGNITION WHILE DEALING WITH A SOCIO-SCIENTIFIC ISSUE: A THINK-ALOUD STUDY

Lida Desikou[1], Athina Koutsianou[2] and Anastassios Emvalotis[2]
[1]Department of Primary Education, University of Patras, Patras, Greece
[2]Department of Primary Education, University of Ioannina, Ioannina, Greece

Framed within the literature of epistemic cognition and multiple-text comprehension, this mixed-method study explores aspects of pre-service primary teachers' epistemic cognition which are enacted while they are dealing with the socio-scientific issue of autonomous vehicles; and whether these aspects are connected to the comprehension and integration of multiple sources. Specifically, 20 pre-service primary teachers were asked to think aloud during a critical reading task, which resembles the real situation of dealing with available controversial information on the internet with regard to this issue. Afterwards, they were asked to form their own critical question and justify its significance regarding the socio-scientific issue, and further answer two integrative short-essay questions. Think-aloud protocols were audio-recorded, transcribed and coded through qualitative content analysis. Three coding rubrics were developed to score participants' critical question and their responses to the integrative questions. Data analyses indicated that many aspects of participants' epistemic cognition enacted while dealing with the SSI, mainly with regard to their justification for knowing, epistemic monitoring and source evaluation, and less with regard to their underlying epistemic beliefs. Furthermore, evidence that participants' epistemic cognition can support or hinder their engagement with the SSI were found. Addressing pre-service primary teachers as both learners and future teachers, it is crucial that we understand how they think about knowledge and knowing within the context of a controversial issue, in order to help them improve their epistemic cognition through tertiary education.

Keywords: epistemic cognition, socio-scientific issues, think-aloud protocols.

INTRODUCTION

In every corner of the world, people often encounter complex and conflicting information in their everyday lives regarding challenging issues, such as human causes of climate change, applications of artificial intelligence and consumption of genetically modified food (Greene & Yu, 2016). Such issues that evolve from the interaction of science and society have been called socio-scientific issues (SSIs) and are difficult for people to deal with, because they are open-ended and ill-structured problems, and consequently, subject to multiple perspectives (see Sadler & Zeidler, 2005). In order to understand and negotiate these issues, people need to understand science and integrate information from multiple sources, including contradictory information and claims, which appear to be very challenging especially for students (Bråten, Britt, Strømsø, & Rouet, 2011; Sinatra, Kienhues, & Hofer, 2014). Even though there are different lines of theory and research in educational research (e.g., scientific, reading and digital literacy) which use different terminology, there is a common interest in exploring learners' higher order cognitive processes which are involved when they engage in these issues (Greene, Sandoval, & Bråten, 2016; Sinatra et al., 2014). A growing body of theory and interdisciplinary research converge on the importance of epistemic cognition in understanding science and engaging in such controversial issues (see Greene & Yu, 2016).

Epistemic cognition "concerns how people acquire, understand, justify, change and use knowledge in formal and informal contexts" (Greene et al., 2016, p. 1); and it includes various aspects, such as epistemic dispositions, beliefs and skills with regard to how people determine what they actually know, believe or doubt (Greene & Yu, 2016). Consequently, when people are confronted with SSIs in their everyday lives, their epistemic cognition affects implicitly how they understand and interpret the available information, and further, whether they integrate different perspectives into a coherent representation of the issue (Bråten, Anmarkrud, Brandmo, & Strømsø, 2014; Bråten et al., 2011; Ferguson & Bråten, 2013; Sinatra et al., 2014). In more detail, according to Bråten et al.'s (2011) review, learners' epistemic beliefs, that is their beliefs about the nature of knowledge and knowing, play an important role in their comprehension of multiple sources and integration of different points of view when they are asked to participate in reading tasks. For example, students who view knowledge about a scientific topic as complex and tentative (more adaptive beliefs), it is more likely to engage in getting an overview of different perspectives, than students who view knowledge as certain, simple and isolated facts (less adaptive beliefs). However, most research has approached epistemic cognition through the construct of epistemic beliefs, by applying self-report questionnaires and interviews especially within the context of research in multiple-text comprehension (Bråten et al., 2011), followed by numerous limitations (Mason, 2016).

More recent studies have conceptualised epistemic cognition as a broader set of cognitive processes than merely epistemic beliefs, and approach it through think-aloud protocols, (Chevrier, Muis, Trevors, Pekrun, & Sinatra, 2019; Cho, Woodward, & Li, 2018; Greene, Yu, & Copeland, 2014), but there are no studies looking for connections between epistemic cognition and multiple-text comprehension in such terms, as far as we know. By adopting an integrative theoretical framework, this study aims to contribute to this growing body of knowledge by exploring aspects of pre-service primary teachers' epistemic cognition through think-aloud protocols, while dealing with a SSI within the context of a critical reading task; and further, examine whether these aspects are connected to the comprehension and integration of multiple sources. Based on an extensive literature review and after taking into account various terminology issues within this interdisciplinary field (for a review, see Greene et al., 2016), this study integrated many existing frameworks in order to define epistemic cognition (Barzilai & Weinstock, 2015; Chevrier et al., 2019; Chinn & Rinehart, 2016; Cho et al., 2018; Feucht, 2011; Greene & Yu, 2016; Greene et al., 2014; Hofer & Pintrich, 1997; Kuhn & Weinstock, 2002). Hence, epistemic cognition conceptualised as a broad set of cognitive processes and beliefs associated with the nature of knowledge and knowing regarding this SSI, including epistemic aims, epistemic beliefs, epistemic monitoring, justification for knowing and source evaluation.

Given that most studies have focused on biological and environmental SSIs, the SSI of this study derived from the field of artificial intelligence and pertains to whether autonomous vehicles (AVs) could replace human-driven vehicles (Fagnant & Kockelman, 2015). The research questions guided this study are following:

1. What aspects of pre-service primary teachers' epistemic cognition are enacted while they are participating in a critical reading task?
2. Are pre-service primary teachers' aspects of epistemic cognition connected with their comprehension and integration of multiple sources?
3. Are there any patterns in pre-service teachers' responses with regard to their epistemic cognition and multiple-text comprehension and integration within the context of the SSI?

METHOD

Participants and research design

Twenty pre-service primary teachers (16 female and 4 male) from three universities in Greece participated in this mixed-method study (Creswell, 2015; Johnson & Onwuegbuzie, 2004), during the spring semester of the academic year 2018-2019. This study is part of a larger research project in which participants participated in a set of pre and post assessments. During this study, participants were attending their last year of undergraduate studies and their mean age was 23.45 years (*SD* = 1.79). All of them had already attended at least three university courses in natural sciences (e.g., physics and computer science). Participants were recruited from regular lectures and participated in this study voluntarily, by adopting convenience sampling (Creswell, 2015).

Measures and procedures

Data were collected through think-aloud protocols (Ericsson & Simon, 1993; Mason, Ariasi, & Boldrin, 2011), the production of a critical question regarding the SSI and the justification of its significance (Cho et al., 2018), and two integrative short-essay questions (Ferguson & Bråten, 2013; Rukavina & Daneman, 1996), within the context of a critical reading task about the SSI of AVs.

In more detail, each and every participant met the first author in an educational laboratory in order to take part in this study individually. Initially, participants were trained how to think aloud and construct a good question for another SSI, that is, the use of drones. The training process endured around 15 minutes. Afterwards, they took part in the critical reading task and were asked to think aloud while reading an introduction and six sources for the SSI of AVs in order to construct their own critical question; and further, justify why they think that their question is an important one for this issue. In total, four empirical studies and two articles published in a scientific website about the AVs were the multiple sources included in the critical reading task, after having been adjusted into the Greek language by the first two authors (for a brief overview of the six sources, see Table 1).

Table 1. Overview of the six documents (multiple sources)

Type of document	Publisher	Author(s) (year of publication)	Content	Number of words into Greek
1. Empirical study	Risk Analysis	Brell, Philipsen, & Ziefle (2019)	Authors investigated German citizens' perceptions of autonomous vehicles, indicating more negative perceptions.	672
2. Empirical study	Safety Science	Hulse, Xie, & Galea (2018)	Authors investigated British citizens' perceptions of autonomous vehicles, indicating more positive perceptions.	603
3. Technical report	University of Michigan Transportation Research Institute	Schoettle & Sivak (2015)	Authors investigated the crashes of conventional and autonomous vehicles, arguing that autonomous vehicles are not safe at present.	587
4. Empirical study	Journal of Safety Research	Teoh & Kidd (2017)	Authors investigated the crashes of conventional and autonomous vehicles, arguing that autonomous driving can be considered safer that conventional.	663
5. Philosopher's article in a scientific website	The Conversation	Evans (2018)	Author stresses the importance of ethics in the field of autonomous driving and argues that autonomous vehicles are not ready to be used on public roads at present.	759
6. Mechanic's article in a scientific website	The Conversation	McDermid (2019)	Author argues that programming ethics in autonomous vehicles is rather impossible based on the current technology; and focuses on improving the safety of these vehicles.	758

By applying a critical reading task, this study attempted to avoid restricting participants in the common practice of asking them to construct arguments and counterarguments; it is crucial that we trigger them take part in this public discussion as citizens and think critically in order to construct a meaningful question. After finishing this task, participants were asked to answer the following direct and indirect integrative questions for the SSI within a short essay: 1) Please, explain the potential benefits and risks that autonomous vehicles will have on public roads (direct); 2) Could autonomous vehicles replace human-driven vehicles in public roads? Please, justify your answer (indirect).

Data analysis

After asking for their consent, participants' verbal reports from their engagement in the critical reading task were audio-recorded and transcribed, resulting in 20 think-aloud protocols (*Mean time* = 52.06 min, *SD* = 13.35; *min* = 25.57 min, *max* = 71.07 min). Think-aloud protocols were coded through qualitative content analysis (Hsieh & Shannon, 2005; Mayring, 2000) by using the Atlas.ti software. Specifically, each protocol was divided into codable segments and the units of analysis defined to be the segments captured the meaning of participants' thoughts or actions (Chi, 1997). The first two authors developed a coding scheme based on a sample of eight participants and relevant literature (Barzilai & Weinstock, 2015; Chevrier et al., 2019; Chinn & Rinehart, 2016; Cho et al., 2018; Greene et al., 2014), through a recursive process (for an overview of the coding scheme, see Table 2). Afterwards, the first author applied this coding scheme to all protocols. Finally, the second author coded independently five protocols and the intercoder agreement was 92%.

Table 2. Coding scheme for think-aloud protocols

Families	Codes	Description
Epistemic aims	Information	Participant simply wants to acquire information without judging whether it is sufficiently warranted.
	Knowledge	Participant states that she/he wants to "know" facts with either the explicit or implicit indication that sufficient warrant/justification is also required.
	Understanding	Participant's goal is to have deep knowledge of not only facts but also warrants for how processes work (if relevant), etc.
Epistemic beliefs	Certainty*Absolutism	Knowledge (about this topic) is certain/can be obtained with certainty.
	Certainty*Multiplism	Knowledge (about this topic) is uncertain and subjective/cannot be obtained with certainty.
	Certainty*Evaluativism	Knowledge (about this topic) cannot be obtained with certainty but it is possible to improve the degree of certainty/evolving and tentative nature of knowledge/ varying degrees of certainty.
	Knowledge is context specific	Participant implies that knowledge is seen as highly contextualised or situated.
	Knowledge is complex	Participant implies that knowledge is seen as a set of highly interconnected complex knowledge claims.
Justification for knowing	Establishing multiple justification	Participant established a warrant for a claim or denies a claim based upon the support of multiple sources of justification (e.g., testimony, coherence, rationality), or evaluates a claim as knowledge based upon the support of multiple sources of justification (e.g., testimony, coherence, rationality) but without definitive conclusion.
	Justification by personal perception	Participant uses one of her/his five senses as warrant for claim as knowledge, or a reason to disregard claim as knowledge, or to evaluate claim as knowledge but without definitive conclusion.
	Justification by rationality/logic/reasoning	Participant establishes warrant for claim or denies a claim based upon thinking, logic, reasoning, or evaluates claim as knowledge based upon thinking, logic, or reasoning but without definitive conclusion.
	Justification by authority/testimony	Participant establishes a warrant for a claim or denies a claim based upon the views/arguments/beliefs of someone that she/he believes is an authority on the matter, or evaluates claim as knowledge based upon the views/arguments/beliefs of someone that he/she believes is an authority on the matter but without definitive conclusion.
	Tentative justification	Stating confidence or likelihood about the veracity of a knowledge claim without definitively accepting it, or stating doubt or unlikelihood about the veracity of a knowledge claim without definitively denying it, or stating that a particular knowledge claim is "possibly" or "tentatively" justified true belief without indication of a strong tendency either for or against its veracity.
Source evaluation	Source evaluation (plus)	Statements indicate that the participant is investigating the quality of the source of a knowledge claim and the source in question can be considered trustworthy for providing knowledge claims whose veracity is high.
	Source evaluation (minus)	Statements indicate that the participant is investigating the quality of the source of a knowledge claim and the source in question cannot be considered trustworthy for providing knowledge claims whose veracity is high.
	Source evaluation (neutral)	Statements indicate that the participant is investigating the quality of the source of a knowledge claim. Despite clearly evaluating the source, no definitive claim is made regarding its trustworthiness for providing knowledge claims whose veracity is high.
	Inferring author bias	Participant indicates a source of knowledge may be biased in some way.
Epistemic monitoring	Active meaning making	Perception of the role of the reader in meaning making and demonstration of an active role in knowledge creation.

Passive information receiving	Acritical orientation to seeking and gaining information and to accepting information as true without judgment.
Integration of multiple perspectives/ sources	Evaluating, comparing and contrasting claims made across multiple sources; providing explanations to account for differences between the various perspectives.

By following equal coding procedures and based on relevant literature (Andresen, Anmarkrud, Salmerón, & Bråten, 2019; Cho et al., 2018; Latini, Bråten, Anmarkrud, & Salmerón, 2019), the first two authors also developed three rubrics (see Table 3) ranging from 0 to 3, in order to score participants' responses to the critical question and its justification, and the two integrative questions (the intercoder agreement for the critical question was: 93%; for the first integrative question: 87%; and for the second integrative question: 94%). All discrepancies were discussed and resolved among the three authors, resulting in 100% intercoder agreement.

Table 3. Rubrics for coding critical question and justification, and integrative short-essay questions

Score	Critical Question & Justification	1st Question (direct)	2nd Question (indirect)
0	Irrelevant question	Irrelevant information	Irrelevant information
1	Question is relevant with the SSI and has logical soundness. However, the justification of the question does not indicate its rationale and significance in order to extend the discussion on the SSI.	Mentioning benefits and risks as a numbered list (without writing a paragraph).	Mentioning one perspective with a brief explanation (the positive or the negative one).
2	**A:** Question is relevant with the SSI and has logical soundness by justifying its rationale with an elaborated explanation. However, the significance of the question in order to extend the discussion on the SSI is not included. **B:** Question is relevant with the SSI and indicates some significance in order to extend the discussion on the SSI. However, the question has low logical soundness without clearly justifying its rationale.	Mentioning benefits and risks (in a paragraph) by adding some more personal thoughts on the given sources without providing further explanations.	**A:** Mentioning both perspectives with an (elaborated) explanation of the one aspect. **B:** Mentioning one perspective with an elaborated explanation of the one perspective (and usually an implicit reference to the second perspective).
3	Question is relevant with the SSI and has logical soundness by justifying its rationale with an elaborated explanation. Also, the significance of the question in order to extend the discussion on the SSI is included.	Mentioning benefits and risks (in a paragraph) with elaborated explanations and further integration of both aspects by comparing and/or contrasting them and trying to reconcile them by demonstrating that they must not be mutually exclusive.	Mentioning both perspectives with elaborated explanations and further integration of both perspectives by comparing and/or contrasting them and trying to reconcile them by demonstrating that they must not be mutually exclusive.

RESULTS

Think-aloud protocols: Aspects of epistemic cognition and integration of multiple sources

Following the first research question, it is noted that all aspects of epistemic cognition found in participants' think-aloud protocols, more or less frequently, as it is depicted in the Table 4.

Table 4. Aspects of epistemic cognition and integration of multiple sources

Aspects	Number of participants	Total frequencies
Epistemic aims	**9**	**18**
Information	5	9
Knowledge	2	2
Understanding	5	7
Epistemic beliefs	**20**	**90**
Certain knowledge (Certainty*Absolutism)	4	4
Uncertain knowledge (Certainty*Multiplism)	10	13
Degrees of certainty (Certainty*Evaluativism)	11	22
Complex knowledge	14	23
Context-specific knowledge	12	28
Justification for knowing	**20**	**188**
By personal perception	19	108
By rationality/logic/reasoning	15	44
By authority/testimony	13	18
Tentative justification	6	7
Establishing multiple justifications	8	11
Source evaluation	**17**	**71**
Source evaluation (plus)	8	16
Source evaluation (minus)	7	14
Source evaluation (neutral)	16	30
Inferring author bias	8	11
Epistemic monitoring	**20**	**379**
Active meaning making	20	340
Passive information receiving	10	39
Integration of multiple perspectives/sources	**18**	**60**

Scores in critical question and its justification, and the integrative questions

Table 5 presents the scores for each and every participant regarding the critical question and its justification, the two integrative questions and in total.

Table 5. Participants' scores in critical question and its justification, the integrative questions and in total

Connections between aspects of epistemic cognition and multiple-text comprehension and integration

Addressing together the second and third research question, some preliminary connections between the aspects of participants' epistemic cognition and their scores in multiple-text comprehension and integration were detected. What follows is a short description of the detected patterns in conjunction with specific quotations derived from the think-aloud protocols and written responses of two participants as representative examples.

In more detail, participants with the lowest total scores (i.e. 4th, 9th, 11th, 15th, and 17th participants, see Table 5) often articulated the epistemic aim of information and referred to total uncertainty, complexity and context-specific nature of knowledge. Also, they justified their claims by using their personal perception and rationality/logic/reasoning frequently. During the task, they also made meaning actively in a very intense way, while they often received information passively. Finally, they often evaluated the sources negatively or in neutral terms; and rarely attempted to integrate knowledge claims from different perspectives and sources.

In contrast, participants with the highest total scores (i.e. 2nd, 5th, 6th, 10th, and 20th participants, see Table 5) often stated epistemic aims such as knowledge and understanding, and referred to the improving degree of certainty, complexity and context-specific nature of knowledge. Furthermore, they justified their claims by using testimony and authority figures and/or by establishing multiple justifications very frequently. During the task, they also made meaning actively in many cases and evaluated the sources positively or in neutral terms. Finally, they frequently attempted to integrate knowledge claims from different perspectives and sources.

There are following two examples of participants' verbalisations during their participation in the critical reading task in combination with their written responses to the critical question and its justification, and the indirect integrative question; in order to give an overview of potential patterns from their way of thinking and acting. These two examples are representative of the participants with low and high total scores mentioned above. Specifically, there are following three extracts from the 15th participant's think-aloud protocol with regard to different aspects of epistemic cognition:

(She was reading) Also, I think that it is very dangerous. I know people who had such kinds of cars and they couldn't escape from them, and there was also a case in which the car was on fire and they couldn't open it." (justification by personal perception)

(She was reading) Young adults are dangerous with every vehicle in general. Their acceptance shouldn't be taken so seriously. (She was reading) Oh, the text agrees with me. Nice! (active meaning making) (She was reading) Also, it surprises me, because every source mentions one country. And every question is answered by different country. Germans have different roads, different law, different care. England is a different case, Greece is a different case, Danes as well. Their positionality is not right. (knowledge is context-specific; source evaluation [minus])

(She was reading) It would be wrong; indeed, it is wrong for a car to think like that. (passive information receiving)

Furthermore, her critical question with regard to the SSI and her response to the indirect integrative question are following:

Are there desirable all these that scientists want to try at times? Is the technology for the human or the human for the technology? I think that all thoughts about everything that the technology wants to insert in our everyday life start from there. (Score: 0)

(Could autonomous vehicles replace human-driven vehicles in public roads? Please, justify your answer.) According to my experience and the way that my opinion has been formed so far, no. There are no infrastructure and education, and they could not replace them. The only thing that I can think is their own road network that would look like the trains one. So, this makes me think that we don't really need them and that we shouldn't be involved in something that appears to bring additional dangers. (Score: 1)

Similarly, there are following four extracts from the 20th participant's think-aloud protocol with regard to different aspects of epistemic cognition:

(She was reading) According to things that I had read in Thessaly's sites, people were scared and could not accept "the different" because it is something different for the norms of Thessaly. But I think that younger and more open-minded people accepted it more positively than the older ones, who have more traditional perceptions and they are not ready to try different things and accept them. (establishing multiple justifications)

(She was reading) Okay, I am interested in learning more about the advantages, for which as I said, my personal opinion is that there will be, for sure, but I would like to read them in depth. And maybe this will help me, this process. (epistemic aim: understanding)

(She was reading) Yes, sure, the passenger has different perception, it is possible for her/him to fear the first time that will use it (an AV). As for the pedestrian, she/he considers it to be less dangerous, because she/he has more control. I think it makes sense. (integration; justification by rationality)

(She was reading) Okay, so, according to this study, they are considered safer in some way than the conventional cars, but the situation should progress in order to make more certain conclusions. (justification by authority; degrees of certainty)

Finally, her critical question with regard to the SSI and its justification, and her response to the indirect integrative question are following:

In order to acquire more adequate data that will be used in studies to prove the safety of AVs, there will be a transitional period, in which the two kinds of vehicles should be driven at the same network. Could the AVs and conventional vehicles coexist harmoniously? I consider this question as very important, because this issue has not been addressed yet in public discussions about AVs; and it could cause concerns about the risks of this transitional period. (Score: 3)

(Could autonomous vehicles replace human-driven vehicles in public roads? Please, justify your answer.) They (AVs) could replace them. However, this is something that requires time and work from experts. I believe that it will take many years before this situation becomes reality. ... Consequently, people, despite their concerns, should keep up with the spirit of the times and be more receptive. (Score: 2)

DISCUSSION & CONCLUSIONS

Overall, think-aloud protocols revealed many aspects of pre-service primary teachers' epistemic cognition in action, mainly with regard to their justification for knowing, epistemic monitoring and source evaluation; and less with regard to their epistemic beliefs which may underlie these cognitive processes. Hence, this study provides evidence that support the broader conceptualisation of epistemic cognition proposed in the literature (Chinn & Rinehart, 2016; Greene et al., 2014; Greene et al., 2016). However, it is likely that participants have beliefs that they did not verbalise during the task and it is crucial that further research attempt to clarify more these aspects of epistemic cognition, likely by also applying cognitive interviewing. Additionally, the kind of the applied task could be an important factor that guided participants to pay more attention to justification issues, without eliciting their typical reading behaviours (e.g., on the internet).

Furthermore, participants with the highest scores in multiple-text comprehension and integration found to a) state their epistemic aims while participating in the critical reading task; b) establish multiple justifications of knowledge claims with reference to authorities, their personal perception and reasoning; c) evaluate the trustworthiness of the provided sources; and d) integrate knowledge claims from different sources. In this respect, this study extends the existing literature (Bråten et al., 2014; Greene & Yu, 2016; Sinatra et al., 2014) which claims that learners' epistemic cognition can support or hinder their engagement with SSIs through their capability to integrate multiple and usually contradictory perspectives into a coherent representation of the issue. However, the results of this study should be interpreted with caution given the rather small sample size especially in terms of statistical analysis. Further research with representative samples is needed to replicate the usefulness of the coding scheme and rubrics, as well as these preliminary findings.

In conclusion, given that pre-service primary teachers at the last year of their undergraduate studies are young adults who have already faced SSIs in today's epistemologically challenging society, it is imperative that support them learn how to make informed decisions for themselves and others, including their future students. If epistemic cognition is the key in decision-making with regard to challenging issues, then more studies should focus on how tertiary education could change to include aspects of epistemic cognition in pre-service teachers' preparation, through both the applied curricula and instruction (Greene et al., 2016; Sinatra et al., 2014).

ACKNOWLEDGEMENT

HOW DO PRIMARY PRE-SERVICE TEACHERS ASSESS CIRCUS WITH ANIMALS AND ITS EDUCATIONAL VALUE? A STUDY WITH PORTUGUESE, SPANISH AND GREEK STUDENTS

António Almeida[1], Beatriz García Fernández [2] and Penelope Papadopoulou [3]
[1]Instituto Politécnico de Lisboa / CICS.NOVA, Universidade Nova de Lisboa, Lisboa, Portugal

[3] University of Western Macedonia, Faculty of Humanities and Social Sciences, Florina, Greece

This study aimed to check the opinion of primary pre-service teachers about circus with animals, including if they recognize any educational value in this type of show and how they assess the animals' treatment in this place. For that, a questionnaire with open and closed questions was administered at the beginning of the school year of 2018/2019 in three higher education institutions, one in Portugal, one in Spain and one in Greece. Among students of the different countries, the results were very similar, and the participants tend to consider that this show has no educational or even recreational interest for children, mainly based on arguments centred on animals. Therefore, they considered that this show mutilates animals' welfare, but one third of the participants showed difficulties in assessing how animals are treated in certain aspects. The results suggest that in their future practice the majority of the students will not convey an uncritical view of this show to their pupils. Even so, only a few Portuguese students recognize the value of circus as a controversial issue to be explicitly approached in class, a reason that could be related to the syllabus content of Didactic of Science, a curricular unit in their course plan.

Keywords: Pre-service teachers, Human-Animals Relationship, Circus

INTRODUCTION

In Science Education the discussion of socio-scientific issues, most of them controversial, is a way to develop students' critical thinking. Therefore, socio-scientific issues are informed by scientific knowledge, involve forming opinions, are frequently media reported and involve values and ethical reasoning (Ratcliffe & Grace, 2003). In the absence of these issues in the curriculum, the awareness of a role as a world citizen is somehow missing.

Human relationship with other animals involves several controversial issues, including performing that seems to be an interdisciplinary point of interest (Grant, Ramos Gay, & Alonso Recarte, 2018), and is a relevant theme in Science Education. There are a number of educational arguments in favour of students undertaking such considerations. Such teaching, apart from its value in learning science issues might: a) heighten the ethical sensitivity of students, b) increase the ethical knowledge of students, c) improve the ethical judgment of students, and d) make students better people in the sense of making them more virtuous or otherwise more likely to implement normatively right choices (Reiss, 2017). However, it has not always received the relevance it deserves, at least in the countries where the present study was developed. And even knowing that several non-profitable associations and also political parties are putting animal issues in the agenda, socio-scientific issues centred on science and technology impacts are more often more selected for discussion (see, for instance, Easton, 2009). Also, environmental education seems to be more focused on other topics. According to Reingard (2016), animal welfare and the care for the environment have taken separate ways, with their own agendas and groups, and also with a dissimilar social and political impact.

The behaviour of teachers during the approach of controversial issues also motivates discussion, especially if they should or not take a position in class. Common knowledge tells us that, teachers are not neutral during their teaching-learning process and tend to transmit their values to pupils in an explicit or implicit way. For instance, a study done by Almeida (2011), involving teachers from the Lisbon area (Portugal), found that the majority of them did not consider the existence of zoos a controversial issue, and the same in the case of the use of animals in cultural acts, even though in a less expressive trend. But if this kind of issues is not considered as controversial, probably an instrumental view of other animals, which includes the assumption that they deserve less moral consideration than humans, is transmitted, since it has been the dominant perspective in the western thought (Steiner, 2005).

In fact, during centuries, animals have been seen in an instrumental way and they have been used for different human purposes, including fun. But according to Franklin (2008), since the sixties, the idea that we can use animals for any human purpose is changing as a result of the emergence of several animal movements. The development of scientific knowledge in the fields of physiology, animal behaviour and animal cognition also helps to this change, since it has allowed a better understanding of the negative impact of certain human uses of animals. According to Bekoff and Bekoff (2017) science can not produce obvious moral 'outputs', but it can inform our ethical judgments and behaviours.

Circus with animals is a show created for humans, an American invention with roots in Roman public exhibitions and medieval travelling exhibitions (DeMello, 2012). However, the use of wild animals has been especially criticized due to several reasons: their welfare lives are affected due to an inadequate diet, poor house conditions, health problems related to the effect of repeated performances, physical and emotional punishment suffering during their training and having to travel constantly in cages (Iossa, Soulsbury, & Harris, 2009). Dorning, Harris, and Pickett (2016) provide an impartial literature review based on scientific evidence of the impact on animals of travelling circuses and other animal performing acts. They highlight the following evidence that confirm the negative impact of these shows both physically and mentally: i) contact with small and poor environments; ii) inappropriate social conditions, as isolation of social groups; iii) difficulties in having adequate food; iv) impossibility to meet climatic and environmental needs of many species; v) submission to coercion, force and aggression; vi) physical deformities, injuries, lameness and psychological distress due to unnatural performances.

Aristotle is responsible for the idea that every living being has its own good only when its natural activity or function is achieved (telos). Based on this idea Rollin (2010) claims that the circus is responsible for the perversion of the *telos* of an animal, as it is possible to confirm with the above mentioned problems caused to animals.

As far as animals in circuses is concerned, to the best of our knowledge, educational research is rare and usually is a part of wider studies related to the use of animals. For example, Stanisstreet, Spofforth, and Williams (1997) found that more than half of a sample of 433 pupils, aged 11-16 years, objected to the use of animals in circuses and a major factor here was apparently the thought that circus activities demean animals. Similarly, Pagani, Robustelli, and Ascione (2007) investigated Italian youths' (9–18 years of age) attitudes and behaviours toward animals. Various aspects of child–animal relationships were analyzed, including the use of animals in circuses. In their findings they recorded that the majority of their sample (82% of the girls and 71% of the boys (difference statistically significant, $p<0.001$) was against the use of animals in circuses, with younger pupils, aged 9–10 years, being more often against the use of animals in circuses when compared with those aged between 11 and 18.

Therefore, the present study tried to identify the opinion of primary pre-service teachers from Portugal, Spain and Greece about the circus, including whether they recognize any didactic purpose in this kind of show. In fact, the circus can be seen as a way to promote children's contact with animals, allowing learning about them, and ignoring the main criticisms already presented. Also, it will be important to identify if at least a few of these negative impacts are recognized by the students and if they inform their opinions about this kind of show.

When the study was designed, the situation about the use of animals in circuses was different in the three countries. In Portugal, the use of wild animals in circuses was banned by law (after the starting of the present research project), and licenses for their use will expire within 6 years. During this transitional period circuses must move animals to rescue centres (Decreto-Lei nº 20/2019); In Spain, the use of wild animals is banned in certain autonomous regions and municipalities ("Nearly 300 Spanish towns," 2016); In Greece the use of animals in circuses was banned by Law nº 4039, 2012. In this country there are no national circuses and foreign circuses with animals are not allowed to perform (Euro group for animals, n.d.). Despite the ban, a dolphinarium was operated in a private zoo in Athens and till 2019 there were shows with dolphins, although high fines were imposed.

Even knowing that the legal situation in the three countries tends not to support this kind of show, the present study is still important for the following reasons: i) the contact with this kind of shows is still possible in Portugal and Spain and in a few border countries of Greece; ii) law and ethical positions are not exactly the same, as the changes in legislation along time have proved. Also, an activity that is illegal today can be made legal again tomorrow.

METHODS

The sample involved 94 Portuguese, 78 Spanish and 49 Greek primary pre-service teachers from three higher school institutions, almost all females, and the average age of the groups was, respectively, 23.4, 23.2 and 22.7 years old. The Portuguese institution was in an urban context; The Spanish and the Greek institutions were from smaller cities, in rural areas. The Greek one is also in a city near the border.

A questionnaire, validated by two experts from each country, was administered on line, using the Google drive tool, at the beginning of the school year of 2018/2019, more precisely in October. The administration was in the main language of each country (Portuguese, Spanish and Greek), but an English version was used during the design process and validation. With the Google drive tool, the students could only see the questions of the next section after answering the previous one, a possibility that was important to check the reliability of their ideas in different moments of the questionnaire. The different sections and questions are in Table 1. In section 1, the inclusion of different shows was a way to know students' opinion about the circus in a more dissimulated way; in the other sections, the questions were exclusively about the circus.

Table 1. The sections and questions of the questionnaire.

Sections	Questions
Section 1	In a scale from 1 to 5 indicate the degree of relevance of including the different shows of animals during primary school activities: exhibitions with birds of prey, circus, racing horses, pets' competitions, exhibitions with aquatic mammals. Justify.
Section 2	1. Have you ever seen a live circus show with animals? Yes No; 1.1. If you said yes, why did you go to this kind of show?
Section 3	1. Do you think that the circus with animals can be an educative show? Yes No. Justify; 2. The circus is a show that can use animals or not. Which kind of show is more relevant for children? a) Circuses with animals; b) Circuses without animals; c) Both kinds of circuses. Justify. 3. Is the circus an adequate place for animals? Yes No. Justify. 4. In your opinion, circuses should exhibit: a) All kinds of animals (wild and domestic ones); b) Only wild animals; c) Only domestic animals; d) Performances without animals. Justify.
Section 4	1. In general, animals in the circus…1.1 Are well fed ; 1.2 Do enough exercise; 1.3 Have their natural features respected; 1.4 Like to show themselves to the viewers; 1.5 Suffer physical and psychological abuse; 1.6 Are in general well treated (For all: Yes, No, Don't know)
Section 5	1. In your opinion, should the use of animals in circuses be forbidden? Yes No. Justify.

The relative frequency of the answers in section 1for each country was analyzed after the categorization of the justifications, including each category ideas which were considered similar. The content analysis of all the answers allowed to create three main categories: animal centred reasons, e.g. "Animals were kept in bad conditions", human centred reasons, e.g. "It could be a way to learn about exotic animals" and mixed reasons, e.g. "It has no educational value and animals are not in their habitats". A few mores examples of answers from these categories are included in the results section.

Two other categories were also created: other kind of reasons, especially those that were inclusive like "It is not good for children" or "I never thought about that", and Don´t know. With question of the questionnaire's first section, related to the circus, the Kruskal Wallis *H* test (inferential statistics) was used to check statically differences between the means obtained from the students of the three countries, concerning the different shows and exhibitions included in the questionnaire. The median for each show by country was also included.

The relative frequencies of the results of the questions from the other sections were also calculated.

RESULTS

In the question of the first section related to the circus, 73.4% of the Portuguese students, 74.3% of the Spanish and 76.3 of the Greek selected value 1 and 2 of the Likert scale, considering that the circus does not have any didactic interest, stating that animals are not in their habitat and are bad treated. Animal centred answers were almost exclusively given by those that value the circus very low, with a high relative percentage (65% in the Portuguese sample, 41.4% in the Spanish and 75.8% in the Greek). A few examples of these answers are “It is not suitable for children since the animals are abused and far from their environment” or “Animals suffer during the training”. Even so, the students from the three countries that value this show with 4 and 5 were 12.7% of the Portuguese sample, 9% of the Spanish and 13.1% of the Greek. In this selection, the arguments were almost exclusively human centred. The difference of the results for 100% is from those that selected value 3 in the Likert scale. The result of applying the Kruskal Wallis *H* test showed no statistical differences between the students of the three countries ($p = 0.412$). Just a few examples of students’ justifications: “At the end of the school period, it can be a leisure activity”, “Children enjoy seeing animals and the show can motivate them to research information about them”, “This show is a way to allow pupils to see exotic animals” or simply “It is a great show”. In the group of students that gave 3 (neutral position), 4 and 5 to the didactic relevance of the circus, some Portuguese students stated that it could be a relevant controversial issue to discuss with children, an argument not presented in the samples of the two other countries.

In Table 2 the median value obtained for each show by country in question 1 is compared.

Table 2. The comparison of the median values for the didactic value of the different shows obtained by the sample of each country.

	Portuguese Students	Spanish Students	Greek Students
Circus	1	1	1
Exhibitions with birds of prey	3	3	2
Racing horses	2.5	3	3
Pets’ competitions	1.5	2	3
Exhibitions with aquatic mammals	3	2.5	3.5

As it is possible to conclude, the circus was rated by the students of the three countries as the show with smaller didactic value for children in a set of five shows involving animals. Even so, the shows with aquatic animals have received much more recognition, and they can be considered very similar to circus acts.

Considering the section 2 of the questionnaire, 94.7% of the Portuguese students, 80.8 of the Spanish and 69.4% of the Greek had seen this kind of show live at least once. The reasons for attending this show were diverse. But in all the samples, families’ options were the main reason stated, and 20% of the Portuguese sample also mentioned that during primary school it was a common activity and few remembered that it was an offer from the town council. This kind of experience during primary school was only evoked by 2.6% of the Spanish and of the Greek students.

The educational value of the circus was considered irrelevant by 73.4% of the Portuguese students, by 67.4% of the Spanish and by 64.6% of the Greek, a result obtained in question 1 of section 3, percentage values quite similar to the ones obtained in the question of section 1 (Table 1). Even so, 15% of the Portuguese said it could be a way to learn about animals, a reason also stated by 14% of the Spanish and by 7% of the Greek. A few Portuguese students stated again the possibility of developing children's critical thinking, a reason absent among the Spanish and quite rear among the Greeks (2.3%).

Considering the presence of animals in circuses, section 3 – question 2 (Table 1), 73.4 of the Portuguese sample, 84.6% of the Spanish and 90% of the Greek were against it, evoking the bad welfare conditions given to animals. But considering the possibility of having wild, domestic or both types of animals in circuses, section 3 – question 3, near 12% of the Portuguese sample, near 7% of the Spanish and 10% of the Greek accepted the third possibility. For defending the circus with animals, the participants evoked mainly two reasons: it is a show that children like; it can only be acceptable if the animals are well treated.

In relation to the assessment of different aspects related to animals in the circus, section 4, the results are present in Table 3.

Table 3. The opinions of primary pre-service teachers about animals' circus conditions. For each statement is included the percentage of agreement (Yes, No and DK – Don't know).

1. In general, animals in the circus…	Portuguese students			Spanish students			Greek students		
Agreement…	Yes	No	DK	Yes	No	DK	Yes	No	DK
1.1 Are well fed;	12,8	27,7	59,5	9	32,1	60	46.9	-	53.1
1.2 Do enough exercise;	7,5	44,6	47,9	15,4	42,3	42,3	28.6	32.7	38.8
1.3 Have their natural features respected;	1,1	86,2	12,7	2,6	87,2	10,2	2	77.6	20.4
1.4 Like to show themselves to the viewers;	5,3	48,9	45,8	3,9	53,9	42,2	6.1	53.1	40.8
1.5 Suffer physical and psychological abuse;	64,9	2,1	33,0	66,7	-	33,3	79.6	-	20.4
1.6 Are in general well treated.	7,4	56,6	36,0	5,2	61,5	33,3	4.1	67.3	28.6

The opinion of the students of the three groups tended to consider that animals are badly treated and are deprived of their natural features. Even so, a high percentage of the students don´t know how to assess several of the aspects considered. It was the case of the items "Are well fed", "Do enough exercise" and "Like to show themselves to the viewers".

Finally, the legal prohibition of the circus with animals, section 5, was supported by 85.1% of the Portuguese sample, by 88.5% of the Spanish and 76% of the Greek based on the harm done to animals.

DISCUSSION AND CONCLUSIONS

In the present study, the results obtained in the different questions were very similar in the samples of the three different countries, since the majority of pre-service teachers did not recognize any relevant didactic value or even recreational interest in the circus with animals, evoking essentially reasons centred on the animals. Even so, about one third of the participants in each country had difficulties in assessing how animals are treated in some specific aspects, and a percentage below 15% tended to think that the circus with animals is a good show. It seems that, at least in the case of the circus, the way animals are treated is not totally known by the participants and more information is needed to increase awareness about this kind of show.

Some Portuguese students evoked that the circus could be a controversial issue to approach in class and this could be related to the fact that only in the course attended by these students there is the inclusion of controversial issues in the syllabus of the curricular unit of Didactic of Science.

Curiously, none of the Greek students evoked in their answers the fact that the present show is not a legal activity in their country, a ban created in Greece in 2012. This may be related to the lack of knowledge about this situation or because they gave priority to other reasons in their justifications.

The results also support the idea that during their future teaching practice a great majority of these students probably will not attend with their future pupils this kind of show, especially in Portugal, where there is still a transitory period of six years until the total prohibition of the use of wild animals in circuses, and in Spain where the circus with wild animals is still possible to be seen in certain regions. This supposition is in line with the idea that, at least in certain subjects, a change is occurring in our society about how animals should be treated. Even so, the recognition of a great didactic value of shows with aquatic mammals is of concern, since they are in fact circus acts, apparently not identified as such by the students.

Finally, the inclusion of controversial issues related with human-animals relationship seems to be a relevant issue to be included in teacher training courses. With this approach, the future teachers will be much more prepared to deal with this kind of subject, helping to build a less instrumental view towards animals.

ACKNOWLEDGEMENT

This study is included in the ANIMALIS project (IPL/2018/ANIMALIS_ESELx), which is funded by the Polytechnic Institute of Lisbon, Portugal.

PROSPECTIVE TEACHERS' PERCEPTION OF THE RELEVANCE OF SCHOOL – INDUSTRY COLLABORATION

Špela Hrast and Vesna Ferk Savec
University of Ljubljana, Faculty of Education, Ljubljana, Slovenia

Unpopularity of science subjects, in particular physics and chemistry, among many students remains one of the major challenges of science education. In order to manage mentioned issues current educational policy recommends that chemistry teachers should make chemistry education more relevant. One of the possibilities to enhance different relevance dimensions suggests chemistry education based on industry collaboration. The article focused on perception of prospective teachers of chemistry contents at primary and secondary level about the relevance of school-industry collaboration. Altogether, 189 prospective teachers of chemistry contents from the University of Ljubljana, Slovenia, were selected with non-random sampling. The data was collected with the questionnaire about the perception of the relevance of school-industry collaboration, and analyzed using content analysis. The most important outcomes indicate that that prospective teachers of chemistry contents at primary and secondary level recognized relevance of the collaboration between school-industry with benefits for schools, students and industry. They pointed out the importance of the collaboration to enhance different relevance dimensions, and thereby focused more on the cognitive domain, and emphasized less the affective and skills domain. The most important value of the results is recognized in revealing the state of art at the national level and the needs for development possibilities in the future.

Keywords: Science Education, Initial Teacher Education, Socioscientific Issues

THEORETICAL FRAMEWORK

To ensure effective learning of chemistry contents, it has to be perceived as relevant in the eyes of students (Hofstein, Eilks, & Bybee, 2011). Stuckey et al. (2013) proposed a model to describe the relevance of the science education focusing on the idea of consequences. Whereby, chemistry learning is defined as a relevant when it has positive consequences for the student's life. The developed model suggests three dimensions of the relevance of the chemistry education: (1) an individual; (2) a societal and (3) a vocational dimension, whereby of each dimension covers intrinsic and extrinsic components, as well as the aspects of present and future meaning (Figure 1). The mentioned dimensions are interrelated and can partially overlap (Eilks & Hofstein, 2015).

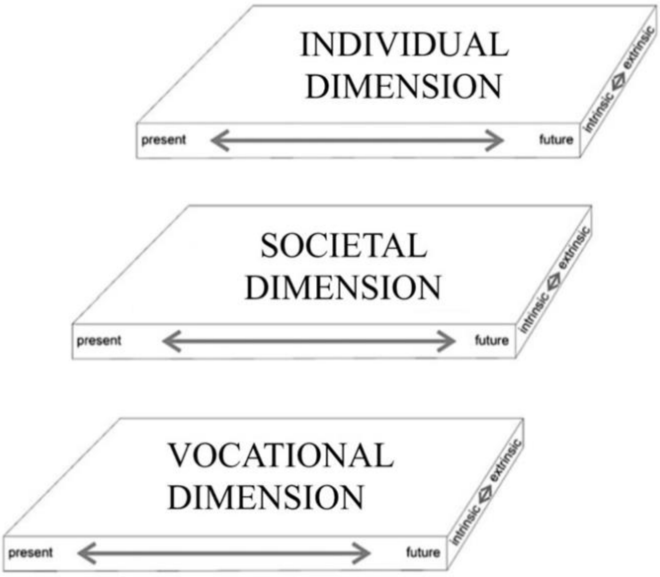

Figure 1. Dimensions of the relevance of the chemistry education: individual, societal and vocational dimension (Stuckey et al., 2013; Eilks & Hofstein, 2015).

To enhance different relevance dimensions Hofstein and Kesner (2006, 2015) suggest applying chemistry education based on industry collaboration in order to include economically and ecologically features of modern life and its technological achievements. Industry-school collaboration enables to emphasize chemistry socio-economic and environmental consequences and therefore represents a possibility for achieving the goals of discipline-oriented education for sustainable development by adding sustainable development issues to the chemistry curriculum (Burmeister, Rauch, & Eilks, 2012; Jegstad & Sinnes, 2015).

Students are encouraged to develop not only their societal relevant chemistry knowledge but also their ability to evaluate chemistry-related issues, such as possible contributions of chemistry to sustainable communities or appropriate natural resources stewardship in the future (Burmeister & Eilks, 2012). Due to the importance of teachers' personal perceptions, which may represent one of the most important factors for inhibiting the effective implementation of relevant chemical education (Lumpe, Haney & Czerniak, 2000), the purpose of the paper is to examine the perception of future teachers who will teach chemical contents in the education vertical.

AIM AND RESEARCH QUESTIONS

The main aim of this study was to investigate the perception of the relevance of school – industry collaboration from the perspective of prospective teachers of chemistry contents at the primary and lower secondary levels.

With regard to this research aim, the following research questions (RQ) were defined:

(**1st RQ**) What is the perception of prospective teachers of chemistry contents at primary level (PST) about the relevance of school-industry collaboration?

(**2nd RQ**) What is the perception of prospective teachers of chemistry contents at secondary level (CT) about the relevance of school-industry collaboration?

RESEARCH METHOD AND DESIGN

Sample. For the purpose of the research, 189 prospective teachers of chemistry contents from the University of Ljubljana were selected with non-random sampling. The sample consisted of 127 prospective teachers at primary level (PST) and 62 prospective chemistry teachers at lower secondary level (CT).

Instrument – Questionnaire about the perception of the relevance of school-industry collaboration. The questionnaire about the perception of the relevance of school-industry collaboration, which was used in the study, was developed for the research purposes. The questionnaire in full text can be obtained from the authors.

Data collection and data analysis. The data was collected in the study years 2016/17 and 2017/18 with the questionnaire about the perception of the relevance of school-industry collaboration, and analyzed using content analysis (Aksela, Wu, & Halonen, 2016; Vogrinc, 2008). Two researchers separately analysed 10 % questionnaires (n=19) to develop categories representing natural units of meaning related to the prospective teachers' perception of the relevance of school-industry collaboration. The reliability of coding was 95% and was achieved by coordinating the independent coding of two researchers, authors of the paper.

FINDINGS

In the Table 1 fifteen categories are described that were recognized as benefits of school – industry collaboration from the perspective of prospective teachers of chemistry contents.

Table 1. Recognised categories of the relevance of school – industry collaboration.

Relevance of collaboration for	Categories	
Students	*Students* get acquainted with the meaning of **chemistry knowledge in the society and for their individual life**	
	Directing *students* to **choosing professions** related to the field of chemistry	
	Students gain new **experiences or knowledge** (in general)	
	Students gain specific **experiences or knowledge**	in the field of **cognitive** domain
		in the field of **affective** domain
		in the field of **skills**
Schools	*School or teachers* gain new **experiences or knowledge** (in general)	
	School or teachers gain specific **experiences or knowledge**	in the field of **cognitive** domain
	School obtains **sponsorship or donations**	
	School obtains the opportunities for **out-of-school learning**	
	Other added value for the learning process	
Industry	**Promotion** of *industry or companies*	
	Industry or industry representatives gain new **knowledge** (in general)	
	Industry or industry representatives gain specific **experiences or knowledge**	in the field of **cognitive** domain
	Industry obtain **quality future staff**	

Prospective teachers of chemistry contents (PST+CT) pointed out mostly the relevance of collaboration for students, thereby CT highlighted categories that emphasize the relevance for students in comparison with PST ($f_{\%PST}$=43,0 %; $f_{\%CT}$=67,3 %). CT have also highlighted the categories of that emphasize the relevance of school – industry collaboration for the industry ($f_{\%PST}$ =12,2 %; $f_{\%CT}$=16,7 %).

Prospective teachers of chemistry contents (PST+CT) mostly indicated the category *Students gain specific experiences or. knowledge in the field of cognitive domain* ($f_{\% PST}$=20,4 %; $f_{\% CT}$=17,3 %).

Examples of responses:

Prospective PST A: »*Students get an insight into the work of companies, what are they making and how, etc.*.«

Prospective CT A: »*Students can get acquainted with the activity of the company, e.g. when visiting a company dealing with plastic packaging, they can learn about polymers and their properties.*«

Besides that, PST emphasized also the importance of the categories *School obtains sponsorship or donations* ($f_{\%PST}$ =28,5 %) and *School obtains the opportunities for out-of-school learning* ($f_{\%PST}$=11,3 %).

Examples of responses:

Prospective PST B: »*Companies can be sponsors, provide funds or some equipment that make work easier and more efficient*.«

Prospective PST C: »*We can visit companies with students and see how things work.*«

On the other hand, CT emphasized also the categories *Students get acquainted with the meaning of chemistry knowledge in the society and for their individual life* ($f_{\% CT}$=25,3 %) and *Students gain new experiences or. knowledge in general* ($f_{\%CT}$=13,3 %).

Examples of responses:

Prospective CT B: »*Students see that chemistry knowledge is useful in their everyday life*«

Prospective CT C: »*In my opinion, participation is beneficial for students as they gain new experiences*«

Prospective teachers of chemistry contents (PST+CT) pointed out the subcategories that include both the individual and the social dimension of relevance of school-industry collaboration from the students' perspective. As can be seen from Table 2, in this regard, especially the following the subcategories: (1) *Students get acquainted with the meaning of chemistry knowledge in society* ($f_{\% PST}$=10,5 %; $f_{\% CT}$=20,8 %), that supports societal dimension, (2) *Students gain specific experiences or knowledge in the field of cognitive domain related to the activity of individual companies* ($f_{\% PST}$=13,7 %; $f_{\% CT}$=15,8 %), that supports vocational dimension were emphasized.

Table 2. Recognised categories of the relevance for students.

Categories with subcategories			Dimensions of the relevance*
Students get acquainted with the meaning of chemistry knowledge		in general	I, S
		for individual life	I
		in society	S
Directing *students* to choosing		professions related to the field of chemistry by stimulating interest in professions related to the field of chemistry	V
		professions related to the field of chemistry resulting from other advantages of collaboration	V
		further education related to the field of chemistry	V
Students gain		new knowledge	I
		new experiences	I
Students gain <u>specific</u> experiences or knowledge	in the field of **cognitive** domain related to	the activity of individual companies	V
		the operation of companies	V
		career opportunities related to the field of chemistry	V
		developing an understanding of the role of chemistry in society	S
	in the field of **affective** domain related to	promoting changes in attitudes towards chemistry	I, S
		promoting interest in chemistry	I, V
	in the field of **skills** related to	developing collaborative skills	S

Additionally, PST emphasized also the subcategories *Students gain specific experiences or knowledge in the field of cognitive domain related to career opportunities related to the field of chemistry* ($f_{\%\,PST}$=21,1 %), *Directing students to choosing professions related to the field of chemistry resulting from other advantages of collaboration* ($f_{\%\,PST}$=15,8 %), and *Students gain specific experiences or. knowledge in the field of cognitive domain related to the operation of companies* ($f_{\%\,PST}$=11,6 %), which all support vocational dimension of relevance for students.

On the other hand, CT pointed out also the subcategory, *Students get acquainted with the meaning of chemistry knowledge for individual life* ($f_{\%CT}$=10,9 %), that emphasized the individual dimension for students.

DISCUSSION OF FINDINGS AND IMPLICATIONS

It is important to note, that prospective teachers of chemistry contents at primary and secondary level recognized the relevance of the collaboration between school-industry with benefits for schools, students and industry. It was found that prospective teachers of chemistry contents at primary and secondary level in Slovenia recognize the important added value of chemical education, which involves the integration of school, university and economy, i.e. to enable students to develop an understanding of chemistry in everyday life and to learn about the links between chemistry, the economy and society (Hofstein and Kesner, 2006, 2015).

They pointed out the importance of the collaboration to enhance different relevance dimensions, and thereby focused more on the cognitive domain, and emphasized less the affective and skills domain, which indicates a need for developing further understanding of the relevance of school-industry collaboration on the national level. At the international level, collaboration with the industry is also defined as a potential approach to achieving sustainable development goals (Burmeister et al., 2012; Jegstad and Sinnes, 2015), while encouraging students to develop their own knowledge in addition to developing understanding of socially relevant chemical knowledge skills for socially responsible behavior and engagement in society (Burmeister and Eilks, 2012).

KNOWLEDGE OF SPANISH PRE-UNIVERSITY STUDENTS REGARDING DIFFERENT AREAS OF BIOTECHNOLOGY

Luisa López-Banet[1], Cristina Ruiz González[1] and Enrique Ayuso Fernández[1]

[1] University of Murcia, Murcia, Spain

This paper analyses the knowledge of 184 students in the last course of secondary education in Spain in relation to different areas of biotechnology: medical, food, agricultural, industrial and environmental. The information was obtained from students in 2nd year of Baccalaureate, the previous year to enroll in a University grade, in six high schools of different characteristic (regarding size, type of environment and the location in the city). The instrument used was a written questionnaire that was designed and validated for this purpose. A descriptive statistical analysis was carried out, which allowed us to better understand the current situation of biotechnology in the classrooms, focusing on those students who manifested a predisposition toward learning science (they were students who had chosen the scientific branch, thus they had to study Biology at this level). The results show that a significant number of students complete secondary education with imprecise notions about applications of biotechnology. Regarding the attitude, this will depend not only on the application and purpose of them but also on the organism involved. Students tend to accept applications with beneficial effects on human health, although they are against them when they perceive a loss of natural character, damage to the environment or moral consequences.

Keywords: Secondary Education, socio-scientific issues, genetics

INTRODUCTION

The scientific and technological training that students receive during secondary education must enable them to engage in responsible decision making in 21st century society (Prieto, España, & Martín, 2012). These kinds of decisions present dilemmas or controversies based on scientific notions related to social, ethical, political and environmental fields (Jiménez, 2010). The growing impact of biotechnology in recent years requires citizens who can understand the notions related to this subject to have adequate intellectual tools to make relatively informed decisions regarding their position about the applications of biotechnology in daily life (Fonseca, Costa, Lencastre, & Tavares, 2012). Being immersed in some socio-scientific controversies, students of biotechnology not only are motivated to know their biological principles, but also to be aware of the possible benefits and risks (of political, social, legal and ethical nature) that derive from its development (Hammann, 2018). These circumstances have had an impact on the curriculum of most advanced countries, and thus, the inclusion of biotechnology in secondary education has become an international tendency. This fact has caused students to have to learn basic concepts of genetics (France, 2007) and a large amount of new knowledge related to the applications of biotechnology, which are not easy to adapt in science classes (Gericke & Wahlberg, 2013). In this sense, simulation games or role-playing activities and debates (Simonneaux, 2002) allow students to analyse and assess the positive and negative aspects of different applications in the context of scientific research and express their opinions on the suitability of their use. Further, the introduction of peer discussions and debates about socio-scientific issues in connection to biotechnology into the teaching of science in schools permit students to progress in ethical reasoning and encouraged them to reason and explain their claims, offering alternative solutions (Berne, 2014).

Regarding the knowledge of basic notions of genetics and of applications of biotechnology, in many studies, basic errors have been found, such as a lack of knowledge of key points of genetics, for instance about the knowledge of DNA itself and its transmission. 'Common tomatoes do not contain genes, while genetically modified tomatoes do contain genes' is a sentence that is usually presented in studies on biotechnology (de la Vega, Lorca, & de las Heras, 2018). Among the numerous investigations carried out on these aspects, some of the most interesting for our work might be related to the location of hereditary information (Banet & Ayuso, 2000; Ruiz, Banet, & López-Banet, 2017a), to the hereditary information in some living beings (Caballero, 2008; Ruiz, Banet, & López-Banet, 2017b), and to the knowledge about biotechnology (Fonseca et al. 2012; Occelli, Vilar, & Valeiras, 2011; Prokop, Lesková, Kubiatko, & Diran, 2007; Usak, Erdogan, Prokop, & Ozel, 2009). About the applications of biotechnology in different fields we could mention food (Chen, Chu, Lin, & Chiang, 2016; Dawson, 2007; Fonseca et al. 2012; Occelli et al. 2011; Öztürk-Akar, 2016; Prokop et al., 2007; Usak et al., 2009), medical (Fonseca et al., 2012; Öztürk-Akar, 2016) or agricultural, livestock and environmental (Ayuso, Ruiz, & López, 2019; Fonseca et al., 2012; Öztürk-Akar, 2016).

In relation to the medical field, studies have suggested that students are favourable to the use of genetic engineering for research (Chen et al., 2016), the use of genetically modified organisms in medicine (Öztürk-Akar, 2016), the production of new medicines and the diagnosis and/or treatment of diseases (Occelli et al., 2011), and gene therapy and classical applications (Fonseca et al. 2012). However, in other cases, it is indicated that the use of techniques such as gene therapy is not widely accepted (Gardner & Troelstrup, 2015). In Spain, Sáez, Gómez-Niño and Carretero (2008, p. 177) identified 'the maxim of health' as one of the values considered by students when they deem that improving the health of people justifies any type of technological intervention, which is an explanation that could explain the previously mentioned studies. Although students are not favourable towards applications that involve the manipulation of animal or human embryos, they recognise that future generations will benefit from advances in biomedical applications (Fonseca et al., 2012). Nor are they in favour of applications that require the modification of animals by introducing genes from human beings, but they are in agreement with the use of animals to produce useful drugs for people (Usak et al., 2009). In the field of food and, in particular, in terms of attitudes towards the consumption of genetically modified foods, many students do not feel that it is safe to buy these products (Öztürk-Akar, 2016). Some consider that they may involve health risks by containing chemicals capable of damaging the human body (Usak et al., 2009). In other cases, students are opposed to the modification of fruit genes (Prokop et al., 2007). With regard to this, in Sáez et al.'s (2008, p. 177) analysis of some assessments made by students, they describe 'the principle of the natural', which is understood as normal or appropriate. On the other hand, many students recognise that they do not usually look at the labels of the food they eat, although they consider the labeling of transgenic foods to be very important (Fonseca et al., 2012; Occelli et al., 2011). According to Chen et al. (2016), students do not favour applications of biotechnology in the agricultural, livestock and environmental fields, showing some concern about the negative impact that the use of genetic engineering in the agricultural industry can cause to the environment. However, students display more positive attitudes towards the elimination of diseases in plants or wastewater treatment (Öztürk-Akar, 2016) and to applications such as plant improvement or livestock production (Occelli et al., 2011). The acceptance by students of research in genetic technology for environmental sustainability is also very high, but they show some concern about the regulation of the risks in the environment associated with biotechnology (Gardner & Troelstrup, 2015). Finally, the use of microorganisms in biotechnological processes (Dawson & Schibeci, 2003) and in wastewater treatment (Usak et al., 2009) has been accepted by students.

Considering the contributions of the bibliographic review, in this study, we analyse, at the beginning and at the end of the second year of baccalaureate (2B onwards), the following research problem: What knowledge do students have about some basic notions of biotechnology?

METHODS

The participants of our investigation were 184 Spanish students (71 at the beginning of the course and 113 at the end) of a scientific modality 2B, belonging to an incidental sample of different secondary schools and with a medium-high academic level, according the opinions of their teachers. We used a written questionnaire whose fine-tuning was carried out as follows. Considering the curricular orientations (Ministry of Education, Culture and Sport [MECD], 2015), as well as the analysed antecedents, a concept map was elaborated (Appendix 1) that, in our opinion, included the most outstanding references to carry out the initial selection of the contents under study. Based on this scheme, an initial questionnaire was designed and was tested through individual interviews with 12 students from diverse centres and different academic performance. We eliminated a question that was too complex and modified the language and the structure of others. The obtained information was analysed through a combination of quantitative and qualitative strategies. The quantitative ones were realised using the Statistical Package of Social Sciences (SPSS) version 20.0 to obtain the descriptive statistics (frequencies and means), non-parametric statistics (Mann-Whitney U test at a significance level $\alpha<0.05$ to reveal the differences between groups) and the Pearson correlation coefficient.

RESULTS

This information was obtained from several questions. For the selection of the areas analysed, we took into account not only the interest they provoked in previous research but also our criteria in considering them to be better known by the students. The first question was an open one for which the students had to write the applications they knew about medicine, food, agriculture, industry and the environment. In the second, which was provided after the students had finished the former one so as not to influence in their answers, they were asked to assess the advantages and disadvantages of a set of applications in some indicated areas and also to indicate their level of knowledge; in the third one, they had to mark as true or false certain affirmations about the applications of biotechnology.

Question 1. Knowledge about certain applications of biotechnology

As they were open questions, many of the answers were very imprecise, so we only considered those that made reference to the name of the application (therapeutic cloning, bioremediation, obtaining transgenic plants, etc.) or should lead one to suppose the nature of it (determining how much kinship there is between two people in the same family, knowing if you are going to have diseases, biotechnology enables you to create more specific food products, etc.) to be adequate. The results (Table 1) show that before having studied biotechnology, the level of knowledge is minimal or medium, while at the end of 2B, the number of students citing three or four applications increases. It also highlights the significant decrease that occurs between those who do not mention any and the increase in those who cite more than seven applications.

Table 1. Applications cited (in%).

No. Applications	Beginning	End	α
0	23.94	4.42	**0.000**
1-2	36.62	38.05	0.845
3-4	30.99	41.59	0.149
5-7	8.45	8.85	0.770
More than 7	0	7.08	**0.033**

As shown in Table 2, at the beginning of the course, the students cite more applications in the medical and food fields (above 55%), while there are very few examples related to the environment. This knowledge increases among students who finish 2B, and it grows significantly in medicine (reaches 85%) and the environment. Nevertheless, the number of students who refer to an application in relation to industry did not reach 40%.

Table 2. Applications cited in each of the areas (in%).

Area	Beginning	End	α
Medicine	56.3	85	**0.000**
Food	56.3	63.7	0.319
Agriculture	43.7	54.9	0.145
Industry	21.1	31.0	0.140
Environment	11.3	36.3	**0.000**

Question 2. Degree of knowledge, advantages and disadvantages of some applications

To analyse the degree of knowledge of the applications of biotechnology, the students could point to 1 (I have never heard of it), 2 (I have heard of it but I do not know what it means) or 3 (I have heard of it and I know what it means). We considered those who marked it and those who gave an adequate definition of it as level 3, even if they had marked 2. The best known applications were those related to food (in particular, transgenic foods) and the use of DNA tests in forensic science (Table 3). Only between 15 and 25% of students knew about other examples in the medical field (preventive molecular diagnosis or gene therapy). The use of plants or bacteria in industry or microorganisms for waste treatment (bioremediation) was not well known.

Table 3. Degree of knowledge of some applications of biotechnology (in%).

Applications	Beginning			End			
	1	2	3	1	2	3	α
Preventive molecular diagnosis	53.5	26.8	15.5	38.9	35.4	25.7	**0.026**
Gene therapy	35.2	36.6	25.4	26.5	29.2	42.5	**0.034**
Fermentation for food production	7.0	49.3	39.4	8.8	36.3	54.0	0.154
Transgenic foods	4.2	23.9	67.6	2.7	17.7	79.6	0.163
Use of plants or bacteria in industry	23.9	40.8	26.8	14.2	42.5	42.5	**0.027**
Use of microorganisms for waste treatment	36.6	33.8	22.5	16.8	21.2	61.9	**0.000**
DNA tests in forensic sciences	9.9	33.8	49.3	8.8	21.2	69.0	**0.041**

The percentage of students who complete the baccalaureate and affirm that they know the meaning of the applications given increases in a statistically significant manner for most of them. However, from our point of view, the results cannot be considered satisfactory. We believe that the low results obtained in the medical field (only 25.7% report knowing the meaning of ‘preventive molecular diagnosis’) may be because they do not recognise the terminology or the proposed applications, because, in the previous question, they indicated many examples in this field. Some examples of the benefits and drawbacks that students mentioned for each of these applications are shown in Table 4.

Table 4. Advantages and disadvantages of biotechnology applications considered by students.

Applications	Advantages	Disadvantages
Preventive molecular diagnosis and gene therapy	Know possible diseases to which a person will be prone and be able to cure it	Moral type
Fermentation for food production	Food production	Derived from the microorganisms that are used to produce them
Transgenic foods	Obtaining food with desired characteristics, without adding chemicals (pesticides)	Unnatural foods that can cause health problems or in the environment
Use of plants or bacteria in industry	Obtaining beneficial products for human beings	Possible damage to the environment
Use of microorganisms for waste treatment	Reduce pollution	--
DNA tests in forensic sciences	Resolve a crime or identify a corpse	--

These results coincide with other investigations in which the main benefits that are indicated have to do with the improvement of human health, while the reasons why they would reject these techniques are related to moral aspects, damage to the environment or the loss of natural character (Sáez et al., 2008).

Question 3. Assessment of some claims related to biotechnology

The results of this part of the questionnaire (Table 5) show that, at the beginning of 2B, the majority of students respond correctly to the first one (genetic screening) and also to the one about which they previously had claimed no knowledge, which is associated with preventive molecular diagnosis. There are also many students who identify the use of enzymes in industry (e).

Table 5. Valuations of claims about biotechnology (correct answers in %).

Affirmation (correct answer)	Beginning	End	α
a. The analysis of the genes of an individual (genetic screening) can help to identify the diseases to which they will be more prone (V)	94.4	89.4	0.658
b. Only genetically modified microorganisms can produce antibiotics (F)	67.6	66.4	0.786
c. Transgenic plants have genes, but non-transgenic plants do not have genes (F)	71.8	88.5	**0.004**
d. It is not possible to transfer genes from one species to another (F)	64.8	72.6	0.320
e. Enzymes have a great applicability in industry in sectors such as food, clothing or paper (V)	63.4	66.4	0.621
f. Bioremediation by genetically modified microorganisms capable of eliminating materials that have difficulty degrading naturally is a decontamination method used, for example, in oil spills (V)	36.6	77.0	**0.000**

Although the results for the term bioremediation (f) are much worse among the students who start the course, there is a significant improvement among those who finish 2B. We did not observe notable differences in relation to two of the three statements that explicitly referred to genes (b and d). However, the knowledge that all plants have genes, not only transgenic ones, improves significantly in students who finish 2B (option c) due to a notable decrease in the number who do not respond to this question. In any case, at the end of the baccalaureate, about 30% maintain that it is not possible to transfer genes from one species to another or that only genetically modified microorganisms can produce antibiotics; these are circumstances that question, from their base, the notion of biotechnology that these students can learn.

CONCLUSIONS AND EDUCATIONAL IMPLICATIONS

The results presented show that a significant number of students complete secondary education with imprecise notions about applications of biotechnology, for instance, there is a high number of students who finish 2B without knowing the meaning of the fermentation processes, despite this course deals with the specific study of this content and even describes some of the metabolic pathways. Moreover, although students who start 2B are able to cite some applications of biotechnology, those who complete this course know more (particularly in medicine and food), thus improving the quality of their explanations about them and the vocabulary they use. Accordingly, our results reveal the incidence of teaching in the last year of baccalaureate. Regarding the advantages and disadvantages of biotechnology applications considered, students tend to accept applications with beneficial effects on human health, although they are against them when they perceive a loss of natural character, damage to the environment or moral consequences. Therefore, many have a favourable attitude towards those applications related to food (but are less favourable when they involve genetic modifications of animals and plants for experimental or even food purposes, about which they express doubts regarding their impact on the environment or on health) and medicine, accepting the alteration of genes in tissue cells whenever it is related to curing diseases.

As regards the educational implications of this research, it seems relevant to highlight the following:

- Before approaching the contents of biotechnology in baccalaureate, it is necessary for the students to possess adequate knowledge about the basic notions of genetics that are fundamental to understand it even at the elementary level (Chen et al., 2016). Otherwise, it is necessary to include in the teaching programme specific activities that allow them to progress from their misconceptions to scientifically more acceptable notions. On the contrary, if teachers assume that the analysed contents have been learned in previous courses, this will contribute to the persistence of many of these ideas, making it difficult to understand biotechnology.

- Due to the complexity of this subject, both because of the nature of its concepts, techniques and applications, as well as its social implications, the contents of biotechnology should be presented to students in an organised manner in order to facilitate their learning and their relationship with knowledge already studied.

- We consider that it is important to take advantage of the interest of students in biotechnology, particularly in relation to applications with direct repercussions on health, taking them as a starting point to present not only more examples but also more areas (genetic modification of microorganisms, plants or animals, industry, environment). In this sense, putting into practice role-playing activities and debates about socio-scientific issues in connection to biotechnology (Berne, 2014; Simonneaux, 2002) could be interesting. On the other hand, it would be appropriate to analyse the analogies and differences between traditional and modern biotechnology, as well as the evolution that has taken place in science to move from the former to the latter. Thus, the latter could not be seen as something new and exclusive to scientists, because the applications of biotechnology have always been used by humanity.

Finally, it seems important to emphasise that, much more often than desirable, the rhythm of the classes implies the introduction of a large number of new terms, concepts or techniques without establishing enough opportunities for students to reflect on new learning and relate it to other learning addressed previously. In our opinion, this circumstance could explain, to a large extent, the difficulties that many students have in understanding, in an adequate way, the knowledge we have analysed in this research.

ACKNOWLEDGEMENT

This research has been carried out within the project PGC2018-097988-A-I00 funded by: FEDER/ Ministry of Science and Innovation (MCI) of Spain - State Research Agency (AEI). The authors would also like to thank teachers of the different schools who participated in this research for their availability to help us to obtain the information we present.

A STUDY ON STEM HUMAN RESOURCES COMMUNITY ABILITY; FOCUS ON HIGHER EDUCATION STUDENTS IN JAPAN AND AFRICA

Tomotaka KURODA [1 2]

[1] Shizuoka University Graduate School of Science and Technology, Shizuoka, JAPAN
[2] Ehime University Faculty of Science, Matsuyama, JAPAN

Higher education in Japan is facing drastic changes. Based on connections between primary and secondary education, "zest for life," "fostering academic abilities," and "three elements of academic abilities" should be continued in higher education, while "fundamental competencies for working people" are being promoted on the industry side in Japan. Both Japan and other countries are preparing to create competencies. With regard to such competencies in international frameworks, it is necessary to attend to comparative study due to the cultural background of the target person. In this research, I focus on the consciousness and recognition required to build a STEM human resources community in the early years of higher education as well as to examine the capacity elements required for STEM human resources. I conducted a survey among Japanese students and students in the Republic of Malawi examining the skills and abilities of people with common abilities in a STEM resources community. The results revealed no significant differences between the students in Japan and Malawi for 5 out of the 21 ability elements. Common abilities in the STEM resources community are "listen closely and carefully to information," "innovate using critical thinking," and "easily disseminate information to other people in different cultural areas, based on control stress." For future research, I will seek to collect more data and conduct further interview research with questionnaire respondents.

Keywords: Scientific competencies / STEM education / Higher education

INTRODUCTION

Higher education in Japan has undergone a transformation promoted by the government. Central Education Council in Japan (2014) stated that the cultivation of "zest for life" and "fostering academic ability," based on connections between primary and secondary education, should be continued in higher education. This transformation covers all fields and includes STEM students as follows: "Three elements of academic ability" from primary education to higher education are required: (1) knowledge and skills, (2) thinking ability, judgment ability, and expression, and (3) initiative and collaboration. In addition, the Minister's Meeting on Human Resource Development for Society (2018) proposed the following definition of STEM and common citizen competence: (1) ability to accurately interpret and respond to writing and information, (2) ability to engage in and apply scientific thinking and inquiry, and (3) sensitivity and ability regarding discovering and creating value; curiosity and inquisitiveness. On the industry side, the Ministry of Economy, Trade and Industry in Japan (METI) has promoted the idea of "fundamental competencies for working persons" (METI, 2006). That is, society (especially in Japan) has expressed a demand for human resources with the basic skills necessary to work in organizations and communities. These skills consist of the following three competencies comprising a total of 12 competency factors: (1) Ability to step forward (action): Initiative, Ability to influence, Execution skill; (2) Ability to think through (thinking): Ability to detect issues, Planning skills, Creativity; (3) Ability to work on a team (teamwork): Ability to deliver messages, Ability to listen closely and carefully, Flexibility, Ability to understand situations, Ability to apply rules and regulations, and Ability to control stress. In addition, many skill sets and competency models around the world, including key-competency from the OECD (Organization for Economic Co-operation and Development) (Rychen & Salganik, 2003) and 21st-century skills (The Partnership for 21st Century Learning, 2015), contain similar concepts.

While Japan and other foreign countries are preparing to create competencies, Aikawa (2007), on the one hand, mentions the limitation of a wide variation in students depending on the culture and background of both the region and the individual. On the other hand, the OECD (2015) states that comparative study is possible in certain cultural areas since concepts such as competency are universal. In other words, when seeking to understand these competencies in the international context, it is necessary to pay attention to comparative study due to the cultural background of the target person; however, such a comparison is only possible in the same cultural sphere (linguistics). It is thus assumed that the STEM community has a unique culture and background, and that by focusing on the STEM community itself, it will be possible to compare the competencies required of STEM human resources on a global level.

Therefore, I focus on the consciousness and recognition required for the STEM human resources community in the early years of their higher education careers and examine the capacity elements required for STEM human resources.

This research has the following RQs. RQ1: To clarify the characteristics of the STEM human resources community for students in the target country. RQ2: To clarify the characteristics of the STEM human resources community by clarifying common consciousness and recognition through an international comparison.

METHOD

I conducted a survey among Japanese students and students in the Republic of Malawi in order to compare, as far as possible, students from two separate cultures. The Japanese students were first-year university students (228 students) studying at the local national university in the Faculty of Science, with the survey conducted at the end of Quarter 2 (the university's year runs according to a quarter system) . In this Faculty, students can major in the fields of mathematics, physics, chemistry, biology and geography, with around 36% currently advancing to graduate schools.

The participants from Malawi were first- and second-year students (82 students) at an ICT vocational school, and the survey was conducted at the end of the year. The Republic of Malawi, as the subject of the survey, is one of the poorest countries in the world, with a GNI (Gross National Income) per capita of 320 US dollars (World Bank, 2018). The country's national policy emphasizes science and technology in economic growth (Republic of Malawi, 2017). The Japanese government has worked for many years in Malawi to implement educational support for science and mathematics as official development assistance. Because of this support, it shares in some characteristics of science and mathematics education with Japan; this makes it an ideal candidate for comparison.

In this research focusing on the consciousness and recognition of STEM human resources, I used five methods to elicit responses concerning the elements of ability required for STEM human resources. The following question was posed: ‘How important are these skills and abilities for people with STEM careers?’ The ability elements comprised 21 items based on ‘Fundamental Competencies for Working Persons’ in Japan and 21st century Skills of 4Cs skills (Critical thinking, Creativity, Collaboration, Communication). The questionnaire permitted responses on a scale of 1–5, with 5 being ‘very important’, 4 ‘important’, 3 ‘somewhat important’, 2 ‘not very important’ and 1 ‘not at all important’, with average values calculated based on the responses.

RESULTS AND DISCUSSION

Figure 1 (Results from Japanese respondents) and Figure 2 (Results from Africa (Malawi) respondents) summarize the results of the responses in Japan and Malawi. Careful attention should be paid to the fact that the responses were mainly positive, and there was a difference in the number of Japan and Malawi respondents.

These data show that many items incurred a response rate of higher than 80 percent positive (choices 5 and 4), and, in particular, in Japan, five items exceeded 90 percent (General Expertise; Executing Plans; Ability to Detect Issues; Creativity; Flexibility), as did four items in Malawi (Leadership; Information, Media, and Technology Literacy; Critical Thinking; Communication). In terms of the characteristics of each country, it is clear that there is a low recognition of the importance of Collaboration and Innovation in Japan, as well as weak recognition of Ethics and Career Development and Planning. By contrast, in Malawi, even for STEM human resources who are professionals, the numerical values of the items were low for both Expertise and Initiative and Ability to Detect Issues.

In addition, a *t*-test was conducted regarding the abilities of the STEM human resources communities of the two countries, with a significant difference seen for 16 of the 21 items (as shown in Table 1). Focusing on the five items that did not reveal any significant differences, it can be seen that the STEM human resources who can also work in the STEM human resources community have several abilities in common: to Listen Closely and Carefully to Information, to Innovate Using Critical Thinking, and to Easily Disseminate Information to Other People in Different Cultural Areas. And then must needs control stress. Since there is no tendency to be biased towards either of the large average values, it is suggested that these items may be strongly influenced by culture.

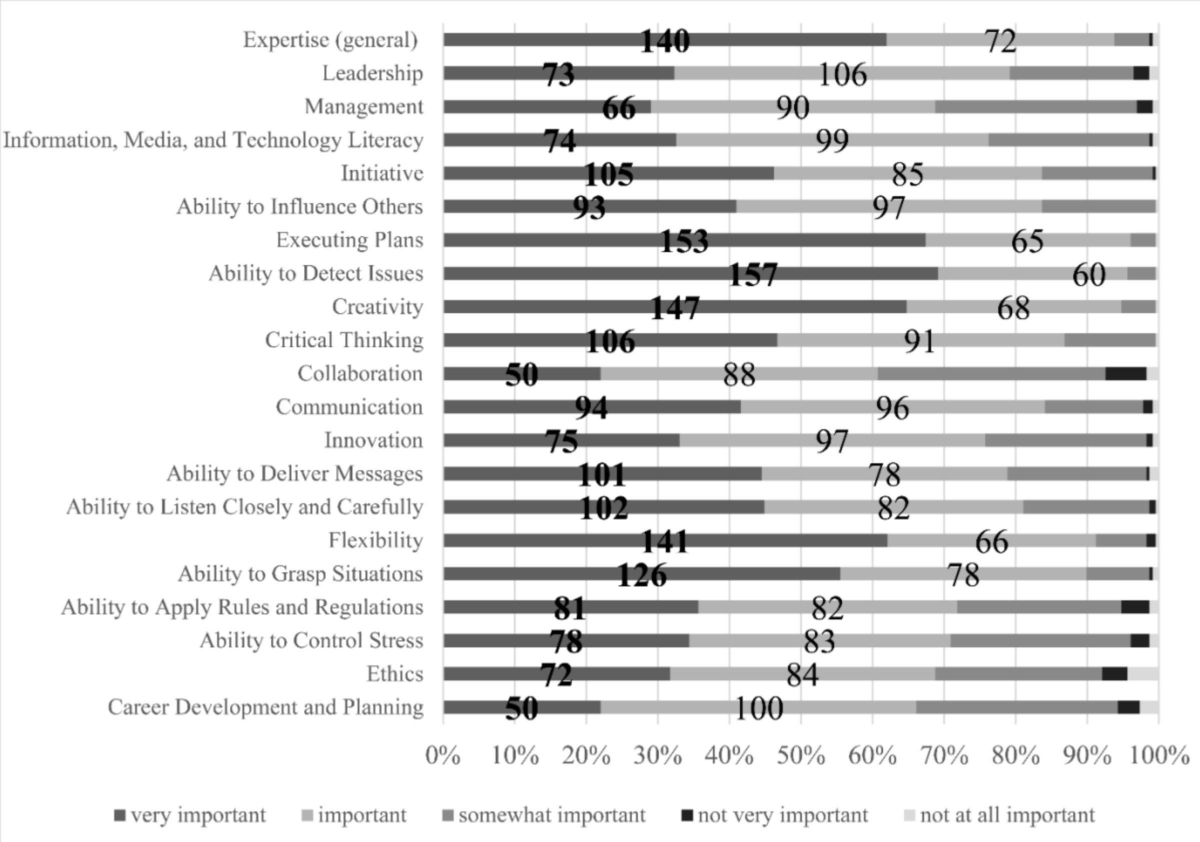

Figure 1. Results from Japanese respondents

CONCLUSION

This paper has focused on perceptions of required abilities within the STEM human resources community. No significant differences were found between Japan and Malawi for 5 out of the 21 ability elements. It was found that students from both countries believe that certain abilities (Listening Closely and Carefully to Information, Innovating Using Critical Thinking, and Disseminating Information Easily to Other People in Different Cultural Areas) are important, based on control stress.

However, the research has a number of limitations. First, it looks at data from only two countries (regions). It is therefore necessary to collect data from more countries. In addition, in the future, we will not focus on ideas and perceptions of these ability elements; it will be necessary to gather additional data and conduct further interview research with questionnaire respondents.

INVESTIGATING PERSPECTIVE-TAKING ON SOCIOSCIENTIFIC ISSUES AMONG JAPANESE PRIMARY SCHOOL STUDENTS

Sayuri Tokura[1], Etsuji Yamaguchi[1], Miki Sakamoto[1], Tomokazu Yamamoto[2], Shigenori Inagaki[1], Kazuya Wakabayashi[1], Motoaki Matano[3]

In recent years, socioscientific issues (SSI) have gained attention in the field of science education research. In the context of socioscientific reasoning, previous researchers suggested the importance of 'perspective-taking', which is one's ability to recognise and consider the diverse cognitive and emotional viewpoints of others. Some studies on SSI have targeted primary school students. However, no studies assessed primary school students' perspective-taking skills prior to SSI-based instruction. In this research, therefore, we assessed primary school students' perspective-taking skills before SSI-based instruction to provide basic data for instructional design. This research targeted 63 Japanese fifth-year (10- and 11-year-old) primary school students. Participants were assigned a decision-making task relating to electric cars, which is SSI in Japan. The descriptions written by the primary school students during the decision-making task clearly showed that these students had indeed already acquired perspective-taking skills. However, it was also clear that these skills were limited. In other words, although these students had obtained perspective-taking skills regarding their own positions and counter-positions, they had not yet learned to integrate these perspectives. These findings suggest that there is still room to improve the perspective-taking skills of Japanese primary school students. This research provides a method for assessing how primary school students engage in perspective-taking on SSI in science education. Further research is needed to examine whether the tasks and evaluation criteria from this study could be applied to the creation of tasks pertaining to SSI in other cultural contexts.

Keywords: socioscientific issues, primary school, elementary school, perspective-taking

THEORETICAL FRAMEWORK

Socioscientific issues (SSI) are social issues concerning science and technology, ethics, or morals that incite controversy (Sadler, Amirshokoohi, Kazempour, & Allspaw, 2005). SSI has gained attention in the field of science education research (Chang, Chang, & Tseng, 2010; Lin, Lin, & Tsai, 2014; Lin, Lin, Potvin, & Tsai, 2018).

In the context of socioscientific reasoning, previous researchers (e.g., Kahn & Zeidler, 2016) have suggested the importance of 'perspective-taking', which is one's ability to recognise and consider the diverse viewpoints of others (Sadler & Donnelly, 2006). Perspective-taking is important for socioscientific reasoning, because the ultimate goal of such a process is to engage in decision-making to resolve SSI. During the decision-making process, it is necessary to consider multiple perspectives and then compare, integrate, and develop them (Eggert, Ostermeyer, Hasselhorn, & Bögeholz, 2013; Fang, Hsu, & Lin, 2018; Sutter, Dauer, & Forbes, 2018). As perspective-taking requires a range of processes, it may be difficult for students.

Some research on SSI has targeted primary school students (Evagorou, 2011; Karpudewan & Roth, 2018; Papadouris & Constantinou, 2010). However, no research has assessed primary school students' perspective-taking skills prior to SSI-based instruction. In this study, therefore, we assessed primary school students' perspective-taking skills before SSI-based instruction to provide basic data for instructional design.

AIM AND RESEARCH QUESTION

The purpose of this study is to assess Japanese students' perspective-taking skills prior to SSI-based instruction. The research question is: Have Japanese primary school students already obtained perspective-taking skills before SSI-based instruction?

METHOD

Participants

This research targeted 63 Japanese fifth-year (10- and 11-year-old) primary school students.

SSI topic

The issue of subsidies for electric cars was chosen as the topic of the decision-making task for two reasons. First, the issue of electric cars is not unique to Japan. Rather, they are a global problem. The question of whether to promote electric cars is one of the typical SSI because it involves various socioscientific aspects including those related to the environment, economy, and public policy. Many countries have actively introduced and continue to introduce electric cars. For example, in 2016, over 750,000 electric cars were sold globally, and the cumulative number of electric cars worldwide exceeded 2 million (Next Generation Vehicle Promotion Center, 2017). However, the introduction of electric cars is influenced significantly by policy support. For example, policy support (evaluation of environmental performance, fuel efficiency regulations, and tax measures, based on local government measures) is still important for the smooth introduction of electric cars (Next Generation Vehicle Promotion Center, 2017).

Second, students are familiar with electric cars because Japanese fifth-grade students have the opportunity to learn about them in social studies classes. Students also learn about environmental issues in fourth grade. Therefore, the issue of electric cars is an appropriate topic for elementary school students with little social experience.

SSI decision-making task

Participants were assigned a SSI decision-making task relating to electric cars. Participants were given 45 minutes to complete this task.

They first learned about electric cars and the supporting and opposing opinions. Table 1 shows three socioscientific aspects related to electric cars, as well as supporting and opposing opinions for each of these aspects. The aspects set as the focus for this topic were 'convenience, the environment, and the economy'. The students studied the supporting and opposing opinions related to these aspects. Under the aspect of economy, the supporting opinion endorsed low fuel costs, while the opposing opinion highlighted that electric cars incur hefty expenses. Under the aspect of convenience, the supporting opinion was that it is easy to charge electric cars, whereas the opposing opinion was that it takes a lot of time to do so. Under the aspect of environment, the supporting opinion was that electric cars are eco-friendly, whereas the opposing opinion was that electric cars are not eco-friendly.

Then, they answered the SSI decision-making question, 'If you are the mayor of Town A, do you agree to provide subsidies for electric cars? In addition, as the mayor, what kind of proposals do you want to give to the residents? Write your opinion or proposal here.' Each student assumed the role of the mayor of the town and was asked to engage in decision-making on whether to provide subsidies for electric cars or not, and to provide grounds for his or her decision in writing.

Table 1. Three aspects of electric cars and opinions

Positions	Aspects	Opinions
Supporting	Convenience	It is easy to charge electric cars. The popularity of electric cars is increasing. Charging stations are increasing. If the use of electric cars increases because of subsidies, the number of charging stations will increase, and we will be able to charge electric cars more easily. Another major advantage is that you can easily charge an electric car at home, and send electricity from your car to your home during a power outage.
	Economy	Its low fuel costs. Fuelling electric cars costs less than half the cost of fuelling gasoline-only cars. Those who drive long distances every day can save on fuel costs. In addition, gas prices can quickly rise because of global conditions, so electric cars are economic for car users.
	Environment	Electric cars are eco-friendly. Electric cars emit half as much carbon dioxide as do conventional cars, and they emit no carbon dioxide while driving. This leads to less air pollution. As they are eco-friendly, we should subsidise and promote the use of electric cars.
Opposing	Convenience	It is not easy to charge electric cars. There 40% fewer charging stations than gas stations. While you can find charging stations in places other than gas stations, it takes time to find them. When the battery is running low, it can be problematic. Even if you find a charging station, it takes long for an electric car to charge and you may have to wait for other cars to finish charging. If you live in a condominium or an apartment, you cannot set the charging stations to suit your own convenience. For these reasons, electric cars are difficult to charge and inconvenient for car users, so we should not subsidise them.
	Economy	Electric cars are expensive to maintain. Although there is no gasoline charge, the purchase price is higher than that of a conventional car, even with subsidies. As they have large batteries, electric cars are larger than conventional ones, and are thus taxable and cannot fit in the parking space for small cars. People who want to charge their cars at home have to pay for the necessary equipment.

Environment	Electric cars are not eco-friendly. In Japan, electricity is mainly provided by thermal and nuclear power, so producing electricity to power electric cars does lead to carbon dioxide emissions. If subsidies are issued and the number of electric vehicle users increases, the electricity required to power the cars will increase and power plants must be expanded. Power plants pose several environmental problems, such as the disposal of spent fuel from nuclear power generation and the emission of carbon dioxide from thermal power generation.

Analysis

The descriptions written by the primary school students during the decision-making task were assessed. Building on the evaluation criteria of Sadler and Donnelly (2006), new evaluation criteria to measure the students' levels of perspective-taking was created. Based on these criteria, each description was categorised according to four levels of perspective-taking, from 0 to 3. Table 2 shows some examples of the descriptions written by students at each level.

Level 3 (multiple perspective-taking) meant that the students were able to state an opinion of the counter-position and proposals to integrate counter-position with their own positions and to solve SSI. Level 2 (plural perspective-taking) means that the students stated an opinion regarding the counter-position. Level 1 (single perspective-taking) means that the students only stated an opinion denoting their own position. Level 0 (non-perspective-taking) means that the students did not state an opinion. To ensure reliability, 20% of the descriptions were assessed independently by two coders.

Table 2. Examples of the descriptions written by students at each level

Level	Examples
3	*Example 1* I do not agree to provide subsidies for electric cars. Some say that it is easy to charge electric cars, and that it is eco-friendly *[supposing opinions]*. However, it is not always possible to find a place to charge or it is not eco-friendly *[opposing opinions]*. There are some suggestions for promoting electric cars. We will install more charging stations for electric cars. For example, we will install charging spots for electric cars at each gas stations *[a proposal]*. It is also necessary to secure electricity through power generation that does not emit carbon dioxide, such as wind power generation *[a proposal]*. Also, for people living in condominiums, I think it would be good to make a parking lot exclusively for electric cars in the area *[a proposal]*. The problem that charging takes a lot of time [would be] solved by increasing the number of charging ports in the car *[a proposal]*. *Example 2* I agree to provide subsidies for electric cars. A town issues a subsidy. There is an opinion that it takes time to find the location of the charging stations *[supposing opinions]*. In order to solve the problem, I think that we should draw up a map describing the location of the charging stations *[a proposal]*. For the opposing opinion that charging electric cars takes time, it is a good idea to expand the number of charging stations *[a proposal]*. This proposal also solves the problem of difficulty in putting in charging stations. While considering car charging, carbon dioxide emission fees are not zero *[opposing opinions]*. However, carbon dioxide emission rates are very low compared to conventional cars, and it can be said that this is eco-friendly *[supposing opinions]*. For this reason, towns should issue subsidies.

2	*Example 1*	
		I agree to provide subsidies for electric cars because, if a disaster occurs and the house loses power, you can send electricity from the electric car to the house to ensure safety *[supporting opinions]*. In addition, fuel costs are lower than those for ordinary cars. The price of gasoline is rising rapidly [supporting opinions], so I think it is better to switch to an electric car early. However, some people say that there are not many charging facilities, and that it is difficult to charge, and that the car itself costs more money *[opposing opinions]*. The popularity of electric cars has increased in recent times. The number of charging stations will increase accordingly *[supporting opinions]*. Considering fuel costs, if you use a car every day, electric cars are definitely economical *[supporting opinions]*. The car itself does not emit carbon dioxide at all, but more improvements are needed. For example, CO_2 is emitted from the factory, and it is not eco-friendly *[opposing opinions]*. However, the money and convenience are better than that of ordinary cars, so I will give residents a subsidy for electric cars.
	Example 2	
		I agree to provide subsidies for electric cars. Electric cars are not always good for the environment *[opposing opinions]*. However, I think there is no doubt that using electric cars can be better for the environment than using a gasoline car for a long time *[supposing opinions]*. The reason is that the total amount of carbon dioxide emissions that cause global warming, from the stage of making electricity to driving, is half. There are still some problems in charging *[opposing opinions]*, but as the number of users increases, it is expected that the number of charging stations will increase. So you can charge wherever you want to charge *[supposing opinions]*. Furthermore, if more people use electric cars, I think that the cost of cars and equipment can be reduced.
1	*Example 1*	
		I agree to provide subsidies for electric cars because they are eco-friendly *[supposing opinions]*. Electric cars emit less carbon dioxide, so we can prevent global warming.
	Ex*ample 2*	
		I do not agree to provide subsidies for electric cars. Town A does not issue subsidies, because it takes time to charge and you have to wait if another car is charging *[opposing opinions]*. Electric cars are bigger than conventional ones, so they are taxable and cannot fit in the parking space for small cars*[opposing opinions]*. It has major problems such as the disposal of spent fuel from nuclear power generation and the emission of carbon dioxide from thermal power generation *[opposing opinions]*. It is not environmentally friendly.
0	*Example 1*	
		I do not agree to provide subsidies for electric cars. If you have an accident, you will lose the security deposit money and the cost of charging the electric cars up to the point of the accident. Using electric cars is not good for residents of apartments. I think that using an electric car costs more than before. It is better to use a gasoline car every day. To put it simply, there are more disadvantages to using an electric car. This is one of the socioscientific issues *[there are no supporting or opposing opinions]*.

RESULTS

Table 3 shows the distribution of students for each level. Level 3 (the highest level) contained a smaller number of students, or 23.8%. Table 3 shows that before SSI-based instruction the students were able to achieve Level 2. However, only a few were able to reach Level 3.

Table 4 lists the aspects stated by students as grounds for their decision (supporting or opposing). Of the 63 students, 39 (62%) supported subsidies for electric cars, while 24 (38%)

were opposed. Table 4 shows that when engaged in decision-making, it was easier for the students to state an opinion from the position they considered as their own, rather than to state an opinion from a counter-position (Nussbaum & Kardash, 2005).

Table 3. Distribution of primary school students for each level

Level	Explanation	N (%)
3	*Multiple perspective-taking* The student is able to state an opinion about the counter-position and integrate it with an opinion (an proposal) based on his/her own position.	15 (23.8)
2	*Plural perspective-taking* The student states an opinion of the counter-position.	21 (33.3)
1	*Single perspective-taking* The student only states an opinion of his/her own position.	24 (38.1)
0	*Non-perspective-taking* The student does not state an opinion.	3 (4.8)

N=63.

Table 4. Aspects stated by students during decision-making

Aspects	Agree (*N*=39) (%)	Disagree (*N*=24) (%)
Supporting opinions		
The aspect of convenience	20 (51)	3 (13)
The aspect of economy	13 (33)	4 (17)
The aspect of environment	27 (69)	4 (17)
Opposing opinions		
The aspect of convenience	14 (36)	17 (71)
The aspect of economy	13 (33)	14 (58)
The aspect of environment	18 (46)	20 (83)

N=63.

DISCUSSION OF FINDINGS AND IMPLICATIONS

Our assessment clearly shows that the Japanese primary school students involved in this study had already acquired perspective-taking skills. However, it was also clear that these skills were limited. Although these students had obtained perspective-taking skills regarding their own positions and counter-positions, they had not integrated these perspectives. These findings suggest that there is still room to improve the perspective-taking skills of Japanese primary school students.

In the decision-making process, it is necessary to consider multiple viewpoints, and compare, integrate, and develop them. Fostering these complex perspective-taking skills in elementary school students will lead to better decision-making skills (Eggert et al., 2013; Fang et al., 2018; Sutter, Dauer, & Forbes, 2018).

This study provides a method for assessing how primary school students engage in perspective-taking on SSI in science education. Further research is necessary to examine whether the tasks and evaluation criteria from this study can be applied to the creation of tasks pertaining to SSI in other cultural contexts.

IDENTIFYING EVERYDAY DECISION SITUATIONS OF LEARNERS IN SCIENCE EDUCATION

Laurence Schmitz[1], Prof. Dr. Christiane S. Reiners [2]
[1]University of Cologne, Cologne, Germany
[2]University of Cologne, Cologne, Germany

According to the concept of Scientific Literacy, students should be empowered to recognise scientific issues in order to make critical decisions by using scientific knowledge. However, results of a previous study reveal that students do not even recognise open decision situations with a scientific issue in everyday life. Therefore, they need to be supported in order to be able to link those situations to appropriate content in chemistry classes. For this purpose, the "decision diary" tool was developed. It aims to make them aware of their everyday decision situations with scientific issues as well as enable them to identify decision situations in which they are willing to adopt new evidence-based decision strategies. This provides the opportunity to initiate fruitful learning processes in students on the basis of the conceptual change theory, since the tool reveals conflicts in everyday decision situations and can thus be used to develop and plan authentic interventions for chemistry courses. First results indicate that the "decision diary" is an appropriate tool for identifying students' decision situations with scientific issues in their everyday lives.

Based on these results, our research project tries to use the identified decision situations for science teaching. The decision diary was tested in 4 chemistry classes with students of different age groups and from different school forms. Data was collected with document analysis of the decision diaries, semi-structured interviews and open-ended questionnaires and analysed by qualitative content analysis. The results so far indicate that the decision diary provides the opportunity to identify open decision situations with cognitive conflict among students for science education.

Keywords: Decision Making, Conceptual Change, Scientific Literacy

INTRODUCTION

PISA 2006 defines Scientific Literacy as *„the capacity of students to identify scientific issues, […] and make decisions in life situations involving science and technology."* (OECD, 2007, p.33). Sadler & Zeidler (2009) criticise that the items of the PISA study are embedded in a backstory that is nonrelevant to the expected answer. This statement differs from the interpretations in the framework of socio-scientific issues, which deal with life-like contexts related to science and affect other domains like psychology or sociology.

Looking at everyday contexts, students rarely use scientific decision criteria (cf. Table 1), but are rather used to habitualised decision routines (Menthe & Parchmann, 2015; Sander & Höttecke, 2016). As an example, the decision tree of a student (see Figure 1) shows her habitualised decision strategy for buying a deodorant. The student says that she currently chooses her deodorant based on the appearance of the packaging. Most important for her is a pink packaging. If it is not pink, she will not take it. Then she smells the deodorant and finally looks at the price. These habitualised routines are a product of her history of socialisation (Bourdieu, 2000) and usually prove to be sustainable in everyday life. And these routines turn out to be very persistent and new arguments that do not fit into the existing decision strategies are rejected out of hand (Chinn & Bewer, 1998). This leads to the hypothesis that students do not use scientific knowledge to make personal decisions in their everyday lives in which scientific knowledge is necessary.

Table 1. Summary of possible decision criteria (Aikenhead, G. S. (1985); Halverson, K. L. Siegel, M. A., & Freyermuth, S. K. (2009); Heitmann, P. (2012); Uskola, A., Maguregi, G., & Jiménez-Aleixandre, M. (2010)).

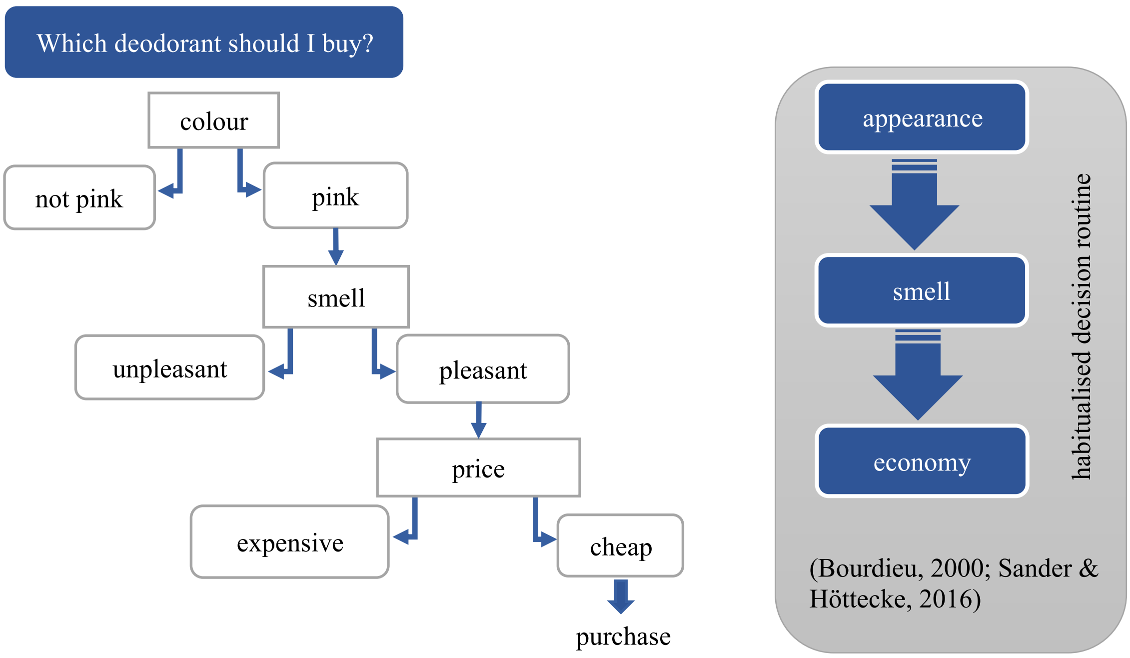

Figure 1. Decision tree of a student to buy deodorant.

But what insights do psychological theories provide in order to break through these habitualised decision making routines, to enable students in the sense of Scientific Literacy to become rational decision makers in everyday life situations?

Kahneman & Tversky (1979) established a decision theory based on two systems: unreflected decisions are assigned to "System 1". It makes decisions fast, unconscious and therefore is susceptible to mistakes (Kahneman, 2011). In everyday life “System 1” helps to decide quickly (Kahneman, 2011). If reasons for the decision are asked for, arguments are generated *post hoc* so that decision routine can be justified. “System 2” is activated if an irritation occurs in “System 1”. Thereupon a conscious and slower process is initiated. The cognitive processing of decision making requires attention and is often perceived as tiring and exhausting. If the complexity of the decision situation is perceived as too high or ineffective, this leads to the abandonment of the process in "System 2" and the routine decision strategy is maintained.

According to this theory, decision situations that lead to an irritation in “System 1” must be found in order to activate “System 2”. Thus, students must be supported in adopting complex scientific decision criteria so that they do not fall back into routines due to excessive demands. In some respects, similarities to the *conceptual growth theory* (Duit & Treagust, 2003) are already obvious. Based on this, dissatisfaction with existing decision strategies is required to make students ready fot the adoption of new concepts. Therefore, the motivation is to develop a tool that evokes dissatisfaction in everyday decisions and makes it tangible for science education.

This gives rise to the research question: In which way is the developed instrument “Decision Diary” suitable to initiate fruitful learning processes in the sense of conceptual change theory?

In order to clarify the general research question, it can be divided in three questions:

1. Is the decision diary an adequate instrument to identify student relevant decision situations? **(Diagnosis)**
2. How can lessons be planned along the decision diaries to provide students with the chemical content they need to decide? **(Structuring)**
3. In which way can the occasions of the decision diaries, together with the necessary expertise, help students make informed decisions? **(Intervention)**

This paper focuses on answering question 1 by considering the following sub-questions:

- How do students work on the task of the decision diary?
- What kind of questions are revealed by the decision diary entries?
- How complex do students perceive the self-chosen decision situations?
- Has the developed tool potential to uncover dissatisfaction with decisions?

The “Decision Diary” tool

The decision diary consists of a request and detailed tasks (cf. Figure 2). The tasks encourage students to identify everyday situations with chemical relevance. After identification, the students must reflect on whether a decision situation is of importance and whether it personally concerned them. During the photographic decision diary, this cognitive process is accompanied by the development of a photo that illustrates the decision situation. In order to meet the demand for individual support, a drawing decision diary was developed in addition to the photographic decision diary.

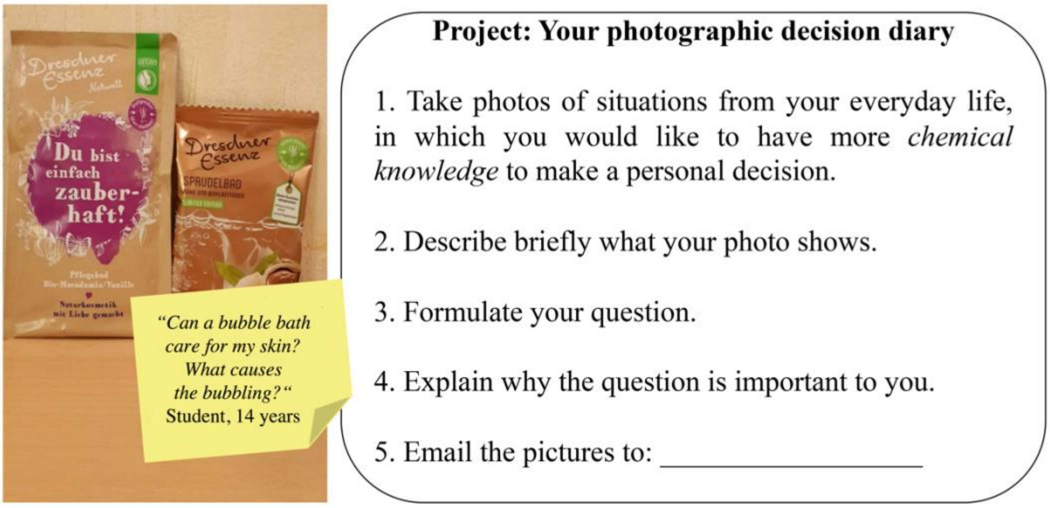

Figure 2. The decision diary tool with a student example. [German quotations were translated by the author.]

RESEARCH DESIGN AND METHODOLOGY

The diagnostic tool was tested in four chemistry classes with students of different age groups and from different school forms. The procedure for data collection is shown in Figure 3. Overall 53 students have participated so far. In each class three students were selected for interviews (n=9) according to the type of processing in decision diary. Participation in the interviews was voluntary. Apart from the semi-structured interviews, empirical data was collected by using open-ended questionnaires and decision diary entries created by the students. Thus, the decision diary serves a double function: as a method to create communication occasions for individual competence development in the chemistry class and as an instrument for collecting empirical data. In addition to the methodological triangulation (Flick, 2017) between interviews, questionnaires and document analysis (Denzin, 2011) of the decision diaries, a theoretical triangulation should contribute to a widening of perspective. Therefore, psychological theories of decision making (Svenson, 1966), motivation (Heckhausen & Rheinberg, 1980) as well as sociological theories (Bourdieu, 2000) were triangulated.

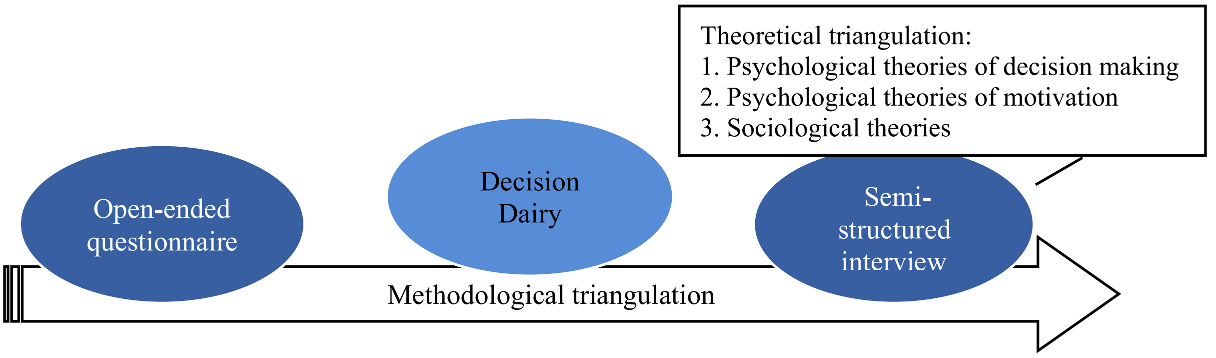

Figure 3. Study design.

So far, data of 136 decision diary entries from 53 students and semi-structured interviews (n = 9) have been analysed. The decision diaries were analysed inductively by qualitative content analysis (Mayring, 2015). The interviews were also analysed inductively and additionally a deductive category assignment based on theories of the complexity of decision situations (Pfister et. al., 2017) was applied. In this theory, a decision situation is characterised by categories "options", "level", "frequency", "information access", "consequences" and "effects" (cf. Table 2). Each of these categories is divided into a lower and a higher complexity. For example, "*Options*": The complexity of a decision situation can be reduced if the number of alternatives is already limited by external factors (*"Options given")*. It becomes more complicated for the decision maker if the options are open and have to be generated themselves (*"Options open")*. All self-chosen decision situations (n = 20) were analysed based on these categories. In the last step, the complexity was scaled from one-dimensional to multidimensional decisions. In the case of a one-dimensional decision, the students did not perceive any category as complex. In a two-dimensional decision a category with a higher complexity was described. It ends up in a multidimensional decision where all categories were perceived as complex.

Table 2. Complexity of decision situations according to Pfister et. al. (2017). Lower complexity is shown by light grey and higher complexity by dark grey.

Decision situation												
Category	*Options*		*Level*		*Frequency*		*Information access*		*Consequences*		*Effects*	
Complexity level	given	open	single	multi	repeated	unique	text-based	experience-based	certain	un-certain	personal	social

RESULTS

The analysis focuses on the processing of the task and the self-chosen decision situations of the students.

Evaluation of the decision diaries

Referring to the first sub-question (How do students work on the task of the decision diary?), three categories were identified inductively (cf. Table 3): The *information level*, on which students gather factual information and the entry does not indicate whether a decision is made. The *judgement level*, where different options are compared on the basis of a specific aspect and finally the *decision level*, where students name concrete alternatives for decision.

The Inter-Coder reliability between two coders for this category system (see Table 3) is $p_0 = 0.85$ while the coefficient κ (Brennan & Prediger, 1981) is 0.77.

The results reveal that most students argue on the *information level* (cf. Table 2). Only 39 entries show concrete decision situations with different options to choose from. This raises the question of whether the students fail to recognise a decision situation with chemical relevance in their everyday lives or whether decision situations are hidden behind *information* or *judgement level*. Therefore, it is necessary to take a closer look at the decision diaries with the interviews and ask what kind of questions are revealed.

Table 3. Number of selected processing levels per decision diary entry.

Category	**Definition**	**Representative quotes**	**Entries (n = 136)**
Information level	Entries that gather only factual information without being linked to a decision or evaluation question. Recognisable by interrogative words (how, what, where, why) and verbs like "interest" and "know".	*"Why is aluminium salt in deodorant?"*	63
Judgement level	Entries that ask for an assessment of different options according to a specific aspect, e.g. health, without necessarily leading to an action. Identifiable by better, healthier, more effective, etc.	*"Are mouth-washes with alcohol better for the teeth?"*	34
Decision level	Entries in which concrete options (alternatives) are already presented by the students and should lead to an action. To be recognised by either… or…, rather x or y, which.	*"Which drink should I buy?" (Multi-vitamin juice vs. Sprite®)*	39

Evaluation of semi-structured interviews

In order to clarify this sub-question (What kind of questions are revealed by the decision diary entries?), categories were formed inductively (Mayring, 2015) from 9 interviews with 23 decision diary entries. In total *four categories* were set up, decisions which have not yet been made (*open*), decisions already made (*taken*), no own decisions (*external*) and only one factual information question without decision-making interests (*none*). The majority of questions (cf. Figure 4) concern open decision situations in which students are still ready for new options or decision criteria. In the second most common category students have already made a decision in favour of an option on the basis of habitualised decision strategies (Bourdieu, 2000) and they just want a scientific justification.

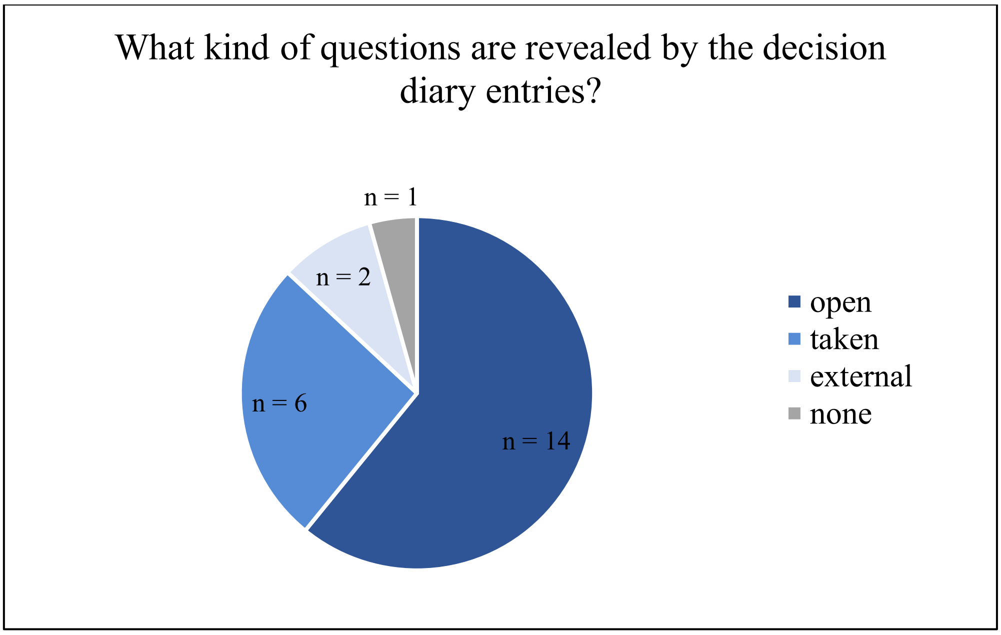

Figure 4. Analysis of 9 interviews with 23 decision dairy entries (n = 23).

After identifying student's decision making situations (*open* & *taken*), their perceived complexity was determined. Due to the task description, it can be expected that particularly *"repeated"* decision situations *(lower complexity)* will be submitted in which students are *"uncertain"* about the consequences *(higher complexity)*. As can be seen from Table 4, 19 of 20 decision situations are "*repeated"* in everyday life. In addition, in 15 of 20 situations students say that they are *"uncertain"* about the possible consequences of their decision. In many cases, students only focus on personal effects (n = 14) when making decisions in everyday life, but not on social ones (n = 6) such as sustainability or ecological considerations. As a result, neither one-dimensional (no category with higher complexity) nor multi-dimensional (all categories with higher complexity) decision situations are made tangible by the tool (see Table 5). Students perceive mainly a medium level of complexity, which can possibly protect them from being overwhelmed in "System 2" and thus from falling back into routines from "System 1" (Kahneman, 2011). In class, students can be supported in progressively becoming aware of the entire complexity of an everyday situation.

Table 4. Perceived complexity of self-chosen decision situations.

Category	*Options*		*Level*		*Frequency*		*Information access*		*Consequences*		*Effects*	
Complexity level	given	open	single	multi	repeated	unique	text-based	experience-based	certain	un-certain	personal	social
Decision situa– tions (n = 20)	18	2	14	6	19	1	6	14	5	15	14	6

Table 5. Complexity of decision situations scaled from one-dimensional to multidimensional.

	one-dimensional					multi-dimensional
Number of categories with higher perceived complexity level	0	1	2	3	4	5	6
Decision situations (n = 20)	0	3	9	7	1	0	0

The question remains whether the tool has the potential to uncover dissatisfaction with decision making situations. In 6 out of 9 interviews, the students expressed dissatisfaction with the decision situations that became tangible through the decision diary. When asked whether the students' current decision strategy is successful in achieving his or her goals, they answered for example as follows:

> "Well I think it's more 'no' than 'yes', but somehow I'm caught between, because I can't inform myself properly, because I don't know whether the gas is harmful or not." (Student, 14 years)

Here the student expresses her dissatisfaction with both her existing chemical knowledge and her competence.

CONCLUSION AND DISCUSSION

In summary, it can be stated that the decision diary leads to different levels of processing (*information*, *judgement* and *decision level*). In most cases open decision situations are submitted, which are perceived by students with a medium level of complexity. Apart from that, it turned out that the students do not perceive everyday decision situations in their entire complexity, but ignore certain aspects such as sustainability. Furthermore, the instrument seems to actually lead to uncertainty in existing decision making situations and even to dissatisfaction with one's own knowledge and competences. This promises a fruitful learning opportunity.

According to these results, the decision diary mostly seems to be an adequate instrument to make the decision situation of students tangible for teaching purposes (**Diagnosis**). However, it should be noted, that qualitative research design only permits the development of theories. The sample size does not allow any generalizable statements at this point. In the long term, quantitative methods will have to be used to support the theories developed with larger samples.

In order to clarify the overarching research questions, the next step is to examine whether the decision situations can be used in chemistry classes. This raises the question of how lessons can be planned based on the questions of the decision diaries (**Structering**) in order to provide students with the chemical knowledge they need for their decisions (**Intervention**).

ANALYZING EPISTEMOLOGICAL, ONTOLOGICAL AND AXIOLOGICAL COMMITMENTS IN STUDENTS' SPEECHES AS THEY DISCUSS ON MEDICINES AND SELF-MEDICATION

Bruna Herculano da Silva Bezerra[1], Edenia Maria Ribeiro do Amaral[2]
[1]Federal University of Pernambuco, Recife-PE, Brazil
[2]Rural Federal University of Pernambuco, Recife-PE, Brazil

This work is part of a broader doctoral research which aimed to identify and understand relations among contexts, common sense and scientific knowledge in studies on socio-scientific issues (SSI). *Here, we focused our analysis on epistemological, ontological and axiological commitments implied in the students' speeches as they are engaged in an SSI approach on medicines and self-medication, in chemistry classes. Research on SSI was considered to plan a teaching and learning sequence (TLS) on the theme and the theory of conceptual profile supported data analysis looking for the heterogeneity of thinking in the students' speeches. A chemistry teacher and 32 students (year 11), in a Brazilian public high school, participated in this investigation. The students were engaged in TLS activities, such as: reading, solving cases, discussing in small groups, analyzing package inserts and responding questions. Eight classes (100 minutes each one) were audio and video recorded, relevant episodes were extracted from the classes and transcripts were analyzed in order to identify thematic items, semantic relations among them and to characterize epistemological, ontological and axiological commitments implied in students' speeches. In this work, we present data from episode 7.2, extracted from the class 7. Results pointed that scientific knowledge was predominant in the students' speeches, in the two last classes, and they did not make position in favor of self-medication, but they considered exceptions in this practice for people who has no easy access to medical assistance, bringing together epistemological and axiological commitments. Different thematic items related to self-medication and medicines were connected by different semantic relations, for instance, medicines/therapeutic action, medicines/side effects, medicines/substance, medicine/active component, self-medication/ needs, self-medication/medical assistance access, self-medication/overdose and others. Despite scientific knowledge was predominant in the students' speeches, it did not seem to be a guarantee for the use of epistemological commitments to guide their positions as most of them declared to practice self-medication. Different ways of thinking emerged in the students' speeches and it can be representative of their heterogeneity of thinking and they assumed different commitments as faced to diverse aspects of the SSI. Common sense or scientific knowledge seemed to be applied by the students depending on the context in which the ideas or models are more appropriated.*

Keywords: socio-scientific issues, heterogeneity of thinking, medicines and self-medication

INTRODUCTION

In this work, we aimed to analyze epistemological, ontological and axiological commitments implied in students' speeches as they engaged in discussions on medicines and self-medication in chemistry classes. The theory of conceptual profile supported the identification of epistemological, ontological and axiological commitments implicated in different modes of thinking, expressed by students in the classroom discussions, which enable us to characterize the heterogeneity of thinking in science classrooms. Research on SSI help us to plan specific strategies to address the theme on medicines and self-medication considering scientific, social and cultural aspects, among others, according to requirements for an SSI approach.

According to the conceptual profile theory (Mortimer et al, 2014), an individual can present different modes of thinking and ways of speaking on a specific concept, which are represented by zones constituted from different epistemological, ontological and axiological commitments. The conceptual profiles zones can be considered as a pool of ideas that characterize distinct worldviews, which are used to understand and to represent the reality. Each zone can be associated with specific contexts in which they make sense. From this perspective, science classrooms are a complex social place of interactions between individuals, who bring social discourses circumscribed in diverse contexts, constituting the heterogeneity of verbal thinking (Tulviste & Hall, 1991; Wertsch, 1988) as a starting and arrival point for plurality in science classes. According to Tulviste & Hall (1991), the heterogeneity of verbal thinking implies that in any culture, for any individual, there are not only a unique, homogeneous ways of thinking on a specific concept. Wertsch (1988) argued that different ways of thinking are somehow articulated to the genetic domains (phylogenesis, sociocultural and ontogenesis) proposed by Vygotsky, considering the influence of the context in the development of ideas and concepts by individuals. According to Mortimer et al (2014), the heterogeneity of thinking is inevitable as teachers and students are engaged in teaching and learning scientific concepts in the classroom and it should be expressed in different ways of speaking on content addressed in classes.

In this work, even though we did not make a proposal of specific zones for a conceptual profile, according to the methodological requirements from the theory, different ways of thinking on the studied theme were identified and characterized by epistemological, ontological and axiological commitments. This could be a start point to propose a conceptual profile in further work, considering conceptual profiles as models of different modes of seeing and conceptualizing the world used by individuals to signify their experience (Mortimer & El-Hani, 2014). In science classrooms, different ways of thinking and speaking emerge in the discussions, and teachers could recognize some culturally relevant ideas, which are appropriate in contexts and spheres of life for students and include these ideas in the making meaning process for scientific concepts. In putting together ideas from social and scientific contexts, teachers address not only problems, solutions and knowledge associated to each context, but they also bring all motivations, values and goals related to the activities addressing scientific subjects, and epistemological, ontological and axiological commitments could be identified in the students' speeches (RODRIGUES, 2009, p. 24).

In school context, the process of meaning making for scientific knowledge should help students to represent and to understand reality in its complexity by coming across different senses and meanings that scientific concepts can acquire in different contexts. Students could be invited to establish relationships among different forms of knowledge and to deal with diverse perspectives on situations and phenomena. We consider that socio-scientific issues (SSI) can be part of didactic strategies that aim to broaden the classroom discussion about scientific knowledge considering the emergence of different ways of thinking that they could make to arise. According to Martinez Pérez (2012), SSI include themes and controversies related with scientific and/or technological knowledge that promote impacts on society. Socio-scientific issues are controversial social issues with conceptual and/or procedural links with science. They can be characterized as open problems without clear solutions, with multiple possibilities of resolution (Sadler, 2004). These issues cover the formation of personal and social opinions and judgments, in decision-making processes that imply in the development of values and ethical aspects and are related to social problems in local, national and global levels (Ratcliffe and Grace, 2003). According to the authors, an SSI approach has potential to explore different contexts in classrooms by addressing political, ideological, cultural and ethical aspects that involve contemporary science. In an SSI approach, it could be considered aspects related with the nature of science and technology, decision making, ethical-moral reasoning, socio-critical reconstruction and actions adjacent to the interactions of the STS movement, for example, formation for citizenship. In this way, we argue that SSI can support teachers to explore different dimensions of human life as they are teaching scientific contents, provoking students to express ideas implicated with their personal experience, in which they assume different epistemological, ontological and axiological commitments.

An SSI approach could enable teachers to contextualize scientific concepts marking different position to the traditional school teaching, in which scientific concepts are presented as unquestionable constructs that could be applied to any context as hegemonic response to questions and challenges faced by the students. We believe that SSI could lead teachers and students to search and discuss scientific models and social experiences that are not necessarily reproducible for any situation, considering the contexts to approach and solve problems. In this way, science learning would involve exploring and understanding different perspectives and views on concepts and how they could be useful to explain and solve situations and problems in diverse context. According to Rodrigues & Mattos (2007), it is important to point out the domains of validity and limits of scientific knowledge when it often does not replace common sense. The complex relations between scientific concepts and contexts open space for the expression of the heterogeneity of thinking, and different modes of thinking can be identified from different epistemological, ontological and axiological commitments assumed by the individuals.

In this investigation, we consider that science teaching and learning implies to be involved in a dynamic interrelationship between common sense, cultural and personal beliefs/ideas and scientific concepts. It does not mean that we expect to convert one into the other, or substitute one by the other, rather we look for promoting dialogue, an articulation between different points of view, in order to establish relations among different ways of thinking, contributing to build a plural knowledge. We believe the conceptual profile theory can help us to understand the process of conceptualization in science teaching and learning by constituting relations among different forms of knowledge. In this sense, the students were invited to study and discuss on medicines and self-medication in chemistry classes, bringing an important social issue present in their lives. Different ways of thinking on medicines, substances, and self-medication, side effects, among others were discussed in the classes, and epistemological, ontological and axiological commitments were identified in the students' speeches.

METHODOLOGY

This work is a qualitative research, part of a broader doctoral research which aimed to identify and understand relations among contexts, common sense and scientific knowledge in studies on socio-scientific issues (SSI). In this work, the purpose was to analyze epistemological, ontological and axiological commitments implied in the students' speeches as they are engaged in an SSI approach on medicines and self-medication, in chemistry classes. Research on SSI was considered to plan a teaching and learning sequence (TLS) on medicines and self-medication and the theory of conceptual profile supported data analysis focused in the heterogeneity of thinking in the students' speeches.

The investigation involved one chemistry teacher and 32 students (aged 16-18), in year 11, in a Brazilian public high school. After short discussions on SSI approaches, a TLS was planned by the teacher with support of the first author in this paper. The students were engaged in activities such as: reading, solving cases, discussing texts and situations in small groups, analyzing package inserts and responding questions, as showed in the table 1.

Table 1: TLS Design according to the 5Es model proposed by Patro (2008)

Teaching and Learning Sequence - Medicines and self-medication		
Content: Organic Chemistry – Functional groups - identification of compounds and molecular structure.		
Aims: Characterizing functional groups from studies on the theme. Analyzing medicines composition, presence of substance in generic, similar, original and natural medicines. Understanding different types of medicines and drugs. Analyzing controversial issues involving medicines and self-medication.		
SSI proposed: Is self-medication a public health problem or a solution in face to public health precariousness? Are there controversies regarding the use of generic, manipulated, natural or original medicines?		
Phases (5Es)	**Activities**	**Classes**
Engagement	Questionnaires to raise initial conceptions and the introduction of the theme	Class 1
Exploration	Video exhibition and debate: The intelligence pill. Questions for debate: is it right to take medicines on your own, even though it promises benefits as we saw in the video? Is it possible that you take the "intelligence pill", in some occasion? Why? What would be the benefits and risks? Do all medicines bring benefits or healing to humans? What are substances? And what are molecules? After video, the students read a report on British BBC journalist who used the intelligence pill to test it.	Class 2 (Episode 2.1)
Explanation	Expositive classes to discuss on chemical concepts - substance, molecule, drug, medicine, active ingredient, origins of medicines. Reading the text: "On the Chemistry of Medicines, Drugs and Remedies" (Barreiro, E.J.; Rodrigues, C.R., 2001). Identification of functional groups and structural formulas in medicines often used by the students.	Classes 3, 4, 5
Elaboration	Group activity: reading package inserts of generic, similar and original medicines and draw up a panel with the main information about them - among others, active components, substances and functional groups. Question for debate: are there differences between original, generic or similar medicines? What? Presentation of the results with the large group.	Class 6
Evaluation	Students working in small groups: solving a case study – Bianca's case. Resolution of the two questions addressing SSI.	Classes 7-8 (Episodes 7.2-8.3)

An overall of 8 classes (100 minutes each) were audio and video recorded and transcripts were analyzed from episodes. Three relevant episodes were extracted for analysis: [2.1] Introducing discussion on self-medication after exhibition of the video "The Intelligence Pill"; [7.2] Discussion on self-medication using a case study and [8.3] Discussion on chemical characteristics and properties of medicines and human health. In this work, we present the analysis and discussion of data extracted from episode 7.2.

The students' speeches were analyzed starting from the identification of thematic items and semantic relations (Lemke, 1997) established among them by the students, and epistemological, ontological and axiological commitments were identified from semantic relations. From the ways of speaking, we identify modes of thinking, taking into account ideas from Mortimer and Wertsch (2003). The authors considered that different modes of thinking are interwoven with different ways of speaking characterized in terms of social languages and discourse genres (Bakhtin, 1981, 1986). They refer to Bakhtin as he states that heterogeneity of speech is related to discourses comprising different social voices. The voices are considered as specific points of view about the world, the ways of conceptualizing the world in words, specific perspectives of the world - each one characterized by its own objects, meanings and values. As such, they can all be juxtaposed to one another and coexist in the consciousness of real people. To identify commitments assumed by the students, we considered scientific or formal knowledge (epistemological), the nature of objects addressed by them (ontological), values and emotional features (axiological) implicated in their speeches as they discuss the SSI.

RESULTS AND DISCUSSION

In general sense, during the classes, we observed most of the students became progressively aware on chemicals aspects related to medicines and they engaged positively in discussions on self-medication, among others. In data analysis, our main point was to capture movements in the students' speeches that could evidence changes in commitments assumed by them as they expressed ideas or positions on the theme. In the beginning of TLS, the students discussed on medicines and self-medication and expressed ideas related to their personal experiences (classes 1-2, see table 1). Most of their ideas were expressed using everyday language, mainly supported by commonsense knowledge, and/or they reproduced information on the theme broadcast by communication media, and axiological commitments were more evident in the students' speeches. In this occasion, we realize that students did not have a well-built opinion about the risks involved in self-medication, as they considered as natural to take medicines by their own. In the classes 3, 4, 5 and 6, the students were engaged in activities to read texts, discuss and solve questions considering chemical and human health aspects related to this theme. In the classes 7 and 8, they brought together different ways of thinking in order to solve a case and questions posed by the teacher.

In class 7, in small groups with mediation of a preservice teacher acting as research assistant, the students were asked to solve a case study which brought the follow situation, in summary:

A young student, Bianca, was immersed in a hard routine of studies for exams. She often felt headaches, a problem that she had since early childhood. She had no time to seek for medical assistance and always took medicines without medical consultation (self-medication). Then, she always sorted and took medicines on their own considering publicity, friends advice or commonsense knowledge (Neosaldina®,

Sonridor®, Tylenol®, dipyrone), and her health problem never has been solved, instead of, headaches have become more frequent.

The students were invited to analyze and discuss the case guided by questions such as: what chemical substances and properties are present in some popular medicines used by Bianca? Are these medicines efficient to relieve headaches? Are they efficient to everyone indistinctly? Are you in favor of self-medication? If positive, in which situations or conditions it could be useful? Do you think there are benefits and risks involved in self-medication? The case brings a situation in which students could be involved in everyday life. Self-medication is a social problem in Brazil as in other places around the world. To support groups' discussion, the students were asked to read a text entitled "What is self-medication: causes and consequences", and the teacher made available cards, elaborated by the researcher (first author), with information on different commercial medicines often used for headaches, and infographics extracted from advertisement on medicine for relieving headache. It was requested that groups discussed ideas in order to answer the questions and make position about Bianca's case. Below, we show a piece of Episode 7.2, with discussion involving the preservice teacher (PT) and the students (S1, S2, S4), in a small group.

Episode 7.2 (piece) **:** Discussion on self-medication using a case study

1	S1: Other question we have here is ... Bianca has no time to seek medical help, in such case self-medicating would be correct? Why?
2	PT: Now, let's look at self-medicating in the texts you have read, the question is...
3	S1: In this case, self-medicating would be a solution or a problem?
4	PT: Come on, for Bianca is self-medication a solution or a problem?
5	S2: It would be a problem
6	S4: In her situation, if she doesn't have an easy access to a hospital or health clinic, for her, (self-medication) would be a solution because it would solve her problem.
7	PT: But let's see, she's been self-medicating for a while.
8	S2: Since her childhood
9	PT: So, in this case, self-medicating by taking Tylenol® or something else would be a solution? It works?
10	S4: It would be a problem, in my opinion, it would be a problem, because she already ...
11	PT: Tylenol is another medicine, let's look now at Neosaldina®, Sonridor® and dipyrone sodium, let's see the active ingredient to check the medicines she was taking, if they have the same active ingredient - is it the same or not?
12	S4: The active ingredient in Tylenol is acetaminophen. The active ingredient of dipyrone is itself.
13	S1: The active ingredient in Sonridor® is acetaminophen and caffeine.
14	S4: In Neosaldina® the active ingredient is dipyrone, caffeine and isometheptene mucate and for Sonridor ® is paracetamol and caffeine, and Tylenol® is just paracetamol.
15	PT: Can you guys see if you have the same active ingredients?
16	S1/ S4: Neosaldina® and Sonridor® have caffeine but none of the others (has).
17	PT: Let's look at the functional group, because we need to see if they have some components or not, if their active component is the same. There are four, Neosaldina®, Sonridor®, Sodium Dipyrone, and Tylenol®. We need to see if they are the same medicine or not, if they have the same active component.
18	S4: They are not the same medicine. They do not have the same active principle
19	S1: So that's why in my opinion it (self-medication) wouldn't be a solution for her, because she was already going to have taken three (different) medicines.
20	S4: They don't have the same active ingredient, but the classification or action is the same for them, which is to reduce fever, analgesic... I say an antipyretic that reduces the...
21	S2: Reducing body temperature
22	S4: Analgesic, in case, relieves pain but not fever
…	(…)
54	S1: So everyone comes to a consensus that she self-medicated would be a problem. Because it would be the accumulation of another medicine with the same active ingredient.
55	All: Yes

56	S1: So, it would be a problem, it wouldn't be a solution

In episode 7.2, the students used scientific arguments to analyze the case, going beyond personal experiences, and they considered that self-medication could be a problem that involves risks. It is interesting to highlight the two different positions assumed by the student S4, as he considered self-medication as a solution (turn 6) and then as a problem (turn 10) for Bianca. In general sense, we verified that students were able to identify chemical substances and active components in the medicines taken by Bianca, and they used scientific knowledge to understand relations between properties and therapeutic effects for them, in order to decide about self-medication as solution or problem for her case. Their conceptions on self-medication seemed to be wider in comparison to they expressed in episode 2.1, as self-medication was considered as something natural. In episode 7.2, the students seemed to assume epistemological commitments to make final decision on the questions proposed in the case (turns 54-56), although axiological commitments also were assumed considering controversial aspects related to the studied case involving Bianca's needs, conditions and health.

During classes 7 and 8, the students improved their speeches by using thematic items such as: self-medication risks, access to medicines, substances accumulation in the body, side effects, dosage, efficacy, adaptation; active component in medicines, medicines composition, substances, therapeutic action, and others. We collected different thematic items and characterized semantic relations among them, in the two episodes extracted from classes 7 and 8, and some of them, related to medicines and self-medication. The most frequent semantic relations between thematic items, as established by the students, were: process/reason (self-medication/needs), identified/identifier (medicines/active component), thing/attribute (medicines/ therapeutic action), cause/consequence (medicine/side effects), whole/part (medicine/substance) and others, are showed in the table 2. In the semantic relations, categories placed before the bar (/) is related to the item in the first column, followed by the categories related to the subsequent item in the third column.

Table 2: Systematization of semantic relations present in students' speech in episode 7.2

Thematic Item	Semantic Relations	Thematic Item
Self-medication	Thing/Attribute	Problem
Self-medication	Process/Reason	Needs
Self-medication	Action/Motivation	Difficulty for medical assistance
Self-medication	Action/Motivation	Access/needs in rural areas
Self-medication	Cause/Consequence	Body adaptation (loss of effect)
Self-medication	Cause/Consequence	Overdose
Self-medication	Cause/Consequence	Allergic reactions
Self-medication	Cause/Consequence	Unexpected reactions
Medicines	Thing/Attribute	Therapeutic action
Medicines	Cause/Consequence	Side effects
Medicines	Whole/Part	Substance
Medicines	Identified/Identifier	Active component

From the table 2, we considered that semantic relations pointed for different ways of thinking on self-medication and medicines, considering they addressed different aspects related to these two concepts – scientific and social ones - and assumed different commitments to express their ideas. We organized these ways of thinking, such we showed below:

Ways of thinking on self-medication	Ways of thinking on medicines
[1] Self-medication as a problem	[5] Medicines as material thing causing problem
[2] Self-medication as process leaded by needs	[6] Medicines as material thing healing diseases
[3] Self-medication as action motivated by difficulties in the access to medical assistance	[7] Medicines constituted by substances
[4] Self-medication as cause for risks and consequences – side effects, loss of therapeutic effect, overdose, unexpected reactions	[8] Medicines identified by active component

From the students' ideas on self-medication, we characterized ways of thinking associated to social and emotional aspects (1, 2, 3), as they raised up possible causes for people practicing self-medication, which suggest axiological commitments guiding their speeches. They applied scientific knowledge to explain consequences for self-medication (4), assuming epistemological commitments. For self-medication, different ontological commitments were identified: process, concrete action (materialized) and cause (abstraction). From the students' ideas on medicines, we find only one ontological commitment – medicines as something material, sometimes addressed from their properties (healing or causing problems – 5, 6), other times explained medicines considering composition or active components (7,8). These ways of thinking and speaking seemed to characterize a heterogeneity of thinking as we put together a topic closely related to chemical aspects (medicines) and a social issue associated to it (self-medication).

To solve Bianca's case, the students looked for differentiating chemical substance (active components) in medicines, seeking for scientific bases to support their positions and they considered social aspects leading to the practice of self-medication. In this sense, they were not in favor of self-medication, considering that medicines can bring undesirable consequences, if it is taken without appropriate indication. However, they make exceptions to this practice considering social conditions of the individuals – no easy access to medical assistance and personal needs. In this sense, it is important to highlight that a meaningful number of students declared to practice self-medication, at different moments, in TLS. In episode 7.2, we realized that scientific knowledge was predominant in classroom discussions, but it did not seem to guarantee that students assumed only epistemological commitments in their positions.

FINAL COMMENTS

In general, in this work, we verified that students associated scientific knowledge with ideas built in their personal experience, in the classroom discussions, in order to understand the SSI from the point of view of science. Texts, videos, lectures, discussions and other didactic materials helped the students to make meaning for chemical content as they were asked to solve questions related to the SSI on self-medication. We realized a movement from predominant axiological commitments assumed by the students, in the beginning of TLS, to more elaborated ideas in which was also implied epistemological and ontological commitments. We believe that students enriched their repertoire of ideas on the theme both in scientific and social view, and it could be fruitful for a meaningful science learning and the development of values, motivations for actions in their lives. In this way, we realized that scientific knowledge gained relevance for students considering that it was applied to understand an important issue present in social context.

The pragmatic value for scientific knowledge seemed to be materialized as the students implicitly or explicitly bring together their epistemological, ontological and axiological commitments, which could favor the expression and articulation of diverse ideas and positions on the theme. In science classes, SSI approach can contribute to make meaning for scientific knowledge in order to understand and signify experiences lived in everyday life. Different ways of thinking can be addressed from a pragmatic value, in an integrative perspective and not for replacing one by the other. The heterogeneity of verbal thinking reflects the existence of different forms of knowledge that constitute the diversity of representations for the world and reality, which can emerge in contextualized educational practices.

PART 9: STRAND 9

Environmental, Health and Outdoor Science Education

Co-editors: *Justin Dillon & Albert Zeyer*

CONTENTS

STRAND 9: INTRODUCTION

ENVIRONMENTAL, HEALTH AND OUTDOOR SCIENCE EDUCATION

Strand 9 includes a number of areas of education including the following: ecological and environmental education; education for sustainable development; environmental health, health education and health promotion; lifestyles and attitudes towards health and the environment; and, developing and evaluating the impact of programmes and experiences outside classrooms, including those organised by institutions other than schools. On first inspection, this grouping might seem to lack the coherence of other strands, however, when viewed from the perspective of the challenges facing the planet and everything that lives on it in 2020, things fall into place.

The Coronavirus pandemic has exposed the failure of science education to adequately prepare scientifically literate citizens (Dillon & Avraamidou, 2020). The strength and depth of the anti-vaccination movement coupled with more general misunderstandings of risk and health should sound a wake-up call to policy-makers, educators and education researchers. Not that some policy-makers seem to appreciate the science, either – few world leaders appear to understand some basic ideas and risk the lives of their populations as a result.

While the global health crisis has dominated the media and the public consciousness, the potentially greater threats of biodiversity loss, food/water security and climate change remain. These wicked problems cannot be solved in the conventional sense, and no amount of inquiry-based or problem-solving approaches are going to prepare students for the values-based decisions they will have to make in their lives.

Part of the problem that has been exposed by recent and longer-term challenges is a widespread lack of engagement with the environment and the outdoors. Enforced lock-down has made people aware, if they weren't already, of the mental and physical health benefits of engagement with the environment. This interrelationship between science, the environment and health underpins ESERA Special Interest Group 4 "Science|environment|health" (Zeyer & Dillon, 2019)

We see science as a both a body of evolving (and established) facts and theories and a way of making knowledge; the environment can be regarded as nature or the natural world; health reflects the physical and mental aspects of well-being. We acknowledge, of course, that all three terms are contested. The fact that they represent different ontological categories does not deny their interrelationship in our lived experience.

Twelve papers constitute this chapter. The 39 authors come from around the world, reflecting the diversity of ESERA and the global nature of research in these topics. Some, like Alexandros Amprazis and Penelope Papadopoulou, address longstanding challenges faced by teachers, such as plant blindness, in their case through a cross-age study of Greek students. Another Greek study, this time by Athanasia Papadopoulou, Dimitrios Charalambous, Alexandros Georgopoulos and Georgios Malandrakis, reports on an exploration of primary students' intention of consuming seasonal, organic and local fruits. The seven-month intervention the authors report on, might offer a way of raising students' awareness of the role of plants in our lives.

Three contributions focus on studies involving pre-service teachers. Elías Amórtegui, Olga Mayoral and Valentin Gavidia report on a successful Colombian study of the development of the pedagogic content knowledge necessary to teach biology fieldwork. Lidia Caño and Oihana Barrutia report on the development of a scale to test environmental literacy and to predict environmental responsible behaviour of Spanish pre-service teachers. As with most studies of pre-service teachers' knowledge, the results were quite disappointing. Anthoula Maidou, Katerina Plakitsi and Hariton Polatoglou present a study which involved introducing pre-service early childhood teachers to education for sustainable development using an approach they call Socrates' House.

Another energy-related study is reported by Shih-Yeh Chen and Shiang-Yao Liu, from Taiwan, who interviewed students three years after they had taken a science-informed energy course. This unusual approach begins to address the challenges of programmes that focus on issues of sustainability – if there's no long-term impact, they probably haven't worked. In a related paper, Maria-Christina Kasimati and Marida Ergazaki, from Greece, look at a neglected area – early-childhood education for education for sustainability; you can never start too young, it seems.

Two studies focus on novel pedagogic strategies. Japanese researchers, Shiho Miyake and Asami Ohnuki, report on the use of a card-type game aimed at providing an opportunity to consider the ethical perspectives of science in students future decision-making related to health and wellbeing.

Another Japanese study, by Emoto Arisa, Hisano Arata, Kawabata Itsuki, Kusunoki Fusako, Inagaki Shigenori, Hanaki Kumiko, Atake Noriko and Nogami Tomoyuki, used augmented reality to help students visiting a zoo to develop their observational skills with a focus on animal skeletons and their movements. While limited in its success, the approach offers huge potential for the future.

Another use of technology in education is provided by Shota Asahina, Shigenroi Inagaki, Yoshiaki Takeda, Etsuji Yamaguchi, Hiroshi Mizoguchi, Fusako Kusunoki, Hideo Funaoi and Masanori Sugimoto from Japan. They present an evaluation of a simulation game focussing on succession as part of forest management – a major issue worldwide.

Gonzalo Guerrero reports on a study involving in-service science teachers learning about science outside the classroom on a Chilean Master's degree programme. This innovative study involved research-practice partnerships and has some salutary lessons about how much teachers can be expected to take on in such situations.

Finally, Christin Sajons and Michael Komorek, from Germany, report on complementary networking of out-of-school learning environments. They describe how the learning and engagement with key environmental issues and ideas can be reinforced by collaborations between schools and institutions such as museums, botanic gardens and environmental centres.

We commend these papers to you as examples of the breadth of research interests with Strand 9 and of the commitment to addressing the key challenges facing the planet now and in the future.

PLANT BLINDNESS INTENSITY THROUGHOUT THE SCHOOL YEARS: A CROSS-AGE STUDY

Alexandros Amprazis, Penelope Papadopoulou
University of Western Macedonia, Florina, Greece

It is really interesting, that even though plants contribute essentially to human life, people don't seem to find them interesting. Humans prefer animals and rarely notice the flora around them. This phenomenon is called plant blindness and the reasons behind it can be found in education, in the cultural framework and in human biology. Apart from being a cause, the educational context can be also a solution to plant blindness as educational activities can elucidate plants' importance and make them more interesting to humans. Above all, plant blindness should be examined as an important issue that can be related to environmental awareness and to Sustainable Development Goals (SDGs). In this study we seek to examine plant blindness' presence in the Greek student population. Moreover, aim of this study is to clarify through a cross age study whether the phenomenon's intensity change throughout the school years. One thousand thirteen (1013) primary, junior and senior high school Greek students participated in this research. Their attitudes towards plants or animals were assessed through a questionnaire with five-point likert-type scale items. According to the results, Greek students do show greater preference for animals comparing to plants. Additionally, as the students get older, they lose interest in flora. Our results highlight plant blindness' presence in the school population and enhance the general concern about the reduced emphasis on plant life in educational systems worldwide. Hence, a need emerges for revising curricula and promoting the education for plants during school life.
Keywords: environment, biology education, society and environment education

INTRODUCTION

"Plant Blindness" refers to humans' tendency to ignore and underestimate plants, especially comparing to animals (Amprazis, Papadopoulou, & Malandrakis, 2019; Wandersee & Schussler, 1999). It is a phenomenon that was firstly assigned during mid 80s (Wandersee, 1986) and since then has received much attention by researchers. Deficiencies in the educational systems, humans' brain function and the characteristics of plants are listed among the causes of this phenomenon (Hersey, 1996). Examining the Greek curriculum for example, it is noteworthy that there is a focus mainly on the plant biology context while references to plants importance in general are lacking (Amprazis & Papadopoulou, 2018). In general, plant blindness seems to be a complex phenomenon that is also affected by cultural aspects (Balding & Williams, 2016). Initially, researchers assessed this phenomenon mainly as a differentiation in preference regarding plants and animals. Recent findings however, point out possible correlations between plant blindness and important issues such as biodiversity loss, sustainable development and a lack of scientific literacy (Kaasinen, 2019; Sharrock & Jackson, 2017). Plants are involved in nutrition, climate issues, air pollution, soil quality, medicine production, habitat provision and human well-being. All the above are top priorities in the Sustainable Development Goals' (SDGs) declaration (Fukuda-Parr, 2016; United Nations, 2015). In that sense, ignoring flora can be an opposing factor to environmental balance and hinder the SDGs' achievement. Plants' preservation is directly integrated in the thirteenth, (Climate Action), fourteenth (Life below

Water) and fifteenth (Life on Land) SDG, but more indirect relationships can be traced out to the other SDGs too.

According to researchers, educational activities can be an effective way to reduce this phenomenon's intensity (Krosnick, Baker, & Moore, 2018; Stagg & Verde, 2018). Assiduously designed educational projects seem to be able to stimulate students' interest in plants (Borsos, 2019; Kissi & Dreesmann, 2018). Outdoor activities, intersectional perspectives and the context of education for sustainability can be effective options for reversing the limited preference for plants during the school years (Cil, 2016; Veiga Ávila et al., 2018).

Considering all that have been mentioned before, it is meaningful to examine plant blindness' intensity in a country that has not been examined before and assess its intensity throughout the school grades. Knowing that, we can have more clues in order to design educational intervention programs that will enhance students' interest in plants during the primary and high school years, the main era to construct knowledge in the typical educational systems worldwide. Aim of this study is to assess Greek students' attitudes towards flora and moreover, examine the development of the plant blindness phenomenon as students move from the primary to the secondary school. The research questions we address here are as follows:

1. What are Greek students' attitudes towards plants, especially comparing to their attitudes towards animals

2. How does the phenomenon's intensity changes as the students move from primary to junior and senior high school

It is noteworthy to mention that no cross age studies exist regarding the plant blindness phenomenon.

METHODOLOGY

The participants of our study were one thousand thirteen Greek students (1013). In particular, 349 students were from the primary school's sixth grade (12 years old), 334 were from the junior high school's third grade (15 years old) and 330 were from the senior high school's third grade (18 years old). In order to clarify whether students of different grade levels share or do not share the same understandings and attitudes, cross-age and longitudinal studies are suggested (Creswell, 2012). Taken under consideration the disadvantages of the longitudinal approach (Schmidt & Teti, 2005), a cross-age study was chosen for our research. A questionnaire was used to assess students' attitudes towards plants. Participants' attitudes were assessed through five-point likert-type scale questions, e.g., "How much do you like plants" - Not at All / Slightly / Moderately / Very / Very Much. The research instrument was constructed according to the basic principles of the quantitative methodology (Creswell, 2012; Kaplan, 2004). After determining the theoretical framework and conducting a number of exploratory semi structured interviews with students, the first edition of our research instrument was formed. The questionnaire was tasted through three pilot implementations. School teachers assessed it in regard to its comprehension and its adequacy. The wording of each grade's questionnaire was based on the different level of comprehension and scientific literacy that older students have comparing to the younger ones. The questionnaire's validity was established by a group of experts in biology education. The instrument's internal consistency was also measured and the value of Cronbach's Alpha was 0.845. Data analysis was performed by using the version 23.0 of the Statistical Package for Social Sciences (SPSS). A Principal

Components Analysis (PCA) was conducted. Four factors (*"Preference in Flora", "Preference in Fauna", "School Knowledge about Flora" and "Plants' Presence & Importance"*) explained 60.96% of the variance. Descriptive statistics were calculated in order to summarize students' answers to the all factors' items

All ethical principles were taking under consideration during the design of the research. The instrument was constructed by considering values such as respect, beneficence and dignity. An authorization was granted by the Greek Ministry of Education before the final implementation. The research instrument was given to the participants during the middle of the school day (between 11.00 and 12.00) as this seems to be the more effective period regarding attention and achievement (Klein 2004). In general, implementing the questionnaire was seamless and trouble free for the vast majority of the schools that participated in the survey.

RESULTS

By reference to Figure 1, we can see the results regarding the main instrument's questions comparing preference for flora and fauna (*"How much do you like plants"; "How much do you like animals"*). Regarding the "Very" and the "Very much" response options, there is a significant gap between plants and animals as 90.1% of our participants claimed that they like fauna "Very" or "Very much", while the respective percentage for flora was only 63.7%. In order to confirm statistically that our students do prefer animals more than plants, we conducted a Wilcoxon Signed-Ranks Test comparing the scores in all items of the factors "*Preference in Flora*" and "*Preference in Fauna*".

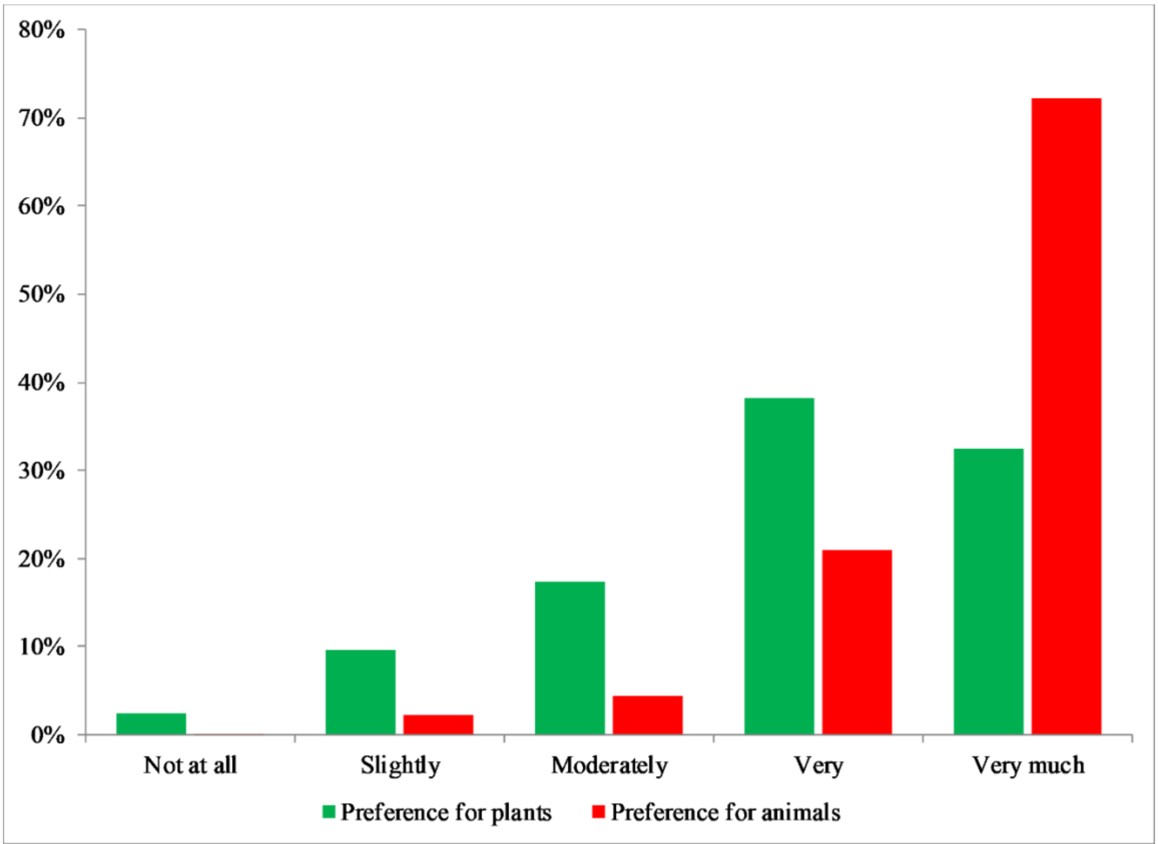

Figure 1. Percentages of students' answers to questions recording preference in plants and animals.

The Wilcoxon Signed-Ranks Test indicated that students' scores regarding preference for animals were statistically significantly higher than their scores regarding preference for plants, Z=-19.01, p<.000. It is also noteworthy that the effect size of this statistical test was large, r=.64.

Regarding our participants' age, a Kruskal-Wallis H test was conducted to clarify whether there is a statistically significant difference in the "*Preference in Flora*" factor among the three age groups of our participants. The test was significant [$X^2(2, n=1013)= 38.82, p<.05$] with a mean rank score of 405.7 for the twelve years old group, 306.5 for the fifteen years old group and 313.3 for the eighteen years old group (Table 1). Follow-up Mann-Whitney U tests were conducted to evaluate pairwise differences among the three groups. The age group of twelve years old recorded the most positive answers regarding preference in flora.

Table 1. Kruskal-Wallis H test results regarding students' age effect on their preference for plants (N=1013)

Students' Grade	N	Mean Ranks	x^2	df	Asymp. Sig
Primary school (12 years old)	349	405.7	38.82	2	.000
Secondary school (15 years old)	334	306.5			
High school (18 years old)	330	313.3			

Descriptive statistics were calculated for the other plant blindness definition aspects, i.e. noticing the flora around and appreciating flora's role for the life phenomenon upon earth. For both these aspects, primary school students appear to be more related to plants. High school students seem to notice flora around them less often (Figure 2) and do not seem to recognize plants importance as much as younger children do (Figure 3). For both these research questions Kruskal-Wallis H tests were conducted and confirmed a statistical significance in regard to these differences.

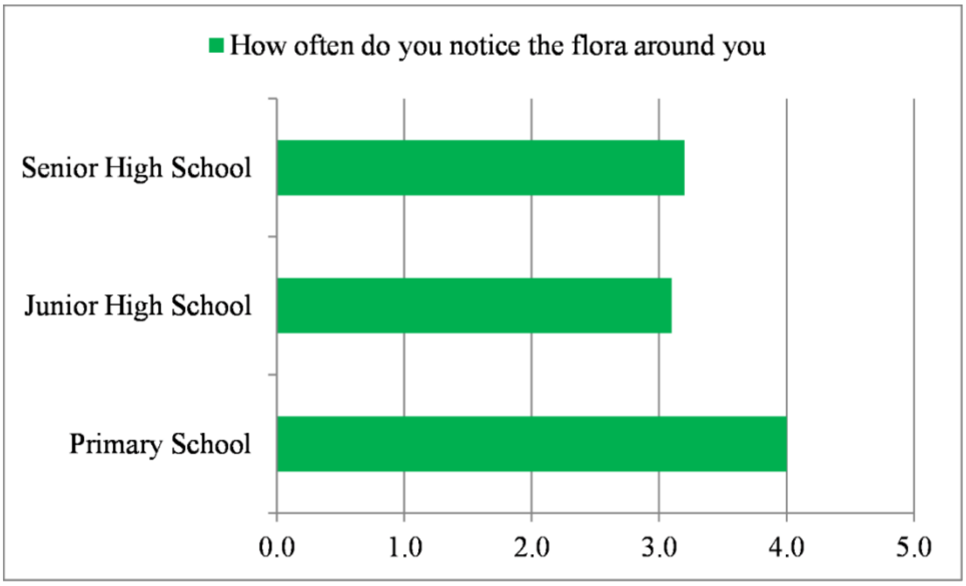

Figure 2. Students' tendency to notice the flora around them

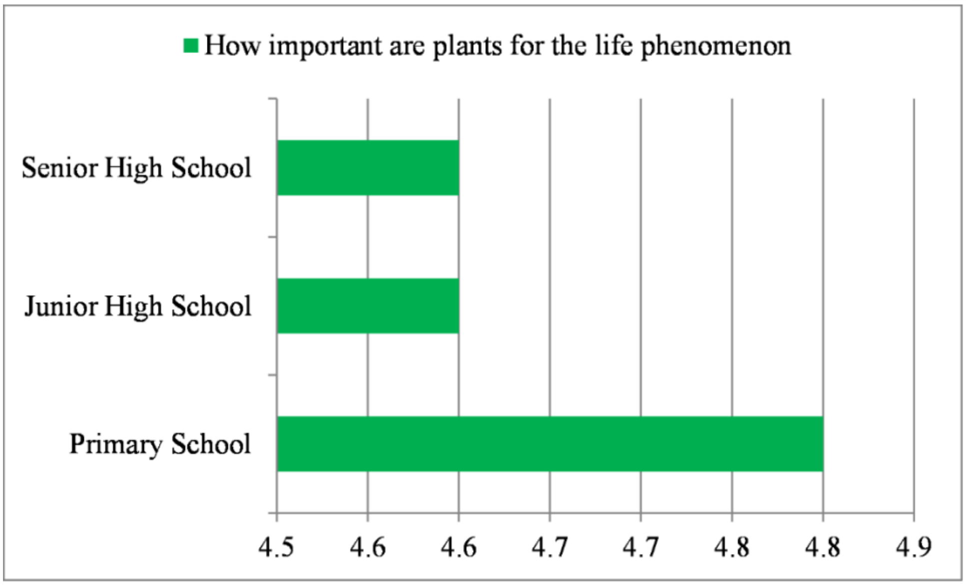

Figure 3. Students' assessment of flora's importance

In order to examine how the other characteristics, affect students' preference for plants, Kruskal–Wallis H and Mann–Whitney U tests were conducted. Regarding the place of residence variable, a Kruskal–Wallis H test was conducted to clarify whether there is a statistically significant difference in the "*Preference in Flora*" factor among the students that come from urban, rural areas and semi-rural areas. The test was significant [$X^2(2, n = 1013) = 9.138, p < .05$] with a mean rank score of 541.87 for the rural, 466.48 for the semi rural and 482.55 for the urban areas (Table 2).

Table 2. Students' characteristics affecting their preference for plants (N=1013)

Students' characteristics		Mean Ranks	x^2	df	Asymp. Sig
Place of residence	Rural	541.87	9.138	2	.010
	Semi rural	466.48			
	Urban	482.55			
Students' characteristics		**Mean Ranks**	**U**	**z**	**Asymp. Sig**
Gender	Boys	419.8	87561	-4.41	.000
	Girls	496.9			
Environmental education projects	Yes	307.9	27968.5	-2.90	.004
	No	261.2			

Follow-up Mann–Whitney U tests were conducted and indicated that the rural group recorded the most positive answers regarding preference in flora.

A Mann–Whitney U test was conducted to evaluate difference among boys and girls regarding their preference in flora. A significant difference was revealed [$U = 87561, z = -4.41, p < .05$] between boys (Md = 419.8) and girls (Md = 496.9) as girls seem to be more interested in plants.

Respectively, a Mann–Whitney U test was conducted in order to highlight any difference in preference in plants of students that have participated in environmental education projects and those who have not. A significant difference was also revealed [$U = 27968.5$, $z = -2.90$, $p < .05$] and indicated that environmental education projects do can enhance students' interest in flora (Table 2).

CONCLUSIONS

Our findings support the general idea of greater preference in animals than plants and overlap with the conclusions of other analogous studies which also indicate low interest rates regarding plant life (Fančovičová & Prokop, 2011; Strgar, 2007). The strong effect size of our statistical analysis leaves no room for doubt whether children aged between twelve and eighteen years old are more interested in plants or animals. Regarding students' characteristics affecting their preference in plants, greater preference for plants has been recorded by girls, by students coming from rural areas and by students that have participated in environmental education projects. The most remarkable result to emerge from the data has to do with plant blindness' incremental development. Our participants seem to lose their interest in flora as they get older. A possible explanation about this finding can be that during adolescence children seldom show interested in issues such as the environment, as they are more focused on themselves.

Plant blindness doesn't seem to be a philosophical issue. It is rather a well-documented phenomenon with a growing body of literature. If we want to prevent plant blindness, we need to create a new learning direction regarding plant life. We have to move out the strict biology framework and highlight plants' importance through every school subject. This need becomes more obvious during the junior and the senior high school years that seem to be the more intense period for this problem. Towards this direction, the role of education for sustainability should be enhanced as this educational context can offer the opportunity to highlight the importance of plants for human wellbeing and for the life phenomenon in general. Bringing flora in the limelight can lay the foundations of environmental awareness, nurture the concept of environmental citizenship and above all, contribute to the achievement of the Sustainable Development Goals. In that sense, education for sustainability seems an ideal framework for providing comprehensive scientific literacy about plants that will establish flora as an utterly important natural resource in students' consciousness.

Relatively to future research suggestions, there is no doubt that more cross age studies are required in order to draw complementary conclusions about the phenomenon's intensity in other countries. Any similar future inquiries concerning students' attitudes towards plants throughout their education years could be a comprehensive guide for changes in the curriculum, enriching textbooks with plant science and implementing long lasting educational projects. Studies focusing on restricting plant blindness' intensity specifically through education for sustainability could also be highly valued.

EXPLORING GREEK PRIMARY STUDENTS' INTENTION OF CONSUMING SEASONAL, ORGANIC, LOCAL FRUITS

Athanasia S. Papadopoulou[1], Dimitrios Charalambous[1], Alexandros Georgopoulos[2], Georgios Malandrakis[1]
[1]Department of Primary Education, School of Education, Aristotle University of Thessaloniki, Greece
[2]Department of Early Childhood Education, Aristotle University of Thessaloniki, Greece

Food production, transport and consumption are linked with various environmental issues, including, among other, the greenhouse gases emissions. Food consumption in the western world has been estimated to be responsible for approximately the 20-30% of the total environmental impact. In order to achieve a more sustainable diet, one of the major dietary changes proposed is the consumption of more seasonal and locally produced food, especially fruits and vegetables. Present study explores Greek primary students' intention to consume seasonal, locally produced and organic fruits before and after experiential teaching intervention. Participants were 82 third grade students (8-9 years old) from schools located at the east and the west of the greater metropolitan area of Thessaloniki, Greece. Data collected with the use of a closed-form questionnaire consisted of fourteen questions. Analysis was primarily quantitative and focused, beyond descriptive, on significant differences in students' answers before and after teaching intervention. Results indicate that before the experiential teaching, students' intention of consuming seasonal, organic fruit was medium ($Mean_{SEAS\text{-}pre}=1.02$*, theoretical maximum=2), and also medium was their intention of consuming local fruits (*$Mean_{.LOC\text{-}pre}=1.07$*, theoretical maximum=2). After intervention, statistically significant differences in students' answers were recorded in both variables under study (*$Mean_{SEAS\text{-}post}=1.73$*, *$p=0.000$*, *$Mean_{LOC\text{-}post}=1.73$*, *$p=0.000$*). The seven-month, experiential teaching intervention triggered the interest, engagement and enjoy of students at every phase of the learning process, especially at the phase of the creation of the organic school garden, leading to fruitful outcomes.*

Keywords: experiential learning, primary school, outdoor learning

INRODUCTION

Nowadays, globalization has permitted the whole-year availability of a wide variety of fruits and vegetables. Southern produced products can easily reach northern hemisphere and vice versa. Consumption has become independent from seasons. The use of new technologies caused the intensification of agriculture and the extension of natural production and growing seasons, and also increased the international trade. This caused a food culture with variety of foods in a lot of countries otherwise this couldn't be possible. (Macdiarmid, 2013). Unfortunately, this was made with a high environmental cost, including the need of more energy, and the change in land use that resulted to the loss of environmental biodiversity and loss of species. Moreover, it required the increased use of monocultures in agriculture (DeClarke, 2013).

Food production, transport and consumption are linked with environmental problems such as greenhouse gases emissions (Tukker & Jansen, 2006). In the western world, food consumption has been evaluated to account for approximately 20-30% of total CO_2 environment impact. In order to achieve a more sustainable diet, one of the dietary changes proposed is the consumption of more seasonal and locally produced food, especially fruits and vegetables (Garnett, 2008).

For some, seasonally produced food doesn't have geographical limits and incorporates any food that is produced in the natural production season but consumed anywhere in the world. For others, seasonality is linked with locally produced food, produced in the natural production season and consumed within the same climatic zone (Brooks, Foster, Holmes & Wiltshire, 2011). However, although there is not a universally accepted definition for seasonality, there is a common point among the various approaches, stressing that the food need to be produced in its natural growing season, outdoors, and without the use of additional energy, having as a result that no additional greenhouse gas emissions are released (Macdiarmid, 2014).

One of the benefits of consuming seasonal food that is produced outdoors, is the reduction of greenhouse gases emissions because of no artificial heating or lightening required. Studies have shown that open-field produced food, grown and consumed in season in the same country-region, in general have lower energy requirements and carbon footprints per unit of product in contrary with food produced under protection, stored or even imported (Edwards-Jones, 2010). The term 'food miles' introduced in the early 1990's by Professor Tim Lang (Lang, 2006) to describe the distance our groceries have to travel to reach us. Although that originally the concept was not used as a measure of the environmental impact, in nowadays, we mean the distance that the food is transported from the place and time of its production until it reaches the consumer (DEFRA, 2005). However, food miles is a very controversial concept because it focuses primarily or even exclusively to the distance that the food travels (Wynen & Vanzetti, 2008), and there is no distinction about the transportation type used that can have very different emissions (Coley, 2011).

Different transportation types produces different amounts of greenhouse gases emissions, so it is reasonable to assume that consumption of locally produced food can reduce greenhouse gases emissions (Edwards-Jones et al., 2008). But this is not quite true. In the case that the local transport is inefficient (e.g. with vans), the greenhouse gases emissions can exceed those from imported foods (Mundler & Rumpus, 2012). So, locally produced food compared with imported products, does not always have lower greenhouse gases emissions but it depends on the way that food is transported.

Organic agriculture is a holistic production management system which promotes and enhances agro-ecosystem health, including biodiversity, biological cycles, and soil biological activity. It emphasizes the use of management practices in preference to the use of off-farm inputs, taking into account that regional conditions require locally adapted systems (FAO/WHO Codex Alimentarius Commission, 1999). Moreover, regenerative organic agriculture and its management practices are potentially significant means to sequester more than current global annual emissions and to reverse the greenhouse effect (Rodale Institute, 2014).

In the field of education, there are many benefits of incorporating school garden in teaching, including the social, academic and emotional development of children, the deepen and enrichment of classical teaching by enhancing interdisciplinarity, and providing the basis for scientific and research thinking (Passy, 2014). Moreover, school gardens are considered as among the best tool for experiential learning, and they have also been reported as positively influencing children's eating habits (Parmer, 2009). Experiential learning asserts that learning is built on our emotions and emphasizes on the experience, promoting the active participation of students in a teaching approach in which teachers are just facilitators of learning (Georgopoulos, 2014).

Also, experiential learning as a teaching innovative approach, offers significant benefits. The use of outdoor classroom and school gardens, contrary to the traditional schooling that takes place within walls, engages students in experiential lessons that deepen understanding and accelerates learning (McCarty, Ford & Ludes, 2018). School gardens as a component of nutrition education can increase fruit and vegetable knowledge and can facilitate behavior change among children towards more sustainable and healthy consumption patterns (Parmer, Salisbury-Glennon, Shannon & Struempler, 2009)

Given the above, the goal of the present study is to explore the learning gains in elementary Greek students, produced from the use of school gardens in teaching sustainability issues related to the consumption of seasonable, organic, local fruits. This study is part of a doctoral research which focuses on changing students' knowledge, perceptions and eating habits towards more healthy and sustainable choices that include, among other, more frequent vegetable and fruit consumption. In order to explore the above, an experiential teaching intervention, accompanied by the creation and implementation of a biological school garden took place. This paper pays attention on changes in students' intentions to consume seasonal, local and organic fruits after their participation to the project.

METHOD

The teaching intervention took place for seven months during the 2017-'18 school year, with weekly meetings between the main researcher and the students, each one lasting two hours. The main researcher (first author) was delivered the module to students, but she was not the teacher of the classes participating to the project. The theoretical aspects of the course were mostly covered by experiential activities, while the major teaching approach was the creation of an organic school garden. By that, we tried to maximize the learning outcomes of the educational process and trigger the interest, participation, engagement, and enjoyment of students at every stage of the learning process.

Participants were 82 third grade students (41 males and 41 females, 8-9 years old) from four classes of four public, elementary schools from the east and west greater metropolitan area of Thessaloniki, Greece. East Thessaloniki is considered as an area of medium to high socio-economic level, whereas west Thessaloniki is considered as an area having medium to low socio-economic level.

The data collection tool was a closed-type questionnaire comprised of 14 questions, completed before and about two weeks after the end of the project. Its completion time was 20-25', and the collected data were mainly subjected to quantitative analysis using the SPSS v.24.

RESULTS

Intentions to consume seasonable organic fruits

According to Table 1, before the intervention, students' intention of consuming seasonal, organic fruits was medium (*Mean=1.02, SD=0.72*, theoretical maximum=2). However, after intervention, their scores were significantly increased (Mean=1.73, p=0.000). Significant testing was also implemented based to the two independent variables under study, i.e., students' gender (boys and girls) and school location (east and west Thessaloniki). Through the analysis we also found significant differences before and after the intervention for the boys *(Mean $_{BOYS.BEF}$=0.90, Mean $_{BOYS.AFTER}$=1.78, p=0.000),* and for the girls *(Mean $_{GIRLS.BEF.}$=1.15, Mean $_{GIRLS.AFTER.}$=1.68, p=0.000),* but not between boys and girls either before or after the intervention.

Table 1: Students' intention to consume **SEASONAL, ORGANIC FRUITS** based to **GENDER**

		Before		After		1 year after	
	N	*Mean*#	*SD*	*Mean*#	*SD*	*Mean*#	*SD*
Boys	**41**	0.90	*0.77*	1.78***	*0.42*	1.66	*0.53*
Girls	**41**	1.15	*0.65*	1.68***	*0.47*	1.56	*0.55*

Table 2: Students' intention to consume **SEASONAL, ORGANIC FRUITS** based to **SCHOOL AREA**

		Before		After		1 year after	
	N	*Mean*#	*SD*	*Mean*#	*SD*	*Mean*#	*SD*
East Thessaloniki	**37**	1.08	*0.80*	1.76***	*0.44*	1.62	*0.55*
West Thessaloniki	**45**	0.98	*0.66*	1.71***	*0.46*	1.60	*0.54*
Total	**82**	**1.02**	***0.72***	**1.73*** **	***0.45***	**1.61**	***0.54***

#Theoretical min= 0, theoretical max=2
**p <0.05, **p<0.01, ***p<0.001 (based on Sign Test)*

In respect of the school location, according to Table 2, we found significant differences between before and after the intervention for the schools of East Thessaloniki *(Mean$_{EAST.BEF..}$=1.08, Mean $_{EAST.AFTER}$=1.76, p=0.000),* and for the schools of West Thessaloniki *(Mean $_{WEST.BEF.}$=0.98, Mean $_{WEST.AFTER.}$=1.71, p=0.000),* but not between the school locations either before or after the teaching.

Intentions to consume local fruits

According to Table 3, before the intervention, students' intention of consuming local fruits was medium (*Mean=1.07, SD=0.75*, theoretical maximum=2). However, after intervention, students' scores were significantly increased (Mean=1.73, p=0.000). We also found significant differences before and after the intervention for the boys *(Mean$_{BOYS.BEF.}$=1.17, Mean $_{BOYS.AFTER}$=1.80, p=0.000),* and for the girls *(Mean $_{GIRLS.BEF.}$=0.98, Mean $_{GIRLS.AFTER.}$=1.66, p=0.000),* but not between boys and girls either before or after the teaching.

Table 3: Students' intentions to consume **LOCAL FRUITS** based to **GENDER**

		Before		After		1 year after	
	N	*Mean*#	*SD*	*Mean*#	*SD*	*Mean*#	*SD*
Boys	**41**	1.17	*0.74*	1.80***	*0.40*	1.66	*0.53*
Girls	**41**	0.98	*0.76*	1.66***	*0.48*	1.61	*0.59*
Total	**82**	**1.07**	***0.75***	**1.73*** **	***0.45***	**1.63**	***0.56***

#Theoretical min= 0, theoretical max=2
**p <0.05, **p<0.01, ***p<0.001 (based on Sign Test)*

In respect of the school location, according to Table 4, we found significant differences between before and after the intervention for the schools of East Thessaloniki *($Mean_{EAST.BEF..}=0.89$, $Mean_{EAST.AFTER}=1.84$, $p=0.000$)*, and for the schools of West Thessaloniki *($Mean_{WEST.BEF.=}1.22$, $Mean_{WEST.AFTER.}=1.64$, $p=0.000$)*, but not between the two school locations either before or after the intervention

Table 4: Students' intentions to consume **LOCAL FRUITS** according to **SCHOOL AREA**

		Before		After		1 year after	
	N	*Mean*#	*SD*	*Mean*#	*SD*	*Mean*#	*SD*
East Thessaloniki	**37**	0.89	*0.74*	1.84***	*0.38*	1.68	*0.58*
West Thessaloniki	**45**	1.22	*0.74*	1.64**	*0.48*	1.60	*0.54*
Total	**82**	**1.07**	***0.75***	**1.73*** **	***0.45***	**1.63**	***0.56***

#Theoretical min= 0, theoretical max=2
*p <0.05, **p<0.01, ***p<0.001 (based on Sign Test)

Furthermore, for both variables under study (i.e., students' intention of consuming seasonal, organic fruits and students' intention of consuming local fruits) and for the two independent variables (i.e., gender and school location) no statistically significant differences were observed between the end of the teaching and one year after. That means all variables were significantly increased after teaching and remained high even one year after.

DISCUSSION

In our study, students' intention to consume seasonable and local fruits, before teaching, was medium. This is consistent with the findings reported by Tamurro et al., (2017) where student-teachers' knowledge about seasonal food was inadequate, as they were unable to correctly identify the seasonal period of strawberries (April-August, 62%) and correctly identify the seasonal period of kiwi fruit (November-May, 48%). Moreover, our results are in line with those reported by Kemp et al. (2010) in which only the 19% of them correctly knew the place of origin of their chosen food item (food miles), and only the 17% stated that this knowledge had influenced their purchase decision. Ozer (2007) reports that garden-based experiences and programs provide a context that helps the understanding of seasonality, add a great impact on learning approach, and foster a better understanding of how the natural world is sustained and where food comes from.

ACKNOWLEDGMENT

The research work was supported by the Hellenic Foundation for Research and Innovation (HFRI) and the General Secretariat for Research and Technology (GSRT), under the HFRI PhD Fellowship grant (GA. no. *129*).

WHAT DO THE FUTURE TEACHERS TEACH WHEN MAKING A BIOLOGY FIELD TRIP? A STUDY IN SOUTHERN COLOMBIA

Elías Amórtegui[1], Olga Mayoral[2] and Valentin Gavidia[3]
[1]Bachelor of Natural Sciences and Environmental Education-Universidad Surcolombiana, Neiva, Colombia
[2, 3] Department of Didactics of Experimental and Social Sciences-Univetsitat de València, España.

Field Works are fundamental in the teaching-learning of biology, facilitate the understanding of the dynamic nature as a network of relationships, the acquisition of scientific skills and the generation of attitudes on the conservation of ecosystems and the protection of the natural heritage. However, teacher training does not seem to address what and how to teach in natural environments. We conducted a research in the context of southern Colombia (Neiva-Huila), with 27 future teachers of the Degree Program in Natural Sciences and Environmental Education of the Universidad Surcolombiana. Based on a mixed approach (qualitative and quantitative) and using questionnaires, participant observations, conducting a training seminar and monitoring the development of field practices with secondary school students, we approached the conceptions of pre-service teachers about the consubstantial elements of Field Works. The evolution of their initial reductionist ideas towards more complex and desirable conceptions, in accordance with the research in Science Didactics, were also addressed.

Keywords: Teacher preparation, Outdoor education, Secondary school.

INTRODUCTION

There is the idea, socially underlying, that in order to teach it is enough to have a deep theoretical knowledge of what is taught, in this case Biology; as education professionals we know that teachers have specific knowledge that, in addition to including content knowledge, has didactic, pedagogical, and curricular aspects, among others, that allow them to carry out didactic transposition processes in an appropriate manner (Mellado, 2011). This has been called Professional Teacher Knowledge (Shulman 1986; Gess-Newsome, 2015).

In other hand, Field Work offers educational opportunities of unquestionable value, related to the affective, cognitive and environmental dimension, and is essential in the interest and valuation of biodiversity, the generation of attitudes in favor of the conservation of living beings, the acquisition of skills of the scientific work and direct contact with natural environments (Gavidia & Cristerna, 2000; Hamilton-Ekeke, 2007; Rennie, 2014). In this sense, Field Work acquires a special value in the teaching and learning of Biology because it promotes the students to approach "the living", as close as possible to their natural conditions, with a systemic and holistic perspective. Authors like Morag & Tal (2012) and Morag, Tal & Rotem-Keren (2013), show that natural environments and field practices differ in several characteristics in relation to visits to museums, planetariums or science centers, because they allow direct experience with the real phenomena of nature, more than any other activity outside the school.

According to Behrendt & Franklin (2014) teachers do not have enough training on how to teach in nature, because neither the initial training courses nor the ongoing training courses have allowed them to develop an adequate knowledge of the content and competences needed to teach outside the school in natural environments that is, how to design and carry out field practices. For Lavie Alon & Tal (2016) the research on the role of the teacher in field practices has shown that in most cases they prefer not to play an active role and be fully involved in the outputs and their preparation, and give all the didactic acting to professionals external to the school and in charge of the activity (guides, instructors). Generally the teachers in their initial training have participated as students in Field Trips, without having experiences in which they should plan and teach outside the classroom (Tal & Morag, 2009). Our main research goal was to analyze the contribution of Field Work to the construction of Professional Knowledge in future teachers of Natural Sciences at the Universidad Surcolombiana.

RESEARCH DESIGN AND METHOD

We conducted a mixed -quantitative and qualitative- study, in order to capture with greater effectiveness, the various components of the Professional Teacher Knowledge and specifically the contributions of field practices in teacher training. Our study was also a longitudinal prospective type, with the aim of highlighting the progression of the teachers' own professional learning. The sample is formed by 100% of the students who took the "Didactic I" course (sixth semester) of the Degree Program in Natural Sciences and Environmental Education at the Universidad Surcolombiana (Huila-Colombia). This university is public and the only one that has a teacher training program in the region. The data collection occurred during the second semester of 2016 (July to December). The group consisted of 27 students, of which 21 female and 6 male, the ages of these future teachers ranged between 19 and 23 years old. To obtain data, we chose to implement a questionnaire (applied at the beginning and end of the training process), enriching the research with participant observation (through the video recording of the development of the didactic intervention) and the follow-up of the development of the seminar "Field Work in the teaching of biology and teacher training". The questionnaire consists of two large sections: the first six questions focus on general elements on Field Work, while in the second section a hypothetical scenario is presented in which the participants find themselves as teachers of an educational institution of Huila and must perform Field Work. We have systematized the information based on the content analysis (Álvarez & Jurgenson, 2003) through the Software Atlas.Ti 7.0 and for the case of the questionnaire we have applied a t-student, following the guidelines of Cohen, Manion & Morrison (2011).

Finally, we emphasize that the instrument designed consists of a system of categories and subcategories that have considered the main characteristics of Field Work. These categories are based on a study by Amórtegui and Correa (2012) and expanded by an extensive literature review, from which we propose to add the categories Field Work Nature, Planning and Difficulties. The resulting instrument is presented in Table 1.

Table 1. Categories system for the analysis of field work in biology teaching and teacher training

FIELD WORK NATURE	Going out Experience Teaching strategy Professional development
LEARNING PURPOSES	Concepts Processes Attitudes
PLANNING	Teaching model Field guide Previous ideas Students motivation Preparation (place, subject, materials, cost, permission)
DIFFICULTIES	School culture Teachers Preparation (place, subject, materials, cost, permit, risk) Students behavior Understanding the subject
CONTRIBUTION TO TEACHER TRAINING	Biology Learning Teaching experience Teaching Biology Professional development
5 Categories	21 subcategories

To develop our seminar, the pre-service teachers, were organized five groups with specific biological themes and focused on specific courses: ecosystems and trophic networks (G1-8th grade students), insects and their environments (G2-8th grade students), plants (G3-7th grade students), arthropods (G4-6th grade students) and insects (G5-6th grade students). The ages of the students to whom the Practices were directed ranged between 10 and 15 years old.

All the groups had one or two sessions (of 2 hours each one) prior to classroom preparation with secondary students, one morning for their application in the field (3-4 hours) and one or two sessions for the conclusion again in the classroom (2 hours each one). Field Practices were carried out in the following way: in two cases in the forest of the educational institution itself (G3, G5); in two other cases in a forest that contained a stream outside the school, although close to it, so that it was possible to walk from school (G1, G2); finally, a group in a wetland on the outskirts of the city and therefore had to be transported by bus (G4).

RESULTS AND DISCUSSION

Given the volume of results of our research and the extension limitations of this paper, we will focus on the following aspects: a) address some of the findings at the beginning of the training process (pretest) and b) the progression in the future teachers' conceptions after the development of a sequence of learning as a seminar (posttest). Among all the categories of analysis we address five of them: *Field Work Nature; Learning purposes*, *Planning*, *Difficulties* and *Contribution to teacher training.*

The categories have been grouped considering whether they refer to the A) initial conceptions or B) final conceptions. Within each category, after the heading, a word or sentence that synthesizes the major perception of the students is included in italics. Included in brackets, in the next line is the question that addressed the issue along with a representative response by the students.

A) Initial Conceptions

According to Field Work Nature: *Going out*
{From your point of view, what is a Field Work activity?} *"... It is an activity where the student is taken to a specific place..."*

15 students (55.5%) consider that Field Work refers only to the fact of going out of school. In some cases, reference is made to spaces of formal education (as to other universities) and in others to non-formal spaces (technological centers, scientific studies, among others). It is striking that in these cases there is no reference to a natural place such as an ecosystem, forest, among others. Similarly, future teachers do not consider didactic elements of this teaching strategy, for example their learning purposes, their evaluation, the working roles or their planning. We consider that this type of conceptions can reaffirm the difficulty posed by Morag and Tal (2012) and Dourado and Leite (2013), about the diversity of meanings, both in Spanish and in English, that the literature report on the term of Field Work, including field activities, educational field activities, field trips, study visits out of school, excursions, experiential education, environmental interpretation, among others. On teachers' conceptions, Glackin (2016) states that teachers who identify with traditional teaching approaches tend to have conceptions in which Field Practices are considered exclusively as fun activities.

According to Learning purposes: *Concepts*

{What do you think the students learn when they go on a Field Work?} *"... The students would consolidate their knowledge and help them to a better understanding of the topics...."*

For 21 future teachers (77.7%), Field Work is carried out so that the students confirm the concepts and definitions that the teacher previously taught in the classroom. They specify that students learn concrete and particular objects and themes, for example about plants, animals, natural environments, biotic, abiotic factors, etc.

From this perspective where conceptual contents predominate, Field Work is not usually framed within a problem, nor in a specific context. Field Work only shows secondary school students a phenomenon, in this case biological, as something finished as an absolute truth, so there is no space for discussion or construction.

From this approach, no manipulation or intervention on the object of study is evident, therefore it is enough to merely observe the phenomenon (Dourado and Leites, 2013) and it is not necessary to develop research skills and abilities.

According to Planning: *Logistics preparation*

{What would you consider in order to carry out a Field Work activity?} *"... To carry out field practice, the first thing that must be taken into account is that there is consent on the part of the parents ..."*

Taking the elements that the future teachers would consider when planning Field Work, we highlight that 23 pre-service teachers (85.2%) affirm that it is enough with adequate logistical preparation for the development of the activity. Thus, the teacher must be responsible for specifying the subject to be treated, establishing the place of development of the activity, specifying the duration of the output, getting the transport, the materials, etc. Didactic aspects, such as the *Field Guide* (2 students-7.4%), *Students motivation* (5 students-18.5%) and *Previous ideas* (6 students-22.2%) are hardly contemplated. Considering that logistical aspects are enough to plan the field practice, could be related to traditional teaching approaches, in which the field activity is focused on the teacher and therefore the degree of student participation is minimal. Pedrinaci (2012) considered this approach, as the most frequent field activity.

According to Difficulties: *School Culture*

{What difficulties could you have to carry out a Field Work activity*?} "... The main difficulty is to get permission from both the institution and the parents, either by economic conditions or security. ..."*

With regard to aspects such as the administrative context of the educational institution and the characteristics of the school culture, 14 future teachers (51.8%) believe that only aspects of this style make it difficult to carry out a field practice. Scott et al. (2015) identify, from the point of view of teachers in initial and in-service training, the school culture as a difficulty to develop Field Work as a Biology teaching strategy, due to: administrative issues, the educational priorities, the inspections, the established educational practices, the allocation of time, the bureaucratic burden, the little support of classmates, etc.

For this reason, for Tal and Morag (2013), the school culture focused only on learning and exclusively at school (education school-based), must be reevaluated by a teaching outside of it (outdoor education). The idea of considering the teacher as an element that can facilitate the development of the field activity, as long as he has the knowledge, skills and expertise in it, is considered only by one student (3.7%).

According to the Contribution to teacher training: *Biology Learning*

{What does Field Work provide to your training?} *"... I would bring much knowledge and more than that experience to complete my studies and improve. ..."*

In a majority way, 16 future teachers (59.2%) conceive that the main contribution of field practices in their training as teachers so far, has been that they have learned Biology (they take field trips in the courses of Botany, Systematic, Zoology and Ecology). Only two students (7.4%) value the *Teaching Experience* and 7 of them (26%) *Teaching Biology*. Generally, the teachers in their initial training have participated as apprentices in Field Trips, without having experiences in which they should plan and teach outside the classroom. In addition to this, Lavie Alon and Tal (2016; 2017) affirm that there are quite a few studies on the design of learning environments in the field, however, research on how teachers use the natural environment in teaching remains scarce.

B) Final Conceptions

After carrying out the Training Seminar and the planning and development of field trips with high school students, the conceptions of future teachers in training present the following evolution:

According to Field Work Nature: *Biology Teaching*

{From your point of view, what is a Field Work activity?} "… *A field practice is a teaching strategy in which different activities are carried out depending on the subject to be worked on and in which there are different attitudinal, procedural and conceptual objectives being as integral as possible...."*

For this case, we highlight that 23 future teachers (85.2%), unlike the two at the beginning, make explicit that Field Work is a biology teaching strategy that they can develop with their students in their future work as teachers. They also explain consubstantial aspects of this strategy, for example that Field Work will make their students work in "reality", under "direct contact" and will facilitate studying the living phenomenon as close to their natural conditions. From the statistical point of view, the comparison between the pre and posttest shows a high significance of the data and therefore an important progression in the conceptions of this future teaching staff (p value ≤ 0.001).

Unlike the beginning of the training process, here the approach taken by pre-service teachers is more concrete from the importance of Field Practice as fundamental teaching strategy in learning Biology, with great effectiveness in the acquisition of concepts, procedures and attitudes that help students understand, from a systemic perspective and as a network of relationships, the phenomenon of the living. Unlike other strategies such as museums or zoos, the understanding of wildlife is favored along with a high power in the generation of behaviors in favor of ecosystem conservation (Morag & Tal, 2012).

According to Learning purposes: *Attitudes*

{What do you think the students learn when they do a Field Work activity?} *" … They also have motivation to investigate, curiosity develops, the generation of questions and love for nature ..."*

Unlike the *Conceptual* and *Procedural* contents, in this case we observe the greatest change in the number of students that agree with importance of the *Attitudinal* contents as the learning objective. In this sense, there has been an increase in the number of future teachers -from 12 (44.4%) to 25 (92.6%) who affirm that in outdoor activities, students learn about responsibility, teamwork, respect towards the environment and its conservation, in addition to generating attitudes such as critical viewpoint, reflection and attitudes about scientific work such as the socialization of results, among others. From the statistical point of view, in the *Attitude* subcategory we find a high significance, (p-value ≤ 0.001), unlike the *Concepts* (p-value = 0.327) and *Processes* (p-value = 0.083) contents. For Gavidia (2008), the school has a socializing role and its function is to train critical people with the capacity to make decisions and face the daily problems of today's society, in this case through field practices. The aim is to provide students with the acquisition of basic competences to live with other people and be responsible with the environment. Research such as that of Lavie Alon and Tal (2017) have shown the predominance of conceptual learning of students in the field, however, these emphasize the desire to develop values and reflections on the proper behavior in nature.

According to Planning: *Previous ideas*

{What would you consider in order to carry out a Field Work activity?} *"... I would develop it in my preference beforehand, since it has allowed me, based on previous ideas, to structure more solid knowledge based on experience ..."*

Only six future teachers (22.2%) said at the beginning of the training process, that they would consider the previous ideas of their students to develop a field practice, while 13 (48.2%) consider this concept after our didactic intervention. The comparison between the pre and posttest showed a p-value = 0.056, very close to ≤ 0.05. We can infer that with a larger population, the data could tend towards greater significance. For Behrendt and Franklin (2014), the teacher must take into account the previous ideas of their students and allow a high degree of participation in the field activity, which generates greater motivation in them. On the other hand, for Dourado and Leites (2013), it is ideal that the field activities are planned by the teacher from a constructivist perspective.

According to Difficulties: *Teachers*

{What difficulties could you have to carry out a Field Work activity?} *" … that the students do not want to do it, the permission of the parents or the directors of the school, the space to do it, not knowing how to handle the disabilities of the students ...”*

Unlike the pretest, where the future teachers had contemplated the ideas *School Culture* and *Preparation*, here pre-service teachers identified with greater emphasis these subcategories (63% and 96.2% respectively) and also included in a greater proportion the *Students behavior* (11 students-40.7%) and the *Teacher* (6 students-22.2%). Studies like the one made by Glackin (2016) have shown that one of the main difficulties that new teachers consider to teach in the field is the management of student behavior outside of school. The management of the students both in class and in the field was favored by the fact that each group consisted of around 5 future teachers, so that they could be supported much more in teams and each one focused on small groups of students. For Scott et al. (2015), training, knowledge and trust, are the teacher's own difficulties for the full realization of field activities and therefore recognizing them involves a process of reflection and metacognition, a situation that had been absent in the pretest. From the statistical point of view, the comparison between the pre and posttest yielded a p-value = 0.05 for the *Professor* subcategory.

According to Contribution to teacher training: *Biology Teaching*

{What does Field Work activities provide to your training as a teacher?} *" ... The field practices will allow a better management of the students, strengthen certain knowledge, know the theoretical level that the students have, get ideas to do research within the classroom and finally get a motivation on the part of the students for the subject... "*

Pre-service teachers (21 cases -77.7%) highlight the fundamental role of Field Work as a teaching strategy of great importance that they hope to actively develop in their teaching practice. They highlight the impact and contribution of this activity in the learning of their students from the integration of conceptual, procedural and attitudinal learning, which will also allow them to break the traditional school schemes and to better understand the characteristics of their students, their learning rhythms, their context and their daily life. The comparison between the pre and posttest (p-value = 0.003) shows a high degree of significance. The above corresponds to the approaches of Dourado (2006) and Del Carmen (2011) that conceive Field Work as a fundamental teaching strategy of Biology. Specifically, we emphasize here that future teachers must be aware that Field Work as a teaching strategy contributes explicitly in the construction of the Professional Teacher Knowledge and in the enrichment of the Pedagogical Content Knowledge, their relationships and components (Costillo et al., 2014; Behrendt and Franklin, 2014).

Professional Development

{How does Field Work contribute to your training?} *"… A great satisfaction for having carried out an activity that can end up marking the lives of the students, of having taught them in a different way to the traditional one...."*

15 pre-service teachers (55.5%) explained that the design, implementation and evaluation of a field practice with high school students had contributed to their professional development. These future teachers identified that field work, as a teaching strategy of Biology, could favor the development of affective bonds with their students, professional satisfaction for the proper management in natural environments, project ethics and the image of an integral teacher and how with this activity they contributed to the improvement of the educational processes of the schools where they carried out the experience. The comparison between the pre and posttest showed a p-value = 0.029. The planning, development and evaluation of Field Work in Biology teaching helps generating attitudes of self-efficacy, confidence in their work as teachers (Ateskan & Lane, 2016) and professional development (Tal, 2001).

CONCLUSIONS

The results of this study support the thesis that a training proposal for teachers focused on the design, development and evaluation of Field Work for the teaching of a biological theme addressed to secondary school students, allows the configuration of a specific Pedagogical Content Knowledge. In particular, the teaching experience and the effective preparation of Field Work activities is fundamental for the construction of the Professional Teacher Knowledge, since it allows to consider that in the field students learn by establishing direct contact with biological phenomena, not only through the mere observation but through its investigation, which implies the development of scientific skills and abilities that allow them to generate behaviors in favor of the conservation of biological diversity and sustainability.

From a professional development point of view, it is necessary that the initial training of teachers includes Field Work in the curriculum, considering the need for planning, participating and reflection promotion of students during its implementation, a situation that until the time of our investigation, had not occurred for the first three years of training of these future teachers.

Finally, we have seen that although teachers usually participate in Field Work during their initial training, their conceptions about the didactic characteristics of this teaching strategy, are reductionist. In this sense, they consider that it is enough with the teacher selecting a place and a topic to carry out a field practice, where mainly what students do is corroborate what the teacher has previously transmitted in the classroom. Therefore, training interventions are required in which the teachers design, apply and evaluate Field Work for the teaching of specific biological topics. This will allow the enrichment of their conceptions towards more desirable positions from the framework of research in didactics of the natural sciences.

DEVELOPMENT OF A SCALE TO TEST ENVIRONMENTAL LITERACY AND TO PREDICT ENVIRONMENTAL RESPONSIBLE BEHAVIOUR OF PRE-SERVICE TEACHERS

Lidia Caño and Oihana Barrutia
University of the Basque Country (UPV/EHU), Donostia-San Sebastián, Spain

Education for sustainable development (ESD) from early educational stages requires the guarantee of an adequate environmental literacy (EL) of pre-service teachers. Although different attempts have been made to assess the EL of pre-service teachers, few studies have assessed scientific knowledge that fit that of the target educational curriculum. Also, almost no information has been provided on the major predictors of their environmental responsible behaviour, therefore impeding designing educational programs accordingly. In order to meet this need, we have designed and validated an instrument based on the existing literature to properly assess environmental literacy (EL) of pre-service teachers and to provide insights into the potential predictors of environmental behaviour. The instrument tests three components of the EL: environmental attitudes, behaviour and ecological knowledge. The behaviour scale incorporates emerging understudied environmental behaviours. The knowledge scale consists on scientific concepts included in the compulsory education science curriculum considered as core ideas for the understating of the causes and consequences of environmental problems, specifically those dealing with biodiversity loss. The questionnaire has been pretested and validated by 182 university students (pre-service teachers) and showed to be highly reliable considering its good psychometric properties. The three components were significantly correlated. Factor analysis allowed us to identify two bidimensional domains in the attitude and behaviour scales. Specifically, we identified two levels of actual commitment, one referring to integrated habits and a second one corresponding to self-demanding emergent habits, which accounts for the adequacy of the instrument for assessing behaviour's predictors. Preliminary results show that participant pre-service teachers showed good levels of environmental attitude but moderate levels of ecological knowledge and lower levels of responsible environmental behaviour.

Keywords: Environmental Literacy scale, Pre-service teacher's education, Environment Education

INTRODUCTION

Sustainability in the curricula of prospective teachers is key to ensure an effective Education for Sustainable Development (ESD) from early educational stages, including the guarantee of an adequate environmental literacy (EL). As regards the latter, becoming an environmentally literate person involves the acquisition of values, attitudes and skills that allow transforming knowledge into action. Hence, although different components of EL have been proposed (Roth, 1992; Hollweg et al., 2011; McBeth, Hungerford, Marcinkowski, Volk, & Meyers, 2008; McBride, Brewer, Berkowitz, & Borrie, 2013; NAAEE, 2010; Nolet, 2009; Warren et al., 2014) they all can be summarized into three major components: attitudes, behaviour and knowledge. Indeed, the environmental responsible behaviour might be influenced by the affective dimension, including attitudes and values necessary to motivate action, and driven by a comprehensive understanding of environmental problems. In addition, a number of studies have shown that increasing environmental knowledge may improve environmental attitudes (Bradley, Waliczek, & Zajicek, 1999; McMillan, Wright, & Beazley 2004; Pe'er, Goldman, & Yavetz, 2007) and promote environmentally responsible behaviour (Hsu 2004, Liu & Lin, 2015).

Since pre-service teachers will be responsible for the education of future citizenship, assessment of their EL is key in order to select the best educational approaches for their proper training. Although different attempts have been made to assess the EL of pre-service teachers, most studies have focused on their understanding of particular environmental problems (Alvarez-García, Sureda-Negre & Comas-Forgas, 2018 Michail, Stamou, & Stamou, 2007; Pe'er et al., 2007; Teksoz, Sahin & Ertepinar, 2010; Timur, Timur & Yilmaz, 2013; Tuncer et al., 2009) and only a few ones have assessed fundamental understanding of scientific concepts (Muda, Ismail, Suandi, & Rashid, 2011; Yavetz, Goldman, & Pe'er, 2009). Since an environmentally literate individual should be able to make sense of environmental realities by specifically identifying their cause and effect relationships based on scientific knowledge (McBride et al., 2013), instruments assessing EL should incorporate items asking on scientific concepts and processes that enable the interpretation of environmental issues rather than querying on the issues themselves. When it comes to the evaluation of the EL of compulsory school teachers (both prospective and experienced ones), it seems reasonable that the level of scientific knowledge evaluated should fit that of the target educational curriculum. However, this approach has not been commonly undertaken in the design of teachers' EL assessment diagnostic tools (but see Yavetz et al., 2009).

Many studies conducted so far in different countries have revealed that teachers (including pre-service ones) overall display good environmental attitudes but have important gaps and misconceptions regarding environmental knowledge (Teksoz et al., 2010; Tuncer et al., 2009; Yavetz et al., 2009). In this sense, despite the recognized need to prepare effective environmental educators, there is almost no information on the level of EL of teachers in Spain. Interestingly, Alvarez-García et al. (2018) have reported a low knowledge level about environmental realities among Spanish pre-service teachers attending two universities, while simultaneously displaying environmentally responsible attitudes and an ecocentric view of the world.

If the ultimate goal of environmental education is to change pupils' and future citizens' behaviour, in addition to evaluate the level of EL (and its components) of prospective teachers, there is an urgent need to identify the major predictors of their environmental responsible behaviour in order to incorporate those components into educational programs and instructional practices. Yet, there is scarce information on which variables best predict their behaviour (Hsu & Roth, 1999) and no data on how their environmental attitudes and knowledge affect their actual commitment in undertaken environmental responsible actions. Furthermore, there is an additional difficulty nowadays when designing an appropriate environmental behaviour scales since there is increasing information on emergent environmental issues and corresponding responsible behaviours both in the scientific literature and public media. Consequently, traditionally used items should be updated to fulfil current trends on responsible behaviour. For instance, although many environmental behaviour scales systematically include items referring to recycling habits or household energy or water saving (e.g. Kaiser, Wölfing, & Fuhrer, 1999; Leeming Dwyer, & Bracken, 1995; Liu & Lin 2015) items referring to habits oriented to alleviate emergent issues such as microplastic accumulation in oceans or high greenhouse effect gas emissions by intensive farming have not been covered so far.

Account taken of all above, we have developed an instrument to measure pre-service teacher's EL based on the literature concerning EL's indicators, i.e. environmental attitudes and behaviours and ecological knowledge (e.g. AAAS, 2018; Amérigo, Aragonés, & García, 2012;

Leeming et al., 1995; Liu & Lin, 2015; Milfont & Duckitt, 2010) and by incorporating scientific concepts included in the compulsory school science curriculum considered as core ideas for the understanding of the causes and consequences of environmental problems. Since the ultimate goal of ESD is to train for environmental responsible behaviour, our instrument was designed to provide insights into the potential predictors of environmental behavior, including self-demanding understudied behaviours towards emergent little-known environmental issues such as food production's effect on global change, microbeads or endocrine disruptors. We aim at assessing the reliability, validity and psychometric properties of this instrument and to show preliminary results.

METHODS

Instrument development

The designed instrument includes one scale for each of the three components of the EL: environmental attitudes (17 items), behaviours (19 items) and knowledge (28 items). Each scale comprises several domains (Table 1). The environmental attitude scale was adapted from Leeming et al. (1995), Mayer and Frantz (2004), Milfont and Duckitt (2010), Amérigo et al. (2012) and Liu and Lin (2015) and includes three domains: interest in nature, emotional link with nature and anthropocentrism. The environmental behavior scale includes items modified from Leeming et al. (1995), Kaiser et al. (1999) and Liu and Lin (2015) and comprises two sub-dimensions typically found in the bibliography: verbal commitment and actual commitment. The actual commitment dimension was adapted to fit emergent environmental issues (e.g. usage of plastics, meat consumption, etc.).

Attitude and behaviour's scales consist on 5-point Likert-type items ranging from "strongly disagree" to "totally agree". An additional option named "NA" (not applicable) was also added. Based on the premises that ecologically literacy implies the ability of understanding environmental issues by specifically identifying their cause and effect relationships (McBride et al., 2013) and that pre-service teachers should first teach curricular concepts, the following criteria were fulfilled in the designed knowledge scale:

- questions in the knowledge scale were placed in context.
- knowledge scale refers to the understanding of curricular key ecological concepts.
- key ecological concepts included in the scale were considered as indispensable for the comprehension of the causes and consequences of environmental problems, specifically those dealing with biodiversity loss.

The main environmental issues causing biodiversity loss considered here were: greenhouse gas emissions (climate change), toxic gas emissions (acid rain), persistent bioaccumulative and toxic substances (pesticides, microplastics, etc.), nitrate and phosphate contamination (eutrophication), resource overexploitation and habitat destruction (deforestation, agricultural and farming expansion, pollution, etc.) and exotic invasions. The corresponding 6 curricular key ecological concepts considered as necessary to correctly interpret these issues were identified based on the Framework for K-12 education (National Research Council 2012) and the Next Generation Science Standards (NGSS Lead States 2013) and comprise: life functions, biotic and abiotic interactions, environmental fluctuations, dynamics, resistance and resilience, matter cycle and energy fluxes, systems' interconnections and evolution.

Knowledge scale consists on multiple choice questions with a single correct answer (scientific conception) and two answers corresponding to misconceptions of different level of misunderstanding. An additional option was included as "DK/NA" (Do not know/ No answer). Items were adapted from AAAS (2018), Kalinowski, Leonard, and Taper (2016), Leeming et al. (1995), McBeth et al. (2008), Morrone, Mancl, and Carr (2001), and Ozay and Oztas (2003). We also incorporated 11 new items to cover underrepresented concepts such as sexual reproduction or nutrition function and specific fundamental ideas for the correct understanding of the present causes of biodiversity loss such as the understanding of organisms' and ecosystems' response to environmental changes and the origin of biodiversity.

In order to examine factors influencing environmental literacy of pre-service teachers, questionnaires included: (i) demographic characteristics such as gender, age, number of habitants in their hometown, having family farm, (ii) academic data such as having studied Biology during their baccalaureate (16-18 years old) and the mark obtained in that subject, the university entrance mark, the year pursuing in the Bachelor's Degree and the mark obtained in the Biology course during the Degree (if applicable) and (iii) information on their leisure activities such as frequency of going to the nature and traveling to rural areas through the year.

First validation process

The first version of the questionnaire was submitted to evaluation by two experts: one expert in Science Education and professor of pre-service teachers and one Ecologist researcher. Comments by the experts were used to modify pertinent items to elaborate a second version of the questionnaire. The second version of the questionnaire was applied to a sample of 64 students who will not take part in further steps. For each item, the frequency distribution of the response was evaluated. Items showing more than 15% of cases distributed in the extreme values (1 or 5) or showing kurtosis values above 1.5 were reformulated in order to enhance normal distribution in further attempts. As a result a third version of the questionnaire (final version hereafter) was issued.

Participants and data collection

The final version of the questionnaire was administered to 182 pre-service primary education students of the University of the Basque Country. The sex ratio (F:M) of the participants was 2.2 and most represented age range was 18-25 years old. Data was collected during students' free time at the classrooms of the University of the Basque Country. Previously, students were informed about the objectives of the research and they had to sign up a paper stating that they consented their data to be used for research purposes. Students filled in the questionnaire voluntarily. They were sat in separated tables and the test was conducted in absolute silence. Despite the questionnaire was anonymous, each student was provided with an identification number in order to effectively register their data and have the chance to deeply re-analyze their responses (for instance by calling them for a further/more exhaustive study) or to enable a temporary assessment of their ideas. Before starting the task, students were also given some time (approximately 1 minute) to clarify their doubts about the commitment. Afterwards, although there was no time limitation for conducting the task, students were encouraged to finish it in approximately 30′.

Data analysis

Since positive and negative items were used in the attitude and behavior scales, negative items were scored in the reverse order. All scores for a particular participant were added for each scale and dimension. In the case of the knowledge scale the cumulative scores for each core concept were also calculated. In order to account for the DK/NA and NA responses, the total score obtained for a participant was weighed based on the total number of the items responded by this participant according to the maximum possible score that can be obtained in each scale or dimension. Total scores were expressed as a percentage of the maximum scoring that can be obtained for a particular scale or domain.

The consistency of the scales and domains were assessed using the Cronbach alpha reliability index. The validity of each item and core concept was assessed using the corrected

discrimination index (r) which measures the correlation coefficient between a particular item and the total score for corresponding domain after removing that item. The level of discrimination of each item was considered as very good when r ≥ 0.4, good when 0.39 ≥ r ≥ 0.3, deficient when 0.29 ≥ r ≥ 0.20 and inadequate when r ≤ 0.19.
Skewness and kurtosis indices were calculated to assess the normality of the distributions of domains and core concepts. The dimensionality of each domain was assessed through factorial analyses. The dimensionality of each scale and domain was assessed through factorial analyses using the maximum likelihood estimation. The following criteria were used to assess the dimensionality of the scale and domain: percent of accumulated variance must be > 40%, KMO value > 0.6 with level of signification p<0.05 and communalities of items > 0.2 in most cases. Pearson's inter- and intra-correlations between domains and core ideas were also calculated within and among each scale.
General linear models were also performed in order to assess the preliminary results on the influence of demographic and academic and factors on the EL of participants.

RESULTS

After removing items with low discrimination indexes, the instrument showed good psychometric properties (Table 1 & 2). Regarding the attitude scale, two items displayed discrimination indexes < 0.3 and were conflicting within domains too. After removing these items attitude scale's Cronbach alpha was 0.845 and all items' discrimination indexes ≥ 0.3 (Table 1). "Interest for nature" domain was bidimensional (KMO=0.74, chi-sq=1.09, p=0.90) (Table 1). The first factor was interpreted as "support for environmental policies" and the second one as "consciousness of the fragility of nature" as in Milfont and Duckitt (2010). "Emotional connection" and "Anthropocentrism" domains were unidimensional.
Concerning the behaviour scale, two items displayed very low discrimination indexes due to the high number of "NA" responses. These items asked about pre-service teachers' voting intention and about car use respectively. After removing these items, the behaviour scale's Cronbach alpha was 0.806 and most discrimination indexes were ≥ 0.29 except in the case of items referring to the use of energy saving light bulbs and to food shopping criteria, respectively (Table 1). "Actual commitment" domain was bidimensional (KMO=0.73, chi-sq=34.55, p=0.44) (Table 1). Items with lowest and highest scores were associated with factor 1 and 2, respectively. Factor 1 was thus interpreted as "self-demanding emergent habits" and factor 2 as "Integrated ordinary habits". "Verbal commitment" dimension was unidimensional.
Two items were removed from the knowledge scale due to their low discrimination index. The Cronbach's alpha for the new knowledge scale was 0.669 and for the cumulative scores for the 6 core concepts was 0.670.
All inter-correlations within each scale were significant at the 0.05 level except in the case of "Responsiveness to change" vs. "Evolution" correlation (p=0.08). Moreover, the correlation between scales was also significant which supports the validity of the instrument.

Table 1. Attitude and behaviour scales' and domains' statistics.

Scale Domains	Items	Cronbach's alpha	Range	Mean score	Mean score (%)	SD	Skewness	Kurtosis
Attitude	**15**	**0.845**	**0-60**	**40.67**	**67.79**	**1.17**	**-0.39**	**-0.46**
Interest for nature	6	0.734	0-24	17.04	70.99	1.37	-0.49	-0.25
Support environmental policies	3	0.682	0-12	9.22	76.90	1.24	-0.84	2.09
Fragility of nature	3	0.734	0-12	7.81	65.11	2.08	-0.83	-0.12

Emotional connection with nature	5	0.637	0-20	12.78	63.88	1.34	-0.38	-0.56
Anthropocentrism	4	0.583	0-16	10.85	67.79	1.38	-0.34	-0.28
Behaviour	**17**	**0.806**	**0-68**	**34.45**	**50.67**	**0.10**	**-0.6**	**0.12**
Verbal commitment	6	0.728	0-24	12.18	50.74	1.16	-0.29	-0.53
Actual commitment	11	0.629	0-44	20.07	45.61	1.26	0.24	-0.31
Integrated habits	4	0.704	0-16	10.45	65.30	1.99	-0.48	-0.83
Emerging habits	7	0.705	0-28	9.75	34.84	1.39	0.57	0.00

Table 2. Ecological knowledge scale's and core concepts' statistics. Core concepts are arranged from less to high difficulty level.

Scale Core concept	Items	Range	Mean score	Mean score (%)	SD	Skewness	Kurtosis
Knowledge	**26**	**0-26**	**14.39**	**55.35**	**1.11**	**-0.44**	**-0.56**
Large-scale systems interactions	3	0-3	1.83	60.93	0.18	-1.07	2.44

Preliminary results show that participants obtained a better score in the attitude scale (M=67.79, SD=1.17) than in the behaviour (M=50.67 SD=0.10) and the knowledge scale (M=55.35, SD=1.11) (table 2). The "interest for nature" domain in the attitude scale showed the highest mean score (M=70.99 SD=1.37) mostly driven by the mean score obtained in the subdomain "Support for environmental policies" (M=76.90 SD=1.24). In contrast, the lowest mean score was obtained in the "Actual commitment" domain of the behaviour scale (M=76.90 SD=1.24) due to the very low mean score obtained in the "Emerging habits" subdomain (M=34.84 SD=1.39). The effect of the gender on scores was not significant but preliminary results show that going more frequently to the nature may improve the environmental attitude ($p<0.005$).

Concerning the knowledge items, participants' understanding of the idea that large-scale systems are connected, and the existences of cycle and fluxes, was better than that of basic mechanisms of life functions or they responsiveness to environmental changes.

DISCUSSION AND CONCLUSIONS

Our results show that the designed instrument shows good psychometric properties, strong validity and reliable scores. High correlation within scale domains indicates the relevance of the items and concepts. However, it is noteworthy that items of the behaviour scale related to voting intention, car use or household consumption did not prove to be pertinent when assessing the EL of pre-service teachers and, thus, they were removed from the scale. This might be due to the young age of this particular social group who often have limited access to car use and independent housing in Spain. This finding highlights the need to adequate and validate specific diagnosis tools to the actual reality of participant pre-service teachers.

Preliminary results show that participants showed good levels of environmental attitude but moderate levels of ecological knowledge and lower levels of responsible environmental behaviour, which is in line with what has been found by other studies (Alvarez-García et al., 2018; Teksoz et al., 2010; Tuncer et al., 2009; Yavetz et al., 2009). Moreover, our factor analysis allowed us a more accurate interpretation of the results since we were able to identify two sub-domains in the "interest for nature" and "actual commitment" domains within the attitude and behaviour scales respectively. For instance, our instrument allowed us to detect that the highest and lowest relative scores were precisely obtained for the subdomains "support of environmental policies" and "self-demanding emergent behaviours" respectively which enables us to conclude that the demanding attitude towards institutions concerning the environment conservation tends to be more intense that actual personal commitment. Other studies have also pointed out that despite the awareness of prospective teachers of the importance of responsible environmental behaviour, this rarely results in actual behaviour (Goldman, Yavetz & Pe'er, 2006).

In our study we also found that participants showed a high level of commitment concerning integrated ordinary habits such as recycling habits, which contrast with the low commitment with respect to more self-demanding and less known habits such as sustainable consumer behaviours. Since our instrument was designed to provide insights into the potential predictors of environmental behaviour, having detected the "self-demanding emergent behaviours" subdomain in the behaviour scale strengthens the predictive ability of our instrument. This way, when assessing factors affecting the responsible behaviour of pre-service teachers, we could separately consider most integrated habits and self-demanding less known behaviours affecting emergent environmental issues such as food consumption effect on global change, consequences of endocrine disruptors' consumption, etc.

Our results concerning the knowledge scale indicated that, although pre-service teachers taking part in this study seem to have an intuitive idea of the global and interrelated effects of the environmental issues, they may lack the underlying mechanistic explanations of basic biological processes occurring at the organism and ecosystem level. A comprehensive understanding of the ultimate consequences of environmental issues causing biodiversity loss might influence the environmental attitude and the responsive behaviour of pre-service teachers. Therefore, administrating this instrument to a larger sample of pre-service teachers will allow further specific and accurate analysis on the relationships among the EL's dimensions and subdimensions found in this study and the relative influence of the understanding of core scientific concepts that are part of Primary and Secondary School curriculum.

INTRODUCING PRE-SERVICE EARLY CHILDHOOD TEACHERS TO EDUCATION FOR SUSTAINABLE DEVELOPMENT USING SOCRATES' HOUSE

Anthoula Maidou[1], Katerina Plakitsi[1] and Hariton M. Polatoglou[2]
[1]School of Education, University of Ioannina, Ioannina, Greece
[2]School of Physics, Aristotle University of Thessaloniki, Greece

Humankind is facing critical situations concerning environmental, societal and financial problems. Through Education for Sustainable Development (ESD) students of all educational levels could gain knowledge and positive attitudes to become democratic and informed citizens, aware of the current problems, and able to take actions. A questionnaire we used to inquire about pre-service early childhood teachers' knowledge, views and attitudes towards ESD showed that most of them had never ESD lessons during formal education. Furthermore, while most students expressed positive attitudes, a clear majority, had very little knowledge what ESD is, with almost all students acknowledging only environmental aspects, half of them also societal issues, and only one third stated in addition economic problems. When asked if they need more education on sustainability, most agreed strongly, while the clear majority stated that including ESD in their curriculum could help them teach about sustainability. To address the above problems, we designed and conducted Teaching Interventions (TIs) using houses as the main theme. Houses constitute a familiar experience to all people throughout time, have environmental impact, are social constructs, and are economic entities. Thus, through houses we can analyze all dimensions of ESD. Highlighting at the same time that a very familiar subject can be complex and multifaceted. In this study we present the outcomes of the TIs we conducted with pre-service Early Childhood teachers. Comparing the findings of the pre- and post- application of the questionnaire we observe the short TIs had a clear increase of the students' knowledge of SD, while students' views and attitudes also improved.

Keywords: Education for Sustainable Development, Initial Teacher Education, Socrates' house, Teaching Interventions

INTRODUCTION

The major problems of our time, as the climate crisis, the migration problems, the extended use of plastic, which ends up in our environment and our food chain, etc. are all issues of Sustainable Development (SD). Therefore, Education for Sustainable Development (ESD) is a complex and multifaceted subject, including environmental, societal and economic aspects and their interrelatedness. Furthermore, ESD is a subject still evolving (McKeown 2002) and it is not just a set of knowledge that can be learned and applied. In addition, successfully applied solutions to local problems seem often unsuitable for other places.

It is imperative to include sustainable development courses at all educational levels if we want to ensure quality life for future generations. However, to achieve changes, not only knowledge, but also positive attitudes and values towards ESD, should be acquired (Dillon & Gayford, 1997). Teachers can influence positive attitudes and values by making pupils aware from youngest ages through formal and informal education. Aspects of ESD can be incorporated in all subjects, while interdisciplinary, interactive and experiential approaches have shown to be appropriate pedagogies. There have been many attempts to incorporate ESD in the higher institutions' curricula worldwide (Cebrián, 2016; Burmeister & Eilks, 2013). Many scholars also suggest including short interventions in all subjects (McKeown, 2014).

Since ESD is such a crucial subject, we wanted to inquire about the knowledge, beliefs and attitudes of pre-service Early Childhood teachers. We used a questionnaire consisting of two parts, of which the first was an inquiry about the knowledge, perceptions and attitudes of students towards ESD issues (Maidou, Plakitsi & Polatoglou, 2019a), while the second part contained questions about heat transfer from everyday life experiences, thermal behavior of building materials, and the form and function of traditional houses and especially traditional houses in Greece. The questionnaire was applied to measure the results of pre-service teachers' knowledge, perceptions and attitudes before and after the Teaching Interventions TIs. We are aware that it is difficult to estimate improvements of attitudes, since a positive expression on something might only show enthusiasm, without necessarily leading to actions or teaching ability. We started the research during the year 2014-15, and since we adapted the teaching approach, tasks, and activities. Here we will report about the outcome of the academic year 2017-18.

Pre-test findings of the questionnaire revealed that 47% of the students consider their knowledge of ESD issues moderate, around 28% little and 11% inadequate. In addition, a large percentage, about 64%, said they never had ESD or Environmental Education (EE) courses. When asked about their stance on sustainability issues, most (about 70%) answered that they believe that it is important for people to be interested about sustainability, but only 12% said they are interested and contribute wherever they can, while nearly 12% stated that they do not know what sustainability is about. Most of the students did not know about the three SD components – 95% acknowledged environmental issues, about 50% mentioned societal problems, and only 34% financial matters. Furthermore, 77% of the pre-service teachers agreed strongly/agreed that ESD should be included in the curricula of future teachers and that the inclusion of ESD would support them in their teachings. When asked if they feel that they need more ESD training, 32% responded 'very much' and 46% 'much'. In conclusion, the findings showed lack of content knowledge about ESD, but positive beliefs and attitudes towards ESD. For all the above reasons, we decided to conduct TIs on ESD using houses. We chose houses to approach ESD, and examined them as cultural phenomena, as social constructs, and as financial entities, and focused on their environmental influences, more specifically on energy consumption in houses.

Furthermore, including history and philosophy in the teaching of sciences, according to Seroglou and Adúriz-Bravo (2012) leads to a more meaningful science education. In the same line, Matthews (2009) supports the inclusion of aspects of history and philosophy of sciences in curricula and classrooms arguing that in this way we can humanize the sciences, connecting students with personal, ethical, cultural, and political concerns, making classrooms more challenging, enhancing critical thinking skills, and contributing to the understanding of the scientific subject. Koliopoulos, Dossis, and Stamoulis (2007) advocate the use of authentic or transformed historical material, mainly text. This approach combines the discovery and explanatory framework and is often connected to the story-line approach.

We conducted TIs using houses and a historical text to elaborate aspects of ESD. Our research questions were:

1. Can short term TIs raise students' knowledge of ESD aspects?
2. Can short term TIs positively affect students' attitudes towards ESD issues?
3. Are houses suitable examples to be used to study several ESD aspects?

METHOD

To enhance the knowledge of the pre-service teachers, we used an inquiry-based approach. We discussed explicitly about the various issues of ESD, allowing them to express their perceptions on why an issue is considered critical for the environment, society and/or economy. We stressed the importance of teachers in the education of critical thinking democratic citizens, willing to take responsibility and face the problems of humankind. In this process, we followed the paradigm of teaching about the Nature of Science (NOS), according to which NOS needs to be explicitly addressed and planned for, through reflective questioning and discussions of the NOS aspects (Abd-El-Khalick & Lederman, 2000; Khishfe, 2012). We furthermore stressed the importance of ESD by presenting the efforts of UNESCO with the Decade of ESD and the following initiative of the 17 SD goals.

ESD can be accessed through the teachings of any key aspect of ESD. We chose houses since they are a very familiar subject to any person of any age, they have profound environmental impact, are social constructs bearing psychological value and are an economic entity.

Buildings consume the highest percentage of the energy consumption in the US (47.6%) and EU (38.1%), higher than industry and transportation. Since at our houses we can control our consumption, the question posed to the students was: 'Can we consume less energy in our homes without compromising our wellbeing?'. When asked where students consume energy at home, they replied mostly for warm water and heating during winter and cooling during summer.

We then presented and discussed traditional architectural solutions to housing from around the world. Igloos and African huts are houses in extreme weather conditions, which offer protection to their inhabitants and are adapted to the local conditions. The same holds for traditional houses in Greece, houses from mountainous areas and from islands. And this adaptation to the local climate conditions and building materials is not new, as can be observed from the excerpt of Xenophon's Memorabilia (1923) of book Γ', 3.8.8-3.8.9, where Socrates mentions how houses should be built:

> '… Is it pleasant to have it [house] cool in summer and warm in winter? Now in houses with a south aspect, the sun's rays penetrate the porticoes in winter, but in summer the path of the sun is right over our heads and above the roof, so that there is shade. … we should build the south side loftier to get the winter sun and the north side lower to keep out the cold winds.'

These building principles were applied until the beginnings of the modern era, to build traditional houses in Greece, both in islands and mountains. Adaptation to local climate conditions, locally available building materials, etc. can be observed in traditional buildings globally. Currently, bioclimatic designers have rediscovered these principles.

After the presentation of the excerpt about the Socrates' house, the students were asked to present drawings of the house, discussing and working in groups of 4-6. They produced correct representations of Socrates' house mostly with the South façade higher than the North façade, while some groups prepared some quite elaborate sketches which were published in Maidou, Plakitsi and Polatoglou (2019b).

Socrates had deep knowledge of the principles of bioclimatic architecture, and the apparent path of the sun in the sky during the year. In the Northern Hemisphere the sun-path reaches the highest noon point at the summer solstice and the lowest one at the winter solstice. In order to comprehend the function of this house we must understand the importance of its orientation, and also grasp the apparent motion of the sun throughout the year. During winter and before the spring equinox the sun rises and sets closer to a southeast and southwest position respectively, reaching the most distant point during the winter solstice. On the other hand, moving from spring to summer and before the autumn equinox, the sun rises northeast and sets northwest, with the most distant point during the summer solstice. A depiction of these phenomena for the Northern Hemisphere is presented in Figure 1. During the TIs we explained with the help of a presentation with picture, simulations and with the help of a house model and a torch the difference of the sun-path during summer and winter.

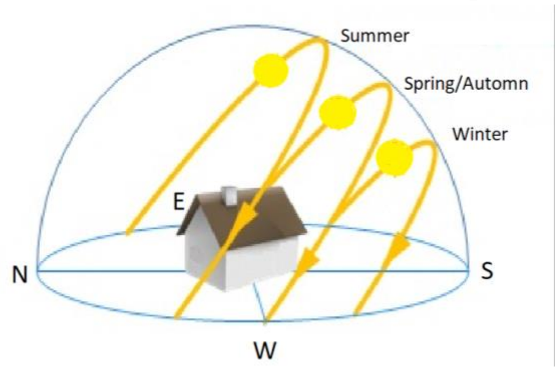

Figure 1. Apparent sun-path during summer, spring and autumn, and winter for the Northern Hemisphere.

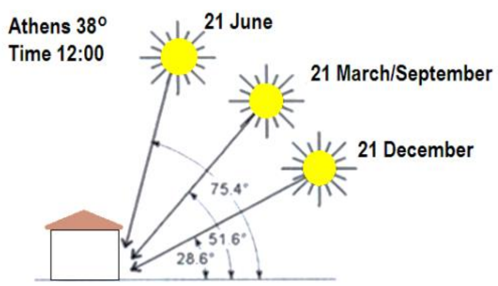
In addition, the apparent sun-path reaches during summer a much higher point in the sky in comparison to the much lower highest point it can reach during winter. For example, for Athens at 12:00 on 21st June, the sun rays arrive with an angle 75.4° while on 21st December, the sun rays have an angle of 28.6°, as can be seen in Figure 2. This means that during the winter months the sun-rays reach deeper into the house through the South windows, offering a free heating source, as mentioned by Socrates. This does not cause an overheating problem during summer, since the sun-rays can easily be screened by a small protrusion of the roof – one meter is enough to screen windows and balcony doors of a house in Greece.



Picture 2. Height of the sun at noon during summer and winter solstice and the spring/autumn equinox.

The thermal behavior of buildings is influenced by the buildings materials used. For a bioclimatic building apart from a south aspect with large windows, the building must have materials with high thermal capacity, which are able to store the heat gained by the sun-rays and the building must have good heating insulation in order to keep the heat inside and hinder its escape to the environment, To emphasize the importance of the building materials, the pre-service teachers performed some experiments in groups of 4-6. They were presented with some pieces of building materials: stone, piece of metal, wood, extruded polystyrene, plastic foil. They were asked to list the materials in writing. Afterwards they were asked if they believe that the materials have all the same temperature – the experiment was conducted during the winter semester with relatively low temperatures. All groups answered that the metallic object had the lowest temperature, while all groups agreed that the polystyrene was the warmest material. They had again to prepare a list from the coldest to the warmest material. All groups got a digital thermometer and were asked to measure the materials and write their findings next to each material. The pre-service teachers were highly surprised, finding almost the same temperature for all materials – some thought that the thermometer was malfunctioning. After some discussions among them they reached the result that all materials were in the same room and therefore they all had to have the room temperature. When we insisted how it was possible to feel with their hands such a huge difference, and what kind of materials showed such a discrepancy, after discussing it in each group, they found that metallic materials were good heat conductors, thus allowing heat from their hands to flow to the object and in this way they experienced it as cold, while the polystyrene, an insulator, hindering the heat flow from their hand to the object was experienced as a warm material.

In addition, to show a difference in heat capacity, we used a piece of stone and a piece of metal of approximately the same shape. The instructor (teacher) performed this experiment with the assistance of a student. The student had the digital thermometer and measured both materials, finding initially the same temperature for both. The teacher lit a flame and held one end of the materials in her hand while the other end was in the flame. During short time intervals both materials were removed from the fire and the student measured and reported the temperatures of both materials to the class. The experiment showed that the metallic object gained heat with a much higher rate than the stone. When we stopped the heat flow to the objects the metallic object had reached a higher temperature than the stone. We set both objects down on a wooden board and the student continued the measurements, reporting the temperatures to the class. Again, for the metallic object a quicker drop of its temperature was observed than for the stone, and at the end of the experiment both the metallic object and the stone had the same temperature.

The theoretical background for the design of the TIs was the Cultural-Historical Activity Theory (CHAT). According to Engeström (1999), the socio-cultural frame of Activity theory provides a context of human activity, linking the individual level to the social. The unit of analysis is the activity. This includes the person or group acting towards an object, applying certain rules and the dynamic relationships that develop within the activity system (Engeström, 1999; Barab, Evans & Baek, 2003). Roth and Lee (2004) understand science education as/for participation in the community and state that participation in the collective praxis of a community precedes over individuals and science. Engagement in science activities occurs with tools for dealing with a scientific concept, interacting with each another and with tools, building a community of learners, and working towards knowledge construction with scientifically accurate outcomes (Engeström, 2005). Within the CHAT framework, the individual and its learning experience are correlated with the social environment of the individual. Human interactions with the environment are socially defined. This aspect is linked to the principles of an activity system. The basic principles of CHAT include the hierarchical structure of activity, object-orientedness, internalization/externalization, tool mediation, and development. It is necessary to define object-orientedness to understand the hierarchical structure of an activity and the transformations that take place in the process of development. These transformations are interrelated with the tools of mediation. In addition, the dialectic relation of the principles of internalization/externalization allows individuals to act and transform their sociocultural background (Kaptelinin & Nardi, 2006). CHAT seems to be a coherent theoretical framework which can achieve the scope of real scientific literacy, enhance interdisciplinarity, and develop a new mentality that could reform science education from within. (Plakitsi, 2013).

The participants were Early Childhood Education pre-service teachers, mainly belonging to the age group 20-24 years (94.5%) and mostly female (98%). The same questionnaire was applied prior to the TIs and immediately after it. 192 students completed the pre-test and 184 the post-test questionnaire.

The teaching approaches we applied were student-centered (McNaughton 2012; Tomas, Girgenti & Jackson, 2017) experiential and participatory (Lysgaard & Simovska, 2016), inquiry-based and transformational (Biasutti, 2015; Corney & Reid, 2007; Tomas, Girgenti & Jackson, 2017). These teaching and learning methods promote changes in behaviors and ways of thinking and relate to knowledge and to processes, because these methods teach learners how to think (Biasutti 2015).

RESULTS

We present here the quantitative results of the questionnaire. After the TIs 98.4% of the students acknowledged environmental issues to be aspects of SD, 89.8% societal issues and 85.2% financial, exhibiting a profound improvement of the dimensions of ESD. From Table 1 we can also observe that the total percentages for the answers concerning ‘strongly agree’ or ‘agree’ have improved after the TIs.

Table 1: Students’ views on key elements of SD

Sustainable development implies:	% agree/strongly agree Pre-test (N=192)	% agree/strongly agree Post-test (N=184)
Maintaining biodiversity in the local environment	55.2	89.1
Recycling waste products	64.4	85.1
Helping people to avoid starvation and disease	44.5	80.5
Exploiting natural resources for human benefit while maintaining critical natural capital	55.5	88.3
Significant local production and consumption	43.1	75
Maintaining economic growth	35.1	82.7
Acting now is expensive but may offer quality life for future generations	69.3	81.3
Social progress recognizing the needs of everyone	49.7	82
Gender equality	20.6	82.7

Sustainable urbanization	41.7	87.5

By examining questions on the perceptions pre-service teachers have about ESD we can also observe improvement (table 2).

Table 2: Pre-service teachers' perceptions about ESD

Perceptions about ESD	% Pre-test (N=192)	% Post-test (N=184)
How do you evaluate your knowledge on ESD issues (very good/good)	14.6	46.9
Do you believe you need further training on ESD issues (very much/much)	78.5	81.9
Including ESD in my curricula would influence my ability to teach about it (strongly agree/agree)	72.8	87.4
It is important to include ESD training in future teachers education (strongly agree/agree)	76.8	86.7
Teachers can lead to solutions of environmental problems through their teachings (strongly agree/agree)	70.2	87.5

The same can be observed about the pre-service teachers attitudes towards ESD as illustrated in figure 3 and 2. They state that ESD issues are important for their teachings and their personal stances (pre-test 90% - past-test 98%). They also support that it is important to include sustainability issues in their teachings (80% before and 91% after the TIs).

As to the second part of the questionnaire, students had already a very high understanding of heat transfer and heat capacity phenomena of their everyday life experiences. Concerning the sun-path, before the TIs, when asked if the apparent sun-path is the same during summer and winter, 20% answered yes, 28% no, and 52% I don't know, while after the TI no one answered yes, 98% no and 2% I don't know. As for the building materials, the majority (71%) named polystyrene as an insulator while 64% before. In addition, when asked to identify materials with high heat capacity, 76% named stone and 61% concrete, while before the TIs these materials ranked to 47% for stone and 27% for concrete.

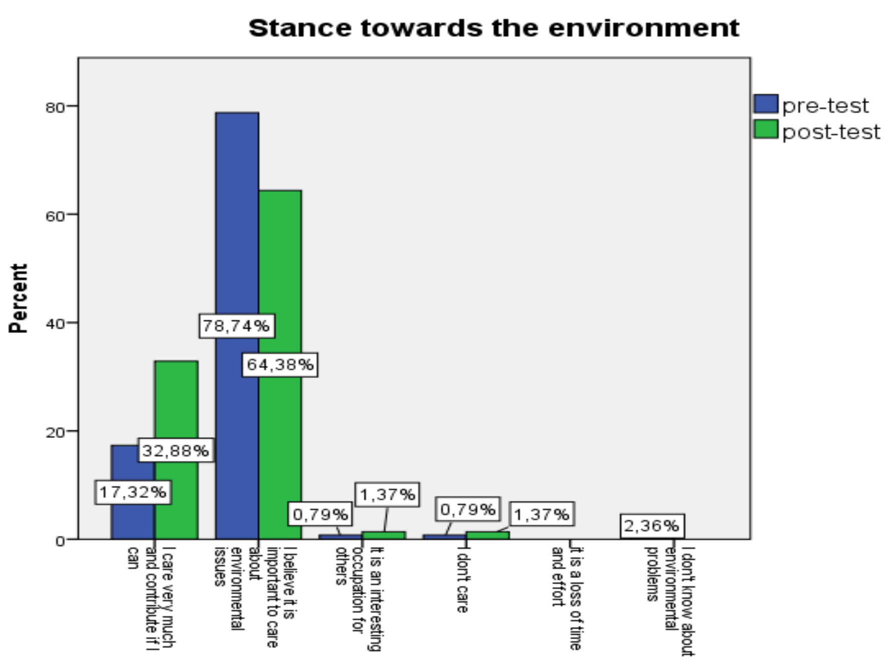


Figure 3. Stance of the pre-service teachers towards the environment.

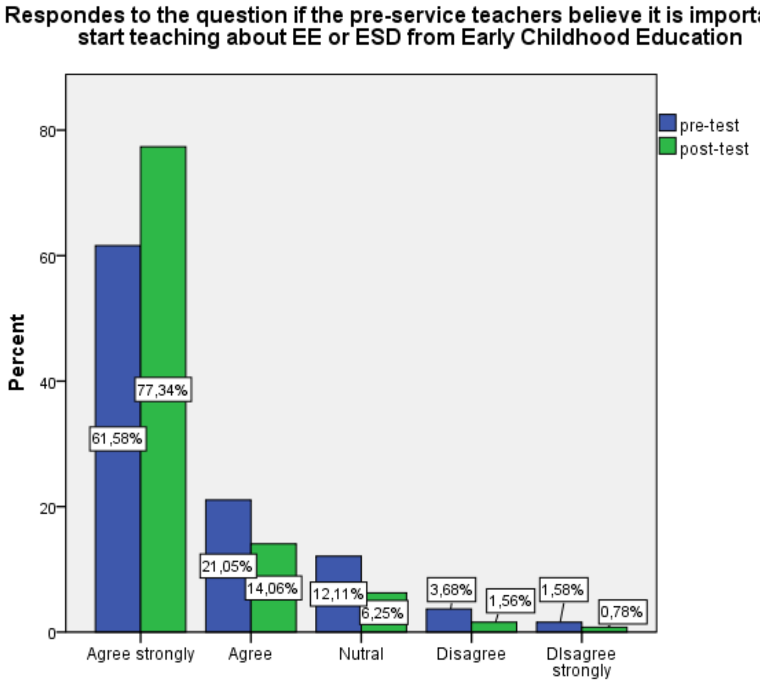

Figure 4. Pre-service teachers' responses to the question if they believe that it is important to start teaching EE or ESD starting from early childhood education.

DISCUSSION AND CONCLUSIONS

ESD is a complex and complicated notion covering environmental, societal and economic aspects and their interrelatedness. To access such a difficult subject, we used houses, a familiar concept to all, of any age and any cultural background.

The inclusion of the excerpt of Xenophon's Memorabilia, where Socrates describes the way a house should be built, to offer comfortable living conditions during winter and summer, proved to be a useful asset in catching the pre-service teachers interest, in order to analyze the sustainability dimensions through the notion house. In this way we connect a familiar subject, the houses, and studied them through the lenses of ESD, focusing on energy consumption in houses. Socrates' house proved to be an excellent starting point, connecting ESD with personal, cultural, ethical, and political concerns. The overall process proved that through aspects of history and philosophy of sciences, classrooms can be more challenging, enhancing critical thinking skills, and contributing to understanding of the scientific subject.

Pre-service teachers showed great interest and participated actively in the whole process, contributing to the discussions and participating in the activities.

We could observe a clear improvement of the knowledge and perception of the pre-service teachers on SD. Furthermore, we found improvement of their attitudes towards ESD. Students stated that they believe that ESD is important for them personally and for their teachings and intent to teach about ESD. They expressed the need for more education on sustainability issues and the importance for introducing ESD into the curriculum of future teachers, as well as that this would improve their teaching ability on this subject. From our findings, it seems that even short-term TIs can have positive outcomes, strengthening the suggestion to include ESD teachings in all subjects.

In addition, also their knowledge of building materials, insulators and heat capacity materials improved, as well as their understanding of the form and function of traditional houses, which apply the principles of the Socrates' house. The later refer to the open-ended questions and will be presented elsewhere.

To assist pre-service teachers in their difficult job of educating critically thinking democratic citizens, universities must help them with proper education and training during their studies and continue with life-long learning during their working life.

WHAT STUDENTS THINK AND DO FOR AN ALTERNATIVE FUTURE: THREE YEARS AFTER A SCIENCE-INFORMED ENERGY COURSE

Shih-Yeh Chen[1] and Shiang-Yao Liu[2]
[1] Taichung Municipal Dali High School, Taichung, Taiwan
[2] Graduate Institute of Science Education, National Taiwan Normal University, Taipei, Taiwan

Enabling students to act as public-minded citizens is an urgent task if society is to effectively address and resolve critical issues related to environmental sustainability and human well-being. Thus, teaching students the competencies that are critical to making the world a better place should be a vital component and objective of science education today. In this research, a group of 12th graders were interviewed to assess what actions they had taken to make the world a better place three years after taking a science-informed energy course. Content analysis that focused on the actions and rationales related to scientific concepts was conducted on the interview data of 30 students. Four categories of intentional and purposive actions were identified, including personal actions, participatory actions, transformative actions, and preparing for actions. A minority of the students took actions at the highly involved or action-preparing level, while most took actions at the personal or participatory level. A small but significant percentage of the students reported not having taking any action to make the world a better place. Empowering students with the competencies necessary to take positive and meaningful actions that lead to a better future for the environment and humanity should be prioritized in science education.

Keywords: Environment, Science Education, Secondary School

INTRODUCTION

Although the importance of science education in preparing students to be good future citizens has been promoted for several decades, the chronic shortcomings in current science teaching and the lack of consensus regarding the science education curriculum necessary to achieve "good future citizen" goals have frustrated progress on this issue (Choi, Lee, Shin, Kim, & Krajcik, 2011; Roth and Lee, 2004; Deboer, 2000). Efforts in recent years to engage students in discussions and constructing arguments on controversial topics such as socio-scientific issues have been shown to broaden the views and enhance the abilities of students (Dawson & Carson, 2016; Osborne, Donovan, Henderson, MacPherson, & Wild, 2016). In related interventions, students learn to make decisions that reflect their perspectives. However, making informed decisions and expressing positive intent often do not accurately predict subsequent actions or follow-through (Hodson, 2003; 2010). As citizens, students should be encouraged to act to improve social conditions and values in the public sphere (Hodson, 2010; 2017).

In recent science education reforms (National Resource Council, 2012; Next Generation Science Standards Lead States, 2013) have been designed to encourage educators and teachers to involve students in meaningful learning through science-based ideas and practice. However, methodologies to promote problem-solving competencies in students in authentic environments are lacking. Meanwhile, because of the close-ended nature of current school education and the use of predetermined learning content, teachers have been generally hostile to integrating critical approaches into their courses (Barrett & Sutter, 2006; Birshall, 2010; Sinakou, Donche, Boeve-de Pauw, & Van Petegem, 2019; Westheimer, 2015). Therefore, using scientific knowledge to address real-world problems is rare in education today (Birmingham & Calabrese Barton, 2014; Birmingham et al., 2017). However, science is recognized as a discipline that may not only alleviate the effects of a problem but also address and resolve its root causes (UN, 1972). Taking action to resolve societal problems impacts not only how people live in the world today but also the chances for subsequent generations to survive (Hodson, 2003). Empowering students with the competencies necessary to change the world is an urgent task for social and environmental justice (Dittmer et al., 2018; Riemer et al., 2016).

In line with this goal, students' actions are based on the concept of action competence, the objective of which is to "make present and future citizens capable of acting on a societal as well as a personal level" (Jensen & Schnack, 2006, p. 472). Apart from setting this goal in advance, students must be conscious of the existence of the problem and become committed to solving the problems facing this world with the motivation and reason. Moreover, the rationale of the action is important to understanding which scientific concepts are embedded in their actions (Vesterinen, Tolppanen, & Aksela, 2016). Therefore, this study was designed to explore the types of actions and the scientific concepts used by a group of high school students that had taken a science-informed energy course three years earlier with the goal of rethinking the role of science education in developing students as future citizens.

CITIZENSHIP ACTION

Public education has long been designed to promote competencies in students that will better enable them to shape the future as public-minded citizens. However, the efficacy of school education in achieving this goal has fallen far short of policy goals and societal expectations (Reichert & Print, 2018). Scholars have proposed a number of different definitions of citizenship in the context of educating for citizenship. Castro (2013) interviewed pre-service teachers to investigate their views on "ideal citizens", with two views on citizenship emerging. One of these, conservative-value-based citizenship, emphasizes traditional and loyalty-centered citizenship, with citizens in this category equipped with good morals and contributing to the maintenance of their community. The other view, awareness-based citizenship, emphasizes being aware of issues important to the community, with aware and informed citizens participating in local affairs ultimately improving the community. The latter, using negotiation and bargaining, stands in the middle of critical and non-critical forms of citizenship and accepts the need for compromise and give-and-take. Knowles and Castro (2019) analyzed the survey responses of teachers and corresponding actions of students and identified three types of citizens (Westheimer & Kahne, 2004). The conservative perspective on civic education focuses on helping students take personally responsible actions such as obeying laws and recycling. From the liberal perspective, students take participatory action when they learn how the government works and concern themselves with political issues. When they protesting / challenging the status quo, students promote social change with critical perspective.

Citizenship actions have been proposed in the context of education, especially in environmental education, which aims to promote responsible citizenship (Hungerford & Volk, 1990). To minimize the influence of moralistic paradigms on behavior, educating for action should be prioritized in democratic societies to face the problems that are currently threatening our world. Stern (2000) was the first to define environmentally significant behaviors as incorporating both intent-oriented and impact-oriented facets. This category of behaviors reflects a desire to impact positively on the environment. Jensen and Schnack (2006) subsequently criticized the currently accepted definitions of behavior, arguing instead that action should be discerned from behavior, and focusing on decision-making and problem-solving in the real world as a way to redirect the target of EE to educating future citizens on both personal and societal levels. The collective nature of action for citizenship has been highlighted by scholars (Alisat & Riemer, 2015; Chawla & Cushing, 2007; Uzzell, 1999) with regard to solving problems that are embedded at the institutional and systemic levels. Therefore, students learn citizenship through the process of taking sociopolitical action by inspecting root causes and finding solutions. The category of collective action was derived within a democratic context.

Riemer, Lynes, and Hickman (2014) reported that differences exist in student action in terms of the degree and impact of participation. Alisat and Riemer (2015) stated that citizenship action may be categorized according to difficulty, involvement, political pressure, supportiveness, and action competence. In contrast to low-intensity and simple participatory action, leadership action is more committed, organized, and politically oriented. However, self-education for future involvement represents an entry-level participatory action only. Vesterinen et al. (2016) investigated the actions taken by gifted and highly motivated youth at a summer camp, finding that their actions could be divided into three categories. In addition to personal and participatory actions taken in the private and public spheres, actions related to preparing for the future have also been considered in the literature. In this latter category, individuals take actions that are intended to prepare them to act to achieve a better outcome in the future because they currently lack the capabilities necessary to take meaningful action in the present. Therefore, the objective of this study was to identify the types of citizenship action that students take to solve problems and to elucidate their reasons for taking these actions.

RESEARCH CONTEXTS

Participants were recruited from a group of students who had attended a course three years ago as part of their 9th grade chemistry-physics curriculum. This course extended the standard learning unit on batteries to include lessons on energy use and argumentation in the realm of solar energy and on strategies for reducing energy use and carbon emissions in daily life (Chen & Liu, 2018). One of the researchers involved in this study was the chemistry teacher for this group of students, which allowed him to contact this group via social network three years after the course had ended. Thirty students accepted the researchers' invitation to participate in this study. All of the participants were in their twelfth grade in both public and private education systems, with 11 enrolled in senior high school, 18 enrolled in vocational high school, and 1 enrolled in junior college.

DATA COLLECTION AND ANALYSIS

A semi-structured interview was used to collect the data. At the beginning of each interview, participants were asked to describe their impression of the course. The content of the interview focused on two questions: (a) What actions have you taken to improve the environment or society during the past three years and (b) what problems do you desire to solve. Interviews were tape-recorded and each interview session lasted 20-30 minutes. The questions were based on the related literature (Ernst, Blood, & Beery, 2017; Jensen & Schnack, 2006; Vesterinen et al., 2016) and validated by a science-education scholar. The data collected from the interviews were transcribed verbatim by the first author. The unit of analysis was each discrete action that the participants considered as contributing to a better environmental or societal future. After condensing and grouping the units, the data were distilled into several categories using inductive content analysis (Elo & Kyngas, 2008).

Table 1. The category, description, exemplar, and corresponding amount of student actions.

Category	Personal actions	Participatory actions	Transformative actions	Preparing for actions
Description	Acting toward the environment or personally helping people	Participating in school and community projects or sharing issues with others	Organizing actions or influencing government policies	Cultivating oneself for an alternative future
Sample actions	1. Using eco-friendly bags for purchases 2. Reducing the use of air conditioner 3. Helping older adults in need	1. Participating in community cleaning activity 2. Discussing issues on social media 3. Co-tutoring students with learning difficulties	1. Organizing student groups to clean up the community 2. Launching a petition to influence government policy related to the petrochemical industry	1. Learning the technology of brain-computer interface to help people in need. 2. Gaining knowledge on natural resources and ecology to influence people’s actions.
No. of instances	14	10	3	3
References	Jensen (2002)、Kollmuss & Agyeman (2002)、Stern (2000)、Vesterinen et al. (2016)、Westheimer & Kahne (2004)	Alisat & Riemer (2015)、Westheimer & Kahne (2004)、Uzzell (1999)	Alisat & Riemer (2015)、Westheimer & Kahne (2004)、Chawla & Cushing (2007)	Alisat & Riemer (2015)、Reichert & Print (2018)、Vesterinen et al. (2016)

Inductive and deductive analysis of the participants’ responses and the relevant literature (Alisat & Riemer, 2015; Vesterinen et al., 2016; Westheimer & Kahne, 2004) led to the emergence of four categories that, together, described the many actions of the participants and the scientific concepts behind their rationales. The categories, descriptions, sample actions, number of instances, and references for the actions of the participants are listed in Table 1. The inter-rater reliability of data analyses was confirmed after two authors analyzed the data independently. The percentage of agreement was above 85%, and all discrepancies were solved by discussion.

RESULTS AND DISCUSSION

Most of the actions of the participants focused either on environmental problems or on helping others in need. In the following, each subsection demonstrates one kind of action category with two examples providing additional details (S: student; M: Male; F: Female; e.g., SF27: Female student, no. 27).

Personal actions

One-third (33.3%) of the participants remarked during the interview that they had personally taken action to make the world better. Most of these actions were related either to preserving the environment or to helping others in need. In several cases, the participants expressed an intention to save the earth through personal actions. Student SM19 stated that he reduced his use of air conditioning to reduce his contribution to global warming. Student SF13 stated that she took the bus instead of a car whenever possible, noting that emissions from vehicles are a major source of greenhouse gasses.

SM19: *Some time ago, because of energy saving and carbon reduction, that is, the problem that the earth is warming, it was quite a major story at that time. ... Even when the weather was really hot, I just used it for one or two days out of every ten. I mean to say that I reduced using air conditioning. I did it to reduce ... to stop global warming. I wanted to prevent global warming.*
SF13: *The king crab has migrated into the Antarctic due to global warming, and then ... caused an environmental catastrophe. This migration is endangering those creatures in Antarctica because there are too many crabs. It's a disaster for the environment, so it needs to be reduced ... Carbon dioxide causes the greenhouse effect, which makes the earth hotter and hotter, and then the ice will melt.*

Student SM19 was not only aware of the effect of global warming but also had a strategy for alleviating the situation. Student SF13 was aware of the effect as well and described the science behind the effect. This category describes direct action taken within the private sphere, with character and personal responsibility (Kollmuss & Agyeman, 2002), the possible factors affecting these actions. Although the participants have expressed specific reasons for their actions, these reasons reflected aspects of loyalty and duty and were not affected by organizational or policy considerations (Westheimer, 2015). Nonetheless, this category of action actually benefits the world through personal effort.

Participatory actions

One-third (33.3%) of the respondents described having participated in school or community projects such as cleaning up a street or beach or visiting senior citizens in the community. While some students engaged in direct environmental action (see SM11), others promoted greater awareness of issues through indirect action via social networks (see SM01).

SM01: *There is serious air pollution in Taichung because of the thermal power plant. I have tracked the articles posted by Chia-Lung Lin, the mayor of Taichung City. He has been doing some things to improve air pollution ... Yeah, Facebook. I clicked the "like" button and learned more about the types of pollution he is reducing ... Sometimes I would share information (through Facebook and discussions) with my family. It is about the quality of our air in Taichung. Because we were all born in Taichung and are responsible for the health of each other, we must take care of it ... (My classmates) also read these articles and discussed the issue more frequently.*
SM11: *Our fishing club held some coastal cleanup activities near the Zhangbin Industrial Zone ... The garbage is mainly PET bottles and Styrofoam ... mainly Styrofoam. Because these things are lighter and are easier to fall. In fact, they endanger the survival of fish. The crumbs that fish eat include plastic. Fishermen catch fish and sell it to people. This is a vicious cycle.*

Student SM01 was aware of the severity of the air pollution and environmental impacts caused by Taiwan's power-generation plants in the Taichung area, including the photovoltaic haze over the region and a myriad of public health problems. The student wanted others to be conscious of this problem in a way that motivated them to contribute to resolving these problems. Student SM11 engaged in direct action, monitoring the sources of pollution and studying the damage of this pollution to humans. Action is a complex process (Alisat & Riemer, 2015; Birdsall, 2010). Personal action is relatively easy to initiate because of the few social and normative limitations / barriers to this type of action, while participatory action involves a collective decision-making process that allows students to reflect concern on issues that are relatively complicated (Knowles & Castro, 2019). Thus, participatory action enhances not only students' social skills and commitment but also their understanding of environmental science (Birmingham & Calabrese Barton, 2014).

Transformative actions

Ten percent of the participants reported having organized actions or having tried to influence government policies. They had attempted to influence the actions of others through the power of organizations (SF29) or policymakers (SF04).

SF29: *We (the student council) united with other schools into a league. We held a garbage clean-up campaign in Taichung Metropolitan Park ... We initiated a (environmentally) meaningful activity using emotional communication ... Almost 10 schools (joined in this activity). I was vice president of the student council ... I was responsible for counting the number of participants, planning the sites ... and negotiating with park staff.*
SF04: *Once online petitions reach a certain threshold of signatures, it will be proposed and discussed in the Legislature. No one should feel that their power is insignificant, because society can be changed through collective strength ... Everyone just ignores the problem of ecological damage. I don't think we can do so anymore because it will cause more and more serious problems. Therefore, I take the initiative and call on others to work together to change the current situation.*

In taking transformative action, student SF29 learned how to coordinate actions with other student councils and to negotiate with government staff. Student SF04 signed a petition related to industry pollution and encouraged others to follow her example. Unlike participatory action, transformative action has the potential to organize a group to influence a social institution or policy, which has the potential to change the structure of economic, social, and political systems (Birdsall, 2010; Chawla & Cushing, 2007). In taking action, the participants were both conscious of the problem and motivated to assess its root causes in order to engage in problem solving. Thus, social justice is a potential result of this action (Hodson, 2010). Furthermore, students who more frequently engage in indirect actions gain a better familiarity with the different dimensions of action competences (Birdsall, 2010).

Preparing for actions

Ten percent of the participants engaged in actions related to the goal of improving the environment and quality of life. For example, these participants studied innovative technologies (SM24) and worked to improve their communication abilities (SM21) as strategies to achieve their goals.

SM24: *Well, it can solve a lot of problems. For example, if he is in a car accident today, he may break his foot. He may want to install a prosthetic in a few days. But controlling prosthetic limbs is difficult! He may need a brain-computer interface to control his prosthetic limb ... It can help underprivileged groups ... The main thing is to enrich myself and study in this field. By researching this issue more, I can apply my findings in real life, and then I hope to promote it to ... help those who are physically handicapped ... and change the society in the long run*.
SM21: *I will tell them the importance of environmental conservation in terms of the long-term effects of environmental degradation. Therefore, I want to improve my understanding of the natural ecosystem in aspects such as the conservation of marine ecologies and the depletion of natural resources as well as to enrich the content of my dialogue with others. Through communication, some people who may not be aware of the ecological environment and natural resources may become more aware of these damaged environments. Let them understand how we can help the environment, stop environmental degradation, and change those behaviors that may damage the environment in order to protect our environment*.

Scientific and technological innovation has the potential to improve the quality of life of people by applying scientific knowledge to create environmentally beneficial applications. In addition, scientific knowledge may be used as a medium to communicate and convince others of the importance of our shared natural resources, environment, and ecosystem. The participants stated a belief that scientific knowledge has the potential to change the future. Although the participants in this category delayed the timing of their action, they still believed that science could promote change, which echoes the perspective on the role of science taken up in the Stockholm Declaration (UN, 1972). This vision stimulated the participants to prepare to take appropriate actions later in life. Teachers should be facilitators that guide students to deal with problems in order to prevent action paralysis (Jensen, 2004). Gaining relevant knowledge and experience in a critical area of expertise enables individuals to create a better environment and accomplish desired social changes.

CONCLUSION AND IMPLICATIONS

In our analysis, four categories emerged from the responses of the participants. Although they all engaged actively in personal and participatory actions during their three years of high school, only a small number engaged actively in political activism (Alisat & Riemer, 2015). Activist action is considered the realization of democratic citizenship and fundamental to changing the world. As taking action is not a simple process (Birdsall, 2010), some students, especially those concentrating on science-based issues, require more time to prepare themselves for future roles as social influencers. On the other hand, teachers should not be hesitant regarding incorporating the concept of action competence into course material. Teachers should foster a learner-centered, action-oriented, and transformative approach that empowers students to take action in their local and daily lives to attain a sustainable future. In addition, the descriptions of the actions of some scientific concepts provide the reasons or motivations to act. Therefore, science may be an important element and may contribute to actions, as science is the result of human endeavors. Nevertheless, 33.3% of the participants in this study, half of who performed well in their science courses, had not taken any type of action. As action is the ultimate goal of education, further study into how best to motivate students to improve the world is recommended.

FAMILIARIZING YOUNG CHILDREN WITH THE IDEA OF SUSTAINABILITY

Maria-Christina Kasimati[1], *Marida Ergazaki*[2]
[1] University of Patras, Patras, Greece,
[2] University of Patras, Patras, Greece

Humanity's sustainable future is undermined by serious environmental and socio-economic problems all over the world. However, 'Early Childhood Education for Sustainability' (ECEfS) is not yet a high priority and research about it remains rather limited. Our study addresses the question of whether it is feasible to design a learning environment that could effectively combine biology education and EfS to help preschoolers enhance their conceptual understanding about nature along with their socio-environmental awareness. Our focus here is set on identifying whether and how preschoolers' understanding about the idea of 'sustainability' in particular, has changed within the 3rd version of our learning environment (LE3). LE3 was designed in the 3rd research cycle of a design research considering the 'possible futures'-approach, and was tested in a case study with thirty, conveniently selected preschoolers (age 4.5-5.5). Children were divided in six small groups which separately attended fifteen, 20-30-minute sessions, organized in three parts and implemented in an eight-week period. The idea of 'sustainability' was first explored with 'decision-making scenarios' in a 'guided dialogue'-session of the 'Intro- part', but it was actually present in almost every session throughout LE3. Children gave pre/post, individual, semi-structured interviews, which were tape-recorded, transcribed and analyzed in 'NVivo'. The question probing their pre-/post-understanding about 'sustainability' was based on a 'decision-making scenario', similarly structured with those of LE3. According to the results, LE3 worked quite well in familiarizing young children with the idea of 'sustainability', since almost all of them were able to apply it in the post-test scenario.

Keywords: Early childhood education, society and environment education, conceptual understanding

INTRODUCTION

Humanity's sustainable future is undermined by environmental and socio-economic problems all over the world. Therefore, it seems absolutely necessary to systematically provide children with educational experiences that will get them familiar with acute socio-environmental issues and help them develop the strong socio-environmental awareness they need to become action-takers for the well-being of the environment and fellow humans (David, 2007; Davis, 2009; Iliopoulou, 2016; Mackey, 2012; Samuelsson & Kaga, 2008). In other words, it seems that, for everyone's sake, nowadays more than ever, the so-called 'Education for Sustainability' (EfS) should be prioritized and also start as early as preschool (Kahriman-Ozturk et al., 2012; Samuelsson, 2011; Samuelsson & Kaga, 2008; Spiteri, 2018).

Despite the progress that has been made with investigating EfS at higher educational levels, research about 'Early Childhood Education for Sustainability' (ECEfS) is not still as rich as it should be (Ärlemalm-Hagsér, 2013; Cutter-Mackenzie & Edwards, 2013; Duhn, 2012; Elliott & Davis, 2018; Reid & Scott, 2006; Smidt, 2018; Spiteri, 2018). The literature on ECEfS is rather limited and, moreover, mostly theoretical; it does make suggestions about how young children might enhance their socio-environmental awareness and develop responsible attitudes and behaviours towards environment and society, but it does not back them up with rich enough empirical data.

One of the most interesting suggestions found in the ECEfS-literature is to create learning environments in which young children could experience the roles of 'problem seekers', 'problem solvers' and 'action takers' (Davis, 2009; Arlemalm-Hagser, 2013); i.e. learning environments in which they would have the opportunity to (a) get more familiar with socio-environmental problems that may have meaning for them, their families or the place they live, (b) look for possible solutions to these problems, and finally (c) plan the implementation of them or even try perform it. Another interesting suggestion concerning ECEfS is the 'possible futures'-approach (Hicks & Holden, 2007, Rogers & Tough, 1996). The idea is to help young children understand the 'present-future' relationship and their own role in it. More specifically, it is suggested that children should be given the opportunity to (a) examine how their present actions may affect the future of environment and humans, (b) decide if they like the future they are heading for, and, in case that they don't really like it, (c) examine what they should change in their current actions in order to be able to head to a more desirable future instead (Hicks & Holden, 2007).

So, it is clear that although not very rich, previous research on ECEfS could be quite useful. Suggestions like the above could possibly serve as 'design principles' for the development of learning environments that aim to provide young children with the socio-environmental awareness they will need as modern adults. On the other hand, another domain of educational research, Biology Didactics, can actually make suggestions of another kind. It can suggest biological concepts that are important for children's understanding about ecosystems whereas they might fit well in a context where 'nature-humans-economy' inter-connectedness needs to be highlighted for young children (Ergazaki & Andriotou, 2010; Palmer & Suggate, 1996). This actually means that combining biology education and ECEfS seems possible in theory. However, more research is needed in order to ascertain whether and how this combination can really work.

Thus, our study addresses the question of whether it is feasible to design a learning environment that could effectively help preschoolers enhance their conceptual understanding about nature, along with their socio-environmental awareness. Such awareness may actually be facilitated by an essential understanding of ecological ideas (e.g. 'habitat', 'food chain'), but it also requires an essential understanding of key socio-environmental ideas (e.g. the relationships of 'present-future', 'local-global' or 'individual-collective') that contribute in shaping the overarching idea of 'sustainability' which is our focus in this paper. Sustainable development is based on three integrated pillars -environmental, socio-cultural, and economic-, that strongly interact with each other (Kahriman-Ozturk et al. 2012). So, 'sustainability' can be conceptualized as the idea that our present actions should consider the future well-being of the environment, fellow humans and economy at the same time. In this paper we are particularly concerned with identifying whether and how preschoolers' understanding about this idea has changed within the 3rd version of our learning environment that was designed and tested in the 3rd research cycle of our design research.

METHODS

The overview of the study

Our study is concerned with the design of a learning environment for young children, which attempts to combine biology education with education for sustainability. Applying the method of design research (McKenney & Reeves, 2018), we performed three research cycles with one or two case studies each. In the case study of the 1st research cycle, we tested the 1st version of the learning environment (LE1) and we used the findings for coming up with an elaborated, new version of the learning environment (LE2). This had two parts: the 'Forest-part', which was tested in a case study of the 2nd research cycle, and the 'Decomposition/Recycling-part' which was tested in another one. The findings of these case studies were used for coming up with a further elaborated, new version of the learning environment (LE3), which included one more part with some first explorations of the target socio-environmental ideas ('Intro-part'). LE3 was tested in two case studies performed within the 3rd research cycle. Here we are concerned with the second case study, since children's understanding about the idea of 'sustainability' which underlies all three parts of LE3, was tested in its context.

The participants

The participants of the case study we present here were pupils of a public kindergarten, situated in a semi-urban area of Patras with medium/high socio-economic status. Children (N=30, 16 girls/14 boys, age 4.5-5.5) were selected conveniently, due to their teacher's wish to facilitate our study. Their parents were thoroughly informed about the study and didn't raise any objections. Children had the opportunity to meet the interviewer before the starting point of the study, get familiar with her and give their own assent for participating. According to their teacher, children were quite familiar with educational interactions and they had not been engaged in formal activities about our target ideas up to that point. For the implementation of LE3, children were divided in six groups of five. Each group (a) included members of mixed age and mixed level, and (b) took separately part in fifteen, 20-30-minute sessions, led by the 1st author in an eight-week period.

The learning environment

The design of LE3 (as well as the design of the two previous versions) was informed by the 'possible futures'-approach (Hicks & Holden, 2007). The learning objectives concern two types of ideas: (a) ecological ideas ('forest impact on abiotic environment and human life', 'habitat', 'food chain', 'decomposition'), and (b) socio-environmental ideas ('present-future', 'humans-nature equality', 'humans-humans equality', 'local-global', 'individual-collective', 'everyday practices *for* the environment and fellow humans') that all contribute to the construction of the overarching idea of 'sustainability' which concerns us in this paper.

The idea of 'sustainability' was first explored in a 'guided dialogue'-session of the 'Intro-part'. Its exploration was carried out with two 'decision-making scenarios'. Both of them had to do with deciding for or against a business idea ('launching ecotourism in a poor African village' and 'opening a new factory next to a poor city), by equally taking into account the pros and cons for the environment, humans and economy at the same time. This requirement was supposed to encourage children to look for ways to reconcile any conflict of interests and thus practice the idea of 'sustainability' in decision-making. For instance, in the second scenario of the session, they needed to explore whether there could be a way to open the new factory and benefit from the pros for humans and economy, while at the same time avoid -or at least minimize- the cons for environment and humans.

Moreover, the idea of 'sustainability' was actually present in almost every session of LE3, in the sense that all the partial socio-environmental ideas explored throughout LE3 contribute to its construction. For instance, the 'Forest-part' of LE3 was guided by a scenario with a city that was facing a serious unemployment-problem and made the decision to cut its huge forest so that people without jobs could be employed as wood-cutters or wood-sellers (Hadzigeorgiou et al., 2011). This decision took into account only the short-term pros for humans and economy, whereas it left out the long-term cons for environment and humans. So, children had the opportunity to thoroughly explore a possible undesired future, as a consequence of a decision that is *not* guided by the idea of 'sustainability'. This was attempted through the different, preschoolers-friendly activities (e.g. storytelling, guided dialogue, brainstorming, puppet-show, role playing) that were integrated in the different parts of LE3. Similarly, the 'Decomposition/Recycling-part' was guided by a scenario with a city that was facing a waste-management problem and made the decision to continue using a landfill (which was a cheap solution) instead of building a recycling-factory (which was an expensive one). This decision took into account only the short-term pros for economy, whereas it left out the long-term cons for environment, humans and economy as well So, children had, once more, the opportunity to thoroughly explore (through hands-on and minds-on, 'young age'-friendly activities) a possible undesired future, as a consequence of a decision that is *not* guided by the idea of 'sustainability'.

The data collection

Children gave us pre/post, individual, semi-structured interviews, lasting approximately 20 minutes each, at a quiet place of their school. The question about 'sustainability' was based on a 'decision-making scenario' about creating a huge entertainment park in a forest with rare biodiversity, which was supposedly located next to a poor city. At the discussion of the city-council about this idea, there were people who agreed and others who disagreed. Those who were supposed to agree with the park-idea appealed to good things that could possibly derive from creating the park. For instance, they claimed that *'people would find jobs', 'more tourists would visit the city', 'there would be more money', 'people would live better lives'*. On the contrary, those who were supposed to disagree with the park-idea appealed to bad things that could possibly derive from creating the park. For instance, they claimed that *'noise, lights and polluted air would disturb the animals that live in the forest and make them migrate somewhere* *else', 'people would possibly leave garbage in the forest, which would ruin the beauty of the forest and possibly put in danger some of its animals that would try to eat these garbage', 'many people would arrive in big airplanes, buses and cars, all releasing bad gases in the air; so the environment would be polluted and people's health would be in danger'.* So, children were asked to decide for or against the park-idea, in the light of the pros and cons about environment, humans and economy, which supposedly emerged in the city-council. The question was addressed to children like this: *'So, what is your opinion about the park-idea? What do you think about it? Do you think they should create this park or not?'.* Children who supported the park-idea were reminded of the cons that emerged in the city-council; and vice versa: children who rejected the park-idea were reminded of the pros. If they remained consistent to their initial response, then they seemed unable to apply the idea of sustainability and we didn't insist further. On the other hand, if they appeared to abandon their initial 'for or against'-certainty and recognize that people should consider all these things at the same time, then they seemed *potentially* able to apply the idea of sustainability and so they were asked *'what exactly should be done'* according to their opinion and *'why'.*

The data analysis

The pre-/post-interviews were tape-recorded and then transcribed and coded in 'NVivo' (qualitative data analysis software). Children's responses to the 'sustainability'-question were coded as 'naïve', 'transitional' and 'informed', as follows:

- 'Naïve': children did *not* consider the pros and cons for the environment, people and economy at the same time, in order to make a decision. For instance, *'I think they should build the park there, because this way they will have a job and they won't be poor any more. They need the money to buy food, so they should build it.'* (pre-response).
- 'Transitional': children *did* consider all these at the same time, but they were *not* able to make a decision. For instance, *'They should think about the animals. But if they don't have money… I don't know… they should do something. Maybe they should build it after all. But animals and people's health are important too. I don't know. I'm confused.'* (post-response).
- 'Informed': children did consider all these at the same time, and they *were* able to make a decision by reconciling conflicts of interests. For instance, *'I think that in order to have a better future they have to think about the environment and the money and other people before they decide to build the park. I think that the best thing to do is to build the park, but further away, not near the forest. This way they can work and make money and also not ruin the environment. And if they also put in strict rules, people's health will not be damaged. That's how they can take into consideration all three: money and the environment and people.'* (post-response).

The coding was simultaneously performed by the authors and cases of disagreement were discussed until consensus was reached.

RESULTS

Although children did not seem to be aware of the idea of sustainability before taking part in LE3, they actually did quite well afterwards. In the pre-interviews, almost all children (28/30) gave 'naïve' responses, very few (2/30) gave 'transitional' and none (0/30) gave 'informed' ones (Figure 1). In children's own words: '*No. They shouldn't build this 'park' even if they will earn money from it. It doesn't matter if they won't have any money. It is not right for the forest's animals, so they shouldn't do it.'* ('naïve' pre-response); '*They should build the 'park' to make money, because they are poor. But they shouldn't harm the forest or people's health. They should find a way to do both. I don't know how.'* ('transitional' pre-response).
On the contrary, in the post-interviews almost all children (27/30) gave 'informed' responses, very few (3/30) gave 'transitional' and none (0/30) gave 'naive' ones (Figure 1). In children's own words: *'They should think about other people's health and also how to make money and also the forest's animals, before they decide to build the park. But what should they decide? I don't know, but I know they should think about all three of them'* ('transitional' post-response); '*They should build the 'park' elsewhere. Not near the forest. They should do it, because then they'll have money. But they must make strict rules so that the 'park' won't harm environment or people's health. Only if they make rules, they can build it. But not near the forest, elsewhere.*' ('informed' post-response).

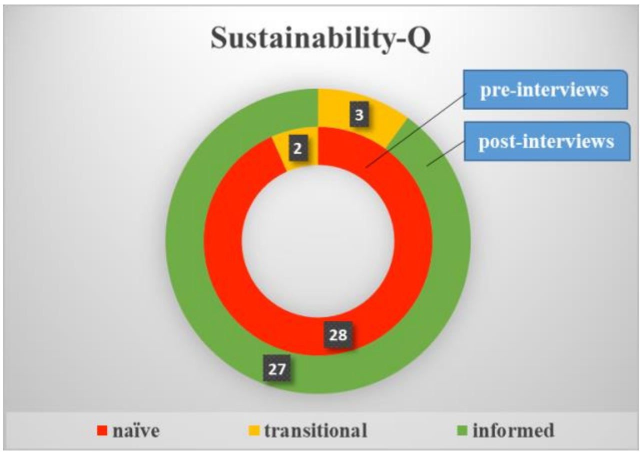

Figure 1. Students' pre/post-responses about the idea of sustainability.

In sum, 'naïve' responses, which were dominant in the pre-interviews (28/30), were absent in the post-interviews (0/30); and reversely, 'informed' responses, which were absent in the pre-interviews (0/30), became dominant in the post- ones (27/30). Finally, it is worth noticing that almost all children (29/30) shifted from lower-level to higher-level response categories (i.e. from 'naïve' to either 'transitional' or 'informed'; and from 'transitional' to 'informed'), whereas just one child (1/30) did not show any progress (both his pre- and post-responses were 'transitional').

DISCUSSION

LE3 seemed to work quite well concerning the idea of 'sustainability'. The shift of children's responses from lower- to higher-level categories indicates that their understanding was enhanced after taking part in LE3. This is further supported by considering that the shift was achieved by almost all children (29/30) *and* in the context of a 'decision-making scenario' that actually requires *applying* the idea of sustainability; i.e. considering all three factors (environment, humans, economy) at the same time and be able to reconcile conflicts of interest between them. Of course, it would be purposeful to carry out a delayed post-test as well, but we did not have such opportunity. However, our findings do show that even very young children can get familiar with demanding socio-environmental ideas such as the overarching idea of 'sustainability'. This is in line with Kahriman-Ozturk et al. (2012), who shed light on young children's potential to understand socio-environmental ideas (e.g. 'recycle', 'respect', 'reuse') that are integrated in the three pillars of sustainability (environmental, sociocultural and economic). These researchers have also stressed the significance of providing young children with educational experiences that promote active learning in ways suitable for their age. In fact, this is probably worth some further discussion, as shown below.

The idea of 'sustainability' or 'sustainable development', which of course is the reference point for EfS and Early Childhood EfS as well, is a complex theoretical construct and so it may very well be considered as developmentally inappropriate for young children, no matter how age-friendly are the types of educational activities through which young children are prompted to explore it. Similarly, this may be claimed (a) for many of the socio-environmental ideas (e.g. 'local-global' or 'individual-collective') that are linked to 'sustainability' and thus are important in the context of ECEfS, as well as (b) for many biological ideas that may have an important place in this context (e.g. decomposition) or not (e.g. genetic inheritance). Fortunately, this is where key-concepts like 'didactic transposition' (Chevallard, 1985) or 'educational reconstruction' (Kattmann et al., 1998; Duit et al., 2012) come into play. Both have to do with simplifying scientific ideas so that they become adapted to children's potential. In other words, they practically have to do with transforming scientific ideas to 'science class ideas' suitable for exploration by young children. And probably more interestingly for our case here, these fundamental concepts that are used to facilitate the early introduction of science can also be used to facilitate the early introduction of 'sustainability' and those socio-environmental ideas that may contribute to shaping it.

So, 'sustainability' can be introduced quite early as the idea that our present actions should consider the future thrives not just of us or other humans, but also of the environment. And since humans' thrive includes money as well, 'sustainability' can be conceptualized as the simultaneous thrive of environment, fellow humans and economy. Helping children get familiar with the idea that all three factors need to be taken into account for 'decision-making' is considered by us as a very significant first step, which will possibly facilitate higher-level explorations of 'sustainability' in the school years to come (Elliott & Davis, 2009).

To sum up, we note the following. Modern adults are expected to have a very strong socio-environmental awareness that will be translated to responsible attitudes towards environment and fellow humans as well as to responsible actions *for* them. Developing such awareness is a life-long process that really calls for an early start. Our study provides evidence that this start is possible and thus contributes to the argument for the feasibility of the highly needed 'Early Childhood Education for Sustainability'.

EXPLORING HOW A CARD-TYPE GAME FOR TERMINAL CARE CAN PROMOTE THE HEALTH AND WELL-BEING AWARENESS OF NON-SCIENCE STUDENTS

Shiho Miyake[1], *Asami Ohnuki*[2]
[1]Department of Biosphere Sciences, Kobe College, Hyogo, Japan
[2]Department of Child Care and Primary Education, Shirayuri University, Tokyo, Japan

In Japan, scientific academic communities are seeking to the reform of the science education curriculum in higher education. They believe that a new curriculum will provide all students, including non-science majors, the opportunity to consider the ethical perspectives of science in their future decision-making. This study aimed to discover what teaching materials would be useful for promoting serious and authentic discussions on ethical perspectives relating to science. The focus was on 'Moshibana', a card game that explores the theme of terminal care, and it was used to investigate how first-year university students reacted to the ethical science issues found in Moshibana. The participants were 47 first-year students (18 years old) in Japan. The students participated in a Moshibana game for 90 minutes at the author's instruction. Out of the 35 Moshibana cards, 27 were chosen by at least one student. This result found that the Japanese first-year university students prioritised the following activities: spending time with their family at home, making independent decisions for medical treatment, and painless treatment for terminal care. The results also revealed that the students tended to find accepting death difficult, and they also lacked religious beliefs. Subsequently, Moshibana can be utilised as an effective teaching material in an ethically focused science education. This game can help students visualise individual ideas and beliefs regarding the ethical aspects of human health and well-being.

Keywords: Higher education, ethics in science, values in science education

INTRODUCTION

Hodoson (2003) argued that in the era of continuous science and technological innovation, the contents and teaching methods of science education needed continuous reform. Specifically, the issues of human health and environment are important in promoting decision-making and discussing moral-dilemmas among people. Hodson advocated for four levels of sophistication in science education (p. 655):

Level 1: Appreciating the societal impact of scientific and technological change, and recognising that science and technology are, to some extent, culturally determined.

Level 2: Recognising that decisions about scientific and technological development are taken in pursuit of particular interests, and that benefits accruing to some may be at the expense of others. Recognising that scientific and technological development are inextricably linked with the distribution of wealth and power.

Level 3: Developing one's own views and establishing one's own underlying value positions.

Level 4: Preparing for and taking action.

The Science Council of Japan (2003) introduced reforms for higher education in science that required all students, regardless of whether they were science majors, to have the opportunity to consider different science-related ethical perspectives. This prepares the students for future decision-making, and to achieve this goal, it was necessary to revise the curriculum of science education in higher education.

Ethical issues in human health and science evolution have been of great concern in medical philosophy (Wear, Bono, Loghe, and McEvoy, 2000). Several academic reports in science education have focused on human health in terms of improving cognition and decision-making for children and young people (e.g., Roth, 2014; Zeyer and Dillon, 2018). The WWF (2018) also noted that education on health and well-being offers significant value for individuals and helps them to live meaningful lives. With this view in mind, promoting youth education is imperative as it helps guide young people into making thoughtful decisions so that they can live more meaningful lives. In particular, it is crucial to identify what kind of materials can spark the interests of young people, as well as their ideas on health and well-being, as this can contribute to the formulation of a contemporary curriculum that incorporates progressive science into meaningful everyday lives.

PURPOSE OF RESEARCH

There are several methods to formulate a concrete educational curriculum. When considering the most appropriate method, understanding how Japanese students participate in complex learning activities that involve ethical issues is essential.

What kinds of teaching materials are useful for non-science students regarding ethical science issues, such as human health and well-being? This research sought to uncover concrete measures that could be used to develop a life-science ethics education tools for non-science students. The study focused on the 'Moshibana' (Institute of Advance Care Planning [iACP], n.d.1), a card game that explores the theme of terminal care, and how first-year university students react when faced with terminal care.

METHOD

Usage of the 'Moshibana (Go Wish)' game

This study used the Moshibana game to examine students' thoughts on the relevance of human health and science, and explore whether this tool encourages the students' discussion abilities and decision-making. The 'Moshibana', originally named 'GoWish' in the United States (Coda Alliance, 2016), consists of 36 cards which are designed to promote discussion on what is important if people were living a shortened life due to serious illness. Moshibana is the Japanese version of GoWish, and was translated, produced, and published by the Institute of Advance Care Planning (iACP) and with permission from the Coda Alliance.

The iACP (n.d.2) reported that Moshibana was effective in encouraging the sharing of ideas about life ethics and the value of life among medical professionals, patients, and their families. However, there have been only a few reports on its educational applicability.

Procedure

The participants were 47 first-year students (18 years old) at Kobe College in Japan. They were taking liberal arts majors in humanities, music, or literature. As part of the author's lecture on human science and environmental life settings, the students participated in a Moshibana game for 90 minutes. The research procedure is llustrated in the Figure 1. Groups of three to four individuals were assigned, and the group members read and talked about the topics founded in Moshibana cards, which contained 35 wishes cards and one free decision card. Then the students discussed their thoughts on each card and why they thought it was important. Next, each student selected the three most important cards and wrote why they chose them. This helped researchers to identify the reasons, as this may reflect their individual values regarding health and well-being.

The students consented to have the results of this study published in an academic form that does not specify their personal information. The use of cards for the research-based purposes and the description for this study were permitted by the iACP.

Quantitative and qualitative assessments were conducted for the commonly selected cards. The qualitative assessment was conducted through a questionnaire that asked why the students chose the particular cards.

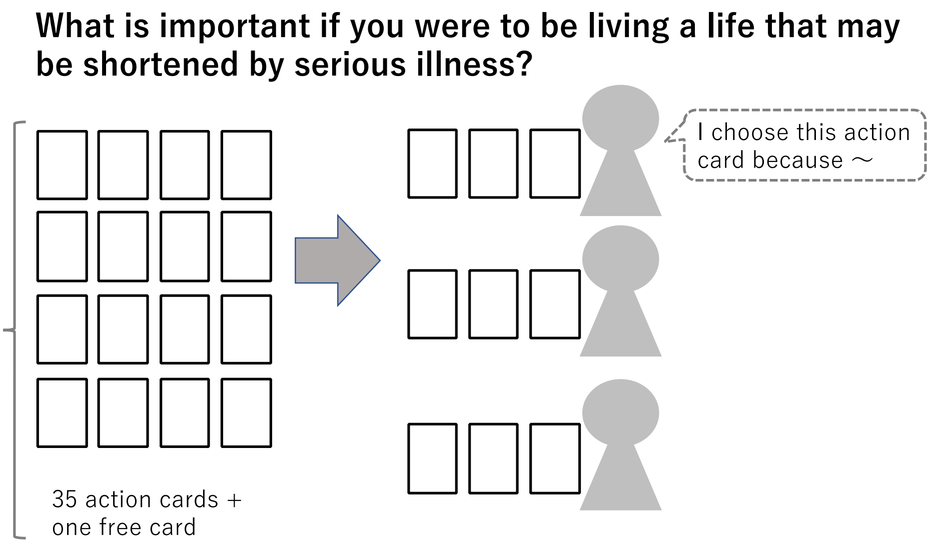

Figure 1. How to play 'Moshibana'

RESULTS AND DISCUSSION

Twenty-seven out of the thirty-five Moshibana cards were chosen by at least one student, while eight cards were not chosen at all.

The Words in the Most Selected Cards

The top ten selected cards are shown in Table 1. The top 10 cards indicate that over 70% of students believed that those ten wishes were important when faced with terminal care. In particular, the top two wishes cards were chosen by more than 10% of the participants. These are: 'To feel that my life is complete' and 'To be free from pain'. Interestingly, the first and second most popular cards involve different senses of time. While 'To feel that my life is complete (#1)' is a long and comprehensive retrospective wishes, 'To be free from pain (#2)' is a temporary event. Other commonly chosen cards demonstrate that the students' desire to spend time with family at home (#3 and #7), and to choose their own medical treatment and care (#4, #9, and #10). In addition, 'not dying alone' (#5) means a strong desire to avoid loneliness among the participants.

Table 1. Top Ten Cards

Wishes	Responses (%)
1. To feel that my life is complete	19 (12.2)
2. To be free from pain	18 (11.5)
3. To have my family with me	14 (9.0)
4. To be treated the way I want to be treated	13 (8.3)
5. Not dying alone	13 (8.3)
6. To take care of unfinished business with family and friends	8 (5.1)
7. To die at home	7 (4.5)
8. Not being a burden to my family	7 (4.5)
9. Not being connected to machines	7 (4.5)
10. Not being short of breath	6 (3.8)
Total	112 (71.8)

The Unchosen Wishes

The unchosen cards relate to four items related to preparation for death, religious issues, and the presence of nurses (Table 2). Since the students were not asked to explain why they did not choose these particular cards, their reasons for avoiding the cards are unknown. However, the unchosen cards imply that the students found it difficult to accept death (#1 and #3) and that they lacked religious beliefs (#2). As the contents in Moshibana were originally created in the United States, some Japanese students might not prioritise some of the wishes because of cultural differences, especially those related to the value of death. Another interesting point is that the presence of a nurse is not important for students if faced with terminal care (#4). This also implies that the students were not aware that nurses could play an important role in terminal care.

Table 2. Cards Items Not Chosen

1. To talk with a family and friends about preparation and fear of death
2. Issues related to religion, praying, and God
3. To know how the body will change
4. The presence of nurses

Qualitative Assessment of the Most Important Wishes

A qualitative assessment was conducted based on the students' written comments for the selected cards. Table 3 provides the representative reasons that students gave for their cards.

Table 3. Reasons behind the Most Selected Cards

Moshibana Card Text	Students' Reasons for their Choices
1. To feel that my life is complete	1-a. I want to believe that my life was happy at my last moment. 1-b. This is my motivation to live my life. 1-c. I want to die with a fresh mind, not negative thinking
2. To be free from pain	2-a. I want to have a peaceful death. 2-b. I saw my grandmother in pain. 2-c. I hate to be in pain.
3. To have my family with me	3-a. I feel calm with my family, as they are always stand by me. 3-b. I want to spend my last moments with my family. 3-c. I want to be with my family, as usual.
4. To be treated the way I want to be treated	4-a. I want to have the care that I want. 4-b. Painful treatment or undesired care means a low quality of life. 4-c. I feel alive if my will is respected.
5. Not dying alone	5-a. It is hard to die alone. 5-b. I want to be with many people to support me, like family, friends, doctors, and nurses. 5-c. Uneasy feeling and suffering will be more severe if I am alone in the end.
6. To take care of unfinished business with family and friends	6-a. I do not want to spend a time alone. 6-b. I want to organise my possessions and save the things I enjoyed. 6-c. If there is something left to do, I will have regrets.
7. To die at home	7-a. I hate to staying in hospitals. 7-b. Dying alone is lonely. 7-c. I want to die in a place of full of memories.
8. Not being a burden to my family	8-a. I would be sorry if my family struggled mentally or physically to solve the issue I left behind. 8-b. I would be sorry if my family had to come to the hospital every day. 8-c. I don't want medical treatment to put a financial burden on my family.

9. Not being connected to machines	9-a. My appearance could be concerning to someone else, and life-prolonging treatment is expensive. 9-b. I want to be able to move freely. 9-c. People who see others in such conditions are worried.
10. Not being short of breath	10-a. I cannot feel calm if my breathing is difficult. 10-b. I had asthma and many breathing difficulties. 10-c. It could make it difficult to talk to people or participate in activities.

One of the most significant elements found in all selected cards was the word ‘family’. For example, the word is appears in 3-a, 3-b, 3-c, 5-b, 8-a, 8-b, and 8-c. It is also interesting that the words ‘happy’, ‘peaceful’, ‘respect’, ‘motivate’, ‘enjoy’, and ‘full of memories’ were selected as dying with dignity. In contrast, the words of ‘alone’, ‘lonely’, and ‘painful’ represent issues to avoid when facing terminal care. Only a few students mentioned the presence of doctors and nurses, whereas most students valued the presence of their families and friends in several responses.

CONCLUSION

This study found that the participating Japanese first-year university students who participated prioritised spending time with their families at home, making their own decisions with regard to medical treatment, and having painless treatment for terminal care.

The participant students in this study were young and generally healthy, so they may not be particularly interested in topics related to death. There were no specific ideas as to their preference regarding medical professionals such as doctors and nurses. Rather, they emphasised that they yearn for family and friends to be present when faced with terminal care. Moshibana proved to be an effective tool that promoted serious contemplation and visualisation of individual ideas and beliefs. However, there is still room for improvement in discussing the ethical aspects of applying science and medical technology to humans.

Scientific and technological innovations in medicine and pharmacology continue to progress on a global scale, and how those advancements are used is left up to the consumers. The author would like to conduct further studies to explore the effective educational use of this material among participants of different ages and different nationalities.

ACKNOWLEDGEMENT

This study was supported by the JSPS KAKENHI Grant Number 17H01982, 15K00998, and 17H04490 from the Ministry of Education, Culture, Sports, and Technology in Japan.

ANIMALPOCKY: AN OBSERVATION LEARNING SUPPORT APPLICATION FOR ZOOS USING AUGMENTED REALITY

Emoto Arisa[*1], Hisano Arata*[*2], Kawabata Itsuki*[*2],*
Kusunoki Fusako[*2], Inagaki Shigenori*[*1], Hanaki Kumiko*[*3], Atake Noriko*[*3],*
Nogami Tomoyuki[*1]*
[*1]Kobe University, [*2]Tama Art University, [*3]Kobe Oji Zoo

This study proposes the use of a three-dimensional computer graphics (3DCG) application in zoos to support children's observation of animal skeletons and their movements to facilitate their learning about zoo animals. This 3DCG application uses augmented reality (AR) to represent the skeletal structures and movements of three animals: lions, penguins, and pandas. It is characterised by its use of 3DCG to seamlessly display information about the animal under observation, including its skeletal form and structure, so that (1) the skeleton of the animal can be observed from all angles, 360 degrees; (2) details can be observed by selecting a part of the skeleton and enlarging it; and (3) movements of the animal can be observed by moving the skeleton (however, the movements of lions were limited to walking, penguins to swimming, and pandas to feeding).

Zoos are optimal places for learning about animals, and are likely ideal for informal science education. However, children primarily visit zoos for leisure and play, and learning based on scientific observations does not tend to occur in zoos. Moreover, a certain level of expert knowledge needs to be acquired before making scientific observations in zoos; the provision of this knowledge to children is insufficient. For example, they are not generally provided with the morphological knowledge related to animal skeletons which would allow them to make informed observations.

Researchers in the present study developed an AR-based 3DCG application to support the observation of animal skeletons. User assessment was held to consider the effectiveness of learning support for the 3DCG application. At Kobe Oji Zoo, in Kobe, Japan, twenty lower primary school students were provided with iPads with the 3DCG application installed. Students participated in pre and post-usage questionnaires about their interests in animals and their skeletons, and in post-survey questionnaires about the usability of the application.

The results indicate that the children's curiosity towards animal skeletons was aroused by the 3DCG AR application. Their interest towards the application, its simple operational method, and realistic rendering of 3DCG-created images were also assessed positively. This indicates that this 3DCG application provides effective support for children to learn about animals.

Keywords: Augmented Reality, Zoos, Science Education

INTRODUCTION AND BACKGROUND: BACKGROUND OF THE STUDY AND PROBLEM IDENTIFICATION

Zoos are considered arenas that facilitate informal science education (Rennie & McClafferty, 1995; Patrick & Tunnicliffe, 2013). However, it is not necessarily easy for learners to make scientific observations in zoos. One reason for the difficulty is because the original motive for

the visit; children generally visit zoos for leisure and play, not for learning. Another reason is that even if children did visit a zoo with learning in mind, they may lack the level of expert knowledge required for making scientific observations (Eberbach & Crowley, 2009).
Most children were found to have insufficient knowledge about the animal skeletons that are the subject of this study (Prokop et al., 2007). However, zoos do not necessarily implement sufficient and effective learning support for children to acquire expert knowledge. Zoos tend to stop at the creation of commentary panels regarding the animals. Some recent attempt were made to provide learning support in zoos using Internet technology situation (e.g., Webber, 2016). However, no attempts were made to effectively provide children with the prerequisite information on the skeletons and movements of the animals that are the subject of observation.
In an attempt to provide a solution, this study developed a three-dimensional computer graphics (3DCG) application which offers visualisations of animal skeletons using augmented reality (AR). This application can represent the skeletons and movements of three types of animals: lions, penguins, and pandas. This AR functions seamlessly to display information on the animal subject to observation, and its skeletal form and structure, so that (1) the skeleton of the animal can be observed from any angle, (2) the details can be observed by selecting a part of the skeleton and enlarging it, and (3) movements of the animal can be observed by moving the skeleton (however, lions' movements were limited to walking, penguins to swimming, and pandas to feeding). The skeletal content reflect advice from animal experts, and detailed observations of real skeletal specimens. A preliminary evaluation experiment was performed at Kobe Oji Zoo to assess the effectiveness of the 3DCG application for learning, and lower primary students were the subjects for this experiment. The following summarises the 3DCG application and reports the results of a preliminary user assessment.

SYSTEM OVERVIEW

The development of the 3DCG application can be divided into two parts.

1. System

The following software was used for this application so that images could be displayed using AR on iPads. Unity was used for the AR platform, and Vuforia was used for the AR library. The methods for using the application and its subsequent process of information are as follows (Fig. 1). (1) Users hold out their iPads in front of the marker of the animal they wish to observe. (2) When the iPad camera acquires the marker's information, the software (Unity + Vuforia) creates an object image, a 3DCG image of the animal's skeleton, based on this information. (3) The object image is displayed on the iPad screen. The designers of the operating system considered the young age of the users and avoided using words as much as possible so that children could operate the system smoothly. The size and positioning of the buttons, and the sizes of the screen icons, were decided after considering the size of children's hands (Fig. 2).

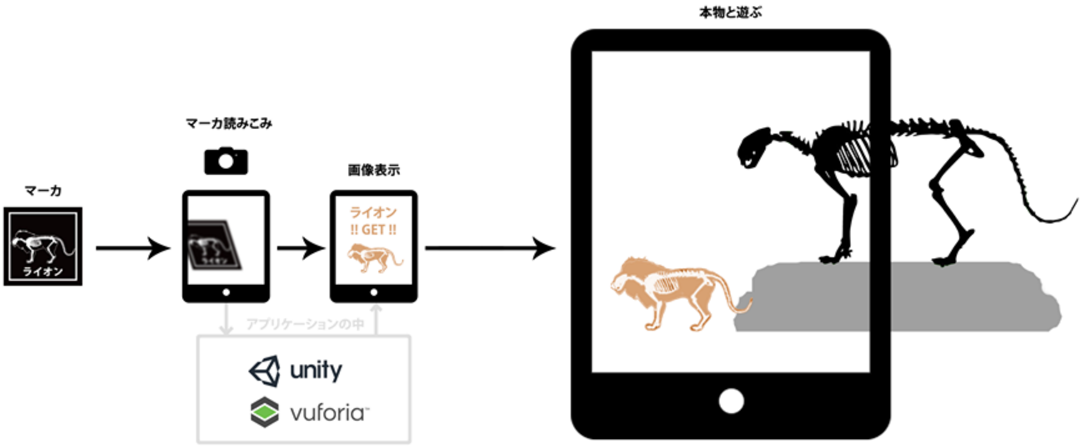

Fig. 1: Summary of the flow of information for the 3DCG application

Fig. 2: The interface of the 3DCG application: For lions. If you select a part of the lion's skeleton, as seen on the bottom right, the selected part will be displayed so that you can observe its detailed form and structure. If you tap the bottom centre, the skeleton will start walking.

2. Skeletal Images Using 3DCG

Graphic representations can be made for three types of animals, penguins, pandas, and lions. Figures 3, 4, and 5 are examples of 3DCG-created skeletal images for each animal. All skeletal images were designed using Maya. Users can observe the images from all angles, at 360 degrees, as they are created using 3DCG technology. In addition, each part of the skeleton can be selected and enlarged so that its detailed form and structure can be observed. Moving images were created so the skeletons moved, demonstrating each animal's strength and flexibility. The moving images were designed so viewers could understand the movements unique to each animal, and how each skeleton moved. For example, leg movements were stressed when representing the movements of the lion, while the moving images of penguins stressed swimming. Because limited data existed on penguins' foot bone movements during swimming, other animals with similar movements were referred to when designing the moving images. The moving images of pandas in the act of feeding focused on the panda's hand usage. For maximum accuracy, the 3DCG created skeletal images based on observations of actual skeletal specimens.

Fig. 3: An example of a 3DCG-created skeletal image of a panda

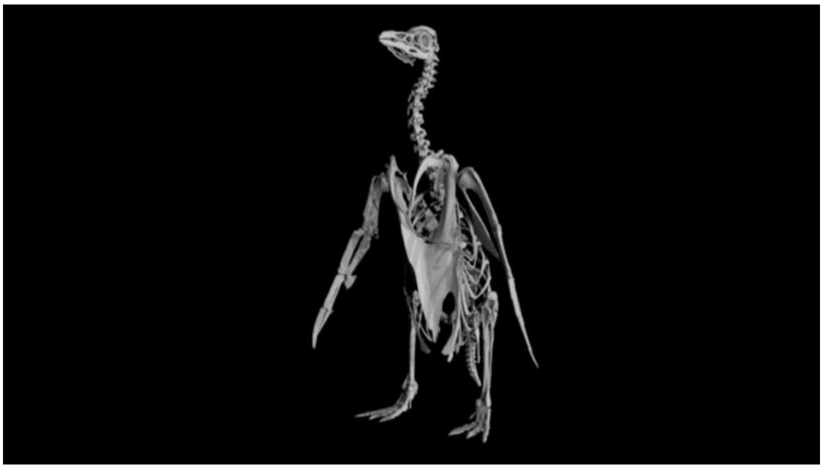

Fig. 4: An example of a 3DCG created skeletal image of a penguin

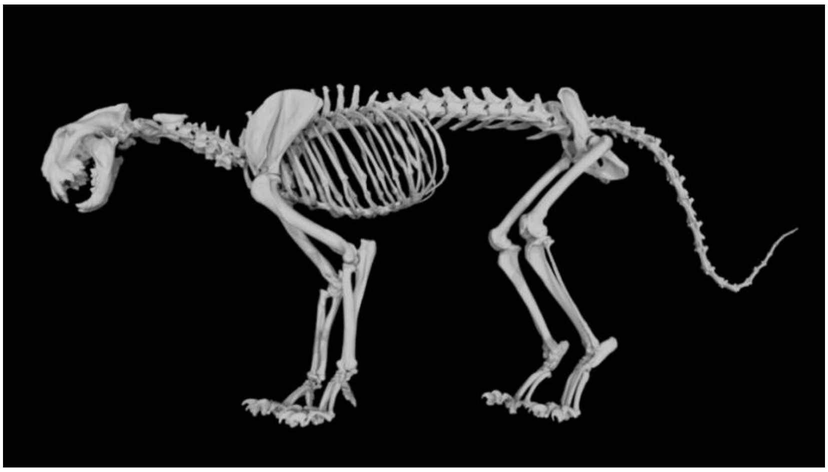

Fig. 5: An example of a 3DCG-created skeletal image of a lion

EVALUATION EXPERIMENT

Research questions: The two research questions for evaluation were as follows:

- Does the 3DCG application, which provides skeletal information on animals, arouse interest in animal skeletons among lower primary students?
- Is the 3DCG application, which provides skeletal information on animals, usable for lower primary students?

Participants: 20 lower primary students (12 students in first grade, eight in second grade)
Assignment: Two assessments were conducted using questionnaires; one was held before the students' usage of the 3DCG application, and the other, after. The pre-usage assessment comprised six items related to children's interest in animals and their skeletons. The post-usage assessment asked questions similar to those in the prior assessment, as well as seven additional question related to the usability of the 3DCG application. All items in the questionnaire were answered on a five-point rating scale (strongly agree, agree, neutral, disagree, strongly disagree). The post usage assessment also sought freely written answers from students on their opinions about the 3DCG application.
Procedure: Lions, penguins, and pandas were the subject animals of this observation. First, students answered survey questions about their interest in each animal and its skeleton. Second, students toured the zoo and observed the animals represented in the application for 30 minutes. Finally, students answered the post-usage survey (Fig. 6). The preliminary survey required three minutes to complete, and the post-usage survey required 15 minutes. The date of the evaluation experiment was October 18, 2018.

Fig. 5: a user at the Kobe Oji Zoo

RESULTS

Table 1 represents the interest of the students toward the subject animals and their skeletons in the pre and post-usage surveys. While students showed interest in the animals in the preliminary survey, relatively few students had a similar degree of interest in the skeletons. However, when compared with the preliminary survey, the post-survey showed a significant increase in the number of participants who had a positive interest in all featured animal skeletons ($p<.05$). Therefore, the students were found to have the same degree of interest towards animals and their skeletons by using the 3DCG application.

Table 2 demonstrates the results of the post-usage survey related to the usability of the 3DCG application. The answers for each item were divided into positive answers (strongly agree, agree) and other answers (neutral, disagree, strongly disagree). The bias of these results was considered using the direct probability calculation, which led to the finding of the significant increase in positive answers compared to other answers for all items. Participants were found to have positively assessed their interest towards the 3DCG application, its simple operational method, and realness of the 3DCG-created images. Lastly, for the freely written answers in the post-usage study, 12 students wrote answers including words related to bones and six students wrote answers regarding how fun it was to use the application.

Table 1: The change in children's interest towards animals and skeletons in the preliminary and post surveys (n=20)

	Strongly agree	agree	neutral	disagree	strongly disagree
I am interested in pandas	14/17	4/3	2/0	0/0	0/0
I am interested in pandas' bones*	5/13	4/6	7/1	2/0	2/0
I am interested in lions	10/15	6/3	2/2	2/0	0/0
I am interested in lions' bones*	5/12	4/7	6/1	4/0	1/0
I am interested in penguins	17/15	0/5	2/0	0/0	1/0
I am interested in penguins' bones*	10/13	3/5	4/2	0/0	3/0

The table shows the number of respondents in the preliminary/post-surveys. The first number shown for each item represents the number of respondents for the preliminary study and the second the number of respondents for the post-usage study.

* ; $p<.05$ (Sign test, two-sided test)

Table 2: A post-usage assessment related to the usability of the 3DCG application (n=20)

	strongly agree	agree	neutral	disagree	strongly disagree
Animal Pocky was fun＊	17	2	1	0	0
I became interested in bones after seeing Animal Pocky＊	14	4	2	0	0
it is interesting that the bones of Animal Pocky move＊	15	4	0	1	0
the bones of Animal Pocky seemed real＊	16	3	1	0	0
I want to see other animal bones with Animal Pocky＊	17	3	0	0	0
using Animal Pocky was easy＊	16	2	2	0	0
I could see bones from wherever I wanted using Animal Pocky＊	13	5	2	0	0

＊The 3DCG application was called *Animal Pocky.*

CONCLUSION AND FUTURE WORKS

The present study proposed using a 3DCG application to support observation of animal skeletons for children to learn about animals in zoos. To this aim, lower primary students were requested to participate in a preliminary user assessment for the application. As a result, children's interest in the featured animals and their skeletons was aroused, and the 3DCG application received positive reviews. This feedback suggests that the use of AR in zoos to provide information could prove to be effective. The following functions were used by the participating students and were designed to enhance their motivation towards learning about animals: (i) the animal skeletons represented through the 3DCG application, (ii) being able to observe the skeletons from all angles, (iii) being able to observe individual parts of the skeleton by selecting and focusing on them, and (iv) being able to observe skeletons which simulate the movements of the real animals.

Zoos are considered arenas for science education, able to facilitate important learning opportunities. Methods to encourage and support scientific learning in zoos must be considered in the near future so that zoos can function as places where visitors acquire scientific knowledge, rather than simply acquiring leisure or entertainment. The distribution of skeletal information using the 3DCG AR application can be considered an effective means to potentially achieve this objective. Future challenges may include increasing the types of subject animals and additional variations of animal movements.

Sustainable Development Goal 15 'Life on Land', addresses deforestation and desertification caused by over development, resulting in a biodiversity crisis in most countries. Japan has a unique problem that forests herein have no longer been managed. Forests in Japan that are traditionally and manually managed are known as Satoyama (woodlands adjacent to a village). Its biodiversity is much better protected when they are managed instead of being left unmanaged. Therefore, it is important to learn the methods in managing Satoyama in terms of biodiversity conservation. However, it is difficult because of the large time scale of vegetation succession. In order to solve this problem, a simulation game called the 'Satoyama Management Game' was developed. This game aids the player to be interested in Satoyama management and to effectively learn about it. Earlier studies reveal that primary school students have the ability to learn methods of Satoyama management to some extent. There is an area for learning support found on top of the game screen. This study analysed the eye movements of university students who hardly knew of Satoyama, and experts, in managing Satoyama during the game to demonstrate the effectiveness of the said area. The results showed that all of the students scored higher in the sixth game than in the first game, and that the university students watched the area for learning support more frequently than the experts did. These results suggested that an inexperienced person needs the area for learning support and that the said area enables even an inexperienced person to learn the methods in managing Satoyama effectively.

Keywords: Vegetation succession, environmental education, simulation game

INTRODUCTION AND BACKGROUND

The United Nations (UN) set the Sustainable Development Goals, universally known as the SDGs. Amongst the 17 SDGs, 'Life on Land' aims to address biodiversity risks by preventing deforestation and desertification (United Nations, 2019). The UN has identified that the populace is in danger of losing biodiversity due to the over development of the human race. Japan, on the other hand, believes that its biodiversity has been lost in a different way. In the past several decades, biodiversity loss has been aggravated by the fact that people who lived in areas adjoining the forest have failed to manage the same. In fact, this is leading cause of biodiversity loss because there is a plethora of species found within Satoyama and rely on a well-managed environment.

Approximately two thirds of Japan's land area are composed of forests. Two thirds of the forests are traditionally and manually managed by the people who live near them (Ministry of the Environment Government of Japan, 2017), which are called Satoyama where both wild and second-growth species live. Records show that more than the half of the forests are Satoyama managed by inhabitants living nearby, which have kept biodiversity high. Biodiversity in Satoyama can be maintained at a high level when they are appropriately managed manually instead of being left unmanaged. According to Ichikawa et al. (2006), Satoyama management has been abandoned because the inhabitants living nearby are ageing and industrial structures are changing. Based on the foregoing, in Japan, less interference with forests will cause biodiversity loss.

Based on the context above, Kawaguchi et al. (2017) developed a simulation game called 'Satoyama Management Game', which enables the player to learn how to manage Satoyama from the perspective of vegetation succession. Ideally, it would be more desirable to learn vegetation succession in an actual Satoyama, but such is unattainable since succession takes over tens or even hundreds of years. To understand the phenomenon that occurs during this large period of time, Clark, Tanner-Smith, & Killingsworth (2015) analysed numerous researches on digital game and suggested the effectiveness of simulation games. Therefore, using a simulation game to learn the methods in managing Satoyama would be an appropriate way. In fact, an earlier study revealed that students who played the Satoyama Management Game learned, to some extent, the process in managing Satoyama (Kawaguchi et al., 2018).

PURPOSE OF THE STUDY

The effectiveness of simulation games and the Satoyama Management Game have been confirmed by prior research. On top of the game screen of the Satoyama Management Game is an area that helps a player learn the methods in managing Satoyama. By measuring the players' line of sight, this report attempted to reveal whether the player learned the methods from the said area or whether they learned through other areas of the game. Additionally, this report aimed to discuss how the game enabled the understanding of biodiversity from the viewpoint of vegetation succession.

SATOYAMA MANAGEMENT GAME

The 'Satoyama Management Game' is a simulation game that models a Satoyama in Hyogo, Japan. By playing the game, a player is expected to be interested in Satoyama and to learn the methods of managing them. The game also expects the player to understand complex vegetation succession after the playing the game. The factors such as the relationship between trees, the impact of harmful insects and animals, and the player's management approaches influence the succession.

The game covers 10 species, which can be sorted into three types: two early-stage species, five middle-stage species and three late-stage species. There are plenty of complicated rules in the game that are also found in real forests. For instance, evergreen trees block the sunlight which prevents early- or middle-stage species from growing.

The game screen composed of three areas, the area for learning support, the area of visualised Satoyama, and the area of management option buttons, as shown in Figure 2. Figure 1 is an example of the game screen. On top of it is the area made for learning support, which this report focused on. The following can be found in the said area in Figure 1: the stage, the name of each tree, its population and its picture. The metre representing the population of each tree is also displayed therein. The centre of the game screens is where the player looks to comprehend the Satoyama that he or she is managing. The player also finds pictures of harmful insects (pine weevils) and animals (deer), and the current turn in this area. The player chooses one of the six methods, which are marked as buttons found at the bottom of the game screen: clear-cutting, evergreen tree-cutting, planting trees, pest control, deer culling and doing nothing. The player has to choose one of six buttons for every turn within the allotted time (twenty seconds). Failure to choose a button will result to 'doing nothing' as automatically selected.

After twenty turns, the player finds out his or her score on the game screen. Each tree has an ideal number for its population, and the score therein is calculated based on the difference between the ideal number and the number of trees in the Satoyama in the game. One turn corresponds to approximately fifteen years. In the game, the player is tasked to keep a high biodiversity for about three hundred years.

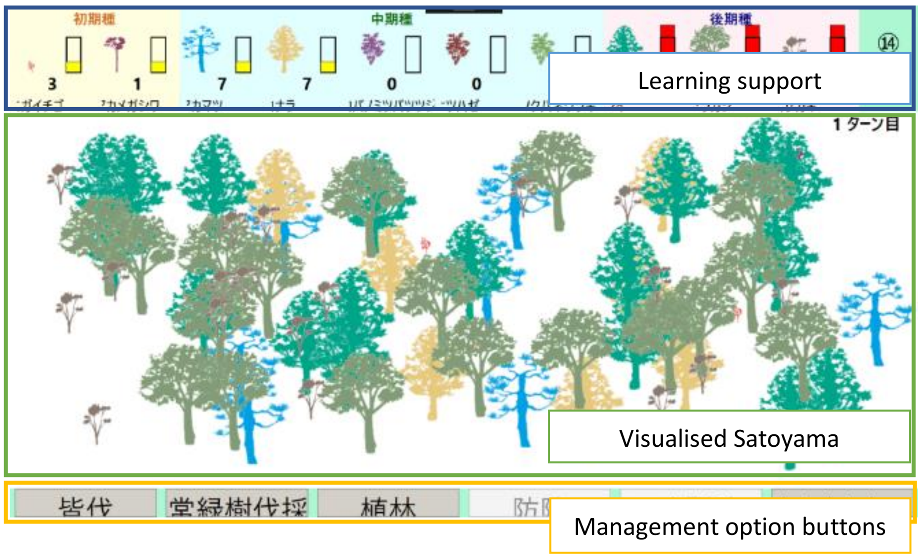

Figure 2. Example of the game screen

EXPERIMENTAL METHOD

Participants

Eighteen people participated in the experiment. Amongst them, nine are students at Tokyo University of Science and three are students at Kobe University. They hardly knew Satoyama

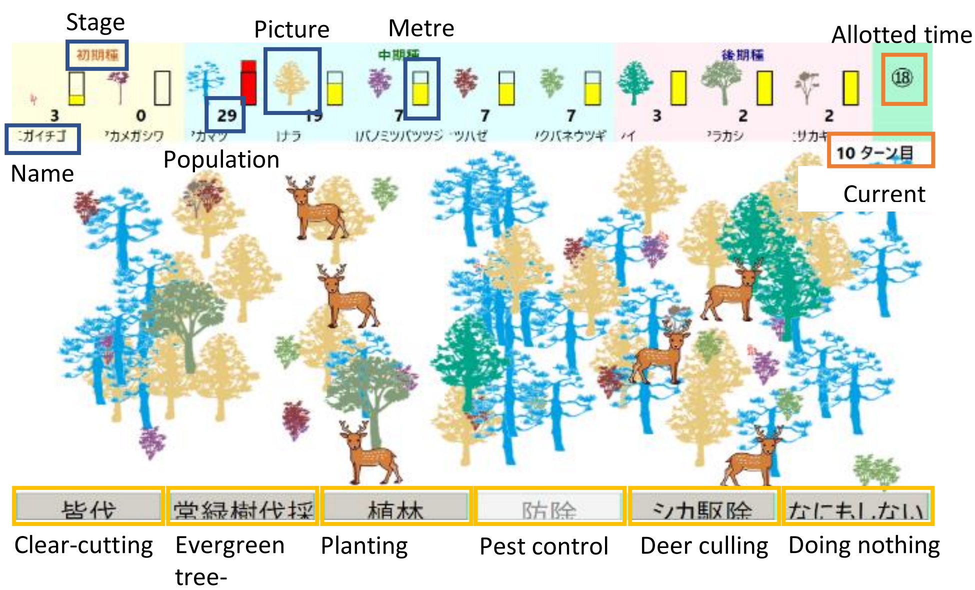

Figure 1. Example of the game screen

and did not specialise in biology or any other field related to vegetation succession. Meanwhile, the six other participants were experts in the management of Satoyama. Amongst the six experts, four of them had been managing Satoyama for more than five years, while two of them were researchers of the fields relating to Satoyama.

In spite of the fact that eighteen people participated in the experiment, no more than six of the students and three of the experts could be analysed. This is because the eye-tracking device EMR-9 (nac Image Technology Inc.) sometimes caused errors, and the line of sight was not correctly measured for the other participants.

Procedure

The experiment began by explaining to the participants how the game operated, the purpose of the experiment was, and that they would play the game six times. The participants were not informed of the rules before the game, for if they had known, they may not have tried to discover other rules and may have watched limited areas. One of the rules is that it is difficult for small species, such as early- or middle-stage species, to grow when there are evergreen trees in Satoyama. The explanation was followed by the fitting of the EMR-9 on the participants. This was preceded by calibration. After calibration, each player would play the game six times.

Analysis

The participants' scores and stationary points were analysed. The latter were analysed using a software called EMR-dFactory (nac Image Technology Inc.). The stationary points are ones where the line of sight stops for more than 0.1 seconds. The stationary points were compared between the students and the experts.

RESULTS

Scores

Table 1 indicates the participants' scores. Because of the small number of the participants, the tendencies of their scores were not clear. The fact is, however, that eight of the nine participants scored higher in the sixth game than in the first one.

Stationary points

Figure 3 shows the proportion of the stationary points which were on the top of the game screen (the area for learning support). In this figure, the lines of the experts were thickened for comparison. This graph reveals that the students relied on the area for learning support more frequently than the experts. Moreover, this implied that students sought more information by referring to the said area. Figure 4 and Figure 5, respectively, indicate student 6's and expert 1's stationary points. Figure 4 shows that there are large circles on the area for learning support. The larger the circle is, the longer the participant saw one point. Figure 5 shows that most of the stationary points of the expert were limited to the area of visualised Satoyama.

The results of the student 1 is interesting because his stationary points were shifted from the area of late-stage species to the area of the middle-stage species, as shown in Table 2. It suggested that he realised that he should have kept the middle-stage species while playing the game. Additionally, the students perhaps found out that cutting evergreen trees regularly was important to keep biodiversity in Satoyama, thus he did not feel that he had to see the area of late-stage species.

Table 1. Scores of the participants

Participants		Play					
		1st	2nd	3rd	4th	5th	6th
Students	1	67	69	69	69	57	69
	2	58	34	30	70	58	81

Table 2. Proportion of the stationary points on the area of early-, middle-, and late-stage species out of all the stationary points on the area for learning support (%)

		Play					
Participant	Stage of species	1st	2nd	3rd	4th	5th	6th
Student 1	Early	4	2	4	12	6	9
	Middle	26	30	50	59	63	64
	Late	70	68	47	29	31	27

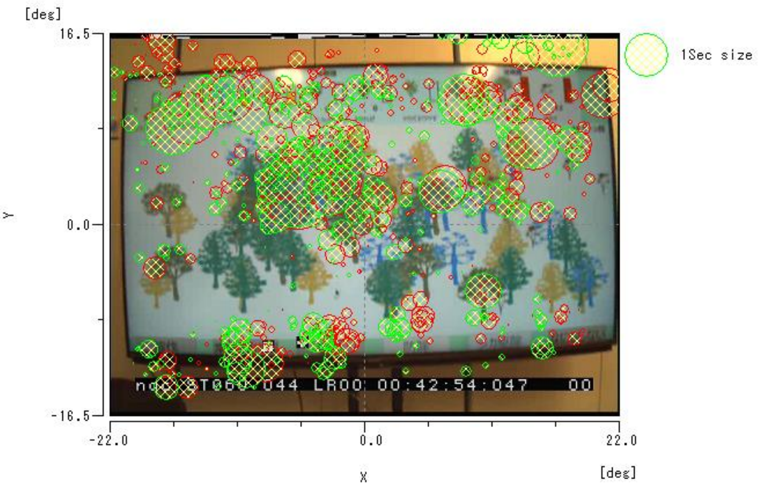

Figure 4. Student 6's stationary points

DISCUSSION AND CONCLUSION

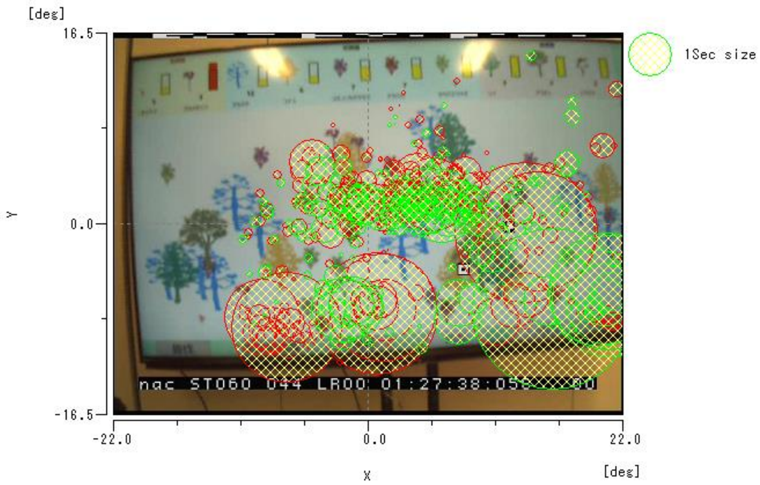

Figure 5. Expert 1's stationary points

This study aimed to reveal the effectiveness of the area for learning support found on top of the game screen. The results showed that all of the students and two of the three experts scored higher in the sixth game than in the first one, and that the students incessantly looked at the area for learning support found on top of the game screen, while the experts merely relied at the visualised Satoyama. These two results suggest that the students needed the area for learning support to get higher scores in the game. Moreover, the results indicated that the stationary points of one student shifted from the area of the late-stage species to that of the middle-stage species. This result meant that he realised the importance of keeping the middle-stage species for biodiversity in Satoyama.

This study perhaps confirmed that the area for learning support in the Satoyama Management Game is effective for an inexperienced player who has no particular knowledge on Satoyama, and that it successfully enabled them to learn how to manage Satoyama, its biodiversity, and vegetation succession.

This study only involved eighteen participants. Due to the small number of participants, the correlation between their scores in the game and where they watched are not conclusive. More data must be collected and analysed in detail to make the suggestions herein more conclusive. Also, the kind of information the participants pay attention to in responding to the appearance of pine weevils and deer should be analysed. This will let us know what the player learned when a specific event takes place in the game. In sum, understanding what types of user interface attracts a player's attention will be useful to improve the Satoyama Management Game. It will help the player learn the methods in managing Satoyama more effectively.

INTERDISCIPLINARY SCIENCE OUTDOORS': EXPLORING OPPORTUNITIES FROM RESEARCH–PRACTICE PARTNERSHIPS

Gonzalo Guerrero
University College London, Institute of Education, London, United Kingdom
Universidad de Santiago de Chile, Santiago, Chile

This proposal presents an outdoor science activity based on Interdisciplinary Teaching and Learning of Science (ITLS) undertaken with a collaborative research methodology as a Research-Practice Partnership (RPP). The ITLS activity was carry out in the Río Clarillo National Reserve in Chile as part of a continuing professional development unit. It was co-designed by in-service science teachers on a Chilean Master's degree programme and researchers. The study aimed at answering the following research questions: 1) How do in-service teachers, working in a RPP, connect and articulate different science topics through methodological and theoretical interdisciplinary perspectives? 2) Can a RPP be a pedagogical resource to generate positive changes in professional development within the practice of managing outdoor science activities? This analysis was qualitative and based on content analysis of data collected from (a) questionnaires about the teachers' perceptions and (b) scientific posters designed by the teachers as part of the final assessment of their course. The main findings revealed that teachers were able to connect interdisciplinary topics – using theoretical and methodological interdisciplinarity – to solve real problems that arise from the environment within a field trip. In addition, findings reveal benefits of RPP and ITLS, as a tool for the management of outdoors activities, supporting the importance and relevance of learning of science outside the classroom. However, the boundaries between researchers and science teachers should consider the cultural worlds of participants in the partnerships.
Keywords: Outdoor Education, Interdisciplinarity, Collaborative learning

INTRODUCTION

In recent years, growing attention has been paid to out-of-school science teaching settings and its impact on students' learning. Outdoor science activities positively influence attitudinal, physical/behavioural and inter-social constructs among students (Rickinson et al., 2004). In particular, researchers, teachers and policy-makers have highlighted the crucial role of the learning of science outside the classroom regarding the promotion of more connections with complex and real-life (Braund & Reiss, 2005). In this context, where science education lacks authenticity – because many concepts are taught in an abstract way – it has been claimed that more connection with real life contexts should be established to counterbalance this situation (Bencze & Hodson, 1999). Nevertheless, some studies highlight a significant challenge related to outdoor science learning, namely that most science teachers have limited pedagogical expertise in terms of planning and preparing activities outside the classroom (Ayotte-Beaudet, Potvin, Lapierre, & Glackin, 2017). Relatedly, K-12 science teachers infrequently incorporate outdoor learning into their practices (Power, Taylor, Rees, & Jones, 2009). For that reason, teachers need to be supported in their initial and continuing professional development, to cultivate dispositions to feel confident to work with activities outside the classroom .

Within this scenario, interdisciplinarity and interdisciplinary teaching and learning of science (ITLS) has appeared as a pedagogical resource to promote the learning of science outside the classroom (Klein, 2005), particularly as a way to: i) encourage K-12 science teachers in their development and planning of outdoor activities, integrating propositions and concepts across disciplines (theoretical interdisciplinarity) and borrowing methods from other disciplines (methodological interdisciplinarity) ; and, ii) as a resource to lead students to the understanding of their own environment and/or, at the same time, of the global environment (Boix Mansilla, 2017). Thus, students might become aware of their 'glocal' (global and local) environment, to develop the ability to relate local problems to global scenarios. This study proposes a methodology based on Research-Practice Partnerships (RPPs) (Penuel, Allen, Coburn, & Farrell, 2015) as a potential pedagogical and collaborative tool to support and generate positive changes in the process of management of outdoor science teaching, and, at the same time, to fulfil the potential of interdisciplinarity as a resource to strengthen learning and teaching outside the classroom. Furthermore, this research therefore examines an ITLS activity outside the classroom conducted in the Río Clarillo National Reserve, in the central zone of Chile.

Teaching and learning of science outside the classroom

Science outside the classroom is usually envisaged as trips or pedagogical itineraries that are designed for an educational purpose in which students interact with the environment or exhibitions (e.g. local nature reserves, zoos, botanic gardens, museums, farms, streetscapes, and so on). These activities provide pedagogical opportunities to develop experiential connections and knowledge of an object, idea, concept, theme or operation (Nabors, Edwards, & Murray, 2009; Scarce, 1997). In terms of students' learning, science education in contexts other than the classroom can show significant benefits (Amos & Reiss, 2012). In particular, activities carried out outside the classroom complement pedagogical resources to help students in multiples domains of learning – cognitive, affective, physical and behavioural (Mohamed, Perez, & Montero, 2017). It is through contact with reality that students can be helped to relate theory to the practical value of the learning they are building, which can generate meaning and a positive attitude towards the topics addressed in the outdoor activities (Behrendt & Franklin, 2014). Such learning motivates students to develop connections between theoretical concepts seen in classes and what they experience empirically (Hudak, 2003). Moreover, learning beyond the classroom has been shown to have the capacity to link knowledge to most areas of curriculum and can be a positive influence on students' understanding, interest and motivation (Braund & Reiss, 2006). With regards to the nature of outdoor science activities, some studies indicate that in order to reach optimal levels of learning, outdoor science activities must be carefully planned (Dillon et al., 2005). These findings imply that outdoor science activities must be related to activities developed in the classroom in order to favour inquisitive behaviour involving conceptual and attitudinal learning and development of skills in science. Nevertheless, although several studies indicate that students increase their knowledge as a result of outdoor activities, teachers typically have difficulties developing outdoor initiatives related to its implementation in the classroom (Ayotte-Beaudet et al., 2017). Furthermore, most science teachers have limited pedagogic knowledge and teacher training regarding the process of planning and preparing such activities (Michie, 1998; Tal & Morag, 2009).

Theoretical and methodological approach to interdisciplinarity

The synthesis, integration or blending of knowledge has been understood as the defining characteristic of interdisciplinarity. However, the definition of interdisciplinarity and a set of terms to delineate interactions of disciplines into classifications of multi-, pluri-, inter-, and trans-disciplinarity is complex. The initial use of interdisciplinarity emerged during the 1970s, created for an international conference co-sponsored by the Organization for Economic Cooperation and Development (OECD) (Klein, 2017). The OECD's definition of interdisciplinarity was broad, including any kinds of interaction defined as "simple communication of ideas to the mutual integration of organizing concepts, methodology, procedures, epistemology, terminology, data, and organization of research and education" According to this definition, interdisciplinarity tends to be conceptualized epistemologically, in terms of using a simple 'blend', 'integration' or 'combination' of different types of disciplinary knowledge (Frodeman, 2014). Nevertheless, 'simple communication' does not involve key attributes of interdisciplinarity . For that reason, we favour the definition of interdisciplinarity provided by (Boix Mansilla, Gardner, & Miller, 2000, p. 219):

> The capacity to integrate knowledge and modes of thinking in two or more disciplines or established areas of expertise to produce a cognitive advancement – such as explaining a phenomenon, solving a problem, or creating a product – in ways that would have been impossible or unlikely through single disciplinary means.

This definition builds on a performance-based view of understanding, meaning that individuals understand a concept when they are able to apply it – or think with it – accurately and flexibly in novel situations . Differences are further evident in the distinction between methodological and theoretical interdisciplinarity, and there are both narrow and broad definitions of interdisciplinarity, depending on the number of disciplines involved and the compatibility of their epistemological paradigms and methodologies (Klein, 2017). Theoretical interdisciplinarity "implies an epistemological form embodied in creating conceptual frameworks for analysing particular problems, integrating propositions and concepts, connecting topics across disciplines, and synthesizing continuities between models and analogies" (Klein, 2017, p. 7). On the other hand, methodological interdisciplinarity "promote[s] the improvement of the quality of results, typically by borrowing a method from another discipline to test a hypothesis, to answer a research question, or to help develop a theory" (Bruun, Hukkinen, Huutoniemi, & Klein, 2005). In the area of science education, previous studies have reported an explosion in the number of educational programmes which intend to promote and integrate theoretical and methodological interdisciplinarity across a wide variety of curriculum proposals (Tobi & Kampen, 2017), and there is a growing recognition of the importance of teaching and learning science through an interdisciplinary approach (You, 2017). For instance, the Next Generation Science Standards (NGSS) highlight that students need to integrate modes of thinking and knowledge informed by a variety of science and engineering disciplines – e.g. STEM (Science, Technology, Engineering and Mathematics), STEAM (Science, Technology, Engineering, Arts and Mathematics) and others . Moreover, various international standards have already proposed the need for interdisciplinary learning for the development of scientific knowledge (OECD, 2018). There is today a greater enthusiasm for ITLS due to a growing recognition that many of today's global scientific challenges – such as climate change, pollution, use of energy, among many others – involve interactions between humans and their environment. A monodisciplinary approach is unable to capture the complexity of these challenges (Gehlert et al., 2010). Moreover, studying the complexity of a natural system it is not easy, and to succeed necessitates interdisciplinary understanding informed by the integration of different disciplinary backgrounds (You, 2017). Therefore, ITLS can provide an integration of knowledge, theories and methods from the different subjects that influence the construction of learning among students in outdoor science activities (Guerrero, Joglar, & Carrasco, 2019).

METHODS

This research adopted a qualitative approach while investigating interdisciplinary science projects that were undertaken outside the classroom and involved a total of nine in-service science teachers and three science education researchers working in three Research-Practice Partnership (RPPs). The study was implemented in the Río Clarillo National Reserve, which preserves native species and their natural environment, being the closest national park to Santiago, the capital of Chile. Nine teachers were enrolled on a Science Master's degree programme for which developing an outdoor science activity in one of physics, earth sciences, chemistry or biology was the final assignment. Qualitative data from interviews with the teachers, field observations of teachers' management and organisation during the outdoor science activity, and materials generated as a result of the interdisciplinary projects were analysed using the Software NVIVO 12. To analyse the data from the scientific posters we applied thematic and directed analysis of content . In the first stage, we started by creating a code bank with predetermined categories and codes of analysis from the literature. This was done both for: (1) Theoretical interdisciplinary codes: (i) integrating propositions and concepts, (ii) connecting topics across disciplines, and (iii) synthesizing continuities between models or analogies from other disciplines (Klein, 2017); (2) Methodological interdisciplinary codes: (i) borrowing a method from another discipline to collect data, (ii) analysing data connecting different methods across disciplines, (iii) testing a hypothesis from different approaches, and (iv) answering the research question or developing a theory. For ethical reasons, the study did not use the real names of the participants. Instead, an encoding process was employed with code names in the transcripts. Informed consent was obtained according to the research ethics committee requirements of the university in Chile.

Research-Practice Partnerships (RPPs) and interdisciplinary projects

In this study, we propose a methodology based on the conceptual framework of Research-Practice Partnerships (RPPs) (Penuel et al., 2015) as a pedagogical resource for bringing about positive outcomes in the process of managing outdoor science teaching and achieving the potential of interdisciplinarity as a resource to strengthen learning outside the classroom. RPPs are collaborative partnerships between researchers and practitioners contributing to more robust educational theory and practice (Penuel et al., 2015). A RPP can enhance the role of teacher as researcher on in-service teachers' professional development. In this case, we developed RPPs as a resource to manage and support interdisciplinary science learning outside the classroom. The activity carried out through RPPs resulted in three different interdisciplinary projects where in-service teachers identified problems and proposed common work objectives, addressing conceptual, procedural and attitudinal aspects.

Data collection

As part of the data collected, at the end of the activity and as part of the final assessment of the courses (physics, chemistry and biology), teachers had the task of making scientific posters. The posters aimed at teachers developing tools for research and planning an interdisciplinary activity outside the classroom. The posters addressed the research problems, objectives, a theoretical framework, methodology, results and conclusions of the activity. Based on the information from the three scientific posters, a content analysis was conducted to answer the first research question of this paper: ‘How do in-service teachers, working in an RPP, connect and articulate different science topics through methodological and theoretical interdisciplinary perspectives?’. In addition, the teachers completed questionnaires which were designed to reveal the teachers’ perceptions of ITLS through outdoors science activities set in a RPP and to establish their views about RPP and ITLS as tools towards improving the management of outdoor science activities.

Findings

Theoretical and methodological interdisciplinarity within the learning of science outside the classroom

From the content analysis of the scientific posters designed by the teachers, it was evident that there was a clear interdisciplinary approach. Teachers connected and articulated different disciplines, topics, content and methods to improve the quality of each project according to codes presented above. Most of the projects integrated disciplinary content, methodologies and topics from chemistry, physics and biology (with a special focus on ecology, plant physiology and botany). Furthermore, two of the groups also connected geography, geology, biochemistry, agrochemistry and agrophysics. In this paper for reasons of the rules for submission and space only one example based on project 1 will be presented. In the case of this project, the research question and the study objective draw on theoretical interdisciplinary concepts as is indicated by the title of the project: ‘Analysing the incidence and effects of temperature and humidity on the development of the *Cestrum parqui* species in the Clarillo River National Reserve’. Teachers began by connecting different topics and concepts across disciplines to investigate how temperature and weather affect *Cestrum parqui*, also known as willow-leaved jessamine – a fast-growing shrub. For instance, a Physics’ in-service teacher attributed some connections of the problem to the effect of temperature in the phenomena of capillarity in the plant, linking with Physics and the dynamics of fluids. Also, he connected the effect of the temperature, frosts or frozen dews and relative humidity on changes in the frequency of light to change the green colour and produce a ‘new’ colour in the damaged leaf. The Biology teacher explained the problem, talking about photosynthesis and leaves’ stomata, evapotranspiration and its impact on the absorption of water and nutrients, which may consequently result in the rupture of cell membranes. At the same time, together they were able to connect these topics with an absence of chlorophyll, connecting with Physics again, talking about solar exposure, and length of waves and a phenomenon called ‘chlorosis’ (insufficient production of chlorophyll by leaves). This information is highlighted in the poster of project 1. On the other hand, the Chemistry teacher connected the deficit of minerals and the lack of nutrients with the deceleration of chemical reactions, for instance, the production and exchange of CO_2 which impacts, again, the weakening of structures such as the cell membrane. This was summarised in his contribution to the initial working hypothesis 'low temperatures and high humidity would directly affect the photosynthetic activity and the chemical composition of *Cestrum parqui*, preventing its normal development'. In order to answer the research question, teachers used elements of botany and plant physiology regarding the transpiration of plants (see figure 1). At the same time, the teachers used elements of geography and climatology to investigate what occurs to the leaves when there is a frost. Also, they were measuring the temperature of the soil and the external environment using methods from physics and chemistry.

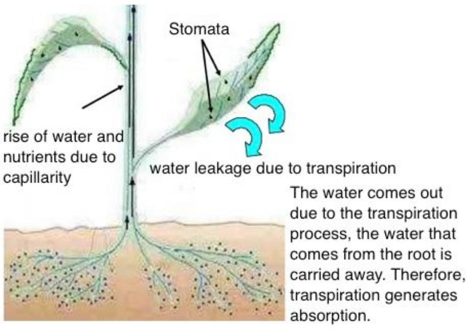

Figure 1. Part of the poster produced by the teachers undertaking project 1. Effects of transpiration on water absorption in plants. (Source: Diagram from scientific poster made by in-service teachers in project 1.)

The results of project 1 show that teachers were able to use theoretical and methodological interdisciplinarity to answer their initial research question. This approach of the teachers is indicated in Figure 2, which is taken from the results section of their scientific poster.

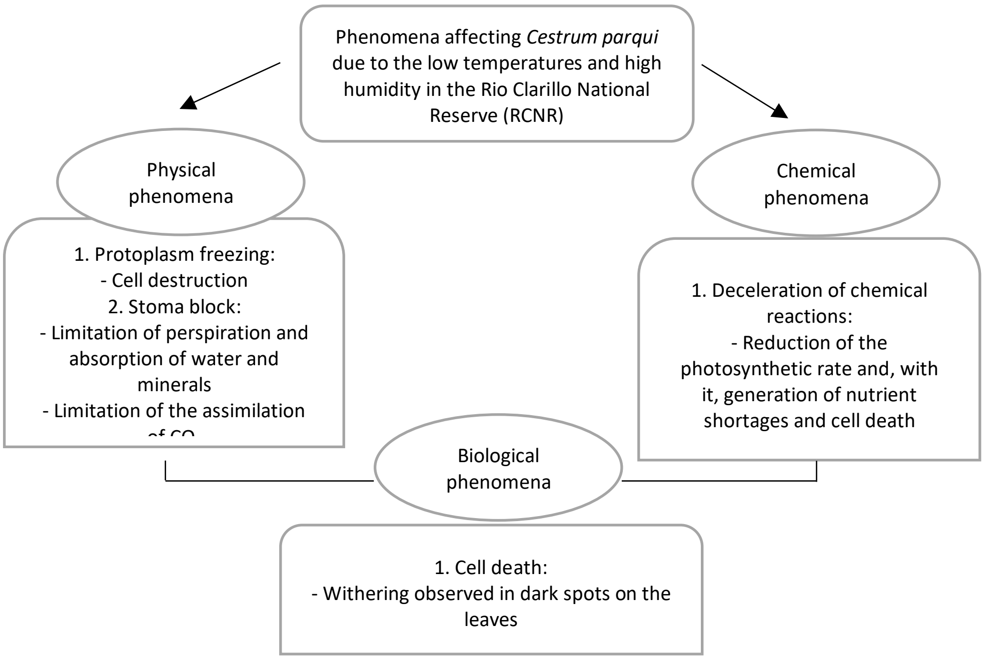

Figure 2. Example of theoretical interdisciplinarity: Effects of low temperatures and high humidity on Cestrum parqui in the Río Clarillo National Reserve. (Source: Diagram from scientific poster made by in-service teachers in project 1.)

From Figure 2, we can appreciate that teachers were able to connect different concepts and disciplines, finding an answer to the problem. In this case, the temperature and humidity affect the species Cestrum parqui in the River Clarillo National Reserve:

> "These phenomena are producing black spots on the leaves of Cestrum parqui, which is attributed to the cell death which is generated by the alteration of various biological, chemical and physical process that occur in the plant." (Findings from scientific poster in project 1).

Teaching and learning of science through RPPs in outdoor science activities

Regarding the perceptions about teaching and learning outside the classroom, teachers suggested that these types of activities are essential for science education. Teachers mentioned that the importance of working in this way is based on developing a broader understanding of complex issues and real-life problems, saving time and simplifying their work in the classroom,

> The differences are related to saving time and simplifying our work. Normally, you tend to fall into unnecessary repetitions of the subjects, and as a teacher of the subjects of biology and chemistry at the same time, I visualize that students lose interest when one teaches something they already know or repeats. (Biochemistry teacher)

In addition, teachers suggested that a pedagogical fieldtrip would help consolidate the content covered in classes, also benefiting the development of learning, the appropriation of concepts, thinking, reasoning and research skills from a real-life problem:

> I think that addressing a problem in real life, was key to consolidating the contents worked, to 'download' and apply them and to be able to relate the different specialties, I think it would not have been possible to have seen it only in the class sessions (...) I feel that benefited learning, thinking reasoning and research skills. (Biology teacher)

Teachers working through RPPs were able to connect different topics seen during their Master's modules with their visit to the Río Clarillo National Reserve through the ITLS approach. According to the perceptions of teachers about ITLS and science outdoors, activities developed through the ITLS approach facilitated teachers' thinking about natural phenomena by familiarising them with real-world problems, as highlighted by one science teacher:

> Contributions of interdisciplinary teaching through science outdoors activities for the teaching-learning process are evident (…) it allows us to solve issues that through distinct subjects would not have been possible, such as the case of environmental issues (…) I think they allow us to develop critical thinking, scientific reasoning, drawing conclusions from different perspectives and encouraging meaningful learning. (Biochemistry teacher)

Perceptions about RPP and collaborative work are clear. Teachers consider a key aspect of the outdoor science activity to be the work developed through collaborative partnerships. This appears as a contribution to the management of science activities outside the classroom. Indeed, teachers highlight the experience as a contribution to their teaching practice and also to the development and an impact on the researcher-teacher role:

> The topics were born from conversations with my colleagues, where we could share experiences about some activities that we have wanted to be developed in our subjects and with our students but had never been translated. That is why I think that this pedagogical outdoor activity is a great contribution to our teaching practice and future activities that can be developed outside of our schools (…) The researchers were very

> helpful, because important questions about the methodology were solved. (Physics teacher)

However, some obstacles are related to the time required and for the need to make a previous visit to the National Reserve. The majority of the teachers complained about the time needed for the implementation, and there were also complaints about the guidelines given by researchers at each stage. On the other hand, one teacher wanted more time to have been spent on the implementation:

> I think it would have been favourable, to have made more than one visit to the place, in the first instance to identify the problem and then to be able to measure the variables, since we could have carried more appropriate instruments. (Biology teacher)

In addition, another obstacle was related to the guidelines provided by the researchers during the process and to limitations between the roles of the teachers and of the researchers. In this case, some teachers maintained that the decisions about what to do emerged from the teachers without help from the researchers:

> I feel that the professors / researchers were willing to contribute in our work, however we as students proposed what and how to do it, I think that, if we had been very disoriented, they would have helped us more, but it was not the case. (Biology teacher).

However, and conversely, teachers felt supported during the development and production of the scientific posters:

> Especially in the preparation of the scientific poster, they helped us to limit the problem, find information about the variables, relate everything and translate it in an understandable and summarised way, that was the challenge. (Chemistry teacher)

Overall, the findings from teachers' perceptions reveal benefits of RPP and ITLS, as tools for the management of outdoor activities, supporting the importance, relevance and feasibility of learning science outside the classroom.

DISCUSSION AND CONCLUSION

As a result of outdoor science activities using an interdisciplinary approach, teachers may find their disciplinary knowledge and skills improved, with the result that they are more able to answer research questions in real environments. Moreover, through theoretical and methodological interdisciplinarity, teachers may foster the creation of new conceptual categories and methodological tools, using concepts or procedures from other disciplines in an auxiliary relationship (Klein, 2017). From this perspective, interdisciplinary outdoor science activities have the potential to organise scientific topics and ideas and answer questions across different disciplines (DeZure, 2017). Furthermore, these kinds of activities provide an opportunity to develop problem-solving abilities, generally considered as an instance of higher order thinking within science courses. Thus, interdisciplinary teaching outside the classroom leads learners to have more meaningful learning experiences. Interdisciplinary outdoor science activities carried out through RPPs appear to generate common work objectives, addressing conceptual, procedural and attitudinal aspects across science subjects. Nevertheless, the teachers in this study found it difficult to specify quality teaching itineraries for implementation in the classroom. Therefore, collaboration with researchers can play a key role in facilitating interdisciplinary teaching. This research revealed some benefits of RPPs and ITLS as pedagogical approaches to supporting learning outside the classroom. In the research presented in this article, the experience provided a rationale for more collaborative-action work projects to foster curricular planning of outdoor science activities and in-service teacher education. RPPs benefit from collaborative learning in all the phases of an outdoor science activity. However, the cultural, professional, and disciplinary boundaries between practitioners and researchers must be considered (Penuel et al., 2015). Collaboration between researchers and in-service teachers allows the science education community to respond to some of the dissuasive elements faced by teachers when considering research work. Although it would become a key requirement within RPPs that teachers develop skills and knowledge in research as part of their professional development, there are some difficulties to position and articulate research with the daily practice of teachers in terms of implications and the relationships between teaching practice, formative research and self-reflection activities for the transformation of practice.

COMPLEMENTARY NETWORKING OF OUT-OF-SCHOOL LEARNING ENVIRONMENTS

Christin Sajons, Michael Komorek
University of Oldenburg, Oldenburg, Germany

During the past two decades, extracurricular educational institutions like museums, science centres, student labs, environmental education centres and others have received increasing attention in their educational function throughout Europe (Tal, 2012). The study presented here uses the educational development research approach. Based on empirical data about learning processes in out-of-school learning environments existing educational offers are developed. At the same time, generalisable findings on learning at extracurricular educational institutions are gained. The study examines how the offerings of different out-of-school educational institutions can be systematically related so that they complement each other. Subject-related clarifications and empirical investigations form the basis for combining the offers of individual learning locations into a new, complex educational offer. The research framework is the Model of Educational Reconstruction (Duit, Gropengießer, Kattmann, Komorek & Parchmann, 2012).

Keywords: Cognitive Skills, Design Based Research, Non-formal Learning Environments

INTRODUCTION: THE CONCEPT OF COMPLEMENTARY NETWORKING

The development of educational regions is a declared objective of the UNESCO (2008). This mainly refers to an organisational link between schools and extracurricular educational institutions. The extracurricular learning environments among themselves are also often organisationally linked, above all similar out-of-school training facilities through their interest groups, such as Student laboratories or museums. Complementary networking goes beyond organisational contacts (Richter, Sajons, Gorr, Michelsen & Komorek, 2018). Here different types of learning venues such as museums, student laboratories, science centres, environmental education centres connect their offers to each other in terms of their content, methodological approaches or even their social perspectives.

A possible complementary connection between different out-of-school education offers can be a similar topic of all as for example the topic “coastal protection”. For this, e.g. a National Park House, a museum and a student laboratory offer very different, but complementary approaches. In the student laboratory, students can build and try out various dike variants by themselves, while in the museum they learn about storm surges and historical aspects of dike construction and the changes in the coastal area. The National Park House visualises the conflicts of interest between coastal protection, nature conservation and tourism.

Common educational goals such as education for sustainable development (ESD) or the education of interested laypersons in the sense of a public understanding of science can also be achieved through complementary networking. Scientific, cultural, historical, economic, ecological, ethical, technical, political and other perspectives are introduced by the complementary networked extracurricular educational institutions according to their orientations and strengths. The development of certain competences of the visitors or the sharing of objects and products can also be starting points for the complementary cooperation. There are several "paths" of complementary networking that can be supported by instruments such as flyers, signposts with connecting questions at the respective extracurricular educational institutions or apps for smartphones.

Advantages for all sides involved. Complementary networking is currently rarely implemented, although the added value for all participants can be very high:

- Visitors to extracurricular educational institutions, tourists, laypeople, and especially students, can gain better understanding of complex issues such as coastline, climate, environmental protection, energy supply, or regional development through complementary approaches, increasing their sensitivity to the complexity of topics that often lead to social conflicts and dilemmas. Interdisciplinary subject related understanding can also be better achieved by networking out-of-school educational institutions.
- Complementary networking helps teachers to reach their subject related and interdisciplinary goals; they have access to new extracurricular education environments and can be advised by the network on the complementary use of learning venues.
- The learning venues are more effective when focussing on their strengths, which can also help to profile and enhance the offerings. Because a place can be focussed on certain offers additions, if it is known that other places offer additions. It also opens possibilities for often required innovation.
- The participation in education increases throughout the educational region regarding those who are particularly interested but also those who are otherwise disadvantaged in education. In addition, the flexibility with regard to social challenges and key problems is also increased if these are addressed in a networked way.

METHOD

In this study, six extracurricular educational institutions have worked in a network. All together these extracurricular learning sites attract around 8,000 visitors per year. The learning venues are a national park house, a historical museum, a botanical garden, a naval museum, a student laboratory and an environmental education centre. This study is based on the model of Educational Reconstruction (Duit, Gropengießer, Kattmann, Komorek & Parchmann, 2012), in which subject-related clarifications of the offers of the extracurricular learning environments, empirical studies on learning, and the design of complementary offers at different types of learning venues are closely related. The model was applied to the situation of out-of-school learning (see Laherto, 2013) in order to systematically redesign the educational offers at the cooperating learning venues and design a complementary offer by combining them

Clarification of the subject matter structure and elaboration of basic ideas. The educational offerings of the participating extracurricular educational institutions were analysed in terms of specific characteristics, which can be related to one another according to a shared educational objective. For this purpose, the subject-related structure of educational offers was examined using methods of content analysis (see Mayring, 2014) in order to develop specific networking paths (Pollmann, 2018).

Empirical Studies. The empirical research focuses on the teacher`s needs for complementary networked offerings and on how they would embed these offerings in their lessons. For this purpose, a questionnaire study and an interview study with a structured guideline interview are taking place. In order to know the perspectives of teachers, the participating learning venues have offered a teacher training day that introduces teachers to the networked offerings of the six learning venues explaining the concept of complementary networking. The aim is to investigate to what extent teachers expect that networked offers support their pupils' subject-specific learning and their motivation in terms of perceiving the relevance of connected offers and the perception of self-efficacy (Deci & Ryan, 2008). Visitors to the learning locations were also asked (Schetzberg, 2018) how they perceived the added value of the networked offers.

Design of complementary networked offerings. The results of the analysis of the offerings of the learning sites and the empirical results on the needs of the teachers and the first attempts at networking were the basis for the design of networked educational offers. For this a number of didactic means have been developed (Pollmann, 2018). Core of the educational design of the offer was that a main topic was defined and that key questions were asked, that could only be answered if the visitors compare the information from two learning environments with each other.

RESULTS

Two complementary networked educational programs have been designed and tested. One of the offers is titled "The Challenge of Life at the Coast". It discusses from different perspectives the difficulties people have faced on the coast for centuries. This includes the perspective of nature, which is altered by forces of nature, and the cultural activity of humans, including the military use of the coast. Also, the dyke construction and the importance of plants for coastal protection is discussed. The visitors experience in each place, how it contributes to the main topic. The operators of the learning venues embed their special offer in the main topic and refer it to the offers of the other learning venues. Flyers and hand-on turntables support networking. The visitors themselves carry out scientific experiments at the learning locations. Empirical data show (Schetzberg, 2018) that the visitors establish the relation of the learning places to the respective main topic, that they work out the differences in the perspective of the places of learning and that they can also name conflicts that exist between environmental protection, industrial use and tourism at the coast.

Another designed offer is the format of a project week for school classes about the topic "The challenge of life in climate change". With the project week, five of the out-of-school learning places wanted to raise the pupils' awareness of the topic of climate change and convey important basics. The central goal of the project week was to develop a complex picture of the challenges of life in climate change. 130 sixth graders from five school classes (comprehensive school, high school) took part in the project week. On the first four days of the week, they visited one of the learning locations each day. Each learning location aligned one of its existing offers with the main topic and made explicit references to the other learning locations at the beginning and at the end of the visit days (fig. 1). On the fifth day they reflected and brought together the experiences and impressions in their schools. For this purpose, accompanying material and a handout were developed for the teachers and the leaders of the learning locations (Zinn, 2019).

In the student laboratory "Lernort Technik und Natur" the pupils produced a solar boat, which stands for the use of clean energy to reduce the CO_2 entry into the atmosphere. At the "climate breakfast" of the environmental education centre, the pupils worked out their behaviour when buying food and the consequences of their consumption. The offerings from these two learning venues complemented each other by highlighting various measures that can be used to slow down climate change. From a historical perspective, the coastal museum illustrated protective measures taken by coastal residents against storm surges and against the natural and man-made rise in sea levels. The coastal museum and the environmental education centre complemented each other in that they combined a look into the past with one's own behaviour in the future. The offer of the coastal museum and that of the botanical garden complemented each other in that both learning places deal with the meaning of dikes. In addition, there was the perspective of the Wadden Sea Visitor Centre, which focused on the global consequences of climate

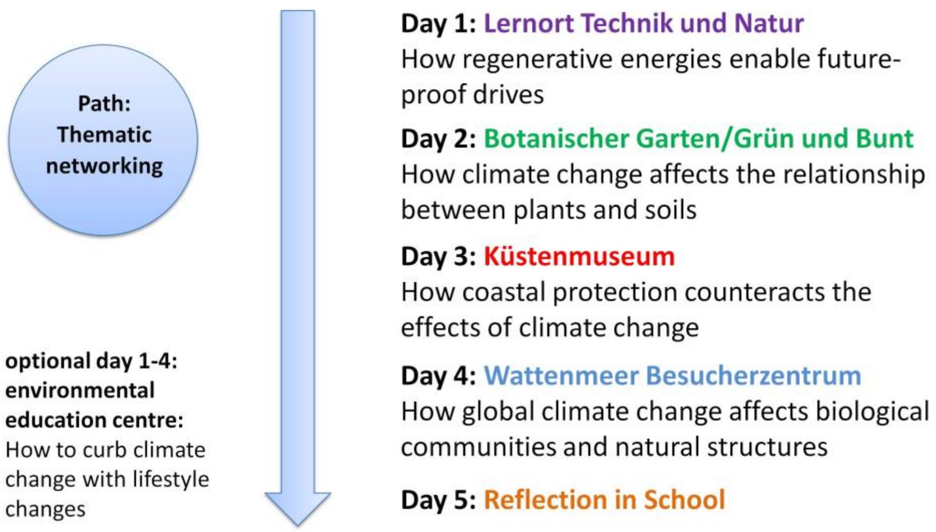

Figure 1: project week for school classes about the topic "The challenge of life in climate change"

change.
In the accompanying research for the project week (master thesis by Jonas Tischer, in progress) pupils, their teachers and the leaders of the learning places were interviewed in order to relate the perceptions and insights of these three groups of actors. Regarding the pupils, the following research questions were concerned:

- To what extent can pupils reflect on and justify their actions at the different learning locations?
- To what extent can pupils abstract the different perspectives of the learning locations from the offers visited and relate them to the motto of the project week?
- How can the pupils relate the perspectives of the learning locations to each other and work out similarities, but also differences? To what extent can they understand possible conflicts and dilemmas that arise from the sometimes opposing perspectives?
- And to what extent can the pupils work out and formulate the complex challenges that the coastal population faces due to climate change?

The pupils were interviewed during and after the offers as part of a semi-open structured guideline interview. Field notes during the project week and interviews in schools complemented the data acquisition. The evaluation took place within the framework of qualitative content analysis (Mayring, 2014) of the interview and observation data. First analysis of the data show, that the majority of the pupils were not only able to reproduce the offers of the individual learning locations, but could also name the (abstract) perspectives of the offers (historical, scientific, technical, political, ...) and relate them to each other. This is an astonishingly high level of abstraction by the young pupils. In addition, many of them were able to put the very different offers and perspectives in connection with the overall topic "The challenge of life in climate change" of the project week in the follow-up at school and use them to derive specific dispositions for action.

DISCUSSION AND CONCLUSIONS

The complementary networking of learning offers from different extracurricular educational institutions seems to have great value in understanding open, complex problem situations. This fits in with modern educational discussions, where it is an important goal to prepare young people for a world of ill-defined open problems. The preliminary study in the context of the project week showed that the concept of complementarily networked offers can support pupils in the lower grades to understand the complex challenges that climate change brings. However, project weeks are singular events, which have a high intensity but are not linked to regular lessons, although the school preparation and follow-up of such visits is important. In general, singular formats such as individual visits to non-school learning venues are not of lasting cognitive and motivational impact (Pawek, 2009).
Therefore there is a need for development and research, firstly as regard to the embedding of extra-curricular visits in regular lessons and secondly how several visits can be related to one another over a longer period of time. Encouraged by the positive results of the project week,

two of the participating schools (Neues Gymnasium Wilhelmshaven and Wilhelmshaven Comprehensive School) are interested in trying out the integration of the complementarily networked offers over two school years. Several school subjects should also be involved in this, beyond the STEM area. School climate education should be closely interlinked with extracurricular educational offers; also a digital networking application for smartphones will be designed to help connecting the different learning environments. In addition this offer allows particularly interested pupils to get to know the learning environments and to to take advantage of other offers, even in the afternoon.

These participating schools want to achieve a climate education of their students, which includes climate knowledge, understanding of the climate system, taking different disciplinary perspectives on climate change as well as dispositions of individual and social action. The planned project is based on the Sustainable Development Goals of high-quality education and immediate and urgent action with regard to climate change (UN General Assembly, 2015).

PART 10: STRAND 10

Science Curriculum and Educational Policy

Co-editors: *Andreas Redfors & Jim Ryder*

CONTENTS

STRAND 10: INTRODUCTION

SCIENCE CURRICULUM AND EDUCATIONAL POLICY

Policy is relevant, and often deeply influential, across all educational contexts. Education policy frames priorities and targets resources on themes such as curriculum content, assessment, pedagogy, school governance, teacher education and development. Underpinning such policies are educational aims and values that extend well beyond education contexts to broader societal and cultural settings. The contributions in this section provide diverse analyses of the significance of education policy. They are diverse in terms of geographical context (Asia, Europe, South America), exploring three national projects, with one comparison between two countries – one in Asia and one in Europe. In addition, they demonstrate varied methodologies and conceptual frameworks. Taken together they demonstrate the powerful, yet often hidden, influence of education policy on society, schools, teachers and young people. We hope that the compelling messages of these studies inspire other researchers within the ESERA community and beyond to make policy itself, its development, enactment and outcomes, the focus of sustained and high-quality research internationally.

Michel Pisa Carnio and Marcos Cesar Danhoni Neves examine national policies in Brazil and the nature of authoritarian thinking and its implications for the educational field. They present an analysis of the national project Escola Sem Partido, echoing calls for 'politically neutral schools' seen in many countries. Analysis considers different 'registers of influence' including public policy texts and the experiences of individual stakeholders. They argue that there are misconceptions about science education inherent in the Escola Sem Partido project that are communicated by project advocates. Such misleading projections of education can be damaging for the authority and autonomy of teachers and schools.

Susumu Nozoe and Tetsuo Isozaki presents an analysis of how science teachers' viewpoints and attitudes influence the implementation of curricula in Japan. They report on a survey of lower secondary science teachers in Japan and England. They discuss science teachers' pedagogical perspectives in the two countries and conclude presuppositions about the nature of the world are more contested in Japan where western science is introduced in a differing culture. They report that sociocultural contexts in Japanese society are often accepted implicitly by Japan's science teachers and hence influence implementation of curricula fundamentally.

Teresa Lupión-Cobos, José Hierrezuelo-Osorio, Isabel Cruz-Lorite and Ángel Blanco-López analyse how secondary school science teachers in Spain experience the different stages of a training programme designed to meet the challenges of educational reform. The analysis of two individual interviews and a focus group uses a framework representing personal (individual), internal (school) and external factors of influence. They report on data from four teachers following the training programme. They found that personal (individual) factors were initially important, but influence from program and peers increased as the program continued. They conclude that the analysis framework of personal/internal/external factors can be beneficial for education researchers, designers of training programmes and the development of education policy

Damienne Letmon, Eilish McLoughlin and Odilla E. Finlayson explore 50 years of policy influences on upper secondary physical sciences curricula in Ireland. They examine and compare the cognitive demands of upper secondary level physics and chemistry examination questions from 1966-2016. A sample of ten physics and ten chemistry Leaving Certificate higher-level examinations papers were selected. They found that despite changes in syllabi and question styles there was no significant change in cognitive demand levels. They conclude that the findings of their analysis are relevant for the development of assessment practices that recognise and assess higher order thinking skills.

These contributions demonstrate the commitment within ESERA to researching curriculum and policy using a range of methodologies and including international and comparative studies. We hope that you will enjoy reading the papers and that they provide models for related studies in other policy areas across Europe and beyond.

THE IMPACT OF AUTHORITARIAN THINKING ON PUBLIC POLICIES AND SCIENTIFIC EDUCATION: A BRAZILIAN CASE[1]

Michel Pisa Carnio[1], Marcos Cesar Danhoni Neves[2]
[1]Universidade Federal de São Carlos (UFSCar), São Carlos, Brasil,
[2]Universidade Estadual de Maringá (UEM), Maringá, Brasil,

Considered unconstitutional by the opinion of a Minister of the Federal Supreme Court, the bill "Escola Sem Partido"[2] continues to be referred, discussed and voted in municipal and state chambers throughout Brazil. Through the appropriation of the ideas of thinkers of the Frankfurt School, in the interface between philosophy of education and psychoanalysis, this paper aims to reflect the nature of authoritarian thinking and its implications for the educational field. We performed a qualitative analysis of three records related to the Escola Sem Partido, resulting in five misconceptions that are constantly disseminated by the supporters of the movement. We argue that the fragility of the ego, added to the instrumental rationality of society, results in misleading projections about education and its formative orientation. We highlight the project Escola Sem Partido as a false projection of the educational field, with the presence of many signs of authoritarian thinking directed to education.

Keywords: Educational Reform, Science Education Policy, Culture and Education.

INTRODUCTION

The "Escola Sem Partido" project in the context of recent Brazilian public policies

In a global context of education perspectives in the neoliberal system, in Brazil there is a deepening of the implementation of unpopular public policies after the dismissal of the Dilma government. At first, the National Common Curricular Base (BNCC) underwent major changes in the post-impeachment period (2016), both in the conduct of its process and in its content. Subsequently, the Secondary School Reform (Law 13,415 of 2017), breaking with the democratic rites that followed the Brazilian Constitution of 1988, appears as the imposition of the executive government of an anachronistic proposal, with hasty ballots in the Chamber of Deputies. Finally, the project "Escola Sem Partido" comes on the scene. Although considered unconstitutional by the opinion of the Minister of the Supreme Court Luis Roberto Barroso, continues to process in several municipal and state legislative chambers of Brazil.

In its website, the project is justified as "a reaction to the phenomenon of instrumentalisation of education for political-ideological, partisan and electoral purposes"[3], but its movement has caused disturbing reactions from the point of view of a democratic education. Recent literature has reiterated that the Escola Sem Partido uses a "language close to common sense, resorting to simplistic dichotomies that reduce complex issues to false alternatives" (Penna, 2017), in the

[1] Work presented at the VI National Symposium on Science and Technology Education (SINECT), held in the city of Ponta Grossa, Paraná, Brazil, from 27 to 30 November 2018.
[2] A literal translation could be "Unpolitical School".
[3] Available in: <http://escolasempartido.org/midia/395-entrevista-de-miguel-nagib-a-revista-profissao-mestre>.

case of "proposing supposedly neutral ideas, but which conceal, in fact, a strongly persecutory, repressive and violent content "(Ramos, 2017).

Populist and sensationalist, the movement manages to channel the frustrations of a population weary of daily maladjustments and the sensation of a world in permanent disenchantment - a feeling often reinforced and nourished by the banalization of (in)formation in virtual media. In their supporters, there are tendencies of aggressive and intolerant positioning that, instead of encouraging the debate and the collective construction of the best ways to guide the national education, close to the dialogue and always try to impose their point of view to whom thinks differently. These Brazilian movements are in line with similar international mobilizations that advocate the need for a "neutral school" (as in the case of the United States) or the German "Neutrale Schule Berlin" website of the far right AfD party, which serves as a platform of teacher denunciation.

Contributions of Critical Theory to reflect on authoritarian thinking in education

We turn to the studies of the thinkers of the Frankfurt School to reflect the education and the tendencies of thought that permeate society.

As observed in the capitalist world, the fragmentation of the school, which is subject to the logic of the market, corresponds to an experience with profound implications for the non-realization of a democracy whose foundation is the realization of autonomous and emancipated individuals. For this reason, “the relationship of loss of autonomy for thought, which has been standardized by the administration of the logic of the common denominator and the utility function, implies, according to Adorno, in the process of barbarizing culture” (Carnio, 2012, p. 62).

To this barbarization of culture, Adorno refers mainly to the experience of apology and totalitarianism of German Nazism experienced by him and other members of the Frankfurt School. Recalling that emblematic episode in the history of mankind, he argued that the most basic objective for which education should strive was “that Auschwitz should not be repeated” (Adorno, 1995, p. 1). When emphasizing that “the attempt to overcome barbarism is decisive for the survival of humanity” (Adorno, 1950, p. 156), we list the central point of the author's thought in education, highlighting the need and importance of reviewing the educational and the formative objectives that we want in our schools.

Horkheimer (2002) analyzes the influence of the culture of each epoch on the familiar and psychic constitution of the subjects, in which "each new impression of the world is already preformatted by it" (219). Already Adorno and Horkheimer (1972) understand rationality (or enlightenment) as an escape from the fear of the unknown, where Homer's Odyssey would represent the prototype of the bourgeois individual.

For these thinkers, all perception about the world is the fruit of a projection of the subject to the world. Thus, the outside world would have a similar amplitude to the inner world, where the semiformation (or malformation) of the subjects would result in false projections of reality. In these cases, instead of the internalization of the social imperative (culture) in the subject's psychic structure, there is an immediate identification with stereotyped values scales fed by the subject himself. This lack of a genuine relation to things (Adorno, 1975) is due in large part to the ego's fragility in dealing with its own frustrations and limitations.

In addressing the study of Authoritarian Personality, Adorno (1950) reflects why people are acting against their own interests. In analogous reflection, we aim to analyze how the ideas and educational conceptions propagated by the No-Party School go against the contemporary educational tendencies that cherish the construction of autonomous and critical consciences of the students.

METHOD

It is a research based on historical dialectical materialism that values a historical and contextual treatment of the object. Without disregarding the fact that the social subject is part of the social phenomenon he studies, we value a historical and contextual treatment of the object, in “a supplementary effort to understand the current situation” (Bogdan & Biklen, 1994, p. 91).

In order to provide a broader picture of the foundations of the Escola Sem Partido, the composition of analysis records considered the different spheres of life in which authoritarian thinking is revealed and reproduced (Adorno, 1998; Horkheimer, 2002). Three registers of great influence in the public debate are analyzed: i) the contextual level of public policy, through the Bill in its entirety[4]; ii) the family level, based on a speech by the lawyer Miguel Nagib - who proposed the Law from a case in the school of his son - in a special commission of the project[5] and iii) the individual level, through the story of Ana Caroline Campagnolo, a history teacher who claims to have suffered ideological persecution by her mentor at the graduate school[6]. From these materials we identified five misconceptions that are related to the presence of signs of authoritarian thinking in Brazilian scientific education.

RESULTS

In its Article 1, Bill 867/2015 intends to be inserted in the Laws of Directives and Bases of Brazilian national education, based on VII principles that are exposed in Art. 2 (which it says are based on the Constitution, however with relevant subtractions). The ideological and repressive tone of the proposal takes shape in the following article, when it

> 3rd. In the classroom, the practice of political and ideological indoctrination as well as the transmission of content or activities that may be in conflict with the religious or moral beliefs of parents or guardians of students (PROJETO, 2015, p. 2).

Subsequently, he exposes six "duties of the teacher" which, at first glance, may converge opinions that the teacher should not even take advantage of the "captive audience" of the students to "co-opt" or "harm" them because of their convictions political, ideological, moral or religious, or lack of them "(Project, 2015, p. 4), under a critical eye it is clear that it is an argumentative technique that builds a hypothetical educational scenario where such practices would already be the rule, and not the exception.

The project's justification reveals the concern with the “sexual morality” taught in the textbooks. When this does not coincide with the values preached by the family, they are considered "practice of political and ideological indoctrination in schools, and the usurpation of parents' right to their children to receive moral education that is in accordance with their own convictions" (Project, 2015, p. 4). Finally, 17 topics represent “illicit practices that violate fundamental rights and freedoms of students and their parents or guardians” (Project, 2015, p. 4).

Lawyer Miguel Nagib has gained notoriety as a result of his participation in the preparation and dissemination of the Escola Sem Partido project. In that presentation at a public hearing, the lawyer begins his speech by presenting some examples to justify the need for the project. Among them, i) the audio of a person denouncing the legal excesses in the persecution of former President Lula at the expense of the release of other political figures (0min1sec), ii) the video of a teacher in the schoolyard, criticizing the recent reforms educational and suggesting that students demonstrate (2min30sec); iii) a video of a hall full of students repeatedly shouting “Fora Temer” (6min30sec); and iv) posters and dissemination of a project of the Gender Center of UFSC where the deconstruction of gender prejudices is developed with students of basic education, inviting them to express themselves through drawings (8min30sec).

According to Nagib, “[...] this is what many teachers understand by critical vision, by critical thinking: attacking your enemies, attacking your political, ideological opponents” (2min13sec), “[...] using students as mass of maneuver of their own political and partisan interests ”(6min09sec). In his view, "[...] there are parents who are forced to send their children to school, who disagree with this point of view" (10min30sec), and this would be "[...] the result of this political and party indoctrination , of this systematic propaganda that has been made in the education systems, in the classrooms of public and private schools ”, transmitting“ to the children of others their own moral values ”(10min53sec). Then, the lawyer presents the Bill saying that it was inspired by the consumer protection code, where “the consumer, in this case the consumer of educational services provided by schools, by the State or by the private school, he has the right to know the your rights - this is citizenship ”(15min30sec).

Also in a public audience report, history professor Ana Caroline Campagnolo was invited by the Chamber “[...] exactly to prove that there is indeed indoctrination” (0min27sec). She says she suffered indoctrination and religious persecution from the professor who was her master's advisor from 2013 to 2015. Ana reports that she graduated in history at a private university and passed a master's selection at a public university. In the first e-mails exchanged with the teacher, she was very polite and said that both would do a good job. However, after some colleagues sent e-mails to the advisor teacher denouncing Ana's publications on facebook - containing Bible verses - the teacher suggested that “[...] you have every right to be anti-feminist or conservative, but not it matches this research or the practices we have about achievements ... ”(2min17sec).

Ana claims to have suffered political and partisan persecution in the course, mainly by the teacher, who "[...] has a certain power conferred on her by the State" (7min57sec). When delimiting the extent to which religious thought would be able to dialogue with the line of research in question, she considers that the teacher, who is a civil servant, “[...] a civil servant, who receives money from mine and from your tax, which go to her salary, but in her discipline can only be those who agree with the premises of feminism and other theories ”(16min30sec).

From this first contextualization of the records, we can identify five thematic axes that, still showing traces of authoritarian personality along the lines of the thinkers of the Frankfurt School, also demand new systematizations and resignifications of these references in analyzes of the educational field. Are they:

Teaching authority and parental authority: conflict between public and private interest in the school field

The project is based on a false dichotomy between the teacher's freedom to teach and the students' freedom to learn. As the main pedagogical currents consider that the process of teaching and learning is two-way (teachers and students as beings in permanent formation), the premise that should guide educational practices is that of dialogue, not that of vigilance, punishment, of coercion.

Historically, the family sphere is recognized as the sphere of individual rights and freedoms where the authority of parents over the values, norms, customs, traditions and cultural affinities produced and reproduced in this environment prevails, even reaching, in bourgeois society, little by little. little to transform authority into introjected coercion (Horkheimer, 1990). In contrast, the public and social sphere is characterized by the appropriation of that broader culture that permeates the whole of society, with the school being one of the main institutional means where this enculturation occurs, that is, the learning of values and precepts that enable tolerance, respect, coexistence and learning with perceptions of the world and ways of life naturally different from those of the family.

Therefore, in the school environment, the prevalence of difference would not be an obstacle, but a fundamental aspect for social life and for the formation of citizens. However, it is common in the records analyzed that the school should not “overlap” its teaching with family values. The concern with the students' moral formation is constant throughout the project, which can be mentioned in item 15:

> Now, if it is up to parents to decide what their children should learn in terms of morals, neither the government, nor the school, nor teachers have the right to use the classroom to deal with moral content that has not been previously approved by students' parents (Project, 2015, p. 8).

By not recognizing school and teachers the competent authority to organize and develop pedagogical projects, the project seeks to override the particular interest above the public interest.

False dichotomization between disciplinary content and values

In the words of project proponents, the idea that disciplinary content is "pure" and separate from ethical, moral, and cultural appropriations of society is permanently present. Such a view disregards the fact that scientific knowledge not only represents changes in our ways of understanding the world, but also influences our own constitution as subjects of this world.

> Instead of internalizing the social imperative - which not only gives it a more mandatory and at the same time more open character, but also emancipates from society and even turns it against society - there is a ready and immediate identification with stereotyped value scales (Adorno; Horkheimer, 1985, p. 163).

Coupled with this projection of educational ideas based solely on life experience, there is little evidence of the support of Escola Sem Partido supporters to dialogue with literature or even with education professionals - especially teachers, who are effectively in the classroom. Such a positioning proves to be authoritarian, of those who want to impose their way of seeing others. From a psychoanalytic point of view, this aversion to different thinking is due to the constitution of a weakened ego that, because it is unable to discern its false projection of concrete reality, becomes unable to open up to the different and recognize its own limitations. In this sense, it is imperative that scientific education makes it possible to reflect on the values, beliefs, premises, foundations and attitudes of the subjects.

Between freedom of opinion and arbitrary relativization of scientific knowledge

In Ana Maria Campagnolo's account a conceptual confusion is evident: the claim that, because she is attending an institution of public education - which is supported by taxpayer money - every opinion or view of the world must be accepted, regardless of its validity before the current lines of scientific research historically consolidated.

Upon hearing from the professor “If we are here in this course, it is because we enrolled in a perspective of thought” (5min02sec), Ana interpreted that her teacher would be abusing her power in graduate school, taking the position of banning the student from course. However, it is noted that the teacher aimed to explain that Ana's ideas, although legitimate in the private sphere or in the course as a whole, did not maintain coherence with the historically constructed knowledge related to that discipline.

The characteristics of conventionalism and cynicism are typical of authoritarian thinking (Adorno et al., 1950), in which, through fallacies and false comparisons, the oppressor victimizes himself, revealing difficulties in dealing with his own frustrations. When the prevailing intersubjective discourse is one of hatred and annulment of the other, consciousness, instead of understanding explicit contradictions, is attached to fixed ideas, denying reality. “Individual autonomy disappears with the subjects' psychological impoverishment in the face of objective irrationality (Gomide, 2011, p. 130).

In favor of her freedom of opinion, the teacher makes an arbitrary relativization of scientific knowledge. That is, although they are legitimate in the private sphere, to be recognized as potential scientific research, personal opinions should seek certain coherence with the historically constructed knowledge related to some discipline or line of research.

Another element present in the analyzes was the concept of citizenship supported by the pedagogical common sense. In a reductionist allusion to the concept of citizenship, the bill argues that "the best way to combat abuse of the freedom to teach is to inform students of their right not to be indoctrinated by their teachers" (Project, 2015, p. 8). This passage overlooks the potential of education to provide individuals with critical thinking beyond the sociocultural structures of which they are a part, and thus seems to point to the reproduction rather than the confrontation of the contradictions of social life.

The concept of citizenship based on pedagogical common sense: a defense against critical thinking

In a world totally permeated by science and technology, training for citizenship necessarily requires strong scientific training that includes both elements of science (content, concepts, procedures and methods) and elements about science (the functioning of science, its relationship with society, its relation to ethical, moral, cultural, value, power and economic interests).

Between the true object and the undoubted data of the senses, between the interior and the exterior, an abyss opens up that the subject has to overcome at his own risk. To reflect the thing as it is, the subject must give back more than he receives from it. The subject recreates the world outside him from the vestiges that the world leaves in his senses (Adorno; Horkheimer, 1985, p. 155).

In this case, the subject has already objectified the phenomenon in question (citizenship), and, without realizing the gap of “vestiges that the world leaves in his senses”, he returns to the world only the petrified image of a concept that limits all potential emancipatory that the term citizenship should include. Self-sabotage of the struggle for rights.

The teacher as the origin of all evil: the construction and demonization of the enemy

Finally, the bill and its supporters consider the teacher as the origin of all evil in education, and so build the image of this professional as if it were an enemy to be fought. The use of terms extraneous to contemporary education reinforces the persecutory character of the present proposal, which refers to students as a "captive audience" on which teachers would seize and co-opt "because of their political, ideological, moral or religious convictions, or of their lack ".

Proponents are unaware of the complexities and demands to which teachers are subjected, and, consciously or not, they create a ghostly image (scarecrow) of a teacher and generalize characteristics considered bad - a characteristic process of a group that seeks to unite and legitimize itself by building stereotyped images of outsiders, those who think differently.

Such constructs are part of the subjects' own life repertoire. By disregarding all the theoretical and methodological foundations focused on the pedagogical aspects of teacher training and the effective reality of the school context, it remains to charge that teachers work on political, socio-cultural and economic issues in a “fair way” (item IV), not favoring or harming students. students because of these convictions (item 2). All that remains is the “inability of the subject to discern in the projected material between what comes from him and what is alien” (Adorno; Horkheimer, 1985, p. 154). Phantom images of teachers are created, generalizing characteristics considered bad.

DISCUSSION

We find that the pillars of the argumentation of the Escola Sem Partido Project stem from false projections about the formative sense of education and about the role of the teacher in the teaching process. This is exacerbated by the lack of openness to dialogue and the stereotyped way in which people think differently.

Insofar as, on the whole, there is a growing trend towards the dissolution of the guarantees of the rule of law, the encouragement of meritocracy and the blame of the individual for his ills, studies and research in scientific education must begin to consider the aspects of the subjects' psychic formation, in a dialectical relation. The loss of teaching authority, the overlapping of private interests to the public interest and the relativization of scientific knowledge are elements that can be analyzed in the light of this relation between philosophy, sociology and psychoanalysis.

We believe that the research contributed with theoretical references that propose elements of resistance and emancipation to the authoritarian invested with conservatism in education and scientific education.

ANALYSIS OF IMPLEMENTED SCIENCE CURRICULA: AN APPROACH FROM TEACHERS' PEDAGOGICAL PERSPECTIVES

Susumu Nozoe[1], Tetsuo Isozaki[2]
[1]University of Miyazaki, Miyazaki, Japan,
[2]Hiroshima University, Higashi-Hiroshima, Japan

The science curriculum is delivered to students through a controlled process at different levels and in various contexts. Although it has been said that science teachers' viewpoints and attitudes influence the interpretation of curricula, we were interested in factors affecting their pedagogical perspectives, such as their beliefs and teaching practices. Therefore, the objective of this research was to assess implemented curricula from the pedagogical perspectives of science teachers in Japan. To achieve this objective, we conducted a survey of lower secondary science teachers in Japan and England. We then examined their pedagogical perspectives both quantitatively and comparatively. Based on the empirical research data, we discussed science teachers' pedagogical perspectives in the context of proximal fields of study, and with references to research literature more closely related to the present investigation. Through empirical and theoretical analyses, we concluded that sociocultural contexts imbued in Japanese society serve as universal elements, and are accepted implicitly by Japan's science teachers. These customs serve to regulate implemented science curricula in Japan.

Keywords: Science Curriculum, Pedagogical perspectives, Sociocultural contexts

BACKGROUND AND THEORETICAL FRAMEWORK

Learning contents such as science curricula are delivered to students through a controlled process at different levels and according to various contexts (Goodson & Dowbiggin, 1994; Jenkins, 2000; Lloyd-Staples, 2012). Logically, science curricula, such as the Course of Study in Japan and the National Curriculum in England, affect classroom practices of science teachers. Ryder and Banner (2013) analysed the effect of secondary science teachers by reforming the National Curriculum, and Hanley, Ratcliffe, and Osborne (2007) also examined science teachers' experiences of teaching 'ideas-about-science' in Twenty First Century Science (GCSE Science courses) developed by the University of York Science Education Group (UYSEG) beginning in the early 2000s. All these studies found that changes in science educators' teaching practices were neither uniform nor dramatic; rather, they were various and gradual. However paradoxical it may be, science teachers also shape the science curriculum based upon their own beliefs and knowledge about science lessons. Fensham (2009) referred to many countries' traditions of teaching/learning pedagogy as teachers' authoritative domain, indicating that '[t]he "how" of teaching is seen as the teachers' province' (p. 1086). The research focusing on teachers as important figures who connect policies and classrooms is arguably playing its exact role and significance. It is inevitable that the 'Implemented Curriculum' defined by the International Association for the Evaluation of Educational

Achievement (IEA) has gaps between 'Intended Curriculum' and 'Attained Curriculum' due to diversity in teachers' knowledge and beliefs, as well as other factors that affect science lessons.

Many studies on teachers' knowledge and beliefs have been conducted thus far (e.g. Barnett & Hodson, 2001; Lumpe, Haney, & Czerniak, 2000; Lunn & Solomon, 2000; Magnusson, Krajcik, & Borko, 1999; Nespor, 1987; Pajares, 1992; Shulman, 1986, 1987; Simmons et al., 1999; Van Driel, Beijaard, & Verloop, 2001). Shulman (1986, 1987) advocates pedagogical content knowledge (PCK)—the special amalgam of content and pedagogy that identifies the distinctive bodies of knowledge for teaching—and also discusses the phases of pedagogical reasoning and action (i.e. comprehension, transformation, instruction, evaluation, reflection, and new comprehensions). Magnusson et al. (1999) conceptualise PCK for science teaching as consisting of five components: orientation toward science teaching, knowledge of science curriculum, knowledge of students' understanding of science, knowledge of assessment in science, and knowledge of instructional strategies. The authors indicated that these components function as parts of science teaching by interacting in highly complex ways. These studies assume that science teachers can teach only within the knowledge structure they possess. However, science teachers' beliefs are also involved. It is difficult to make a clear distinction between knowledge and beliefs, and we cannot specify the boundary where knowledge ends, and belief begins. Nespor (1987) and Pajares (1992) attempt to distinguish beliefs from knowledge theoretically, and to identify the structure and features of teachers' educational beliefs. Such studies argue that teachers' beliefs—rather than their knowledge—strongly affects their behaviours in the classroom (Nespor, 1987; Pajares, 1992). In sum, while beliefs and knowledge are closely intertwined, beliefs are acquired through the process of cultural transmission and these beliefs act as a filter when teachers faced something new phenomena. Barnett and Hodson (2001) suggest that good teachers have the ability to respond to shifting contexts in appropriate ways and coined the term pedagogical *context* knowledge. This is an extension of knowledge than PCK, and also considers societal knowledge landscape. Pedagogical *context* knowledge consists of four elements that overlap and interact with each other: academic and research knowledge, PCK, professional knowledge, and classroom knowledge.

Dillon and Manning (2010) note that pedagogy implies the whole philosophy and value system that leads teachers to make choices about what they do and how they teach. In this study, we focus on science teachers' beliefs and teaching practices, defining them as 'science teachers' pedagogical perspectives'.

AIMS AND RESEARCH QUESTIONS

The objective of this study is to assess the implemented curricula from science teachers' pedagogical perspectives using a comparative approach. Hence, the following research questions were formulated:

(1) Is there a difference between Japanese science teachers' perspectives and those of science teachers in England?

(2) If so, how does the sociocultural situation regulate Japanese science teachers' pedagogical perspectives?

SAMPLE AND METHODS

To answer these research questions, we designed a survey for lower secondary science teachers so that we could analyse their pedagogical perspectives. We arranged the direction of this survey at Hiroshima University in Japan and the University of Leeds in England; then, we selected the following three dimensions of science teaching: *science teachers' beliefs*, *the approach used in designing lessons*, and *the method used in teaching science*. The survey instrument used in this research was a questionnaire conducted in Japan (Hiroshima) and England (Leeds) that consisted of carefully selected items, and each question was based on the selection form to analyse the findings objectively and statistically.

First, we conducted a pilot survey of science teachers in a training course for students at Hiroshima University (Japan) and the University of Leeds (England). We collected 24 Japanese data in May 2013, and 11 English data in June 2013, respectively. The questionnaire was modified to make the nuances of Japanese and English equal based on the pilot survey results.

Next, we conducted a final survey of 84 science teachers at lower secondary schools in Hiroshima (Japan) in July 2013, and 24 science teachers at comprehensive schools in Leeds (England) in December 2013. Valid responses were obtained from 79 teachers (Japan) and 24 teachers (England), respectively. In order to exclude special cases, the target schools in both countries were narrowed down to comprehensive schools, and the science teachers working there were randomly selected. By doing this, we tried to approach the derivation of the general characteristics of both countries, although this was a local survey. The quantitative data from the questionnaires were summarised in tabular form and statistical tests were applied.

Finally, we examined the factors involved in forming science teachers' pedagogical perspectives based on the survey results from quantitative and comparative viewpoints. Additionally, we discussed the science teachers' pedagogical perspectives in relation to the proximity field of research and with references to the relevant research literature. Through these research methods, we attempted to clarify the phases of an implemented science curricula in Japan both empirically and theoretically.

DATA COLLECTION AND ANALYSIS

To investigate whether Japanese science teachers' pedagogical perspectives differed from those of science teachers in England, we conducted a survey using a comparative approach. The quantitative data from the questionnaires were summarized in tabular form, and statistical tests were applied. We performed cross-tabulations with regard to science teachers' pedagogical perspectives in Japan and England, respectively. The data collected were qualitative data of nominal scale (categorical data) with small sample sizes, and the frequencies were unevenly distributed. Therefore, we statistically analysed the significant difference between the two groups using Fishers' exact test of nonparametric method. In analysing the significant difference, the numerical value of 'Blank (Unidentified)' has no meaning, and there was a fear that an erroneous result could be obtained in the analysis. Consequently, the numerical value of 'Blank (Unidentified)' was excluded in each statistical test. In addition, some responses regarding personal information were incomplete, so the totals did not coincide with the number of valid responses.

First, we investigated to what extent the differences in terms of country affect science teachers' beliefs. We performed a cross-tabulation with regard to beliefs of science teachers in Japan and England (see Table 1).

Table 1. A Cross-tabulation regarding science teachers' beliefs in Japan and England

	The most important learning objective in school science								
Country (Region)	1. Skills of laboratory work and observation	2. Knowledge and understanding about science	3. "Decision-making" ability based on scientific evidence	4. Scientific thinking	5. Interest in science	6. Ability to explain scientifically	7. Investigation and inquiry	8. The relation between science and daily life	9. The others
Japan (Hiroshima) (n = 74)	3 (4.1)	9 (12.2)	11 (14.9)	10 (13.5)	16 (21.6)	1 (1.4)	4 (5.4)	19 (25.7)	1 (1.4)
England (Leeds) (n = 17)	0	7 (41.2)	0	1 (5.9)	2 (11.8)	2 (11.8)	0	5 (29.4)	0
Total (N = 91)	3 (3.3)	16 (17.6)	11 (12.1)	11 (12.1)	18 (19.8)	3 (3.3)	4 (4.4)	24 (26.4)	1 (1.1)

Figures in parentheses are percentages of n or N values relating to each row.

The percentage of science teachers who considered 'the relation between science and daily life' the most important was high in both countries. But, on the other hand, the percentage of science teachers who considered 'interest in science' the most important was high in Japan, whereas that of science teachers who considered 'knowledge and understanding about science' the most important was high in England. A finding from Fisher's exact test indicated that a significant difference appeared at the 0.05 level ($p < .05$).

Next, we investigated to what extent differences based on country affect the approach used in designing science lessons. We performed a cross-tabulation with regard to the approach used in designing lessons in Japan and England (see Table 2). In Japan, the percentage of science teachers who considered 'textbooks' to be the most useful resource for designing lessons was high, whereas the tendency was different in England. The percentage of science teachers who considered 'national curriculum' and 'the others (e.g. schemes of work, specification, etc.)' as the most useful information for designing lessons was high in England. A finding from Fisher's exact test indicated that a significant difference appeared at the 0.01 level ($p < .01$).

Table 2. A Cross-tabulation regarding the approach used in designing lessons in Japan and England

The most useful information for designing science lessons

Country (Region)	1. Textbooks	2. National curriculum	3. Textbook publishing company's instruction books for teachers	4. Notebooks of your own composition (Your own experience)	5. Pupils' current knowledge	6 The policy of your school	7. Materials of outside seminars and workshops	8. The others
Japan (Hiroshima) (*n* = 72)	30 (41.7)	5 (6.9)	7 (9.7)	12 (16.7)	12 (16.7)	0	4 (5.6)	2 (2.8)
England (Leeds) (*n* = 17)	0	5 (29.4)	0	2 (11.8)	2 (11.8)	2 (11.8)	0	6 (35.3)
Total (*N* = 89)	30 (33.7)	10 (11.2)	7 (7.9)	14 (15.7)	14 (15.7)	2 (2.2)	4 (4.5)	8 (9.0)

Figures in parentheses are percentages of n or N values relating to each row.

Finally, we investigated to what extent differences based on country affect the method used in teaching science. We performed a cross-tabulation regarding this topic for science teachers in Japan and England (see Table 3).

Table 3. A Cross-tabulation regarding the method used in teaching science in Japan and England

The most useful teaching material(s) for science lessons

Country (Region)	1. Textbooks	2. Exercise books	3. Explanatory diagrams	4. Worksheets of your own making	5. Worksheets of textbook publishing company making	6. Teaching materials for experiment and observation	7. ICT resources	8. The others
Japan (Hiroshima) (*n* = 70)	24 (34.3)	0	4 (5.7)	18 (25.7)	1 (1.4)	12 (17.1)	8 (11.4)	3 (4.3)
England (Leeds) (*n* = 16)	0	3 (18.8)	1 (6.3)	4 (25.0)	0	2 (12.5)	4 (25.0)	2 (12.5)
Total (*N* = 86)	24 (27.9)	3 (3.5)	5 (5.8)	22 (25.6)	1 (1.2)	14 (16.3)	12 (14.0)	5 (5.8)

Figures in parentheses are percentages of n or N values relating to each row.

The percentage of science teachers who considered 'Worksheets of your own making' to be the most useful teaching material was high in both countries. But, on the other hand, the percentage of science teachers who considered 'textbooks' the most useful teaching material was high in Japan, whereas that of science teachers who considered 'ICT resources' the most useful teaching material was high in England. A finding from Fisher's exact test indicated that a significant difference appeared at the 0.01 level ($p < .01$).

Results of Fisher's exact test indicated that significant differences appeared in all dimensions, though they differed in degree. Among the three dimensions of science teaching, *the approach used in designing lessons* and *the method used in teaching science* showed a marked difference compared to *science teachers' beliefs*. These results show that the country in which a teacher worked influenced differences involving science teachers' pedagogical perspectives. From analysis of empirical research data (Nozoe & Isozaki, 2016, 2018), we interpreted that a science teacher's pedagogical perspective was informed by the respective country in which he or she taught.

DISCUSSION AND CONCLUSION

Dillon and Manning (2010) argued that science teachers' pedagogical development relates to their perceived need to challenge the orthodox 'teaching values and intentions' (p. 14), which manifest themselves in what many would describe as 'traditional science teaching' (p. 14). 'Traditional science teaching in Japan' should be questioned. Generally, Japanese science teachers are trained at domestic universities; then, they belong to the teacher group at the school and acquire the paradigm, which includes their roles and positions. Kind (2009) indicated that part of the process involved in becoming a science teacher is a re-shaping of subject matter knowledge (SMK), adapting prior personal SMK to an extent that is replaced by a modified version for school use. That is to say, after being science teachers, their professional development has been conducted within their professional societies and in the context of their professional culture (e.g. Isozaki, 2015, 2016). For instance, Japan's 'lesson study' is embedded in the traditional culture of science teachers and may provide significant opportunities for both novice and experienced science teachers to develop appropriate competencies. During their professional development, teachers acquire the paradigm that contains elements of tacit knowledge, which cannot be specified or recognised consciously. In other words, it can be argued that the educational culture of a country regulates its science teachers at a deep level.

Hammond and Brandt (2004), who discussed an anthropological approach to science education, indicated that pedagogical questions of who teaches science, how it is taught, and what ends it serves take on new meanings that can be addressed through research by using a cultural approach that assumes science learning is a cultural as well as a cognitive activity. Since culture is something that be inherited rather than changed, the paradigm possessed by each science teacher inevitably has been inherited to include some room for their improvement; it is not a new creation without an underlying framework. Culture internalised by science teachers in each country involves 'universality' and 'variability'; that is, the former elements which are inherited in the period and society in which they live, and the later elements which are more individualised. What is the universal culture inherited by science teachers in a specific country? Generally, teachers understand their students' cultural experiences, scientific practice (ways of knowing, doing, and talking science), and habits of mind (scientific values, attitudes, and worldviews). Thus, they are able to relate science to students' background experiences (Carlone, Johnson, & Eisenhart, 2014). Japanese science teachers, for instance, have taught science based on Western culture to their students living in Japanese cultural world (Kawasaki, 1996; Ogawa, 1986, 1989, 1995). Specifically, '[c]ultural differences in cognition could affect the way the learner approaches the subject matter of science education because of presuppositions about the nature of the world that the learner brings to the learning situation' (Erickson, 1986, p.121). In other words, teachers have taken on the role of culture brokers (Jegede & Aikenhead, 1999). Such sociocultural contexts are inherited implicitly as universal elements by science teachers, thereby regulating traditional science teaching in Japan directly.

ACKNOWLEDGEMENT

The authors would like to thank the University of Leeds for its helpful support. In particular, we are deeply grateful to Professor Jim Ryder for his insightful suggestions. This research was supported by JSPS KAKENHI under grant numbers JP15K17405, JP19K14344.

ADDITIONAL NOTES

This study has been significantly revised by adding new analysis based on the data presented at EASE2016, EASE2018.

FACTORS INFLUENCING TEACHER RESPONSE TO EXTERNALLY DRIVEN CURRICULUM REFORM. A CASE STUDY

Teresa Lupión-Cobos, José Hierrezuelo-Osorio, Isabel Cruz-Lorite and Ángel Blanco-López
[1] Department of Science Education,
University of Málaga, Campus de Teatinos s/n, 29071 Málaga, Spain

In the framework of the curriculum reforms, the literature emphasizes the importance of contemplating the beliefs of teachers and their perceptions toward it, with aspects that influence the integration of proposed changes in teacher professional identity. This work presents a case study, which examines the factors that manifest a science teacher of secondary education at different stages during the participation in a training program designed to meet the challenges that the reform of the education system poses for science education in Spain. This program involved the completion of tasks of design, implementation, and evaluation of own teaching proposals to promote the development of the scientific competences, using the context-based science teaching approach. For the analysis and categorization of the responses of the teacher, expressed in two individual interviews and a focus group, has been used the proposal of Ryder (2015), complemented with the establishment of the qualifier character, facilitator or obstacle, of the assessments made. The teacher analysed focuses mainly on personal factors, which seems logical considering his short teaching experience. Some of his ideas change, during the training process, to other more in line with the approaches of the reforms, detecting the influence of the peers´ opinions in his own during the focus group.

Keywords: Curriculum reform; In-service Teacher Training; Context-based learning.

INTRODUCTION

In the framework of the curricular reforms, the literature describes a great diversity of factors that determine the integration of the changes required in the teacher professional identity (Donnelly & Jenkins, 2002; Ryder, 2015). To understand the teacher´s responses , numerous investigations highlight the importance of contemplating their beliefs and perceptions toward these reforms (Wallace, 2011; 2016). This work is part of a broader study which analyses the implications for the teaching of sciences of important aspects that are considered by teachers to apply educational reform raised in Spain (Ministry of Education, 2006 & 2013), around the development of scientific competences (Lupión-Cobos, López-Castilla & Blanco-López, 2017) addressed in this research through the use of context-based science teaching (Avargil, Herscovitz & Dori, 2012; Gilbert, Bulte & Pilot, 2011; Pilot & Bulte, 2007).

Among the factors that influence and condition the development, and possible success, of the curricular reforms proposed by the educational administrations, numerous investigations highlight the importance of contemplating teachers' responses to them (De Boer, 2014; De Jong, 2015; Ryder and Banner, 2013) shaped by their beliefs and perceptions about their intentions and their role in them. The specialized literature describes a great diversity of professional factors that participate and condition the teachers' responses and their integration in the face of the changes that their implementation requires in science teachers (Maguire, Ball, & Braun, 2013; Rigano & Ritchie, 2003; Ryder, 2015, 2018).

Ryder (2015), has reviewed the literature that has dealt with the responses of science teachers to curricular reforms from the vision of "what we know about the experiences and reflections of teachers in the enactment of externally driven school science curriculum reform" (Pg. 87). This characteristic of 'Externally driven' is very common in most school curriculum reform processes that make up types of teacher responses, for which it proposes a scheme that includes a large number of factors, in terms of personal, internal and external focus of teachers' work.

The professional identity of the teacher is constructed contemplating his work context, as a socially constituted result and in continuous reformulation process (Squire et al., 2003; Luehmann, 2007), being necessary to contemplate not only the personal perspective but also the social and institutional context in which they produce in the schools (Aikenhead, 2006; Bowe, Ball and Gold, 1992; Spillane, 2006) with aspects of their performance, associated with the social processes involved in the interactions that occur at school and in their relationship with educational structures (Beijaard, Verloop, & Vermunt, 2000; Day, Kington, Stobart, & Sammons, 2006; Leander & Osborne, 2008).

In the search for appropriate strategies to collect the opinions and assessments of teachers, use a variety of scenarios in which teachers participate from more interrogative and individual situations such as the one offered by the interviews, to others that allow the exchange and discussion about the same (Kaplowitz, 2000; Potter & Hepburn, 2005; Guest et al.,2017), as the one contributed by the shared reflection in focus groups (Bloor et al., 2001). The intragroup comparisons promote discussions and a peer contrast that allows access to simultaneously expanded information on their individual identities and makes a collective representation for the researcher (Callaghan, 2005) highlighted differences in the interviewees´ perspectives (Hanley, Maringe & Ratcliffe, 2008; Osborne & Collins, 2001).

With these considerations, in this framework of curriculum reform, this work raised the following issues:

a) What factors do teachers consider that influence the implementation of approaches focused on the development of scientific competences through context-based science teaching?
b) Which of these factors are considered as facilitating and which as obstacles?
c) How these factors evolve along with a training program?

CONTEXT OF STUDY AND DESIGN

As part of a larger project that aims to help science teachers develop the scientific competencies of students in compulsory secondary education (12-16 years) in Spain (Blanco, Franco & Spain, 2016), through the use of a program Long-term training course during the school year (one semester) whose main purpose was to help teachers in the exercise of designing, applying and evaluating their teaching proposals, with which, through the use of the science teaching approach in context (Van Driel, Bulte & Verloop, 2008; Van Driel, Merink, Van Veen & Zwart, 2012), work in the classroom scientific competences (Blanco-López & Lupión-Cobos, 2015; Lupión-Cobos & Blanco-López, 2016).
Four phases were planned (Table 1) that included face-to-face and non-face-to-face training sessions, collecting data from this research at different times during its development with the instruments indicated.

Table *1.* **Phases of the training programme.**

FOCUS GROUP	

methodology

This research has been carried out in the framework of a training program (Author, 2017), to help secondary science teachers to design, apply and evaluate their teaching proposals, with which to work in the classroom the scientific competences through context-based education (Vos, Taconis, Jochems, & Pilot, 2011).

Participants

It was selected a representative sample of participants composed of four teachers, with different degrees of teaching and professional experience in the design of materials and participation in innovation activities and research. In this work, it is presented, as a case study, the analysis of the interventions of one of those teachers.

Instruments

Two individual interviews were conducted with each teacher, the first one after stage 2 (I1) and the second (I2) after stage 3, and also a focus group (FG) meeting, held after the last interview and after completing the teacher training.

In this way, different moments and scenarios (individual and group) were provided to help teachers express and share different types of reflections and also focus them on the professional level of relationships with their classmates, environment and educational community (Vázquez, Jiménez & Mellado, 2007; Mellado, Ruiz, Bermejo & Jiménez, 2006).

Procedure

The analysis started with the identification, in the transcripts of two individual interviews and focus group, of the fragments considered relevant (units of meaning) for the research questions raised, reaching a consensus of the whole team. Then, the categorization of these units was carried out according to the focus (personal, internal and external) and its factors, proposed by Ryder (2015), being complemented by the establishment, the facilitator or qualifier character, namely as facilitating and obstacle (F/O), depending on the orientation given by the teacher in its manifestation, as shows the following extract of next transcript:

> *Unit 061, FG: "As my unit has been an island in the middle of the sea, I am an island in the middle of the sea of companions, because everyone is going to their own, and when I have commented on seeing what you think, look what I have done, they have answered me, yes, they are going to tell you in the Teacher Trainer Centre that it is very good, that you continue, but this in three days you forget about this".*

The categorization considered by the researches was Focus: Internal; Factor: School and departmental leadership style; Character: Obstacle

Contingency tables were developed to study the evolution of the contributions of the teacher, using Fisher's test, with the program R Commander 3.5.0., to study the possible existence of significative differences between the variables analysed (dimensions according to Ryder (2015) and the qualifier character). All tests were performed with a 95% confidence level.

RESULTS

Table 2 shows the results obtained after the categorization of the teacher´s responses in the two individual interviews (I1, I2) and the focus group (FG).

Table 2. Frequency of responses professor in the two individual interviews (I1, I2) and the focus group (FG), in the categories of Ryder (2015) and its character as a Facilitating (F), (O) Obstacle and Total (T).

This teacher is focused mainly on personal factors in the three moments, which, moreover, are increasing throughout the training process. Their responses categorized as (P5) stand out above all.

The qualifier of the references included in P5 changes appreciably from the interviews to the focus group, so that, while the interviews appear with a facilitating nuance, this aspect is balanced in the focus group, as shows the following expression:

> *“The most important idea is perhaps creativity, that is, to realize when you are a student, that you can learn for yourself, and that you can give creative answers to problems that are presented to you. That, in the end, is what one has to know how to do in life, to know how to use the information available so that at any given time, when a situation arises, knowing how to give a new answer.” (I2, Unit 032) (P5F).*

However, in the focus group, there are more obstacles to this category, such as what is indicated in the following intervention about student motivation:

> *“And it is true that you say that the computer, for example, is often said to use it and the motivated student. However, it is not true, it is motivated at the beginning, but then there comes a time when it is the routine, it becomes the same as always, it is not just as motivating”. (FG, Unit 041) (P5O).*

On the other hand, T1 references to project work, group work and student autonomy show a clear identification of this teacher with the intentions of the curriculum reform (P6), almost always with a facilitating character. The personal and professional biography is also important appearing in the second interview and widening its presence in the focus group, as an obstacle element.

The allusions to the pedagogical abilities (P2), appear in the case of T1 in I2 with a facilitating character, while it appears as an obstacle in FG. Also important for T1 is the “professional and personal biography” factor (P8), which appears for the first time in the second interview and is emphasized in the focus group as an obstacle. The evolution that can be justified in a similar way to the P2 factor.

The internal factors appear mainly in the focus group, highlighting two ideas School and departmental leadership style (I8) and What counts as an appropriate assessment of student learning (I9) with an obstacle character. For example, when he says:

> *"I, as I see all the institutes, at least the ones I have known, are very far from doing such work, [...]. I see the environment very far, we will see how it evolves, but with the years that I have been teaching, I see that we are taking a step back, I do not know if I am a little pessimistic, but I began to teach in the 86 or 87, and I saw a different environment" (FG, Unit 067) (I8O).*

On the contrary, references to "availability of teaching resources" (I4) that appear as an obstacle in I1 are no longer cited later. It makes us think that these obstacles did not have a relevant entity since, as the training program has advanced, T1 has not seen them again.

Concerning external factors, highlight the references of T1 to aspects related to "flexible versus prescriptive national/regional curriculum frameworks" (E1), which T1 considers an obstacle in both I1 and FG, an aspect that is raised by this professor in FG. For example:

> *"[...] a proposal made by the administration, as well as an imposition, which becomes law, most teachers have a rejection, and you cannot, there is not even the possibility to discuss the issue, most flats rejects. It seems that one has to feel certain complexes once in a while talking about competencies." (FG, Unit 075) (E1O).*

The results obtained when comparing the manifestations registered for T1 in the three focuses (Personal, Internal and External) are shown in Table 3.

Table 3. Absolut (n) and relative (f) frequencies for each focus at each time of data recording (I1, I2 and GF) for T1

	I1		I2		FG	
	n	f	n	f	n	f
Personal	4	44,4	11	100,0	20	66,7
Internal	3	33,3	0	0,0	8	26,7
External	2	22,2	0	0,0	2	6,7
Total	9	100,0	11	100,0	30	100,0

The analysis by pairs of moments and focus, show statistically significant differences:

a) between I1 and I2 interviews for personal and internal focus (p-value = 0.04 α = 0.05), since in I1 a similar frequency of personal and internal factors appears, while in I2 only personal factors appear. This significant difference may be because Professor T1 has focused on personal factors in I2 given the emphasis of the training program at this time of its development, on the design and implementation of the didactic proposal.

(b) for the qualifiers (F and O) between the second interview and focus group (p-value = 0.01, α = 0.05) and between personal and internal focus (p-value = 0.04, α = 0.05).

CONCLUSIONS

We can consider, with the caution to be dealt with on a case study, that the data obtained confirm to us that the Ryder´s proposal (2015) has been presented as a useful tool to analyse teachers' beliefs, which can be framed in the Personal, Internal, External focus that include various factors associated with each one of them, that are relevant for the teaching staff and show different frequency along the different moments of the study.

The results obtained show the influence of the reflection and communication environment in which the teaching manifestations occur, which allows teachers to make a reflection that allows greater depth and richness to their assessments and beliefs. Personal factors are the focus of the teacher analysed, which seems logical considering his short teaching experience. The training process seems to have helped him to incorporate ideas more in line with the intentions of the reform after the implementation of the didactic proposal given the progress shown about the facilitating character on how students learn and his role in the class. This trend changes in the focus group, a scenario in which shared reflections with other more experienced teachers, emerging obstacle aspects that had not previously referred to.

We have also been able to complement this proposal, qualifying the teacher´s responses with a F/O character according to the trends shown by the expressions analysed.

In this context of curriculum reform, we understand important to continue deepening in the teachers´ assessments whose knowledge will allow us to detect typology of teaching needs and investing in training designs to help them address the challenges posed by current scientific education.

In this sense, we believe that the analysis scheme used can be very useful for designers of training programs, as well as for those responsible for educational policies. It allows an approach to the knowledge of their ideas about how their students learn and to share more the intentions of the curriculum reform.

On the other hand, training programs that involve teachers in the analysis, design and implementation of didactic proposals, focused on the development of skills through the context of teaching approach, as the scenario of this study has helped teachers to reflect on your beliefs about these aspects.

LIMITATIONS

The limitations of the study include the sample size and the non-random teacher sampling method used. The nature of the sample also limits the results. Given that the results show the influence of the setting (i.e., individual interviews vs focus group) on the views that the teachers express, we think it is important to explore the use of other data collection instruments.

50 YEARS OF POLICY INFLUENCES ON UPPER SECONDARY PHYSICAL SCIENCES CURRICULA IN IRELAND

Damienne Letmon[1], Eilish McLoughlin[1], Odilla E. Finlayson[2]
[1]School of Physical Sciences & Centre for Advancement of STEM Teaching and Learning, Dublin City University, Dublin 9, Ireland

[2]School of Chemical Sciences & Centre for Advancement of STEM Teaching and Learning, Dublin City University, Dublin 9, Ireland

Over the past half-century free second level has been introduced in the Irish education system and as a result a steady increase in the number of students completing a third level education has been observed. In tandem with this widening participation in second level education, curricula have been adapted to accommodate the varying needs and abilities of students while at the same time addressing the changing role of science education in the national economy. Between 1966 and 2016 three physics and three chemistry syllabi have been implemented in Irish schools. The focus of this study was to examine what were the cognitive demands of upper secondary level physics and chemistry Leaving Certificate examination questions from 1966-2016. Bloom's taxonomy of educational objectives was used in the analysis of the examination questions, as it had been used by the Irish Department of Education in the drawing up of the examination questions. A sample of ten physics and ten chemistry Leaving Certificate higher-level examinations papers were selected as representative samples of the different syllabi spanning the fifty years. Despite clear changes in both syllabi and in the question styles of the examinations during this time, there was not a notable change in the cognitive demand levels. The cognitive domain 'remember' was the highest for both physics and chemistry (ranging from 65% to 41% for physics and from 75% to 39% for chemistry. Notably, no question or question-part was coded for the higher order domains of 'evaluate' or 'create' in either physics or chemistry.

Keywords: Physics Syllabus, Chemistry Syllabus, Bloom's Taxonomy

INTRODUCTION

Being one of the founder members of the Organization for Economic Development (OECD) in 1960, enabled Ireland to move from its protectionist-isolationist position to being more open and receptive to external influences (Fleming and Harford, 2014). In 1962, the Irish Minister of Education, in cooperation with the OECD, commissioned the *Investment in Education* survey. While the report was analytical and factual, concentrating on the future economic needs in terms of setting targets for the educational infrastructure to ensure sufficiently skilled work force, it nonetheless paved the way for transforming Ireland's education system

(Department of Education, 1965; Loxley et al., 2014; Murray, 2012). In 1963 the Minister of Education announced the establishment of a new type of second level school – comprehensive schools- which would be administered by the Department of Education and referred to as state-run schools. The curricula offered in these state-run schools were that of both the secondary and vocational systems (Clarke, 2010; McKernan, 1984). In 1966, free access to secondary level education was introduced for all students. Up to this time the secondary (academic) education system was regarded as 'purely private institutions' by the Department of Education which 'were built up without any help from the State …which did not exercise any power of veto …over the management of the schools' (An Roinn Oideachais, 1926, p. 7).

The format of the Irish secondary education system in 1966 consisted of two courses – the Junior Course and the Senior Course. The Junior Course was compulsory and was of three years duration, at the end of which students (usually aged sixteen) sat the Junior Certificate Examinations. The Senior Course was of two to three years duration and culminated with the Leaving Certificate Examinations, which provided access to further and third level education programmes. This introduction, in 1966, of free secondary level education for all led to a sharp increase in the number of students seeking admission to universities and third level institutions, with demand outstripping the availability of places. As a consequence, the Leaving Certificate Examinations quickly started to influence the focus of schools rather than a focus on teaching and learning processes (Lorenz et al., 2016). The focus of this study is to examine the impact of changes made in the curriculum and assessment of two Leaving Certificate subjects, namely physics and chemistry, over a fifty-year period from 1966 to 2016.

Leaving Certificate science subject choices, 1966-2016

The widening of second level education to all in 1966, irrespective of financial means or academic ability, presented many opportunities to adapt second level curricula to meet the needs of both students and the economy. However, it resulted in a reduction in the availability of science orientated subjects to just Physics, Chemistry, Physics-Chemistry combination, Agricultural Science and Biology and the discontinuation of General Science, Botany, and Physiology & Hygiene as illustrated in Table 1 below.

Table 1 List of available Leaving Certificate science subjects in 1966 and 2016

Upper secondary science choices in 1966	Upper secondary science choices in 2016	
Physics	Physics	
Chemistry	Chemistry	
Physics-Chemistry combination	Physics-Chemistry combination	
General Science	-discontinued in 1969	
Botany	-discontinued in 1969	Replaced with Biology in 1969
Physiology & Hygiene	-discontinued in 1969	
Agricultural Science	Agricultural Science	

(Source: An Roinn Oideachais 1966; Department of Education & Skills 2016)

Assessment of Leaving Certificate Examinations, 1966 to 2016

The Leaving Certificate examinations, first introduced in 1925, were considered as high-stakes assessments and the students results were "*accepted by a considerable number of universities, professional bodies, training colleges in Ireland and elsewhere"* (An Roinn Oideachais, 1931, p. 57). The examinations branch of the Department of Education had sole responsibility for the setting, administrating, correcting and issuing results of these examinations. Examination statistics, which focused on total number of candidates sitting the various subjects and numbers achieving pass or higher (honours) level were published by the department on an annual basis. However, the department did not publish or make available what was considered sensitive information regarding the marking schemes used or the depth of knowledge required or being assessed by the examinations. This lacuna resulted in teachers using the examination papers to interpreted the subject syllabi (Madaus and MacNamara, 1970, pp. 94, 98).

Overview of Physics syllabus, 1966 to 2016

Syllabus One

The physics syllabus, introduced in 1962 by the Department of Education, consisted of an itemised list of topics to be studied with little indication as to depth of knowledge required, as illustrated by excerpt from the Mechanics topic shown in Figure 1 (Department of Education, 1963).

Mechanics

1. Displacement. Vectors and Scalars. Addition and resolutions of vectors. Velocity and accelerations
2. Newton's laws. Force. Mass. Weight. Conservation of momentum.
3. Force as a vector. Moments. Gravitation.

Figure 1 Extract from the 1962 Leaving Certificate Physics syllabus

Other topics such as Light, Sound, Magnetism, Electrostatics, Magnetism, Current electricity and Modern Physics were similarly presented (An Roinn Oideachais, 1963, pp. 81–82). This succinctness of defining content was in keeping with the Department of Education's long-established policy of maintaining a distance from class room delivery of all syllabi, thus preserving the Department's independence and impartiality in the administration of the state examinations (An Roinn Oideachais, 1926)

Syllabus Two

A revised physics syllabus was introduced in 1984 and first examined in 1986. Background subject information was included in this syllabus, e.g. list of books suitable either as references for teachers or as textbooks for students. This revised syllabus, while retaining the topics of the 1962 syllabus, now contained details as to the depth of knowledge expected of students including a list of 'suitable experiments to be undertaken…essential for a proper understanding of the syllabus content' (An Roinn Oideachais, 1984). The excerpt in table 2 below is an example of the changes, with reference to corresponding topics as present in the 1962 syllabus.

The style of the Leaving Certificate examination questions also varied – multi-choice questions, presentation of data, graphs and diagrams were incorporated in the questions with allocation of marks for question-parts identified in the relevant sections (Malone and Murray, 2016)

Table 2 Extracts illustrating changes between physics Leaving Certificate syllabi of 1962 and 1984

Physics – introduced in 1962	**Revised physics - introduced in 1984**	
Electrostatics	Topic	Notes
Charges. Conductors and insulators. Electroscopes. Induction. Coulomb's law. Electric fields. Field strength and potential. Condensers. Energy of system of charges.	Electric field 1.Coulomb's law	Coulomb's law as an example of the inverse square law. Forces between coplanar charges.
	2.Electric fields	Demonstration of field patterns using oil and semolina or other method. Idea of lines of force. *Electric field intensity, electric flux.*

(Sources: An Roinn Oideachais, 1984, 1962)

Syllabus Three

The Department presented a revised physics syllabus for physics in 2000 in the form of two booklets - the first booklet outlined the syllabus content in a four-column format and included a new component - *Science, Technology and Society* (STS) in order to 'place the content within a relevant context' (An Roinn Oideachais agus Eolaíochta-NCCA, 1999, p. 2). The second booklet '*Guidelines for Teachers'* – provided context for this revised syllabus (An Roinn Oideachais agus Eolaíochta-NCCA, 1999). The syllabus included a list of mandatory experiments as well as associated activities to enhance student learning and to include the component of *Science & Technology in Society.*

There were also changes to the style of the Leaving Certificate examination papers, which were now divided into sections A and B. Questions in Section A focussed on the mandatory experiments while questions in Section B focussed on theoretical and practical applications of physics. From 2006 onwards, students were permitted to bring and use approved calculators during the examinations. A *Formulae and Tables* booklet was available to students during all State examinations from 2011, thus reducing the necessity of memorising all relevant formulae etc.

Overview of Chemistry syllabus, 1966 to 2016

Syllabus One

The chemistry syllabus, introduced in 1962, was first examined in 1966. In the Department of Education's annual report of 1963 inspectors reported that the *transition from the old to the new (modernised courses in Chemistry) has work with great smoothness … great credit is due to the teachers for the enthusiasm with which they have adapted themselves to these changes* (An Roinn Oideachais, 1963, p. 66). The syllabus consisted of list of topics to be studied by all students (at either ordinary- and higher-level) and included additional topics to be studied only at higher-level as shown in table 2 below. There was no guidance as to the depth of knowledge required by students.

Pass level (ordinary level) 1. Properties of gases, liquids and solids; elements. Compounds and mixtures. 2. Atomic theory: the structure of the atom, electrons, protons, neutrons, atomic number, isotopes. 3. Structure of simple molecules; covalent, electrovalent and metallic bonds, crystal structure as exemplified by the sodium chloride lattice; electronegativity. **Honours level** (higher level) As for the Leaving Certificate Pass Course and in addition: - 11. Concepts of energy levels. Ionization potential and electron affinity. 12. the shape of simple summetrical molecules (organic and inorganic; tetrahedral, planar and linear), reference to orbitals and hybridisation. 13. the Periodic Table in relation of Atomic Structure. (An Roinn Oideachais, 1963, pp. 82–84)

Figure 1 Extract from the 1962 Leaving Certificate syllabus 1962

The examination question papers were very text-heavy, with no use of diagrams or tables. The paper consisted of ten questions printed on one to two A4 sized pages. Students were required to answer six out of ten questions within a two- and half-hour examination period. The overall mark achievable was 400 marks, with six of the questions carrying a maximum of 66 mark and the remaining four questions carrying a maximum of 67 marks. There was no indication given as to how these marks were distributed for each part of a question.

Syllabus Two

In 1983, a revised syllabus for chemistry was introduced and first examined in 1985. This syllabus contained details as to the depth of knowledge expected of students in contrast to that of the previous syllabus of 1962 as illustrated in Table 3 below. For example, understanding of the sulphur and its compounds featured in both syllabi- in 1962 six compounds were listed as indicated in the table. However, in the 1983 further details were included. By way of emphasising that laboratory work was intrinsic to the syllabus, the Department of Education recommended that about 40% of teaching time should be devoted to practical work, with a number of related experiments to be carried out by the students (An Roinn Oideachais, 1984).

Table 2 Sulphur as presented in Leaving Certificate Chemistry syllabi of 1962 and 1983

Chemistry – introduced in 1962	**Revised chemistry -introduced in 1983**	
7(a) study of the following compounds	Topic	Notes
Sulphur, hydrogen sulphide, sulphur dioxide, sulphurous acid, sulphur trioxide, sulphuric acid, sulphates	(b) Sulphur -combustion, forming SO_2, reaction of SO_2, sulphites, general properties. Catalytic oxidation of SO_2 to SO_3. Manufacture of sulphuric acid and its properties	SO_2 as acidic oxide. Bleaching as a reduction reaction; reaction of sulphites with acids.

The Leaving Certificate examination paper was now laid out over five to eight pages and included labelled diagrams of apparatus, data tables and detailed chemical reactions. The marks allocated for each question-part were identified in each question. The duration of the exams was increased from two and half hours to three hours.

Syllabus Three

In 2000, a revised syllabus in chemistry was introduced and first examined in 2002. This syllabi and accompanying Guidelines *for Teachers - Chemistry* were issued as separate booklets (NCCA, 1998, 1998). The syllabus was presented as having a Core element and two Options. The Core element consisted of nine topics with each topic further subdivided. Two of the aims of the revised chemistry syllabus were

- *To encourage an appreciation of the scientific, social, economic, environmental and technological aspects of chemistry and an understanding of the historical development of chemistry*
- *To illustrate generally how humanity has benefited from the study and practice of chemistry* (p.2)

These aims were inteded to be addressed by adding the topic of *Social & Applied Aspects* (STS) in the syllabus. There were also changes to the style of the Leaving Certificate examination papers, which were divided into sections A and B. Questions in Section A focussed on the mandatory experiments while questions in Section B focussed on theoretical and practical applications. From 2006 onwards students were permitted to bring and use approved calculators during the examinations. A *Formulae and Tables* booklet was available during all State examinations from 2011 thus reducing the necessity of learning off all relevant formulae etc.

THEORETICAL BASIS

The context and background presented above outlines an historical overview of the physics and chemistry syllabi and the Leaving Certification examinations in Ireland between 1966 and 2016. Over this period, only three studies which focused on analysing the cognitive abilities of Leaving Certificate examination subjects have been reported. In 1970, Madaus and Macnamara published the findings of their study of nine Leaving Certificate examination papers from 1967, which included the subjects of physics and chemistry (Madaus and Macnamara, 1970). This study was sponsored by the Irish Department of Education. One of the aims of their study was to ascertain what level of cognitive abilities were assessed in the Leaving Certificate examinations. Using Bloom's Taxonomy of Educational Objectives (Biehler and Snowman, 1986, pp. 245–246), they presented a profile of the cognitive abilities being demanded across these subjects. Among their findings was a dearth of questions that assessed higher order thinking skills. Although the following comments were made in respect of physics in the light of the findings of this research, they were equally applicable to chemistry …

> *The emphasis in both papers was on the recall of specific items of information. If knowledge of such items was the main purpose for studying physics, then the examinations had a high content validity. If, on the other hand, the courses were aimed at introducing students to the scientific method, if they were aimed at developing in students a general problem-solving ability which would transcend the details of their course and transfer to a wide range of problems in physics, then both examinations failed badly.* (Madaus and Macnamara, 1970, p. 99)

Nearly thirty years later, in 2014, the Irish State Examinations Commission (SEC) sponsored a research study on the *Predictability in the Irish Leaving Certificate* (Baird et al., 2014). Six Leaving Certificate subjects (physics was not one of the six) were analysed using Bloom's taxonomy. The previous nine years' examination papers and accompanying marking schemes formed the basis of this study.. While the 'concerns about predictability of question content in the examinations were not sustained, the authors did highlight several areas for future consideration – more frequent review of syllabi, more emphasis on assessment of higher order thinking skills within the examinations.. The third study was an independent study carried out by Burns et al. in 2018. This study used Bloom's Revised Taxonomy to analyse 23 Leaving Certificate subjects (which included physics and chemistry) over a five-year period 2005-2010. The findings of this study were similar to the previous studies –'the frequency of lower order skills were between 4 and 14 times higher than those of higher order (Burns et al., 2018, p. 359).

In summary, between 1966 and 2016, the physics and chemistry syllabi were revised twice, and changes were made in the Leaving Certificate examination papers of these subjects. The findings of three studies reported over this period indicate that the examination papers focus on assessing lower order skills. These findings inform the research questions examined in this study-

1. What were the cognitive demand of the physics and chemistry Leaving Certificate examinations questions during 1966-2016?
2. Were there differences in the cognitive demands of the physics and chemistry examinations of the various syllabi?

METHODOLOGY

This study analysed the level cognitive abilities assessed in the Irish Leaving Certificate examination in physics and chemistry across a fifty-year period from 1966 to 2016. Table 4 provides details of three years of consecutive examination papers selected as representative samples of the three physics and chemistry syllabi over this period. Each examination paper consisted of ten to twelve questions, which contained several sub question-parts. The number of question-parts ranged from N = 113 to N=391 for physics and from N=132 to N=322 for chemistry, as shown in Table 4.

Table 3 Total number of question-parts coded from samples of each of the syllabi

Syllabus One	Syllabus Two	Syllabus Three

(1962-1983) Physics/Chemistry	(1984-1999) Physics/Chemistry	(2000- to present) Physics/Chemistry
1966, 1967, 1968	1986, 1987, 1988	2006. 2007, 2008
$N_{physics}$ = 113	$N_{physics}$ = 210	$N_{physics}$ = 391
$N_{chemistry}$ = 132	$N_{chemistry}$ = 248	$N_{chemistry}$ = 322

Coding using Bloom's taxonomy

Bloom's Taxonomy of Educational Objectives (Remember, Understand, Analyse, Apply, Evaluate, Create) was the tool used to classify the level cognitive abilities of the physics and chemistry examination questions (Bloom et al., 1971; Krathwohl, 2002). Firstly, Bloom's Taxonomy was the criterion employed in the previous analysis of physics and chemistry examinations and secondly, the State Examination Commission's publication, *A Manual for Drafters, Setters and Assistant Setters,* highlighted that the type of skills to be measured should be within the framework of Bloom's Taxonomy of Educational Objectives. This manual also included a list of cue words recommended to use when compiling the questions. (SEC, 2018, pp. 25–26, 49). he following coding process was adopted in this study. All question items were classified with relevant question cues being highlighted and then assigned to the relevant cognitive level as shown in Figures 3 and 4.

Leaving Certificate Examination Question – 1986 Section C question		Cognitive level
9. Describe an experiment to show that sound is a wave motion.	(15)	Remember
Explain the physical principles underlaying each of the following:		
(i) Sounds can be heard more clearly on a cold night than on a warm day. Understand	(12)	
(ii) A glass can be shattered by a singer singing a high note. Understand	(12)	
When the source of a note moves past a stationary observer the pitch of the note seems to change. What is the name given to this phenomenon?	(6)	Remember
A whistle which is emitting a note of 1kHz is whirled in a horizontal circle on the end of string 1.2m long at a constant angular speed of 50 rad s^{-1}. What is the highest and lowest frequencies heard by a person standing some distance away? (Speed of sound in air = 340 m s^{-1})	(21)	Analyse

Figure 2 Higher-level Leaving Certificate Physics examination paper 1986, Section C, question 9

Leaving Certificate Examination Question – 2008, Section B, question 8 (a).	Cognitive level
8. (a) (i) Write an expression for the self-ionisation of water. (5)	Remember
(ii) Define K_w, the ionic product of water	Remember
The value of K_w at 25 0C is 1.0 x 10-14. Show that the pH of pure water is 7.0 at 25^0C. (12)	Understand
(iii) Calculate the pH of a 0.5M solution of a strong monobasic (monoprotic) acid.	Apply
Calculate the pH of a 0.5M solution of a weak monobasic acid with a Ka value of 1.8×10^{-5}. (12)	Apply

Figure 3 Higher-level Leaving Certificate Chemistry examination paper 2008, section B, question 8 (a)

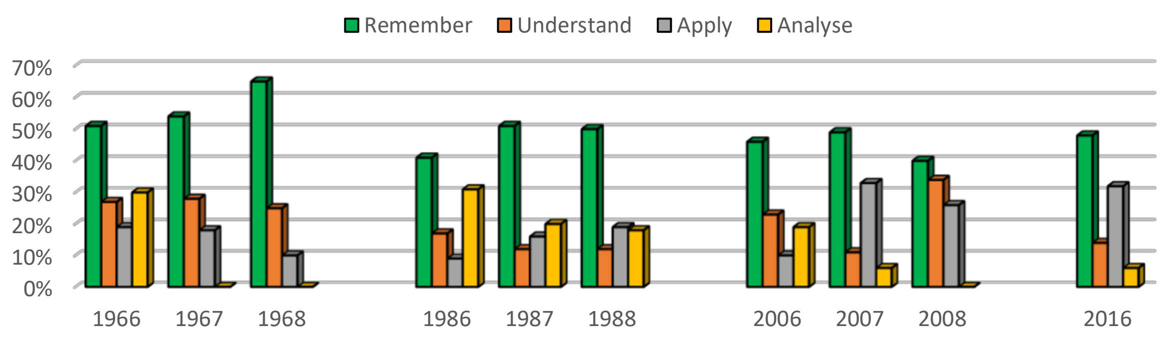
Having coded all question-parts for their respective cognitive levels, the marks - as indicated on examination papers -were then applied. The total marks for each cognitive level were calculated as a percentage of maximum marks available for each paper. For example, analysis of the 1987 Leaving Certificate physics showed that total marks available were 690. Of this total, 41% of the marks coded for the cognitive level **remember**, 17% for **understand**, 9% for **apply**, and 31% for **analyse**. There were no question-parts code for either of the cognitive levels of **evaluate** and **create.**

The selected examination papers for each subject, were analysed independently by three qualified second level teachers of physics and chemistry whom were familiar with Bloom's taxonomy and its levels of cognitive demand. Any discrepancies in coding that arose on the classification or the allocation of question-part marks were discussed by the group and the final classification of cognitive level and assignment of question-part marks were agreed by consensus.

FINDINGS

Cognitive demand level changes in Leaving Certificate physical sciences examinations, 1966-2016

Figure 5 presents the analysis of the representative nine higher-level Leaving Certificate physics examinations over the three syllabi. The examination papers were dominated by questions which were coded for the cognitive domain '**remember**' across all the three syllabi e.g. for the years 1966-1968 on average 57% of the questions were classified in this domain. Twenty years later, for years 1986-1988, the average in this domain was 47% and another twenty years later the average proportion was 46%.
For the three-year period of 1966-1968, on average 27% of the questions were classified in the '**understand**' domain. For the subsequent periods, 1986-1988 and 2006-2008 the average proportion for this domain were 14% and 21% respectively. As there were no question-parts within any of the nine papers which merited classification of 'evaluate' or 'create', these levels



were not included in the graphs in Figure 5.

Figure 2 Cognitive levels of higher-level Leaving Certificate Physics Examinations 1966-2016

The analysis of the representative nine higher-level Leaving Certificate chemistry examinations are shown in figure 6. The examination papers were dominated by questions which coded for the cognitive domain '**remember**' across all the three syllabi e.g. for the years 1966-1968, on average, 68 % of the questions were classified for this domain. Twenty years later, for years 1986-1988, the average proportion of questions classified in this domain was 42% and another twenty years later this average proportion was 59%.

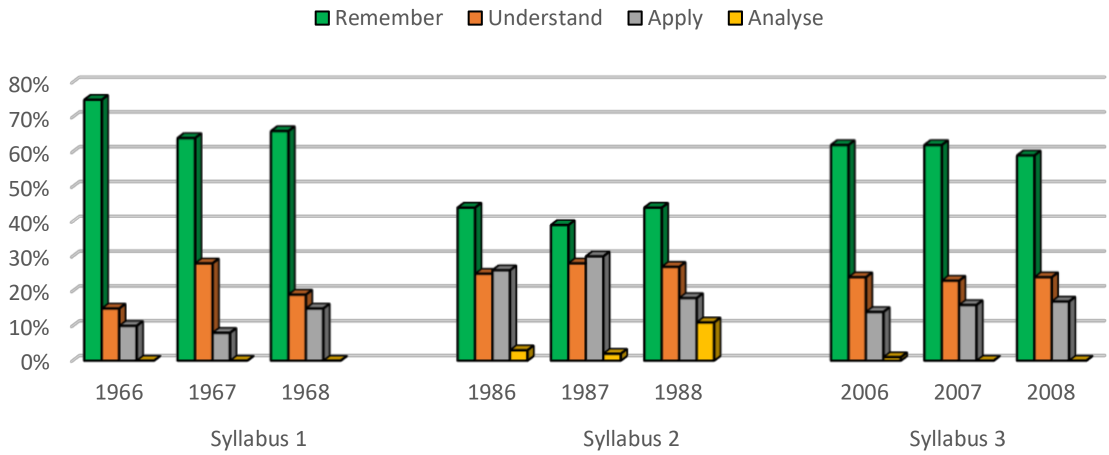


Figure 3 Cognitive levels of higher-level Leaving Certificate Chemistry Examinations 1966-2016

For the three-year band of 1966-1968, on average 21% of the questions/question parts were classified in the '**understand**' domain. For the subsequent years, 1986-1988 and 2006-2008 the average proportion for this domain was 27% and 24% respectively. As there were no question-parts within any of the nine papers which merited classification of 'evaluate' or 'create', they were not included in these graphs.

In the 1960s, students needed to obtain a minimum 60% of the total alloted marks to be awarded an honours grade for a subject. For example, physics and chemistry were each marked out of four hundred marks thus a total of marks greater than 240 merited an honours grade. Based on the annual education statistics published by the Department of Education, Table 4 illustrates the percentage of student who were awarded an honours grade in physics and in chemistry in the nine years 1965-1968, 1986-1988 and 2006-2008.

Table 4 Percentage of students awarded an honours grade in higher-level Leaving Certificate Physics and Chemistry examinations.

Percentage of students awarded an honours grade:	Syllabus One			Syllabus Two			Syllabus Three		
	1966	1967	1968	1986	1987	1988	2006	2007	2008
Physics	42%	42%	41%	No data	62%	58%	77%	72%	71%
Chemistry	47%	43%	44%	No data	60%	62%	76%	79%	79%
Minimum Honours Mark	*60%*	*60%*	*60%*	*55%*	*55%*	*55%*	*55%*	*55%*	*55%*

The cognitive demand levels for the higher-level Leaving Certificate physics and chemistry examinations are shown in Figures 4 and 5, respectively. As an example - in 1968, the analysis of the physics examination paper showed that 65% of the questions were coded for the '**remember**' category. The minimum marks required to achieve an honours grade was set at 60% of the total marks for this examination. However, as shown in Table 8, only 41% of all students who sat the 1968 examination achieved an honours grade – despite the majority of the paper requiring only lower order thinking skills , i.e. the domain of remember was 65% and understand was 25%.

An overall reorganisation of the grading system for Leaving Certificate examinations took place in 1973 and the percentage of total marks required for the awarding of an honours grade was lowered to 55%. This change may explain the increase in the number of proportion of students achieving an honours grade in later years. Table 4 shows that more than three-quarters (76%) of those who sat the 2006 higher-level Leaving Certificate chemistry examination were awarded an honours grade and for the two following years 79% of those sitting this examination obtained an honours grade. The analysis of cognitive demand levels for those years (figure 5) show that 62% of the question-parts coded for remember and 24% for understand levels, again indicating a high reliance on memory and lower order cognitive levels.

CONCLUSION

It was not until 2000 that both the marking schemes used in these examinations and Chief Examiners' reports were published by the State Examinations Committee. Prior to 2000, the only information concerning the examinations was the annual examination statistics issued by the Department of Education. This synoptic review of the higher- level Leaving Certificate examination of two physical sciences, physics and chemistry, over the fifty years period from 1966 to 2016, shows a persistent high reliance on the cognitive levels of **remembering** and **applying** and a low focus on the levels of **understanding** and **analysing**. These findings support the anecdotal belief of pedagogical approaches focussing on 'teaching to the test' and the higher percentage of honours awards to students in recent years. However, further analysing is required to confirm if these findings are representative of all Leaving Certificate physical sciences, at both ordinary- and higher- levels, examinations for this fifthy year period.

This analysis of the higher-level Leaving Certificate physics and chemistry examinations papers over a 50-year period revealed that no questions were coded for the higher order cognitive levels of **evaluating** or **creating.** The physics syllabus two had a greater number of marks coded for level of **analysing** (19-31%) than either of the other two physics syllabi (figure 5). This also the case for chemistry, noting that there were no questions during syllabi one or three that coded for the cognitive ability of **analysing** (figure 6). Although detailed information about the marking system has published by the SEC since 2000, the cognitive demand levels of the questions in the higher-level Leaving Certificate physics and chemistry examinations indicate a persistent low focus on higher order cognitive skills, such as **analysing, evaluating** and **creating**.

The context of this study has solely been in the Irish education system. Introducing a motion on the then recently published report *Investment in Education* in Seanad Eireann, Professor

Quinlan, a senator representing the National University of Ireland (NUI) constituency - said he was '*baffled completely how (you) can investigate an education system without seeing how that system compares with systems…in small countries in Western Europe'* (Seanad Eireann, 1967). Currently, a new specification for Leaving Certificate physics and chemistry are in preparation for national implementaiton. The stated objective of these syllabi are to enable students to develop the ability to explain, evaluate and communicate as well as introducing differentiation in the style of questioning to assess these outcomes. The findings of this review of the assessment of physics and chemistry syllabi are highly relevant and timely in development of appropriate pedagogical and assessment practices that recognise and assess higher order thinking skills.

PART 11: STRAND 11

Evaluation and Assessment of Student Learning and Development

Co-editors: *Lukas Rokos & Mathias Ropohl*

CONTENTS

STRAND 11: INTRODUCTION

EVALUATION AND ASSESSMENT OF STUDENT LEARNING AND DEVELOPMENT

Assessment can be seen as a driving force for student learning and development as it generates and delivers information about their learning progress and learning difficulties that can be used by teachers to adapt teaching. In this sense, strand 11 covers a wide range of issues regarding the assessment ranging from formal to informal types of assessment and from very focused to more broader types of assessment. In total, there are 15 contributions in this chapter from several countries (Austria, Brazil, Cyprus, Czech Republic, Germany, Greece, Spain, USA). In this way, the different chapters present interesting insights into the role of assessments in different educational systems that are useful for the ESERA community. In addition, the respective studies cover various subjects and methodological approaches. The contributions to strand 11 were grouped into five sections according to different foci: 1) formative assessment, 2) comparing students' competences, 3) context-based learning and affective variables, 4) development of specific tests, and 5) assessment in an extra-curricular learning context.

Lukas Rokos & Mathias Ropohl

1) Formative assessment

Formative assessment in the form of on-the-fly interactions is the content of a classroom-based study called *Illustrating the application of interactions on the fly in science teaching with the use of concept maps*. The purpose of this study was to depict, through concept mapping, the depth and coherence of classroom dialogue in upper-secondary physics lessons in which the on-the-fly method was applied.

Peer-assessment as a tool for reflective feedback in pre-service teacher training is a study focusing on pre-service teachers and their ability to provide written formative feedback during their teachers' training in biology lessons at the lower secondary level.

The study called *The use of a mixed methodological approach to analyse the specific coding orientation* describes the use of a mixed approach to analyse the concept of formative assessment. A questionnaire was used in a qualitative part and the data from this part were analysed to characterise the context. In a second part the participants took part in a case study in their real context.

2) Comparing student's competences

Inquiry competence of junior and senior class biology students provides data about inquiry competences in junior and senior classes in Austria and determines whether competences increased.

Science achievement and science motivation of Waldorf students compared to regular students investigated the science learning outcomes of students from Waldorf schools in Austria with curriculum-based emphasis on inquiry-based education and compared them with the outcomes of regular students.

Measuring students' chemistry competences at the transition between primary and secondary school is related to a paper and pencil test referring to content knowledge and procedural knowledge which enables to measure students' chemistry scientific competence.

3) Context-based learning and affective variables

How can the context help to solve a problem? A procedural analysis of contextualized problem solving suggests that the effect of context on performance varies strongly during problem solving in physics lessons.

Identification of chemistry contexts that interest Greek students presents a questionnaire that was used to explore secondary school students' interests in a variety of contexts commonly found in chemistry curriculum documents.

The different typologies describing the interest in science presents Brazil Barometer – a tool which enables to understand students' interest in science and helps to improve the teaching and learning processes. Some specific topics had the greatest potential to boost students' intrinsic motivation.

4) Development of specific tests

Performance analysis of students regarding the complexity and content dimensions of items in the learning of programming logic evaluated with the developed test and quantitative methods high school students' learning with respect to the contents of programming logic.

Development and validation of the negative appraisals of studying school science (NASSS) scale is a study performed with elementary school teachers and it brings evidence to consider NASSS as a valid and reliable instrument for the Spanish educational system.

Evaluation of learning progression on chemical concepts in secondary schools tries to map the hierarchical structure in secondary school chemistry via a strand map and to empirically evaluate this map. Developed performance tests help to analyse the validity of the presupposed interdependencies between the core ideas.

Proposal of the use of scientific literacy indicators to analyse a written evaluation aims at analysing a written evaluation used in the future teacher education sequence related to public health using Scientific Literacy Indicators which was identified as a good instrument to analyse the quality of written evaluations.

5) Assessment in an extra-curricular learning context.

Evaluating divergent thinking among participants of a German science competition is a paper focusing on discovering students' creative potential, divergent thinking abilities and cognitive development in informal learning by using a validated test.

An empirical study on the learning processes and actions of students while interacting with exhibits at a science centre is related to informal learning and primary level. This study clarifies how characteristics of the exhibits and the explanatory media lead to an understanding of selected phenomena.

ILLUSTRATING THE APPLICATION OF INTERACTIONS ON THE FLY IN SCIENCE TEACHING WITH THE USE OF CONCEPT MAPS

Michalis Livitziis, Nicos Papadouris and Costas P. Constantinou
Learning in Science Group, Department of Educational Sciences, University of Cyprus, Nicosia, Cyprus

This paper reports on an empirical, classroom-based study focusing on teachers' efforts to draw on interactions on the fly that unfold in the classroom as a means of formative assessment. This form of assessment occurs spontaneously during the course of a lesson when the teacher engages in the process of interpreting assessment data that arise in the classroom, in real time, to make instructional decisions on a moment by moment basis. The purpose of the study is to depict, through concept mapping, the depth and coherence of classroom dialogue when this formative assessment method is applied. The study is situated in the context of upper secondary physics lessons on Newton's laws of motion and focuses on the respective classroom discussions when teachers explicitly sought to draw on "interactions on the fly" as a means of formative assessment. The discussions were videotaped, coded and represented using concept maps that illustrate the connections between the various concepts that arise during the discussions, the depth and coherence at which these were elaborated and whether there have been critical concepts for students' understanding of the scientific phenomenon under discussion that had been ignored or left out of the discussion. This kind of mapping could serve as a productive resource in supplementing the extant research on discourse analysis by providing rich information in relation to the depth and coherence of the classroom dialogue. In addition, it could provide insights into specific pedagogical challenges encountered by teachers in their attempt to draw on students' contributions to the discussion as a means of formative assessment and thus it could inform attempts to better prepare teachers to anticipate and manage such challenges.

Keywords: Formative assessment, concept maps

INTRODUCTION

"On the fly" interaction as a formative assessment method occurs spontaneously during the course of a lesson when "teachable moments" arise in the classroom and teachers have to make inferences on a moment by moment basis (Heritage, 2007). Dialogue with students has a central part in formative assessment so as to clarify their existing ideas and to help them construct the scientifically accepted ideas. This includes instantaneous feedback as the students take part in a learning activity (Yorke, 2003). Duschl (2003) adopted the term assessment conversation to refer to these daily instructional dialogues that embed assessment into an activity already occurring in the classroom. "On the fly interaction" for assessment is important because it enables the teacher to identify learning problems during the presentation of information while there is an opportunity to recognize and correct misconceptions (Bell & Cowie, 2001). To do so, the teacher must find questions to ask which will help students externalize their understanding or confusion. When students provide feedback on their ongoing learning, they are giving the instructor an opportunity to highlight concepts that require additional explanation (McConnell, Steer & Owens, 2003).

However, there are a number of challenges that teachers encounter when applying such an assessment method. Mastering informal assessment strategies is extremely complex, introducing significant challenges to the assumptions and methods underlying the current practice of most science teachers (Duschl & Gitomer, 1997). Ruiz-Primo & Furtak (2006) proposed the ESRU cycle (Teacher's **E**licitation, **S**tudent's response, Teacher's **R**ecognition of the response, Teacher **U**ses the information collected) for coding and describing teacher – student interaction during informal assessment. Research regarding the use of the ESRU cycle during on the fly interactions that take place in the context of science learning has shown the positive effect that the completion of these cycles has on students' learning outcomes (Ruiz-Primo, 2011).

On the other hand, Coffey et al. (2011) who analysed four publications by prominent researchers in assessment and science education claim that, while researchers and teacher educators seem to believe that strategies are what teachers need first or most to help them engage in formative assessment, there is little focus on the disciplinary substance of what teachers and students assess. There is a need to monitor the learning process and in particular the classroom dialogue during formative assessment in order to assess its quality in terms of responsiveness and focus on the disciplinary substance.

Concept maps have been used extensively as learning products for representing students' understanding in all subject matter fields and for learners of any age. In some cases, students are asked to build their concept maps themselves (Regis et al., 1996), whereas in other cases teachers or researchers construct the concept maps when assessing students, for example by interviewing them (Nicoll, 2001). While concept maps are a qualitative representation of students' conceptual understanding, researchers have attempted to use a variety of scoring techniques on concept maps to be able to quantitate the trends among concept maps. There exists a wide variety of ways to generate and subsequently grade or assess concept maps (Stewart, 1980, Moreira, 1985, Raven, 1985, Stuart, 1985, Shavelson et al., 1993, Liu, 1994). Liu (1994), for instance, proposed using item response theory, which takes into account the number of links, the number of hierarchies, the number of cross-links, and the number of examples when scoring concept maps. The presence of crosslinks in a map reflects the extent of knowledge integration.

We believe that concept maps could be employed also to depict how concepts are discussed in class. This particular study seeks to represent the conceptual completeness, coherence and depth of the classroom dialogue when interaction on the fly is applied, using concept maps. We refer to conceptual completeness of classroom dialogue to describe (a) the degree in which the essential concepts for discussing a scientific phenomenon were brought into the classroom talk when investigating the particular phenomenon; (b) the conceptual coherence of the dialogue to represent the extensiveness of linking concepts in a coherent network and, (c) the conceptual depth of the dialogue to express the extent to which there were multiple references on connections between the relevant concepts during an episode of classroom dialogue.

METHOD

For this purpose, three enactments were applied in Physics classes at higher secondary schools by experienced teachers who had previously participated in a series of three workshops, each lasting about three hours, where they were trained on formative assessment and particularly on the method of "on the fly interaction". Each enactment lasted eleven 45-minute teaching periods and used the contexts of "freefall" and motion on an inclined surface. Teachers focused on the competence of designing and implementing investigations and formative assessment methods were applied for evaluating students' ability on specific components of the competence, as well as their conceptual understanding on the relevant concept that was applied.

These lessons were videotaped and those parts of the classroom dialogue that included interactions "on the fly" were identified and transcribed. The classroom dialogue was then divided to episodes according the theme under discussion (one episode ends and another begins when the theme under discussion changes) and each episode was coded using a concept map developed by the researcher in order to illustrate the conceptual completeness, coherence and depth of each episode of the dialogue. More specifically these maps depict the variety of concepts that emerge in discussion, whether these emerge from the students or the teacher, how much these are interpreted, how well linked they are with each other and the essential but missing or not interpreted concepts.

Dialogues were also coded according to the ESRU (Elicit-Student's response-Recognition-Use) coding scheme (Ruiz-Primo & Furtak, 2006) and examined whether the conceptual completeness, coherence and depth of the classroom dialogue as depicted on the concept maps correlate with the rate of complete ESRU cycles in each episode. In order to do so, aforementioned parameters were quantified as they were depicted on the concept maps. Thereby, the following three dimensions were considered:

- The rate of the essential concepts that were actually used in each episode of the dialogue.
- The rate of connections between concepts that were revisited in at least one more ESRU cycle than the one they appeared in.
- The rate of concepts in each episode that were connected with each other forming loops on the conceptual maps.

To find the rate of the essential concepts that were actually used in each episode of the dialogue, the number of these concepts was divided by the number of concepts that would have been used if concepts were perceived as essential for students' understanding on the particular theme under discussion were also included. The rate of connections between concepts that were revisited in at least one more ESRU cycle than the one they appeared was found by dividing the number of links between concepts in the particular episode which were realised at least in two ESRU cycles with the whole number of links between concepts that were made in the episode. The rate of concepts in each episode that were connected with each other forming loops on the conceptual maps was found by dividing the number of concepts that were included in such loops at each episode by the whole number of concepts that were used in the episode.

Afterwards, Pearson correlation was used to examine whether the rates for the conceptual completeness, coherence and depth of the classroom dialogue relate with the rate of completion of ESRU cycles of each episode.

RESULTS

In an effort to represent the conceptual completeness, coherence and depth of the classroom dialogue, 47 concept maps were developed. Below, three of them are presented as examples in order to illustrate their functionality.

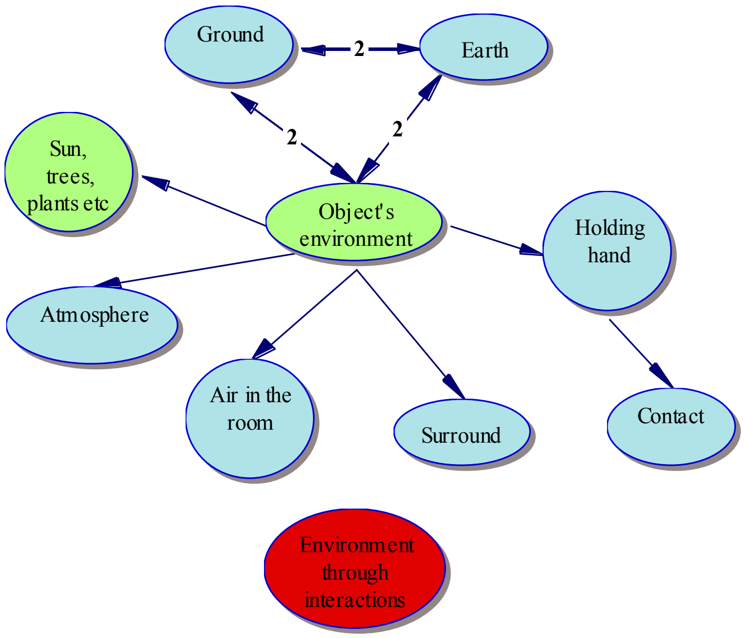

Figure 1. Concept map of an episode of the classroom dialogue in the 2nd implementation

The concept map in Figure 1 is depicting an episode from the 2nd implementation. The theme under discussion is “object’s environment” in terms of forces’ interactions. The main concept (object’s environment) is coloured light green because it was introduced by the teacher. Students link this concept with others, like the atmosphere, the ground etc., which are coloured light blue. During the episode there is no explicit link between the “object’s environment” and the interaction through forces with other objects, which in our opinion should have been made as a key concept in the discussion. That is why the term “environment through” interactions remains unlinked and red coloured on the concept map. The direction of the arrows depicts how concepts were linked, while the number on the arrow declares the number of ESRU cycles that this link was made for (if it was made more than once), indicating the depth of elaboration. In addition, it was observed that that some concepts are connected in some kind of loop, like here for example the terms “object’s environment”, “ground” and “Earth”. These loops can be an indicator of the coherence of the dialogue since concepts are not just connected one by one but in larger groups, forming a more coherent framework related to the phenomenon under discussion.

The next concept map (Figure 2) is also illustrating an episode from the 2nd implementation. The theme of this episode is the discrimination between contact force and force from distance. As can be seen, most of the concepts are provided by the teacher. Nevertheless, weight is thoroughly discussed as an example of field force and it is linked to Earth and mass. This is depicted on the map by the loop between the concepts force from distance, Earth, weight and field, and the multiple visits of some of the links between these concepts in a number of ESRU cycles. Similarly, the term contact force is also mentioned (by students) and well explained. However, despite that the concept of reaction force came up in the particular episode twice by students, the teacher avoided to discuss it. Therefore, this term is depicted crossed on the concept map.

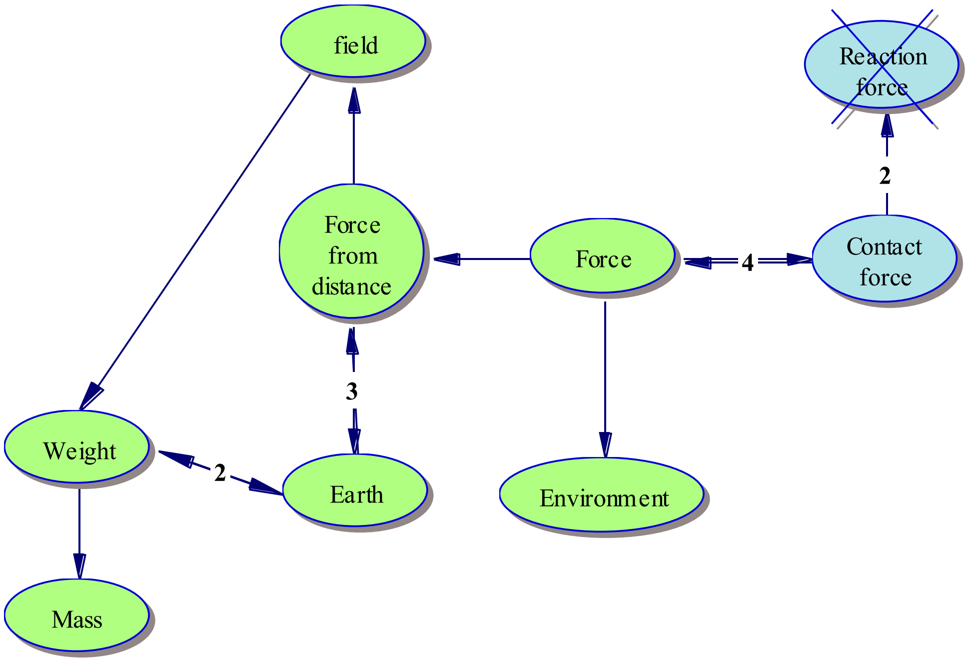

Figure 2: Conceptual map of another episode from the 2nd implementation.

The following concept map (Figure 3) is illustrating an episode from the 1st implementation. The teacher is trying to assess students' understanding on the results of an experiment they did, regarding the factors that influence free fall. As can be observed, it resembles a quite rich discussion, with students introducing half of the concepts that appeared, three loops between some of the concepts and multiple revisits to the links among some of them. However, when students suggested two factors which seemed to influence acceleration to them (because they noticed small differences in measurements for different weight and height), the teacher suggested to round measurements to fewer decimal digits without discussing the significance of any of the digits. Thus, this might have seemed to students mostly like manipulating the numbers the way it suits the teacher. These instances are depicted on the map through the unlinked red boxes. We chose to draw concepts that relate to scientific processes in rectangular shape instead of the oval we use for the concepts that relate with content knowledge in order to discriminate them.

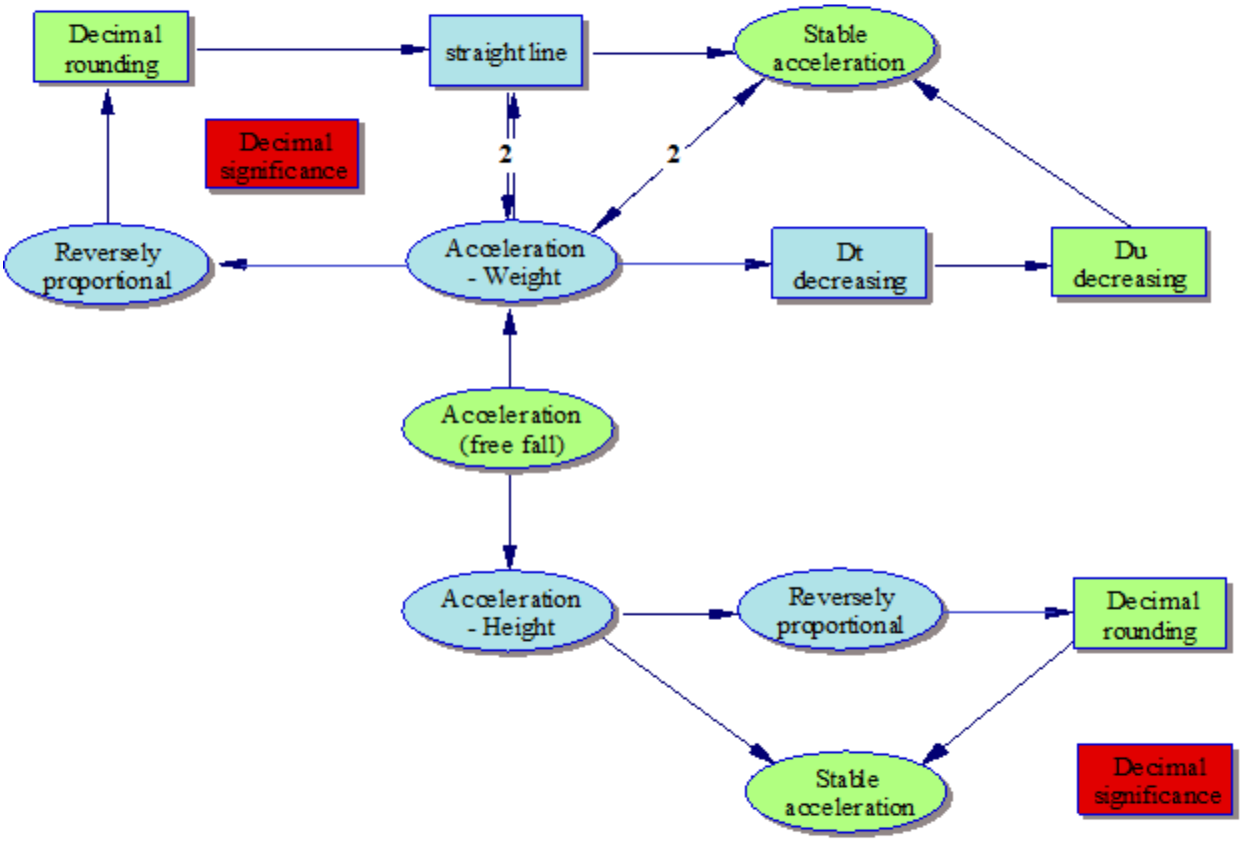

Figure 3: Conceptual map of an episode from the 3rd implementation.

The term "missed opportunities was used to refer to these instances of either not utilizing contributions from students or not doing so in a productive manner. It can be noticed that the previous three examples of concept maps illustrate how different kinds of missed opportunities of using the emergent information can be depicted in these concept maps. At the first and the third case (Figures 1 & 3), concepts that could bridge obvious gaps in students' understanding either related with conceptual knowledge or the scientific method, are depicted as red unlinked boxes, elliptical or rectangular respectively. In addition, by crossing the particular concept on the concept those cases were depicted where the teacher avoids or postpones discussing a concept that emerges in dialogue despite it seems to influence students' understanding.

As mentioned previously, the rate of complete ESRU cycles in each dialogue episode was also found. A complete cycle consists of all four components of ESRU, at least in an implicit way, while broken cycles can be either in ESR format or ES when the teacher does not use the upcoming information of student's response or doesn't even recognize student's contribution. In order to examine how the completion of ESRU cycles relate to the conceptual completeness, coherence and depth of the classroom dialogue, these dimensions were quantified as they were revealed through the parameters that the concept maps consist of. Then, the rate of each parameter was examined in relation to the rate of completion of ESRU cycles of each episode using Pearson correlation. Looking at the correlation of the rate of completion of ESRU cycles of each episode with each one of the three parameters, only for two of them a significance appeared. The correlation is moderate for the coherence of the dialogue ($r=0.45$, $p<0.01$) and weak for the depth of discussion ($r=0.32$, $p<0.05$), while it is insignificant ($p=0.41$) for the rate of the concepts discussed.

These results indicate that the rate of completion of ESRU cycles of each episode can be an indicator for the conceptual coherence and depth of the classroom dialogue. Still, there might be missed opportunities to improve students' understanding, particularly because specific critical concepts were not brought up nor discussed during the dialogue, despite a high rate of completion of ESRU cycles.

DISCUSSION AND CONCLUSIONS

Classroom evaluation practices generally encourage superficial and rote learning, concentrating on recall of isolated details, usually items of knowledge which pupils soon forget (Black & William, 1998). This can be attributed to the fact that concepts are not well linked to each other and thus the learning process lucks in coherence and meaning. In many cases, the evidence suggests that teachers are focused on finding out what students already know of the target information (Coffey et al., 2011). However, perhaps out of a desire to have the widest relevance, many studies have focused on strategies that cut across topics and disciplines, such as wait time or ‘‘stop lighting’’ or questioning, without closely examining the ideas and reasoning they reveal. By not delving into the specific substance of student thinking, the literature - and, subsequently, practice - misses and may undermine its fundamental objective. However, there is evidence that the quality of dialogue in a feedback intervention is important (Graesser & Person, 1995) and can, in fact, be more significant than prior ability and personality factors combined (Clarke, 1988).

An exception is the research by Clarke (1988) on classroom dialogue in science classrooms. He analyzed the discourse of three teachers in four classrooms, grading the quality of the discourse by summation over four criteria. These included the numbers of interpretable themes, the numbers of cross-correlations (an indicator of coherence) and proportions of themes explicitly related to the content of the lessons. As he claims, such a sophisticated analysis of dialogue indicates specific areas of weakness, which could be remedied by appropriate training. It could also be used to produce ideal "templates" of various models of teaching (e.g. Brady; 1985) for the use as a guide for lesson planning.

Recent work in science and math teacher education (Coffey, Edwards & Finkelstein, 2010; Kazemi et al., 2009; Levin, Hammer & Coffey, 2009), has presented evidence of novice teachers' attention to student thinking, novices whose preparation emphasized awareness and interpretation of student thinking as evident in video records and written work. By this reasoning, much depends on how teachers frame what they are doing, and a primary emphasis on strategies may be part of the problem. Assignments that direct teachers and teachers in training to what they are doing may inhibit their attending to what students are thinking.

The presented concept maps enabled us to represent the conceptual completeness, coherence and depth of the classroom dialogue in four dimensions:

- The variety of concepts that emerge in discussions
- The extent to which they are interpreted
- The extent of how well they are linked with each other
- The necessary concepts that are missing or are not interpreted

More specifically the various concepts that emerged in discussions were depicted in boxes that were coloured differently (light blue or light green) to denote whether they were brought into the discussion by the teacher or a student. This allows us to illustrate whether all the essential concepts for describing the phenomenon or scientific process under discussion, in the particular episode, are included in the dialogue. As the concept maps reveal, some episodes were long and rich in concepts relevant to the phenomenon under discussion while other episodes were short and included very few concepts. Often, the teacher seems to assume or to operate under the impression that the students have made the connection with a missing concept in their minds without explicitly referring to it. As observed, in some episodes, necessary concepts for the understanding of the phenomenon were missing from the discussion. These were depicted in red colour in order to illustrate the lack of completeness of the dialogue episode.

Concepts are linked with arrows on the concept maps. The direction of the arrows depicts the order the concepts appeared in the dialogue, while the number on the arrow declares the number of ESRU cycles in which this link was made (if it was made more than once). This number is considered as an indicative measure of the depth to which the particular concepts were discussed. Again, the concept maps developed suggest that episodes of classroom dialogue vary from one another. Some of the maps illustrate that concepts were linked various times to each other, suggesting that the relevance between them and with the phenomenon was well discussed. Other maps show that concepts were just mentioned serially one after the other without much discussion about the relations between them. In addition, concepts that are depicted on the concept maps as crossed are concepts that were mentioned by students but were ignored by the teacher and thus not discussed at all. These items relate to cases when the teacher does not respond to an issue that comes up during discussion, considering it as not part of the particular lesson.

Furthermore, the concept maps developed depict the coherence of the classroom dialogue during each episode. Coherence is indicated with the loops that concepts form when each concept is linked with other concepts, which are also linked with each other. These robust connections suggest that the dialogue included a holistic approach to understanding the phenomenon under discussion instead of a fragmented presentation of various concepts.

Overall, we claim that the concept map illustrations form a representation of the dialogue that indeed reveals the quality of each episode of the classroom dialogue in three dimensions: the completeness of the dialogue, the depth that concepts were discussed and linked to each other and, the coherence of the dialogue. These representations also revealed that the dialogue episodes can be very different between each other regarding several of the aforementioned dimensions, even if they were realized by the same teacher in the same class.

Concept maps developed by a researcher who is observing a class discussion can illustrate additional information regarding the depth and coherence of the dialogue in relation to the disciplinary substance. Such concept maps can be a useful tool for pre-service and in-service teacher educators giving the opportunity to teachers to reflect on their lessons from a different perspective, in their effort to improve their teaching practice. In addition, the results show that that the parameters that comprise the concept maps can be quantified in order to be compared to other dialogue coding schemes. Analyzing the score of each parameter can also help to identify the challenges that teachers encounter when applying informal formative assessment.

Concept maps that depict the completeness, the depth and the coherence of the dialogue might be helpful tools for teacher coaches also in their efforts to assess a lesson they have observed and provide teachers with valuable feedback. On the other hand, the teachers themselves could benefit by developing such concept maps for their own lessons with the purpose to create a holistic representation and reflect on their teaching practice. Further research could explore possible ways to improve the representation of the completeness, the depth and the coherence of the dialogue using concept maps and to triangulate with other classroom observation methods.

PEER-ASSESSMENT AS A TOOL FOR REFLECTIVE FEEDBACK IN PRE-SERVICE TEACHER TRAINING

Lukas Rokos[1], *Jan Petr*[1], *Radka Zavodska*[1]
[1]University of South Bohemia in České Budějovice, Faculty of Education, Department of Biology, České Budějovice, Czech Republic

This study presents implementation of formative assessment, specifically peer-assessment, into the pre-service teacher training. Students of the Faculty of Education used structured assessment forms to evaluate their peers' performance during a pedagogical practice placement, which is a mandatory part of MSc degree in teaching branches in the Czech Republic. This paper deals with the quality of provided written feedback. We found that pre-service teachers have problems with providing supportive feedback to their peers and they rather tend to assess using scales without comprehensive verbal comments. Written comments represented rather a description of observed lesson instead of constructive feedback and only in few cases it had attributes of formative assessment with advice on next steps to make better progress. Only a minimum amount of forms contained justification of students' assessment. It was also found that pre-service teachers have problem identifying instructional goal of the lesson and often mistake it for topic of the lesson or they aim the goal at the teacher instead of students.

Keywords: peer-assessment, pre-service biology teachers, pre-service teacher training

THEORETICAL BACKGROUND

The pre-service teachers practice placement is a mandatory part of a MSc degree in teacher training study programmes at faculties in the Czech Republic. Future teachers visit so-called faculty schools where they perform few lessons under the tutelage of in-service teacher and university teacher. Although the insufficient number of teaching classes incorporated in study programme is the main problem, quality of this placement is also an important issue, mainly the poor connection between theoretical subjects at faculty and pedagogical reality at schools. Implementation of formative assessment methods into the teacher training programme is one possibility to ensure this connection and also to strengthen the diagnostic competencies of future teachers.

The diagnostic competence of pre-service teachers is low in general perspective (Buck, Trauth-Nare & Kaftan, 2010; Plake, Impara & Fager, 1993). Future teachers have to learn how to provide supportive feedback containing an advice on next steps to make better progress and to reach the selected goal (Hattie & Timperley, 2007), but also to define the instructional goal correctly. So, we understand the teachers' diagnostic competence as ability to interpret observed situation, provide informational and constructive feedback and feedback related to improvement of the next lesson (according to the definition of Hattie & Timperley, 2007).

The feedback is one of most important factors in affecting teaching-learning process and the effect on students‘ learning and achievements is also documented (Hattie & Timperley, 2007).

The possibility to try providing the feedback is one of key aspects for successful implementation of this process in education (Ducasse & Hill, 2019). When the feedback is connected with the peer formative assessment the benefit could be seen in better understanding of provided comments because peers have similar point of view and use the same language without complicated academic terminology (Jonsson, 2013; Winstone et al., 2016). The peer assessment is said to be more supportive and easier understandable than the assessment from teacher, mainly because of peers' language (Gibbs & Simpson, 2004; Nicol, Thomson & Breslin, 2014). Although teachers provide the feedback based on their own experience and they are focused on the crucial aspects in the teaching process this feedback is sometimes quite complicated formulated for the students (Mathan & Koedinger, 2005). Providing informational and constructive feedback is important for better understanding of problems for assessors as well as those being assessed (Furtak & Ruiz-Primo, 2008). However, it is useful to provide students the scaffolding at the beginning of their experience with peer-assessment (e.g. Brookhart, 2008; Hattie & Timperley, 2007) because it could help them to pay attention to crucial aspects of their peers' teaching. As it is mentioned by some authors (e.g. Cho & MacArthur, 2011; Meusen-Beekman, Josten-ten Brinke & Boshuizen, 2015) it is possible to improve assessing skills of students if we present them the assessing criteria. It is beneficial to illustrate selected criteria with specific examples (Cho & MacArthur, 2011).

STUDY OBJECTIVE

The main aim was to consider if pre-service teachers are able to recognize important aspects in teaching process performed by their peers and provide them with supportive feedback. We were inspired by research of Ropohl and Rönnebeck (2017), therefore we measured the quality of written feedback provided by pre-service teachers. Three research questions were defined for this purpose: RQ1) Are pre-service teachers able to advice their peers on what steps they need to take to better reach the instructional goal?; RQ2) Do pre-service teachers write justification of their assessment?; RQ3) Are students able to identify the instructional goal?

METHODOLOGY

Sample

In total 29 students from biology MSc degree in teaching were involved in this study – 18 pre-service biology teachers for lower-secondary level schools and 11 pre-service teachers for upper-secondary level schools. All students were studying at the Department of Biology at Faculty of Education, University of South Bohemia in Ceske Budejovice. We worked with 133 assessing forms (80 from pre-service biology teachers for lower-secondary level schools and 53 from pre-service teachers for upper-secondary level schools).

Assessing forms

The assessment form was focused on five dimensions related to conducting a lecture during teaching practice placement. Students commented on performance of a student giving a lesson, specifically in the field of a) preparation of the lesson, b) realization of the lesson, c) didactical transformation of biological topics, d) communication with students and e) organization of particular activities. The assessors had statements available (in total 25, examples are presented in Tab. I) related to each dimension and were to select the level of their agreement or disagreement on the Likert scale 0 – 4 (1 – totally agree; 2 – rather agree; 3 – rather disagree; 4 – totally disagree; 0 – not applicable). The assessing students also had some space for own comments on each dimension to express the strengths and weaknesses of their peer's performance. At the end of the assessment form students were asked to justify their assessment and provide a summarizing feedback for the assessed.

Table 1. The examples of selected statements in the assessing form

Dimension	**Example of statement** **Teaching student…**
I. Preparation	… had well-arranged time schedule for all activities. … prepared clear presentation and/or wrote clear notes on the board.
II. Realization	… explained the instructional goal of the lesson. … used various teaching methods and forms. … fulfilled the selected instructional goal.
III. Didactical transformation	… did not commit mistakes in his or her lesson. … managed to introduce students the curriculum clearly and adequately to their age.
IV. Communication	… spoke lively and adequately loudly. … listened to students and gave them enough space for their opinions and answers. … provided feedback to students.
V. Organization	… managed to keep discipline in the class and responded to disturbing behaviour adequately. … responded to situation in the class and current needs and possibilities.

Data collection and analysis

Students filled the assessment forms on PC after the peer's lesson so they had time to focus on his or her performance. They had five days to submit the form by mail to the placement tutor who summarized all assessments and sent an anonymous summary to the teaching student. Particular assessments were coded using open codes and similar codes were summarized into clusters. The code frequency was then observed. All forms were coded by two coders and the discrepancy level was then considered.

RESULTS

The presented findings were obtained from 29 respondents and there were 133 assessment forms analysed so we do not want to generalize our results.

In relation to RQ1 (*Are pre-service teachers able to advice their peers on what steps they need to take to better reach the instructional goal?*) we found out that future teachers still have problems with providing supportive formative feedback. Their comments often consisted of the observed lesson description. Sometimes they avoided to write comments and assessed the performance using a scale only. We are not able to say whether this reason was caused by their incompetence or laziness – this should be clarified in follow-up interviews with students. On the other hand, they tried to provide advice for their peers in summary of their assessment (in more than 40 % of all cases). We found formative aspects in these commentaries with specific advices on future steps in their next lessons. The level of formative comments in the provided feedback is shown in Figure 1.

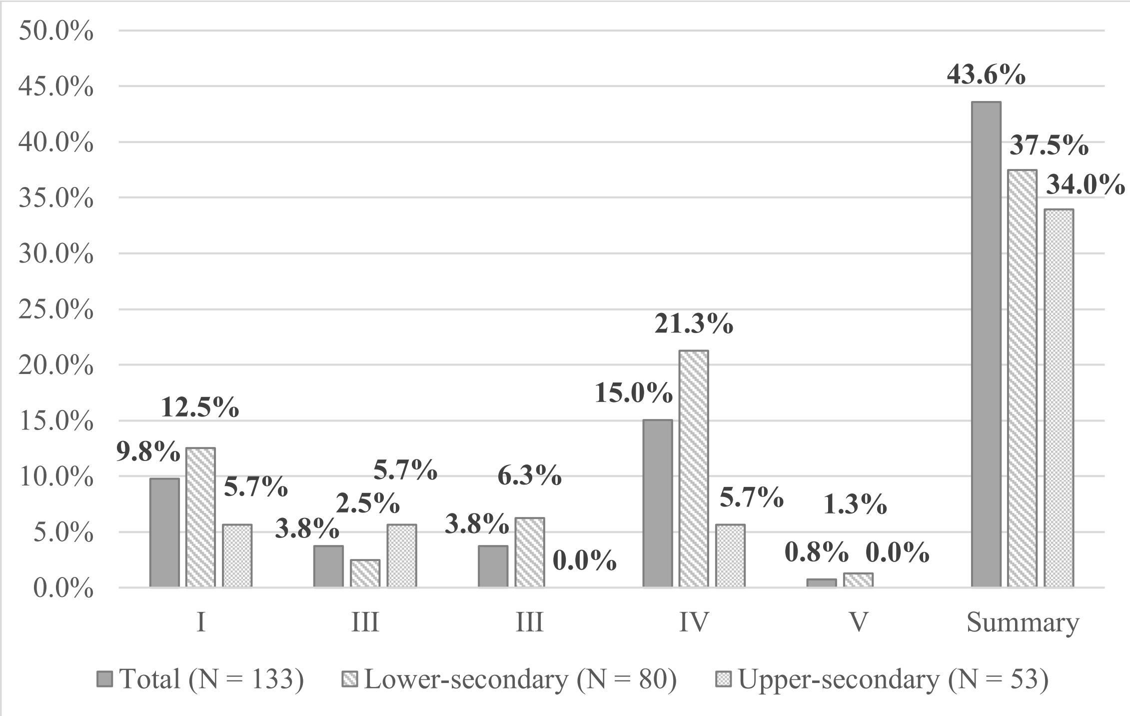

Figure 1. The level of formative comments in the provided feedback.
Legend: Selected dimensions to assess: I – Preparation; II – Realization; III – Didactical transformation; IV – Communication; V – Organization

It is possible to see that the level of formative comments was low. The highest level of these comments was found in the summary at the end of assessing form. It is not surprising conclusion because students are very often used to sum their decisions and overall assessment up. Communication had most frequent formative comments from all dimensions but it was still very low percentage (only 15.0 %). The lowest level of these comments was found in relation to organization dimension but this was often caused by the fact that there were no problems in the classroom and students organized their teaching well so there was no need to provide any comments.

We add some illustrative examples of supportive feedback found in the assessing forms:

- *„I think you should better plan the activity in the way of introducing the steps to students. The order of steps was not clear. If you explain every step and its outcome at the beginning, students will be able to work alone and they will not have so many clarification questions."*

On the other hand, there were also found comments with non-supportive or vague feedback:

- *„It was OK, I like it."*
- *„Some steps were not clear."*

RQ2 (*Do pre-service teachers write justification of their assessment?*) clarified that students tried to attach justification to their assessments. As it was mentioned in the previous paragraph the level of justifications with the formative feedback was quite low. Students often described the lesson and added some assessing phrase to it. A positive finding is the fact that assessors did not focus on mistakes only but tried to praise their peers for their success in practical activities (approx. half of the forms contained praise on the assessed). The assessors also did not reflect any personal relationships into the feedback. If there was found emotional comment it was positive in all cases (e.g. *"I really like your way of teaching"* or *"I would like to be a good in questioning students as you are. Your performance was great!"*). If we compare the level of adequate comments in the feedback provided by future teachers for lower-secondary and upper-secondary level (Fig. 2), there was found no significant difference with exception of two dimensions (Realization and Organization). The lower level of adequate comments was found at the group of future teachers for upper-secondary level. This fact corresponds with the level of non-providing feedback (see Fig. 3).

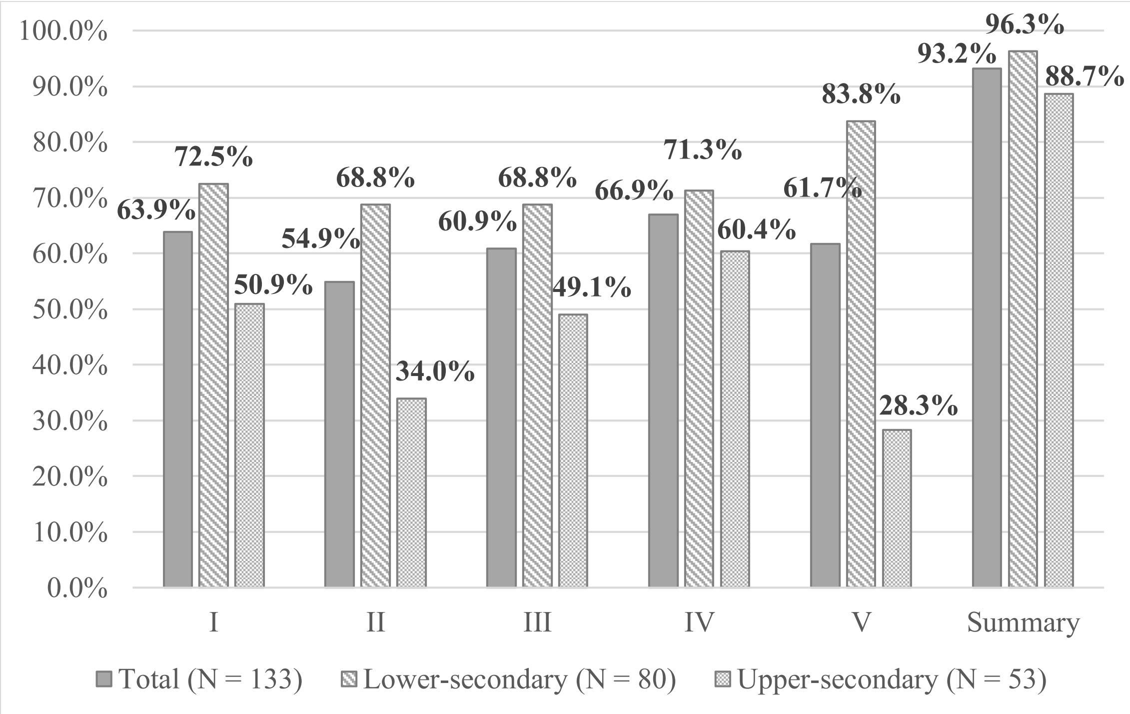

Figure 2. The level of adequate comments in the provided feedback.
Legend: Selected dimensions to assess: I – Preparation; II – Realization; III – Didactical transformation; IV – Communication; V – Organization

The second perspective related to this research question was level of feedback without provided comments. We found that future teachers for upper-secondary level avoided the providing of comments more often that future teachers for lower-secondary level (Fig. 3). The obvious difference was found in the dimension related to Organization of the classes. It was possible to see that assessors skipped these fields in the form and use only the scales and then provide the final commentaries at the end of the assessing form. If we look into the graph it is positive that the final commentaries were provided in almost all cases. However, this still reflects the tradition in the Czech educational system where the teachers are focused mainly on the outcomes and provide the final summative feedback.

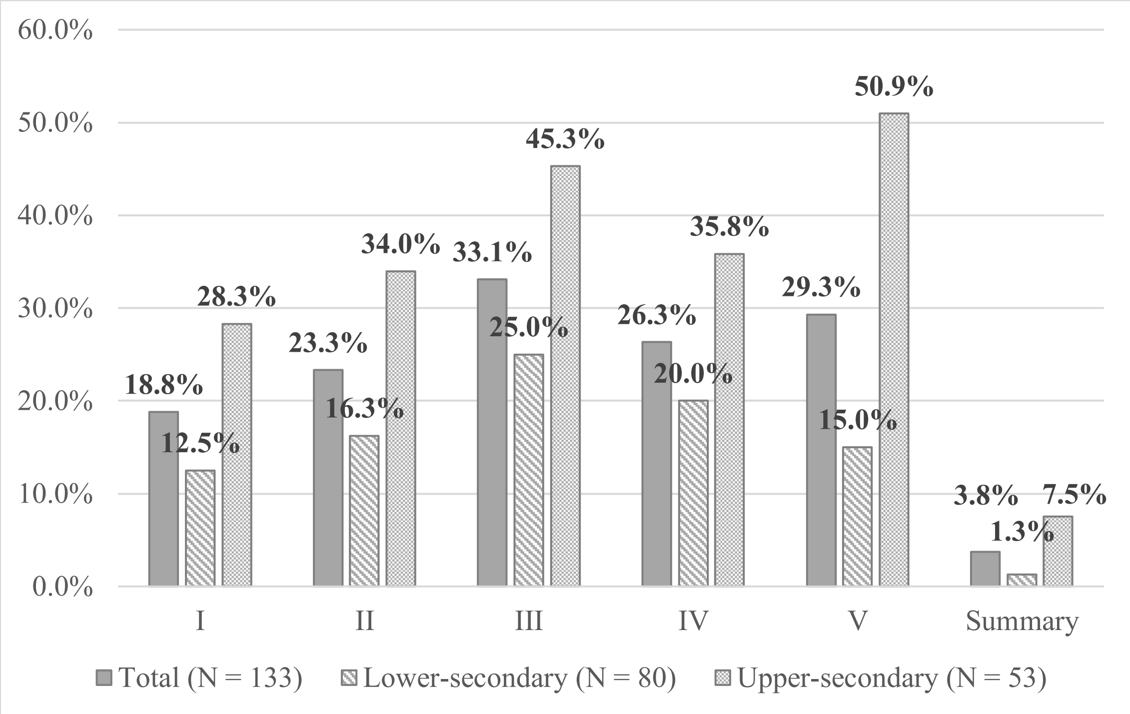

Figure 3. The level of feedback without provided comment.
Legend: Selected dimensions to assess: I – Preparation; II – Realization; III – Didactical transformation; IV – Communication; V – Organization

RQ3 (*Are pre-service teachers able to identify the instructional goal?*) was focused on the level of instructional goal identification. The reorganization of instructional goal was found to be a very significant problem for students (Fig. 4). Only in 27.8 % of all forms the instructional goal was recognized correctly (according to the definition by Prucha, Walterova and Mares, 2013 – commonly used in the Czech educational system). Students often mistook instructional goal for the lesson topic (26.3 %) or they aimed the goal at the teacher instead of pupils (33.1 %). It is necessary to add that in almost all observed lessons the teaching student did not mention and explained the goal to pupils, therefore this field could be said as very problematic for both, teaching students as well as observing students. The higher level of aiming the goal at the teacher was found at future teachers for upper-secondary school. In this case this situation could be caused by lower experience with pedagogical and psychological subjects at general (future teachers for lower-secondary level have these subjects during their bachelor studies). The assessor also mentioned in limited number of cases that the teaching students had not mentioned the goal so the assessor is not able to recognize it.

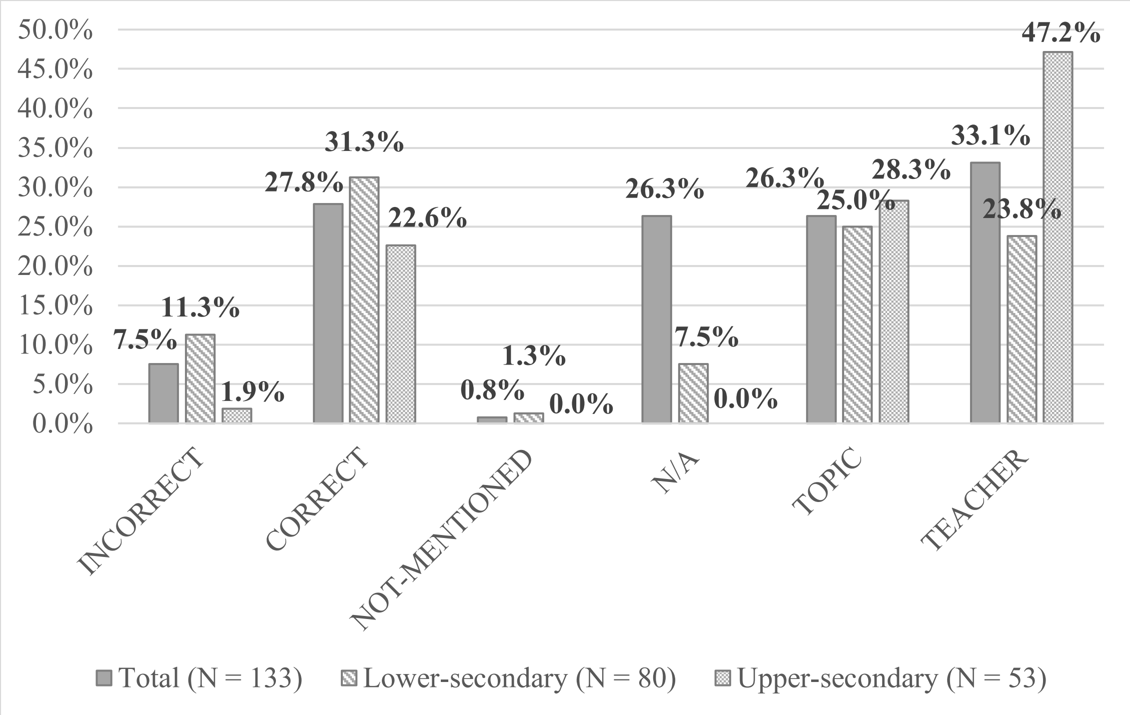

Figure 4. Ability to recognize the instructional goal of the lesson.
Legend: N/A (not available – nothing written in the assessing form); TOPIC – educational goal mistook for topic of the lesson; TEACHER – educational goal oriented on teacher performance instead of students

CONCLUSION AND IMPLEMENTATIONS

Our study showed that peer-assessment is a sufficient form of reflection in pre-service teacher practice placement. It is obvious that students need more experience with this approach to be able to provide supportive feedback with attributes of formative assessment. Students provided supportive feedback mainly in final summaries of their assessments however, lack of relevant justification was found in most of their comments. In addition, a problem with identification of instructional goal was found, the goal was mentioned only in one fifth of the forms. Pre-service teachers often mistook the instructional goal with the lesson topic or they addressed the goal to the teacher instead of the students.

Of course, we know about some limits of this study. At first, the sample is not really representative so the plan is to repeat this study with more students and mainly with the students from different faculties and universities. This time the comparative study is prepared in cooperation with the Department of Chemistry at Charles University in Prague. This also will test the validity of the measurement tools, which were set by our research team. More departments at University of South Bohemia in Ceske Budejovice will be involved in the reflective teachers' training so we are expecting more data from the assessing forms as well as from different fields in the relation to various studying programmes. The need for improving the quality of teachers' training as well as detailed introduction of formative assessment to future teachers are crucial aspects of new accreditation for teaching programmes in the Czech Republic. As it was found in this study, the future teachers need more training to provide appropriate formative feedback so this is a signal for innovations in teachers' preparation and strengthen the position of formative assessment in general as well as branch didactics during the teachers' training at faculties.

THE USE OF A MIXED METHODOLOGICAL APPROACH TO ANALYSE THE SPECIFIC CODING ORIENTATION

Larissa Nascimento[1], Rafael Castro[2] and Marcelo Motokane[2]
[1]Interdepartamental Graduate Program in Science Teaching, São Paulo, Brazil,
[2]University of São Paulo, Ribeirão Preto, Brazil

The aim of this study is to describe the use of a mixed methodological approach to analyse the concept of formative evaluation. Thus, we did a pilot test with the application of questionnaires followed by statistical validation. The clarification of the research question occurred through the triangulation of qualitative and quantitative methods, each one appropriate to a certain part of the process. The formulation of the questionnaire was a qualitative part and its statistical analysis was part of a quantitative stage. The analysis of the data and its context characterise the case study in which the participants are studied in their real context from multiple sources of evidence, proper when the context is complex and has a large set of variables. We defined the parameters and criteria for the formulation of the questionnaire using specific bibliography. The questionnaire was analysed and validated internally by factor analysis and externally by members of a research group focused on science education. Therefore, it was possible to make explicit the evaluation conceptions of the respondents by the specific coding orientation. In this work, we can see the principles of maintenance of the social relations that permeate the classroom. We can also see the potential of going the opposite way to building a more equitable society through the practice of teachers.

Keywords: Formative assessment, Statistics, Equity

INTRODUCTION

School tends to reproduce the excluding social relations present in our society in its dynamic and space. It includes the evaluative practice, that tend to exclude and silence students, cultures and processes of knowledge construction, devaluing different types of knowledge and giving strength to the dominant culture. Besides that, assessment is an essential and central feature of teaching (Black & Wiliam, 2006) and the formative assessment is an alternative way. This type of evaluation contributes to teaching-learning process and it is essential for the democratization because it can improve student's learning and autonomy. The teacher is a social agent directly involved in educational process, including in the evaluative context and, as such, their formation strongly influences the actions in classroom (Nascimento, 2018). The absence of this issue and its discussion in formation courses leads to the acceptance and of the exclusion of students as a natural thing. A traditional assessment comes from the conception of knowledge as fixed and unchangeable. This, allied to a reproductive teacher formation leads to a practice where the search for social transformation is absent. In this pedagogy, teaching consists in the transmission of knowledge from teacher to student and the knowledge is evaluated with a method considered safe and precise. Instead, we defend that the pedagogical practice must be based on a dialectical conception of knowledge, focusing on the process of knowledge construction and not just the results.

Saying that, learning must be in a permanent and continuous assessment, and the education that aims student's development must be based on cooperation between teachers and students. One of the basic characteristics of formative evaluation is its articulation with the teaching-learning process. It can provide deep learning of the contents and elevate the understanding of students' own reality (Crooks, 1988). This kind of teaching is democratic and enable a process of emancipation (Deutsch, 1979). Thereunto, the teacher must share the responsibility with the students, guarantee an efficient and constant model of feedback and be clear about evaluation established criteria. This kind of practice can result in an interfering posture of the individual in his context, likewise in the scientific literacy (DeBoer, 2000), which places the student in the centre of the educational process. Scientific literacy (SL) is one of the aims of science education, seeking to insert students in the scientific culture by providing meaning in the scientific language based in the student's previous knowledge (Lorenzetti & Delizoicov, 2001; Cobern & Aikenhead, 1997). It also helps students to develop the capacity of organising thought in a logical way, helping the construction of a critical view above the world (Hurd, 1997). The results of science – even provisional - must be understandable by students, at least at the level of scientific literacy (Chassot, 2000). In that way, science should be treated as a human activity, subject to influences of all kinds, unlike the often publicized image of science as a neutral and disinterested practice performed by exotic or genius beings.

The practiced evaluation has many characteristics that keep the maintenance of the social hierarchy and the teachers are still reproducing the principles of power in the society with low inclusive actions. Behind those actions it is possible to see the code, it regulates the relations between the contexts and generates principles that guide actions and text production adequate to each context. The specific coding orientation (SCO) is the evidence of the code in a subject level, defined in function of the values acquired in social groups which they are part (social class, graduation, participation in others groups). It defines the transmission mode, acquisition or practice in a determinate context (Bernstein, 1990).

So it is important to analyse if pre-service teachers have democratic and formative views about the evaluation in science classes. Also if pre-service teacher's practices are categorically related with their didactic proposals, especially in assessments. In order to ensure the dissemination of the proper characteristics of the scientific doing in favor of the formation of conscious and critical citizens. Thus, the objective of this research was to investigate the SCO of respondents in order to elucidate the re-contextualization of the code of our interest: formative evaluation and evaluation tools.

METHODS

Morais & Neves (2007) says that the internal validly of research depends on the methodology path, which must be solid between the research objectives and the data collection. Then, we formulated a questionnaire as a data collection instrument that aimed to see the participants' performance in light of the theoretical framework. It was applied to 25 licentiate undergraduate students, 27 post-graduate students with social sciences (Education) background and 14 post-graduate students without any background in social sciences.

The questionnaire and its qualitative validation

The theoretical framework is fundamental to guarantee internal validity of the methodology, providing conceptual accuracy and explanatory power to the data (Morais & Neves, 2007). Thus, the questionnaire was elaborated using specific bibliography of the area of evaluation and teaching (Black & Wiliam, 1998; 2009; Hadji, 2001; Luckesi, 2011). The questionnaire had two parts. The first had objective assertions about evaluation, some with traditional perspectives and others with a more formative view. The second part was about the efficiency of some evaluation tools used in science and biology classes. The level of agreement with the questions was marked in a 5-point Likert-scale. The questionnaire was validated by a research group in which public school teachers, professor doctors, doctoral, master's and undergraduate students participate. The questions should gather the reasons for a specific behaviour or attitude of the interviewee, showing their level of information on the issue (Flick, 2014). The criteria established for validation were: Are the questions necessary? Are they redundant, ambiguous or opposite? Are they biased? Are they formulated in an appropriate, easy and clear way?

The first questionnaire had 21 initial questions and 15 were approved by the research group. After further work with literature and reformulation of the questions, it returned to the group for another validation. Fourteen questions were approved at the end. In the subsequent validation phase, a pilot test was applied to undergraduate and graduate students, which allowed us to verify difficulties in interpreting the questions, which are important in their final adjustment (Nascimento, 2018; Nascimento, Castro, Motokane, 2019). The successive reformulations of the instruments allow a progressive adjustment, clarifying the relationship between the research objectives and the data to be obtained (Morais & Neves, 2007).

Statistical validation and analysis

Statistical validation of the questionnaires consisted of factor analysis using the RStudio® software version 1.0.136. This analysis aims to describe a set of original variables through the creation of a smaller number of variables called factors. Those factors try to explain the correlation between the variables just as good as the original number of variables (Freire & Motokane, 2016). The suitability of matrix data was verified by the Kaiser-Meyer-Olklin (KMO) and Bartlett tests, linearity and collinearity were tested by Pearson's correlation coefficients. The Scree test was used to extract the number of factors. The factors were retained and rotated by the Varimax orthogonal rotation method. In this way, the data treatment allowed us to interpret the results in the light of the theoretical framework on formative evaluation and its sociological perspective. Such interpretations were conducted in a consistent manner with the theoretical aspects of the investigation, allowing the reliability of the methodology. The comparison between data obtained from several sources (triangulation) provides internal validity to it (Morais & Neves, 2007).

RESULTS

Tables 1 and 2 presents the questions and the factor loading of each: table 1 for the questionnaire about formative evaluation and table 2 for the one about evaluation tools. The loadings indicate which variables (questions) are most related to each other. The symbol "-" represents that the loading in that question were less than 0.10.

Table 1. Questions and the factor loading of the factor solution in the questionnaire 01 about formative evaluation.

Factor loading – Questionnaire 01: Formative evaluation

Question	Factor 1
The evaluation criteria should be restricted to the teacher's choice	**0.523**
Assessment tools should be used at the end of the didactic sequence	**0.371**
Any intervention of the teacher in the classroom should have clear objectives for his students	**0.399**
The purpose of the assessment is to compare student performance	**0.395**
The student is aware of his grade guarantees the learning	**0.310**
The moments of evaluation must occur during the didactic sequence	**0.647**
The results of the evaluation process bring to the teacher a diagnosis of his own action in the classroom	**0.401**
Using the same assessment tool facilitates the analysis of students' abilities	**0.308**

Table 2. Questions and the factor loading of the factor solution in the questionnaire 02 about evaluation tools used in science classes.

Factor loading – Questionnaire 02: Evaluation tools

Question	Factor 1	Factor 2
Evaluation with essay questions	-	**0.458**
Experimental report	0.480	**0.570**
Field Notebook	0.473	**0.572**
Seminar	0.200	**0.551**
Oral test	-	**0.678**
Practical Test	0.432	**0.658**
Leisure activities (games)	**0.641**	0.171
Participation in theoretical class	**0.731**	**-**
Participation in practical class	**0.822**	**-**
Seeing the notebook	0.207	**0.373**
Classroom Exercises	**0.599**	0.360
Case study	**0.636**	0.294
Fittings	0.392	**0.420**
Debate	**0.764**	0.264
Extra class research	**0.595**	0.347
Assessment	**0.503**	0.362
Portfolio	**0.633**	0.398

A total of 66 answers were obtained. In the first questionnaire, statistical tests of correlation showed that 32.1% of the number of bivariate correlations was significant ($p<0.05$), so the linearity was proper to factor analysis. All the correlations were inferior to 0.9 in the multicollinearity presuppose. The values in the KMO test was superior to 0.5, and in the Bartlett test, the questionnaire had statistical significant value ($p<2.2e-16$), reinforcing the suitability of the patterns of correlation. In the second questionnaire, 50% of the number of bivariate correlations was significant, all the correlations were inferior to 0.9 in the multicollinearity presuppose. The values in the KMO test was superior to 0.5, but in the Bartlett test, the questionnaire had no statistical significant value ($p>0.1297$). This shows that there is a gradient of tacit knowledge regarding evaluation instruments in Science and Biology classes among the respondents, it overlaps in a way that the difference between them is not significant.

DISCUSSION AND CONCLUSION

The factor analysis of the first questionnaire results in only one factor associated with evaluation in a broad way. It showed that all the questions were related, so the participants tend or to agree or to disagree with all questions. Thus, we can see the evaluation conception of respondents as a spectrum of answers going from more formative to less formative. In the further analysis with cluster script, we should see a gradient of respondents' SCO, from the highest to the lowest recognition.

In the second questionnaire, we obtained two factors that group related questions. In the first factor, we see the measure of different abilities in the students such as writing, resume, reflection, reason, research, communication, and others. Those kinds of evaluation are closer with a formative form, giving students more autonomy to think, reflect and answer. It can also give to the teacher a better opportunity to achieve student's learning construction. The second factor is measuring the same abilities with different tools, it mostly looks on to students' production in order to retake what was spoked by the teacher. This kind of tools gives less autonomy to the student, reinforcing a heteronomy thought. Black & Wiliam (1998) found that most assessments have this characteristic: little focus on outcomes such speculation and critical reflection and more focus on student getting through tasks. This kind of evaluation tent to compare the students and create a large gap between the ones that could achieve the teacher objective and the ones that could not. However, the type of tool is not what makes difference in formative evaluation. The assessments must give feedback about learning instead of ranking in a traditional summative test. When the teacher is committed with student's cognitive and intellectual development the evaluative practice takes a formative dimension, which can help in the formation of class consciousness and emancipation of the student.

In order to answer the questionnaires with a formative form, the participant needed to recognize the micro context of formative evaluation in the questionnaires and knew how to position themselves, evidencing the SCO for this topic. Probably the contact with the social sciences and its discussions influence the SCO of the participants, but often this is not enough for a change. They also need to identify themselves with the theories and internalize it through socio-affective ties.

Bernstein's research (1996) highlights mechanisms that can lead to situations of potential social and cultural transformation. Teachers that have knowledge about the formative assessment and intent to use it to help student's learning has a transformative potential. So we stress the importance of pre-service and in-service teachers to have formative practices that allows their students to appropriate different codes of different social groups. The teacher's practice should be characterized by a formative process, committed with the development of students, helping them to reach different and privileged knowledge.

We concluded that the applied questionnaire and the statistical validation of the data contributed to the elucidate the evaluation conception of the participants. In further analysis, we will apply the data in a cluster separation script to evidence the scores of each group of respondents. Basil Bernstein's theory helps us to explain the hierarchical maintenance mechanism of social relations, and with this kind of analysis, we can see the transforming potential of visions and educational practices with a formative perspective. The appropriation of that code allows us to behold a scenario where teachers are committed to student development and to democracy, helping overcome social inequalities.

ACKNOWLEDGEMENT

We thank CAPES for financing the project, the Interdepartamental Graduate Program in Science Teaching of Physics Institute of University of São Paulo. We also thank colleagues from the LINCE research group for their help and support in this work. A special thanks Rafael Gil de Castro who assisted this research, and teacher Marcelo Tadeu Motokane for his patience, direction and attention.

INQUIRY COMPETENCES OF JUNIOR AND SENIOR CLASS BIOLOGY STUDENTS

Iris Schiffl[1]
[1]University of Salzburg, Salzburg, Austria

Inquiry, as a fundamental part of science education, can be found in all international science standards. In the development process of Austrian science standards, competency levels based on Austrian science competency models were developed. The aim of the presented study is to provide data about inquiry competences of 8th, 10th and 12th grade students in Austria, as no data about senior class students' inquiry competences (e.g. 10th and 12th grade) exists for German speaking countries so far. Therefore, competency levels defined by Austrian science standards were used to develop questionnaires for inquiry competences. These questionnaires examine levels of inquiry competences based on eight fundamental biological topics (e.g. cells, animals, plants and ecology) and were given to 558 students. Summing up the results, inquiry competences of Austrian students in junior and senior classes are situated on a basic level, with most students reaching level 1 or 2 (out of 4 for all examined inquiry competences (asking research questions, disposing hypotheses, planning an experiment and analyzing data)). Although inquiry competences increase from 8th to 12th grade, the results indicate a lack of inquiry competences, especially concerning the use of basic terminology of inquiry and the connection between inquiry and biological knowledge – even for 12th grade students.

Keywords: science standards, inquiry competences, competence levels

THEORETICAL BACKGROUND

Inquiry-based teaching has become a fundamental part of modern science education (Anderson, 2002). Although it is not conceptualized consistently, inquiry based teaching approaches normally involve at least two of the following core elements (Cairns, 2019):

- knowledge about the nature of science and the processes of generating scientific knowledge
- science investigation skills for generating and manipulating data
- simulation of the inquiry process in classroom

For simulating the inquiry process in classroom specific phases of inquiry are used frequently forming an inquiry circle (figure 1).

Inquiry-based teaching is associated with a broad range of benefits for students' understanding of science and scientists' work as it "gives students a better ownership of their learning and allows them to actively navigate the routes of increased understanding, greater motivation, improved attitudes to scientific endeavor and growth in their self-esteem and their ability to handle new data in an increasingly complex world" (Bevins & Price, 2016, p. 19). If it comes to students' achievement, empirical evidence supporting the benefits of inquiry based learning approaches is not that clear. On the one hand, studies which compare the effectiveness of inquiry-based teaching approaches to traditional teaching support the superiority of inquiry-based teaching (Alfieri, Brooks, Aldrich & Tenenbaum, 2011; Minner, Levy & Century, 2010; Schroeder et al., 2007). On the other hand empirical evidence from international large scale assessments revealed a negative relationship between inquiry-based teaching and students' achievement (Cairns & Areepattamannil, 2017). Bringing together these conflicting results, studies proved a curvilinear relationship between inquiry-based teaching and students' achievement, with an increased use of inquiry-based teaching until it reaches an optimum and reduced achievements if inquiry was used more often than that (Cairns, 2019; Teig, Scherer & Nilsen, 2018).

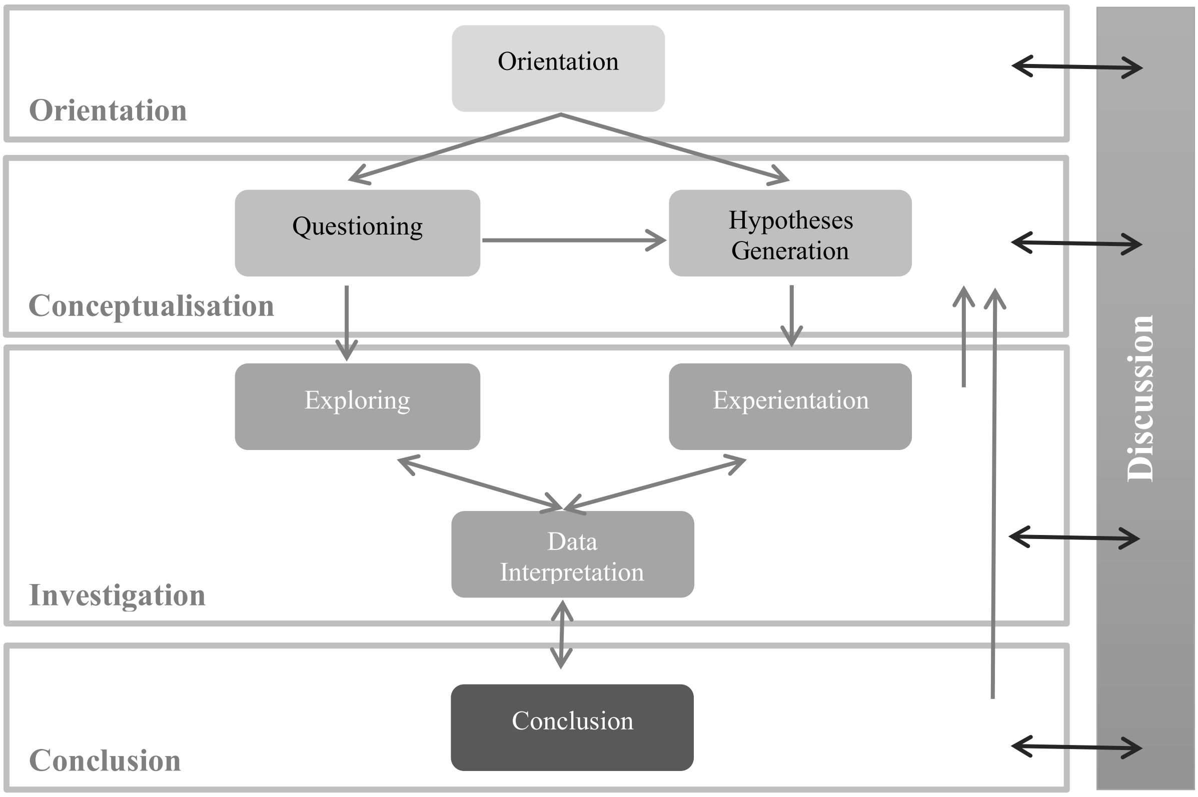

Figure 1. Inquiry based learning phases (Pedaste et al. 2015, p. 56).

International large scale assessments (PISA, TIMSS) emphasize the importance of inquiry competences for science teaching and learning science as well as national science standards (Centurino & Jones, 2017; Department for Science Education, 2014; KMK, 2004; National Research Council, 2012; OECD, 2019a; Singapore Ministry of Education, 2014; Education Bureau Hong Kong, 2016). A common way of integrating inquiry in science standards is by splitting up inquiry in competences which represent the different phases of inquiry (figure 1; BIFIE, 2011; Bybee, 2011; Centurino & Jones, 2017; KMK, 2004).

In Austria, inquiry is one of three subscales of the national science standards. It contains four inquiry competences: (1) asking research questions and deposing hypotheses, (2) planning and performing experiments, (3) writing experimental records and (4) analyzing and interpreting data (BIFIE, 2011). For each inquiry competence, competency levels were specified statistically using RASCH-analysis (table 1; Schiffl, 2016), but as no standardized testing takes place in Austria, students' inquiry competences only have been measured in international studies like PISA, so far.

Table 1. Competency levels for selected inquiry competences of the Austrian competence model for science (Schiffl, 2016).

competence	asking research questions	disposing hypotheses	planning an experiment	analyzing data
level 1	choosing research questions	choosing hypotheses	choosing a correct plan for an experiment	choosing conclusions
level 2	phrasing research questions	phrasing hypotheses	phrasing an experimental plan	phrasing conclusions
level 3	identifying dependent and independent variables	justifying hypotheses	include repeated measures **or** confounding variables	justifying conclusions
level 4	phrasing questions based on a biological concept	phrasing alternate hypotheses	include repeated measures **and** confounding variables	drawing conclusions from statistical data

In PISA 2015, Austrian students reached below OECD-average performance scores in evaluating and designing scientific research, whereas the results of the subscale "interpret data and evidence statistically" was average and the subscale "explain phenomena scientifically" was above average (OECD, 2016). On the whole scientific competences were declining from PISA 2006 to PISA 2018 (OECD, 2019b). The same pattern of competence distribution can be found for German students, who also scored better in knowledge-related tasks than in inquiry tasks (OECD, 2016, Pant et al., 2013). But as international student assessments like PISA or TIMSS and German's national science standards assessments focus on students in 8th and 9th grade, no data is available for inquiry competences of senior class students.

RESEARCH QUESTIONS

The present study addresses the following questions:

- What competence levels (with reference to Austrian science standards, see table 1) do 8th grade, 10th grade and 12th grade students possess when it comes to inquiry competences?
- Are the inquiry skills of 12th grade students more developed than those of 8th grade and 10th grade students?

In PISA 2015, 73 % of the students scored at competence level three and below (OECD, 2016). Therefore we expect to find mostly basic competence levels (level 1 or 2) for 8th grade students. For senior class students, no empirical data is available, but as inquiry is a major part of the Austrian science curriculum for senior classes, we expect an increase in inquiry competence from 8th to 12th grade (BGBl. II 219/2016).

METHODS

558 students from 8th, 10th and 12th grade of Austrian junior and senior high schools participated in the study. They were given a questionnaire for inquiry competences that had to be answered in 50 minutes time (one school lesson). Eight different biological topics (e.g. cells, animals, plants and brain) were used to create these questionnaires. Each questionnaire contained the following competences: asking research questions, disposing hypotheses, planning an experiment and analyzing data from experiments. Levels of competences were rated afterwards from the students' answers. The interrater-reliability (computed using Cohens Kappa), therefore, is satisfying and reaches from .87 for asking research questions to .94 for planning experiments. Data was computed using SPSS 22.0.

RESULTS

When asked to formulate a research questions, about 90 % of the students were able to choose a correct research question for a given experiment (level 1), about 70 % were able to phrase a research question on their own (level 2) and only a third of the students could name dependent and independent variables (level 3). Almost no students were able to phrase correct research questions based on biological concepts (level 4). Students from the three different grades differ in all four competency levels (level 1: $\chi^2 = 17{,}77$; $p \leq .001$; level 2: $\chi^2 = 94{,}71$; $p \leq .001$; level 3: $\chi^2 = 77{,}03$; $p \leq .001$; level 4: $\chi^2 = 65{,}66$; $p \leq .001$) with more students from higher grades reaching each level (each student can reach more than one level, if he/she meets the criterion of the level; figure 2). Concerning the highest reached student level, the median for 8th grade students is 1,00, for 10th grade students it is 2,00 and for 12th grade students it is 3,00.

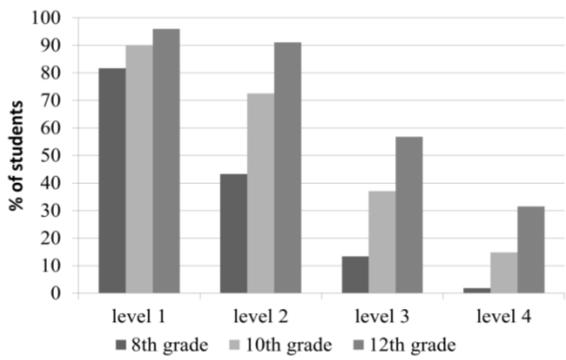

Figure 2. Percent of students on each competence level for asking questions

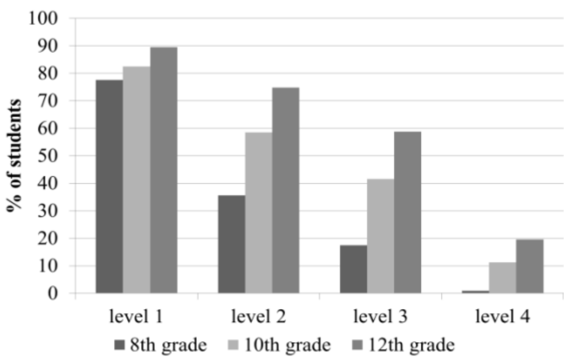

Figure 3. Percent of students on each competence level for disposing hypotheses

In the competence 'disposing hypotheses' 82,3 % of the students over all grades were able to choose a correct hypotheses for a given experiment (level 1). About half of the students phrased a correct hypothesis on their own (level 2) and a third of the students was able to justify their hypothesis in a scientific manner (level 3). Less than 10 % were able to phrase the alternate hypothesis (level 4). Students from the three different grades differ again in all four levels (level 1: $\chi^2 = 8{,}25$; $p \leq .05$; level 2: $\chi^2 = 55{,}47$; $p \leq .001$; level 3: $\chi^2 = 66{,}25$; $p \leq .001$; level 4: $\chi^2 =$

32,67; $p \leq .001$) with more students from higher grades reaching each level (figure 3). If only the highest level a student reached is taken into account, the median for 8th grade is 1,00, for 10th grade is 2,00 and for 12th grade is 3,00.

About 85 % of the students were able to choose a correct experimental plan (level 1), but only half of the students were able to create one on their own (level 2). About a quarter of the students considered confounding variables or repeated measures (level 3) and only five percent considered both (level 4). Students from the three different grades once more in all four levels (level 1: $\chi^2 = 51,27$; $p \leq .001$; level 2: $\chi^2 = 63,46$; $p \leq .001$; level 3: $\chi^2 = 53,72$; $p \leq .001$; level 4: $\chi^2 = 23,33$; $p \leq .001$), with more students from higher grades reaching the levels (figure 4). If the highest level a student reached is concerned, the median for 8th grade is 1,00, for 10th grade and 12th grade it is 2,00.

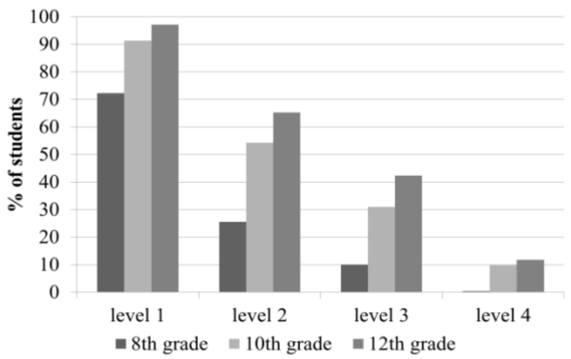

Figure 4. Percent of students on each competence level for planning an experiment

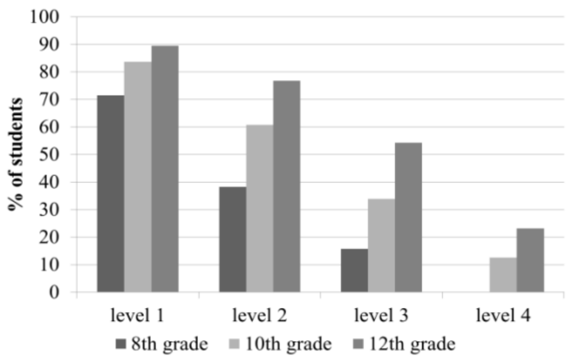

Figure 5. Percent of students on each competence level for analysing data

As far as analyzing data from experiments is concerned, 80 % of the students chose correct conclusions from the given data (level 1) and about half of the students phrased their own conclusions (level 2). 30 % were able to justify their conclusions in a scientific manner (level 3) and about 10 % were able to analyze statistical data correctly (mean and deviation – level 4). Finally, students of the three grades differ in all four levels (level 1: $\chi^2 = 19,28$; $p \leq .001$; level 2: $\chi^2 = 53,48$; $p \leq .001$; level 3: $\chi^2 = 58,06$; $p \leq .001$; level 4: $\chi^2 = 51,38$; $p \leq .001$) with more students from higher grades reaching the levels (figure 5).
If only the highest level a student reached is taken into account, the median for 8th and 10th grade is 1, for 12th grade it is 3.

DISCUSSION AND CONCLUSIONS

Consistent with PISA, Austrian students from 8th grade showed limited inquiry skills in the present study (OECD, 2016; OECD, 2019b). About 70 % of 8th graders reached level 1 on all four inquiry competences which were addressed in this study, about a third reached level 2, 10 to 15 % level 3 and almost no students reached level 4. On level 1, students in this study had to identify appropriate questions, hypotheses, experimental plans or data analysis so it can be compared to maximum level 2 from the PISA levels of proficiency (OECD, 2018). In PISA

2015, 46 % of Austrian students reached this level of competence (OECD, 2016). In Germany´s standard testing, students reach minimal standards, if they are able to phrase research questions or hypotheses, complete experimental plans or choose correct conclusions (Mayer, Wellnitz, Klebba & Kampa, 2019). About one third of the students from 9th grade reached minimal standards as far as inquiry competences in biology are concerned (Weirich, Becker & Holtmann, 2019). These results are consistent with the present study, where 42 % of the students from 8th grade were able to phrase a research question and 35 % of the same students were able to dispose hypotheses.

In the present study inquiry competences increased in high school, but fell short of expectations. Even in 12th grade only about 20 % of the students reached the highest competency level. Students in high school classes showed problems in using biological concepts for asking questions and were not familiar with common concepts of inquiry. As no data for senior classes from German speaking countries is available, US data is used for comparison, because in PISA Austrian and US students virtually reach the same science scores. Data from the United States National Assessment of Education Progress (NAEP) indicate that in 12th grade only about 60 % of the students reach basic or above levels of achievement as far as inquiry is concerned (NAEP, 2015). Although**,** the presented study shows that competency levels have increased from 8th grade to 12th grade, Austrian students at the end of high school showed comparable levels of competence with only 70% percent of students in their last year before university being able to phrase hypotheses and only 60 % being able to plan experiments. When biological background knowledge is necessary**,** the performance is even worse. The inquiry specific terminology (dependent/independent variable, alternate hypotheses and deviation) appears to be unknown to many students (Baur, 2018; Hammann et al., 2008).

Taking into account that even students from 12th grade, who should be able to attend university afterwards, do not possess solid inquiry competences, teaching these competences in school should be given higher priority. With respect to the findings of this study, science teaching should especially contain three aspects of inquiry: building up basic knowledge about inquiry (e.g. terminology, procedure, nature of science), doing inquiry and linking inquiry to biological knowledge. Building on these three aspects of inquiry, teaching concepts have to be implemented and evaluated that could be used by science teachers to pay more attention to teaching inquiry.

SCIENCE ACHIEVEMENT AND SCIENCE MOTIVATION OF WALDORF STUDENTS COMPARED TO REGULAR STUDENTS1

Silvia Salchegger[1], Christian Bertsch[2], and Christina Wallner-Paschon[1]

[2]Pädagogische Hochschule, Vienna, Austria

Although inquiry-based science education (IBSE) is a highly valued and recommended instructional approach, its efficacy has been continually challenged. Recently, PISA 2015 results showed that higher levels of IBSE are associated with lower science achievement in almost all participating countries. The present study investigates if students of schools with a strong, curriculum-based emphasis on IBSE (Waldorf schools) show more positive science learning outcomes than regular students. We applied propensity score matching to control for Waldorf students' more advantageous social background using the Austrian PISA 2015 sample (N = 7,007 15-year old students). After propensity score matching, 1107 matched controls were included alongside all 149 Waldorf students. The results show that Waldorf students report higher enjoyment in learning science and more interest in broad science topics than matched controls. On the other hand, they demonstrate lower science achievement.

Keywords: PISA, inquiry-based science education, Waldorf education

CONTEXT AND THEORETICAL FRAMEWORK

Inquiry-based science education (IBSE) has become a highly valued and recommended instructional approach (Artigue, Dillon, Harlen, & Léna, 2012; European Commission, 2007; Flick & Lederman, 2006; National Research Council, 2000, 2012). Despite this emphasis, the efficacy of IBSE, has been continually challenged (Kirschner, Sweller, & Clark, 2006; Mayer, 2004, Steffens, 2007), although recent meta-studies have supported the effectiveness of IBSE (Minner, Levy, & Century, 2010; Furtak, Seidel, Iverson, & Briggs, 2012). However, most of the evidence was collected in experimental or quasi-experimental research settings rather than in daily teaching and learning settings and many of the (quasi-)experimental investigations into the effectiveness of IBSE performed so far have limitations. These limitations concern the varying operationalization of IBSE (e.g., Furtak et al., 2012, Minner et al., 2010), the short time span covered in many (quasi-) experimental studies (e.g. Echevarria, 2003, Cobern et al., 2010), a lack of differentiation between cognitive and attitudinal student outcomes (as in Furtak et al., 2012), and/or very narrow outcome measures (e. g., understanding the concepts of

---

1 Results of this manuscript are the basis of an article that has been submitted to Large-scale Assessments in Education. This article investigates IBSE as possible reason for the special achievement – motivation constellation of Waldorf students found in the present manuscript.

"floating and sinking" as in Hardy, Jonen, Möller, & Stern, 2006). Therefore we lack information about the effects of long-term curriculum-based IBSE on different forms of learning outcomes, especially on general science achievement.

The present study aims to close this research gap by investigating whether students attending a school type with high emphasis on IBSE in the curriculum demonstrate higher science achievement and more positive attitudes towards science than regular students with similar background characteristics. We include attitudinal outcomes (enjoyment of learning science and interest in broad science topics) in our analysis because developing positive science-related attitudes is an important educational goal alongside fostering science achievement (e.g., Osborne, 2003; Schiepe-Tiska, Roczen, Müller, Prenzel, & Osborne, 2016).

The present study is based on PISA 2015 data. The Programme for International Student Assessment (PISA) 2015 asked students about the amount of IBSE in their everyday science instruction. Results showed that the average amount of IBSE differs decisively by country and that students in Austria, Japan, Korea, and Finland report the lowest amount of IBSE across OECD countries (OECD, 2016a, p. 72). Furthermore, PISA revealed that more IBSE was associated with lower science achievement in most countries (Mostafa, Echazarra, & Guillou, 2018; OECD, 2016a). This result led to ongoing discussions in the science education research community (Osborne, Tiberghien, Le Hebel, Dolin, & Millar, 2017; Sjøberg, 2017).

Based on PISA 2015 data this study follows a different research approach in determining the effectiveness of IBSE. We compare learning outcomes of students who attend a school type with a curriculum-based very high amount of IBSE (Waldorf schools) to regular Austrian students, who typically have very limited contact with IBSE (Krainer & Benke, 2009) by propensity score matching. This method is recommended when determining the effect of a treatment (i.e. high amount of IBSE) in observational data (e.g., Rutkowski, 2016; Stuart, 2010). In addition, the present study systematically differentiates between the effects of IBSE on cognitive outcomes (science achievement) and attitudinal outcomes (enjoyment of learning science and interest in broad science topics).

COMPARISON OF SCIENCE-RELATED LEARNING OUTCOMES BETWEEN WALDORF STUDENTS AND REGULAR STUDENTS

Waldorf schools represent a school type with high emphasis on IBSE. Globally available, this private school system follows concepts outlined by Rudolf Steiner (1861–1925). Waldorf science education is characterized by a high emphasis on the observation and inquiry process. The correctness of an answer is evaluated mainly with respect to the available observation and evidence. The teacher does not perform as the sole bearer of expert knowledge, but provides opportunities to inquire, observe, and negotiate ideas. Indeed a very high prevalence of student investigations in science instruction has been reported by Waldorf students in PISA 2006 (Wallner-Paschon, 2009).

Concerning motivational-affective student outcomes, it was shown that Waldorf students report decisively more enjoyment of learning science, more interest in broad science topics, and a higher science self-concept than regular students (Wallner-Paschon, 2018). Concerning cognitive outcomes, it was shown that Waldorf students slightly outperform Austrian regular students in reading and science but they perform slightly below the population mean in mathematic (Wallner-Paschon, 2018). Considering that Waldorf students' socioeconomic status (SES) is decisively higher than regular students' SES, these results indicate underachievement in Waldorf students as their actual achievement is lower than expected by their SES. Studies that control for the higher SES of Waldorf students when comparing achievement outcomes between Waldorf and regular students were missing until now.

The present study investigates whether IBSE affects science-related learning outcomes when it is a general curriculum-based educational approach that is not only applied for a limited time-span and restricted to specific topics (like in [quasi-]experimental studies).

Provided Waldorf students and regular students are matched by relevant covariates (gender, immigration background, parental education, parental occupational status, and cultural possessions at home), we will look at the prevalence of IBSE in Waldorf schools and compare the two groups concerning important science related aspects like science achievement, science enjoyment and broad interest in science topics.

RESEARCH METHODS AND DESIGN

The present sample is based on the Austrian PISA 2015 sample. PISA assesses country-representative samples of 15-year old students. In Austria all 15-year old students from all ten Austrian Waldorf schools were added to the PISA sample, thus achieving a census of 15-year old Waldorf students in Austria. This resulted in a PISA sample of 6,858 regular students and 149 Waldorf students. As measures we used the PISA 2015 Science Proficiency Scale, Interest in Broad Science Topics Scale, Enjoyment of Learning Science Scale and IBSE Scale. The reliability of the PISA scales were very good to excellent in Austria (ρ between .77 and .93; OECD, 2017).

Propensity score matching was used as a pre-processing strategy to control for systematic differences between Waldorf students and regular students on various background characteristics (SES). If subject groups can reasonably be regarded as statistically equivalent on relevant covariates, average differences on the outcomes could plausibly be attributed to the treatment (Rutkowski, 2016). After matching, standardized mean differences of all covariates were below d = 0.1 and therefore far below the criterion of d = 0.25 for acceptable group differences after matching. For the present study this means that, after statistical equivalence in background characteristics is established, average differences on science achievement and science motivation can plausibly be attributed to Waldorf science instruction.

RESULTS AND DISCUSSION

After matching, standardized mean differences of all covariates were below d = 0.1 and therefore far below the criterion of d = 0.25 for acceptable group differences after matching (Stuart, 2010). Altogether, matching was very successful as group differences in background characteristics were close to zero after matching.

As expected, differences in science achievement increased as a result of matching: While the science achievement gap was d = 0.09 in favor for Waldorf students before matching, it was d = -0.32 to the detriment of Waldorf students after matching. The advantages of Waldorf students in terms of interest (d = 0.30) and enjoyment (d = 0.24) however were still remarkable after matching. Moreover, the much higher level of IBSE reported by Waldorf students was still clear after matching (d = 0.89 before matching and d = 0.82 after matching).

Waldorf education is characterized by a high amount of curriculum-based IBSE, and indeed a very high amount of IBSE was reported by Waldorf students in the present study. Therefore, Waldorf students are an ideal population for revealing the effects of IBSE. In order to investigate the specifics of Waldorf students in terms of IBSE and learning outcomes, we need to compare them to regular students who have – at least in Austria – very limited contact to IBSE. In the present study, students of the regular PISA sample with similar sociodemographic characteristics as Waldorf students were used as the comparison group.

The present study offers new empirical evidence in two substantial respects: First, it showed that Waldorf students are more interested in science topics and report more enjoyment of learning science than regular students. On the other hand, Waldorf students perform remarkably lower in science than expected by their sociodemographic background. In further studies we need to investigate if this conflicting attitude-achievement constellation of Waldorf students may be explained by a higher amount of IBSE in Waldorf education or by general educational principles of Waldorf education rather than in specifics of science instruction (like IBSE). Such general principles may be a lower achievement orientation or a lack of normative achievement feedback (Liebenwein, Barz & Randoll, 2012).

MEASURING STUDENTS' CHEMISTRY COMPETENCES AT THE TRANSITION BETWEEN PRIMARY AND SECONDARY SCHOOL

Alina Behrendt[1], Vanessa Fischer[1] and Maik Walpuski[1]
[1]University of Duisburg-Essen, Essen, Germany

During their learning careers, all students are confronted with transitions between different educational institutions at varying times. Those transitions go hand in hand with general and discipline-specific challenges for students. Referring to chemistry education the transition between different school types is often characterised by the different embedding of chemistry contents in various subjects. In this project subject-specific challenges during the transition from primary school to secondary school in Germany are focused. Aiming at measuring and describing the development of students' chemistry competences at that transition a paper and pencil test referring to content knowledge and procedural knowledge is developed and validated with a sample of 760 students from grade 4 to 8 (at age 9-13). A partial credit model in IRT scaling is used to determine parameters of statistical quality. The results show that the developed paper and pencil test can be used for measuring students' chemistry competences.

Keywords: Primary School, Secondary School, Scientific Competences

INTRODUCTION

An important point in students' learning careers is the transition from primary school to secondary school. At this time students are confronted with different general and also chemistry-specific requirements. The transition often comes along with a change from one integrated subject *science* to separate subjects for all social and natural sciences, which also changes students' perception of chemistry related topics (Möller, 2014). As a result, interruptions in the learning process can arise (Möller, 2010). To find possibilities which ease the transition from primary school to secondary school students' competences are analysed for the transition phase.

In Germany, the transition from primary school to secondary school usually occurs from grade 4 to grade 5 (at age 10). At that time, students leave primary school and start visiting secondary school. Depending on the type of secondary school chemistry contents are either taught in a separate subject *chemistry* or in an integrative subject *natural sciences* (Möller, 2014). *Chemistry* as a separate subject is commonly taught from grade 7 onwards or later (MSW NRW, 2013). Thus, there is a transition phase of two years or longer between *science* in primary school and *chemistry* in secondary school. During that transition phase chemistry contents are either taught in the subject *natural sciences* or not taught at all.

THEORETICAL BACKGROUND

In the context of cumulative learning in chemistry education new contents have to be integrated into students' existing knowledge (Fischer et al., 2007). One example of connecting chemistry contents and creating a cumulative learning process are the learning progressions for the first and second learning year in chemistry education in secondary school developed by Celik and Walpuski (2019). Such a cumulative learning process should not only be ensured in secondary school but also during the transition phase from primary school to secondary school. To avoid interruptions or unrelated repetitions in the learning process, competences acquired at primary school must be aligned with the new requirements of secondary school (Hempel, 2010).

In chemistry education the curricula of primary school and secondary school address competences referring to contents such as combustion, states of matter, substance properties, solutions and energy (MSW NRW, 2013; 2008). The competences stated in the curriculum for secondary school are more complex than in the curriculum for primary school while addressing the same contents. Thus, it should be possible to create a cumulative learning process during the transition phase from primary school to secondary school by means of the curricula of both school types. Due to that cumulative learning process, it would be expected that students' competences develop and improve continuously during the transition phase.

Against these expectations the transition from primary school to secondary school does not always seem to be successful regarding science education as shown in different school comparison studies. While TIMSS 2011 reveals that 78 % of German 4th graders (at age 10) achieve an intermediate or high competence level in science (Bos et al., 2012), only 60.3 % of German 9th graders (at age 15) achieve an intermediate or high competence level in science according to the PISA study of 2015 (OECD, 2016). In large scale assessments in Germany there are similar results for German 9th graders in the subject chemistry for content knowledge (intermediate/high competence level: 56,1 %) as well as knowledge acquisition (intermediate/high competence level: 63,3 %) (Stanat et al., 2019). Thus, the transition from primary school to secondary school in chemistry education should be improved.

To help students manage this transition more successfully primary school as well as secondary school have to be involved. Teachers should know the curricula of both school types to support a productive learning process. The aim of primary school should be to impart the necessary basic competences for students to have a successful start in chemistry education in secondary school (Hempel, 2010). In secondary school then those competences should be taken up and enhanced (Hempel, 2010). To optimise the transition from primary school to secondary school in chemistry education further information about the development of students' chemistry competences at this point of their learning careers are necessary.

AIMS AND RESEARCH QUESTIONS

The aim of this project is to assess the development of students' chemistry competences during the transition phase from primary school to secondary school. To achieve that aim, we designed two studies. In the first study, we developed a test instrument to assess the competences of students at the end of primary school and the beginning of secondary school. This study addresses the following research question:

1. To what extend is the developed test instrument objective, reliable and valid for measuring students' chemistry competences?

In a second study we will use the validated test instrument to assess students' chemistry competences and to describe the development of those competences during the transition phase from primary school to secondary school. This study addresses to the following research questions:

2. Which of the expected chemistry competences have students reached at the end of primary school?

3. How do students' chemistry competences develop in grades 5 and 6 in which chemistry contents are either taught in an integrative subject *natural sciences* or are not taught at all?

4. How do students' chemistry competences – depending on the type of science education in grades 5 and 6 – develop in grades 7 or 8 in which chemistry contents are taught in a separate subject *chemistry*?

The following description of methods, design and results focuses on the first of the two studies referring to the developed test instrument.

METHODS AND DESIGN

In a first step, referring to the curricula of both school systems, we identified chemistry competences described in the curriculum of primary school that are relevant for competences also stated in the curriculum of secondary school. Those competences are regarded as important for assessing the development of competences during the transition phase. In a second step, we used the identified competences to develop a paper and pencil test with 48 items. We designed all items as multiple-choice-items with six answer options. For each option the students have to decide whether it is a right or a wrong answer. If they are not sure, they are asked to tick neither of the boxes. Figure 1 shows the item format.

Question		
	✓ right	✗ wrong
Answer 1	☐	☐
Answer 2	☐	☐
Answer 3	☐	☐
Answer 4	☐	☐
Answer 5	☐	☐
Answer 6	☐	☐

Figure 1. Item format

24 items relate to *content knowledge* which is divided into three categories. We developed eight items for each of the key concepts *chemical reactions*, *structure of matter* and *energy*. 24 items relate to *procedural knowledge* which is – according to the German curriculum – divided into the three categories *knowledge acquisition*, *communication* and *evaluation and judgement*. For each of those categories we also developed eight items. To increase validity of the test seven raters assigned all items to the different categories. Due to an only acceptable interrater reliability ($\kappa_{Fleiss} = .78$) we improved some of the items.

After developing and improving the items we prepared the test booklets for the first study. To reduce test load, we compiled three different test booklets comprising 20 items (for younger students) or 32 items (for older students) each and linked them in an incomplete block design. In each test booklet half of the items refer to two of the key concepts of *content knowledge* and half of the items refer to two areas of *procedural knowledge*. Thus, each item appears in two of the three test booklets.

The data collection for the first study was in May 2019. To secure test objectivity trained testing personnel tested the students. We validated all items in grades 4 to 8 (at age 10-14) because we will assess chemistry competences of students in these grades in the second study. To estimate test quality parameters we aimed at a sample of 150 students per grade. Due to the incomplete block design we expected approximately 100 answers per item per grade which is a sufficient sample size for validating the items (Mendoza, Stafford, & Stauffer, 2000). As a consequence, the whole sample for the first study consists of 760 students.

We used IRT scaling to determine parameters of statistical quality. Based on the results of a preceding pilot study we selected a partial credit model to evaluate the test quality. Additionally, we compared a unidimensional model to a two-dimensional model with the dimensions *content knowledge* and *procedural knowledge*. Based on the results we improved the test instrument for the second study.

RESULTS

Comparing the model fit parameters of the unidimensional and two-dimensional partial credit model reveals that the two-dimensional model with the dimensions *content knowledge* and *procedural knowledge* should be preferred (see Table 1).

Table 1. Comparison of unidimensional and multidimensional partial credit model

Model	Deviance	BIC	Chisq	df	p
Unidimensional	59219.78	61136.81	398.0745	2	0
Two-dimensional	58821.71	60752.00	NA	NA	NA

In the two-dimensional model students' competences are estimated better than in the unidimensional model. Thus, the following results refer to the two-dimensional partial credit model.

Table 2 shows the results of IRT scaling for the dimensions *content knowledge* and *procedural knowledge*.

Table 2. Results for dimension 1 (*content knowledge*) and dimension 2 (*procedural knowledge*)

Dimension	EAP-Reliability	Variance	Infit	Item discrimination
Content knowledge	.761	0.170	0.754 - 1.266	M = 0.211 (CI-95 [0.158; 0.263])
Procedural knowledge	.824	0.204	0.604 - 1.308	M = 0.357 (CI-95 [0.315; 0.398])

The infit values as well as the EAP-reliabilities for both dimensions are satisfying. The variance and the item discrimination, however, are too low for both dimensions. As such, the developed test instrument is objective and valid for measuring students' *content knowledge* and *procedural knowledge*, whereas its reliability, variance and item discrimination should be improved.

IMPLICATIONS

The results of IRT scaling showed that the developed test instrument should be improved. Aiming at increasing reliability, variance and item discrimination we changed the item format shown in figure 1. One possible explanation for many students with high test scores is that they guessed the correct answer instead of not marking an answer if they are not sure. To counteract this we implemented a third box in the answer format. Now there is the option for students to tick a box if they are not sure about an answer. Thus, it should be possible to identify a difference between students who know the right answer and students who do not know the right answer. In this way reliability, variance and item discrimination should increase.

After improving the developed test we will use it for assessing the development of students' chemistry competences in the second study. Aiming at a quasi-longitudinal study from the beginning of grade 5 until the end of grade 7 or 8 we plan to measure the students' competences at different measurement points (see Figure 2).

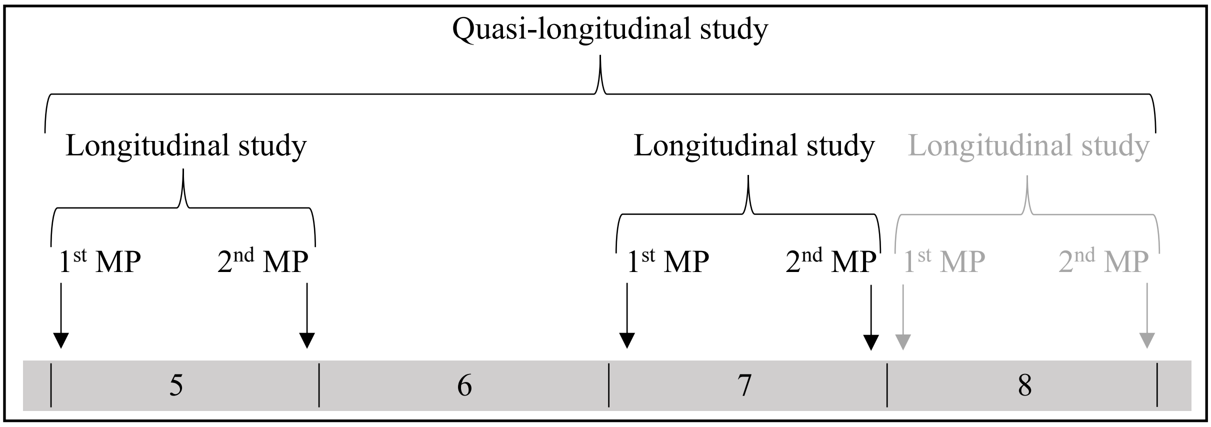

Figure 2. Second study

We will test students at the beginning of grade 5 and 7 and test the same students at the end of grade 5 and 7 again. Thus, there are two longitudinal studies that we can summarise in a quasi-longitudinal study. If the subject chemistry starts in grade 8, we plan to do a third longitudinal study in grade 8 in those schools.

HOW CAN CONTEXT HELP TO SOLVE A PROBLEM? A PROCEDURAL ANALYSIS OF CONTEXTUALIZED PROBLEM-SOLVING

Patrick Löffler[1], Alexander Kauertz[1]
[1]University of Koblenz-Landau, Germany

Context-based learning in a narrower view (Whitelegg & Parry, 1999) typically includes problem-oriented tasks (e.g. Bennett & Lubben, 2006 or Taasoobshirazi & Carr, 2008) that need to be solved by applying science models. While there is no doubt on the positive effects of such context-based approaches on affective variables (e.g. interest), the variance in performance still remains unexplained. Consequently, Bennett, Lubben and Hogarth (2007) only decide to make a rather wary recommendation based on observations of 61 studies on context from 1980 till 2003: "...there are no drawbacks in the development of understanding of science, and considerable benefits in terms of attitudes to school science." (Bennett et al., 2007, p. 368–368). Several approaches tried to shed light on that issue whether by observing the interplay of manifold task characteristics, such as authenticity or relevance, or by taking into account how task characteristics interact with leaner characteristics (van Vorst et al., 2014). However, they still lack to explain the influence between context-based problem-solving and the resulting effect on performance. Along with that, Löffler (2016) also fails to establish a clear connection of Contextualization and performance in the problem-solving process. Yet, he also examines the distinct phases in the process and thereby finally reveals a possible explanation for the heterogeneous observations in research as stated before. Findings from these multiple regression analyses (N = 123) suggest that the effect of context on performance varies strongly during problem-solving. Consequently, further research must take into consideration the procedural character of problem solving to get a deeper insight on how context works.

Keywords: Context; Problem Solving; Modeling; Performance

CHALLENGING CONTEXT

Context-based problems have become a crucial part of science learning since the last decades (Pilot & Bulte, 2006): They allow teachers to encounter negative attitudes towards science (Bennett et al., 2007), but more importantly, there are also many arguments on how such tasks should foster the development of conceptual understanding (Lubben, Campbell, & Dlamini, 1996; Yager, 1999). Nevertheless, there are as well good arguments that support the opposite (Harp & Mayer, 1998; Taasoobshirazi & Carr, 2008). Consequently, research on this topic draws heterogeneous results (Bennett et al., 2007). Park and Lee address this issue by saying: "According to other studies […], it is difficult to observe a consistent effect of contexts on physics problem-solving." (Park & Lee, 2004, p. 1586–1586). Since then, a lot of effort has been put into unravelling context by examining possible topic effects (Gomez, Pozo, & Sanz, 1995; Kölbach, 2011), task characteristics (Löffler, 2016) as well as their interplay with learners' characteristics (van Vorst et al., 2014) and different notions of context (Finkelstein, 2005; Gilbert, 2006). Taken together, the influence of context on performance still lacks for understanding. One possible reason for this issue lies in the measurement of performance, which is usually based on the outcome of the problem-solving process rather than on the distinct phases of the solving process. Hence, we try to answer the question: 'How does context affect these phases?' by reanalyzing a study by Löffler (2016): Overall performance in this study was measured as sum score by rating typical steps in the problem-solving process (see e.g. Pólya, 1985 for the division of steps), thus allowing a more detailed examination in hindsight.

METHOD

Data is taken from a previous study on the effect of context on performance by Löffler (2016) as explained beforehand. The original study investigates three task characteristics: Contextualization (Löffler & Kauertz, 2015 or Löffler, 2016) of the situation described in the task; the Complexity (Kauertz, 2008) of the scientific model underlying the task; and Transparency (Löffler & Kauertz, 2015 respectively Löffler, 2016), which assesses whether and how the learner can identify this model. All of them are coded dichotomously (high and low). Thus, a 2x2x2 –design is used in the 10th grade of three high track schools in Germany ($N = 123$). Each student works on one out of eight task-versions ($t = 13$ min). Students' performance in the problem-solving process is thereby measured in the six phases of the analytic problem-solving process (Löffler, 2016): (1) Understand the problem, (2) Identify the variables, (3) Justify the selection of variables, (4) Formulate a solution proposal, (5) Give an answer to the problem, (6) Name further arguments for the validity of the solution. Each phase is represented by one item in the open-answer paper-and-pencil test by Löffler (2016). Reasons for the instrument's rather low reliability ($\alpha = 0.58$) include the complex interplay of skills involved in the problem-solving process; the small number of items (due to test-time constraints); and the rating process, which added an extra amount of uncertainty to the results (intercoder reliability Kendall's Tau-b: $.48 \leq \tau\beta \leq .97$, depending on the phase). Nevertheless, since operationalizing process-performance is quite challenging, Schmitt (1996) argued (when referring to an example of $\alpha = 0.49$) that if "a measure has other desirable properties, such as meaningful content coverage of some domain and reasonable unidimensionality, this low reliability may not be a major impediment to its use." (Schmitt, 1996, p. 351-352). The contextualized version of the task used within that test is out of the topic of thermodynamics (Kauertz, Löffler & Fischer, 2015) with a task difficulty of $p = 0.46$. The low-contextualized version contains the same physics-problem and has a task difficulty of $p = 0.47$. For 90 minutes, students work on the test booklets that additionally include instruments to encounter covariates such as cognitive abilities: Subscales of the IST-2000R (Liepmann, Beauducel, Brocke & Amthauer, 2007), reliability as reported by the authors: $0.87 \leq \alpha C \leq 0.96$ (depending on the scale) and conceptual pre-knowledge in thermodynamics: Thermal Concept Evaluation (Yeo & Zadnik, 2001), reliability as reported by the authors: Split half – correlation with Spearman-Brown correction: 0.81. Starting from this, the effect of Contextualization on performance in the six phases of the problem-solving process is initially investigated in a single MANCOVA, as several regressions or ANCOVAS alone would lead to an alpha error inflation and would neglect any relationship between the depended variables. Thereby, the other task characteristics (Complexity and Transparency) are statistically treated as covariates, as we only investigate the effect of Contextualization and consequently need to control other influential factors. The total number of covariates in a MANCOVA is limited by the rule of thumb "Maximum number of covariates = (.10 x Sample size) - (Number of groups - 1)" (Hair, Black, Babin, Anderson, & Tatham, 2006, p. 683). With four covariates, we meet this assumption. Other assumptions for MANCOVA include multivariate normality and homogeneity of covariance matrices (Field, 2009, p. 603). The latter can be disregarded "if the groups are of approximately equal size (i.e., largest group size ÷ smallest group size < 1.5)" (Hair et al., 2006, p. 685). We fulfill this precondition with 57 students in the group with the low-contextualized task and 66 students working on the high-contextualized task ($66 / 57 < 1.5$). Regarding multivariate normality, "no direct test is available" (Hair et al., 2006, p. 686). Consequently, Field (2009) among others suggests alternatively checking for univariate normality of each dependent variable. In our study, we do not meet this assumption: Kolmogorov-Smirnov- as well as Shapiro-Wilks - tests produce significant values ($p < .001$) for all dependent variables. On the other hand, Hair et al. (2006, p. 686) concluded, "violations of this assumption have little impact with larger sample sizes". Given that, Hair et al. (2006, p. 679) demand a sample size equal to the number of dependent variables as a bare minimum and recommended a number of 20 observations per group. With roughly 60 observations per group in our study, we therefore consider our sample size as large enough to disregard the violation of univariate normality, as F-tests are generally robust (Hair et al., 2006, p. 687). Among the different test statistics for MANCOVA, Pillai's trace is especially robust against violations of assumptions in case of equal sample sizes (Field, 2009, p. 605). Consequently, we used Pillai's trace to verify a significant overall effect. Based on that, we subsequently conduct several hierarchical regressions with the same set of covariates to get an idea of the effect of Contextualization on each of the phases of the problem solving process.

RESULTS

Using Pillai's trace, there is a significant overall effect of Contextualization on the performance in the phases of the problem solving process, $V = 0.227$, $F(6, 112) = 5.483$, $p < .001$.

Separate hierarchical regressions on the dependent variables reveal significant effects for

- Item 1/Phase 1: Understand the problem: Covariates do not withstand statistical prove ($F(4, 118) = 0,947$, $p = .439$), including Contextualization in the model (standardized beta: .208) changes R^2 significantly ($p = .023$) up to $R^2 = .034$ ($f^2 = .035$).
- Item 2/Phase 2: Identify the variables: Covariates explain 17,6 % of variance ($F(4, 118) = 7,505$, $p < .001$), including Contextualization in the model (standardized beta: -.198) changes R^2 significantly ($p = .017$) up to $R^2 = .209$ ($f^2 = .042$).
- Item 3/Phase 3: Justify the selection of variables: Covariates do not withstand statistical prove ($F(4, 118) = 2,325$, $p = .060$), including Contextualization in the model (standardized beta: .194) changes R^2 significantly ($p = .030$) up to $R^2 = .072$ ($f^2 = .078$).
- Item 4/Phase 4: Formulate a solution proposal: Covariates explain 13,4 % of variance ($F(4, 118) = 5,700$, $p < .001$), including Contextualization in the model (standardized beta: -.200) changes R^2 significantly ($p = .018$) up to $R^2 = .167$ ($f^2 = .040$).

and non-significant effects for

- Item 5/Phase 5: Give an answer to the problem: Neither the covariates nor the extended model including Contextualization withstand statistical prove ($p = .056$ and $p = .443$ respectively).
- Item 6/Phase 6: Name further arguments for the validity of the solution: Covariates explain 23,2 % of variance ($F(4, 118) = 10,947$, $p < .001$), including Contextualization in the model does not change R^2 significantly ($p = .564$).

The summary in table 1 allows a quick comparison of the reported effects of Contextualization on performance in the phases of the problem solving process.

Table 1. Summary of effects of Contextualization on performance. Significant values are in bold.

	Phase 1	Phase 2	Phase 3	Phase 4	Phase 5	Phase 6
R_I^2	-.002	.176	.042	.134	.043	.232
R_{II}^2	.034	.209	.072	.167	.040	.282
ΔR^2	.034	.033	.072	.033	/	/
p	.023	.017	.030	.018	.443	.564
f^2	.035	.042	.078	.040	/	/
β	.208	-.198	.194	-.200	.069	-.047

As pictured in Figure 1, Contextualization has opposing influence on the performance in the first four phases.

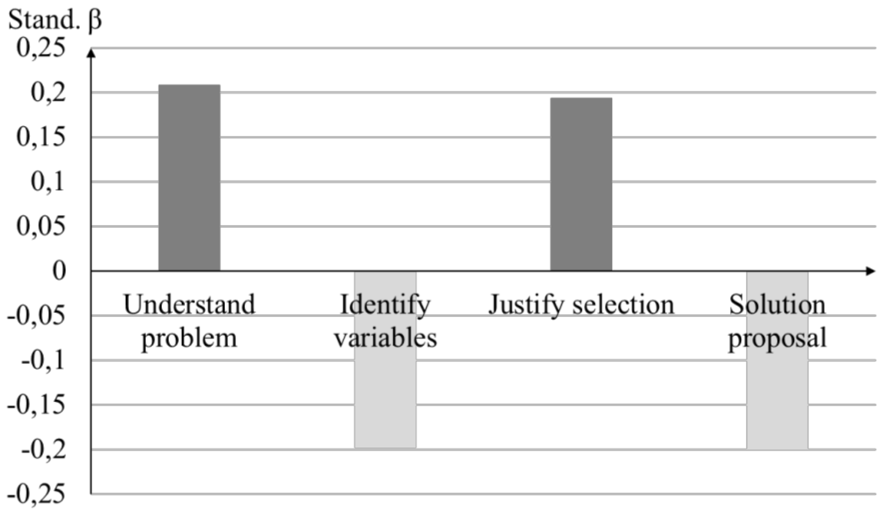

Figure 1. Comparison of standardized betas of the effect of Contextualization on performance in the first four phases of the problem solving process.

DISCUSSION AND CONCLUSIONS

Our results show that the effect of context varies strongly in the problem-solving process: Thus, it fosters students' efforts in understanding the problem while at the same time it hinders them in selecting relevant information to solve the problem. On the opposite, learners seem to benefit from context when it comes to provide a reason for the importance of the selected information. However, context raises the bar for formulating solution proposals. All effects are equally strong and therefore cancel each other out on the process level, which could explain the results in the original study (Löffler, 2016). At the same time, these findings could help to explain the different results in research on context up until now: depending on how performance is measured, either the beneficial effects of context or its drawbacks dominate the outcome, leading to contradicting conclusions, hence making it hard to grasp context. Zhou (2016), for instance, reports: "students in general perform better with physics contexts than with real-life contexts" (Zhou, 2016, p. 12). This conclusion derives from her observation on the amount of additional variables that students consider while working on a task: Whereas students in total came up with five "unnecessary" variables in a physics task, they also brought up 17 additional variables in the real life context. For the latter, Zhou (2016) therefore concludes a tendency for students to consider additional variables other than those given in the problem, which is crucial for the measurement of performance in her study. This finding fits to our observation for phase 2, where context seems to obstruct students in identifying relevant variables. Rennie and Parker (1996) on the other hand reported beneficial effects of context-based problems on performance. However, they focused on the students' ability to understand the given problem, which fits to our findings in phase 1, where context has shown to be helpful. At the same time, Rennie and Parker mention that irrelevant contextual information may confuse students, which goes along with Zhou's and our own observations. Together, these findings strengthen our presumption regarding the origin of heterogeneous results in research on context effects. Consequently, we strongly recommend investigating the impact of context on a more detailed level, that is to say, the distinct phases of the problem solving process.

OUTLOOK

Our findings suggest that students should be supported in identifying relevant variables (Phase 2) as well as in formulating a solution proposal (Phase 4). Transparency can address the first issue (Figure 2) as it facilitates student's access to the underlying scientific model.

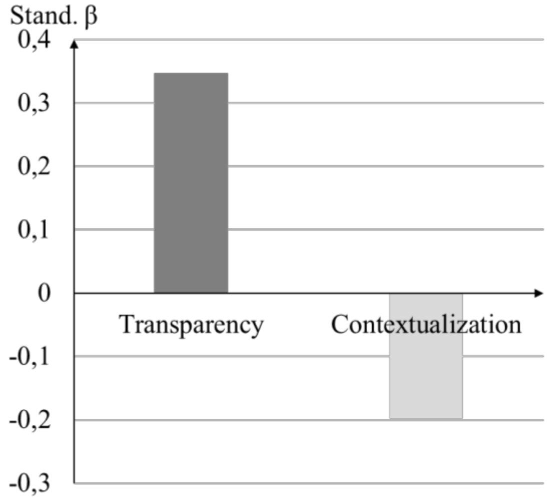

Figure 2. Comparison of standardized betas of the effects of Transparency and Contextualization on performance in Phase 2 of the problem solving process.

Regarding Phase 4, we could surprisingly not observe a positive effect of a low Complexity. However, a proper prior knowledge seems to be especially helpful in formulating a solution proposal (Figure 3).

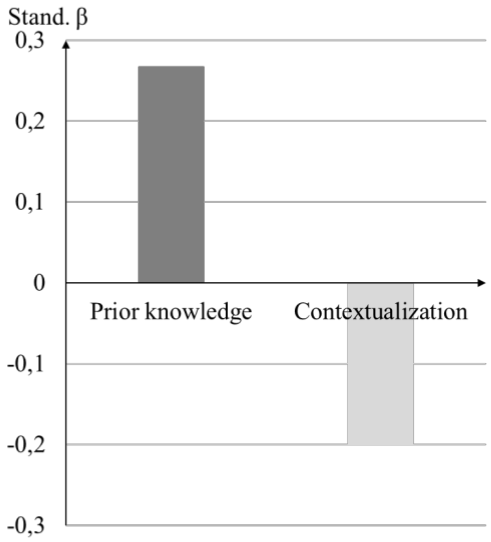

Figure 3. Comparison of standardized betas of the effects of prior knowledge and Contextualization on performance in Phase 4 of the problem solving process.

As it is desirable to compensate the negative effect of context with task characteristics, more research must be done including the analysis of affective variables. In a current project, we therefore analyze the interplay of performance with metacognition, interest and motivation and the task characteristics in different topics (Löffler, Pozas & Kauertz, 2018).

IDENTIFICATION OF CHEMISTRY CONTEXTS THAT INTEREST GREEK STUDENTS

Katerina Salta[1] and Dionysios Koulougliotis[2]
[1]National and Kapodistrian University of Athens, Athens, Greece
[2]Ionian University, Zakynthos, Greece

This study explores students' interests in a variety of contexts commonly found in chemistry curriculum documents via the use of a questionnaire consisting of 50 items. The sample consisted of 314 Greek students, almost equally divided between the two genders, from two levels of secondary school: lower (14–15 years old, 160 students) and upper (16–17 years old, 154 students). Exploratory factor analysis provided evidence for five chemistry contexts that interest students: Aesthetics, Arts and Personal Care (AAPC) - Quality of life (QL) - Environmental Issues (EI) - Hazards, Forensics and Weapons (HFW) - Everyday Life (EL). Evaluation of Cronbach α's provided evidence for satisfactory internal consistency of the scores obtained for each of the five contexts. Further analyses via paired-samples t-tests led to the derivation of the specific interests' profiles of different student groups. Boys' top interest was shown to be related with the context of HFW while the AAPC was the least favorite one. Girls' exhibited the highest interest toward AAPC and the lowest toward EI. The results obtained may have significant implications for the design of chemistry curricula in order to meet the varying interests of different student groups and increase efficiency within the framework of context-based learning.

Keywords: Interest, Context-based learning, Secondary School

INTRODUCTION

Science education literature has revealed a general tendency for an increasing unwillingness of students in many parts of the world to participate in science (Bøe, Henriksen, Lyons, & Schreiner, 2011). Interest in the science subject has been among the most frequently stated factors contributing to this tendency (Osborne, 2008). The content-specific nature of interest related to a particular object, activity, and domain has been well documented (Krapp & Prenzel, 2011). Domain interest refers to students' interest in a defined body of knowledge (e.g. an interest in chemistry). Course interest refers to the interest students have for a defined course (e.g. 11th grade chemistry), which is likely to be directly influenced by how students experience specific course tasks and activities. Science and particularly chemistry courses are often considered to be irrelevant to students' everyday life (Gilbert, 2006). Therefore, many curriculum reforms have focused on the use of contexts and applications of science which may trigger students' interests. Students' prior content knowledge and personal relevance have been identified as potential factors that both trigger and maintain interest in chemistry (Nieswandt & Horowitz, 2015). Thus, studies that focus on the context in which science is taught could supply us with useful insights into disparities between students' interest in chemistry (Tytler, 2014). The aim of this study is to identify the interests associated with the context of chemistry learning in secondary school and examine their variation within specific student groups. Context-based learning and students' interests consist the theoretical frameworks of the present study.

Context-based learning

Context-based learning is one of the 'big ideas' in science education that has influenced teaching and learning science in many countries over the past decades. In 2006 and 2018 Special issues on context-based learning were published in International Journal of Science Education with the first (2006) focusing on context-based curriculum development and the second (2018) addressing the question of how a context influences the learning process.

Although context-based learning has been introduced in order to address a major problem of science classrooms, namely students' indifference and disinterest in learning science content (Fechner, Van Vorst, Kölbach, & Sumfleth, 2015), researchers have not agreed on a single, precise, technical definition of the term "context" in science education (Gilbert, Bulte, & Pilot, 2011). Duranti and Goodwin (1992) suggested that "a context is formed around some 'focal event'—an important or typical event—that draws the attention of learners while remaining imbedded in its cultural setting", while Eijkelhof (2015) defined as "context-based" a variety of science educational approaches that emphasize either the structure, the historical development, or the everyday life application of a discipline (e.g. chemistry). The effect of the context-based approaches on chemistry education has mainly been shown in the development of students' interest (King, 2012).

Students' interests

The theoretical concept of interest has attracted researchers' attention over the past few years (Hidi & Harackiewicz, 2000), and it has been proposed to be connected with intrinsic motivation to learn by educational psychologists (Koballa & Glynn, 2007). Two types of interest have been the primary focus of educational research to date: *situational* and *individual* interest (Renninger & Hidi, 2011). Individual interest can be conceptualized as a part of intrinsic motivation, which refers to a person's predisposition to attend to certain stimuli, events, and objects – including school subjects over time as well as to the immediate psychological state when this predisposition has been activated (Hidi & Renninger, 2006). Situational interest refers to focused attention and the affective reaction that is triggered in a specific time period by environmental stimuli, which may or may not last over time (Hidi & Renninger, 2006).

Person–object theory (Krapp & Prenzel, 2011) and the four-phase model of interest development (Hidi & Renninger, 2006) consider interest as an outcome of the interaction between a person and a particular object. Thus, interest is typically defined as a content and context-specific construct always related to an object, topic, subject, context, activity, or idea, and having a multicomponent structure, i.e. a cognitive and an affective component (Schiefele, 2009). Blankenburg, Höffler, and Parchmann (2016) further differentiate the analysis of interest in science based on a four-dimensional construct: (a) interest in a particular domain (e.g., chemistry); (b) interest in a particular subject matter or topic in a domain (e.g., combustion); (c) interest in a particular context, which is embedded in a topic (e.g., combustion in everyday situations such as burning a candle); (d) interest in a particular activity that is connected to the context and therefore to the topic (e.g., investigating the burning of a candle).

Silvia (2001) discussed the distinction between the terms interest and interests. He characterized interest as a basic emotion like happiness or fear, and interests as self-sustaining motives that lead people to engage in certain idiosyncratic and person-specific activities. Interests are defined as “trait-like preferences for activities, contexts in which activities occur, or outcomes associated with preferred activities” that orient individuals toward certain environments and motivate goal-oriented behaviors within environments (Rounds & Su, 2014). Such interests directly influence educational choices as people tend to be attracted to academic environments that are congruent with their interests (Su, Murdock, & Rounds, 2014). Although interests are contextualized, there exists a small number of subject-specific studies which examine interests in relation with context and, specifically, with the way context is used in chemistry courses.

Students’ interests differentiation

Brickhouse and Potter (2001) have shown that students’ interests related to science are significantly differentiated according to age and gender, as well as to socio-economic and cultural background. A number of studies have identified four interacting factors that influence student interest in school science: prior content knowledge, gender, family-cultural issues, and the quality of teaching (Nieswandt & Horowitz, 2015; Tytler, 2014). Moreover, students’ interest, as a part of intrinsic motivation, is strongly related with career motivation (Salta & Koulougliotis, 2015) and has a large impact on career choices (Lent et al., 2003; Salta, Gekos, Petsimeri, & Koulougliotis, 2012).

Some studies (e.g. ROSE) reported gender differences regarding interest in science topics, activities, and science contexts (Sjøberg & Schreiner, 2007; Blankenburg et al., 2016). Boys were found to have higher interest in the science school subject relative to the girls, with the pattern being however more differentiated upon examination of trends within specific school subjects (e.g. physics, chemistry, biology), or single topics within each subject (Murray & Reiss, 2005). There appears to be a tendency for boys to be concerned with the subject itself, whereas girls are interested in topics which may help them in their relations with themselves and other people (e.g. physics with more human-related content) (Krogh & Thomsen, 2005). Generally, girls express stronger interest in issues related with human health and well-being, whereas boys are more interested in themes related with technology and physics (Hazari, Sadler, & Tai, 2008; Jones, Howe, & Rua, 2000). The Greek ROSE study (Christidou, 2006) also revealed significant gender differences: girls were more interested in topics related to “human biology, health, and fitness”, while boys were more interested in both “science, technology, and their social dimension”, and “the threatening aspects of science and technology”.

In chemistry, the gender differences are less pronounced (Salta & Tzougraki, 2004), and research has indicated that students find chemistry topics, like molecular mass, periodic table and other intangible and microscopic entities mostly unintelligible and irrelevant for their lives (Osborne & Collins, 2001). Topics attracting interests in chemistry are "mixing chemicals", "smells and colours" and "elements of danger" (Osborne & Collins, 2001), with explosive chemicals being among the top five most interest topics for English boys (Jenkins & Nelson, 2005). German female students revealed primary interest in topics with reference to hygiene, nutrition, and health, while male students showed higher interest in industrial and technical matters. Both female and male students indicated to be strongly interested in socially relevant topics like pollution or power supply (Gräber, 2011).

Interests may also depend on other factors such as environment or culture, but the research results are diverse (Dierks, Höffler, & Parchmann, 2014; Hagay & Baram-Tsabari, 2011). In addition, students' interests could change over time (Dawson, 2000). A context that was found interesting and relevant may lose its popularity over years, or even weeks (Baram-Tsabari & Segev, 2015). Thus, the generalizability of students' interest in a specific context remains unclear and more studies that focus on the context in which science (chemistry) is taught could supply us with useful insights into disparities between students' interests (Tytler, 2014).

The present study

Since the relevance of the chemistry curriculum affects interest and learning, determining the specific students' interests in various contexts of school chemistry should provide a basis for informed discussions on how to improve curricula and enhance students' interest and engagement in chemistry. Based on the domain, activity, and context nature of interests (Fryer, Ainley, & Thompson, 2016; Renninger & Hidi, 2011), there is a large need to investigate in more detail students' opinions about chemistry and more specifically starting with the question of what students are interested in learning in chemistry courses and continuing with the one of how students' interests are differentiated within age and gender. Such an investigation, specifically concerning Greek students, could reveal chemistry contexts with thematic coherence which students are interested in learning about and possible both age (school level) and gender differentiations with respect to these contexts. Therefore, the results of the present study could contribute to the development of a more relevant and meaningful curriculum for the students.

Taking into consideration all of the above, the purpose of the present study is on one hand to identify the students' interests associated with the context of chemistry learning in secondary school and on the other to investigate the possible differentiation of the identified interests within various student groups. More specifically the specific questions that have guided this study can be summarized as follows:

- What are the chemistry contexts that Greek secondary school students' have more interest to learn?
- How are Greek students' context-related interests differentiated within each school level and gender?

METHOD

Sample

The sample consisted of 314 secondary school students (157 boys, 156 girls, and one who did not mention gender), of which 160 were in lower secondary school (14–15 years old) and 154 were in upper secondary school (16–17 years old). Intact classes drawn from 4 urban public secondary schools in four districts located in the metropolitan area of the Greek capital, Athens, participated in study. Most students in the sample were of middle socioeconomic status. The students participated voluntarily without extra credit or compensation for their participation. The students and their parents were informed about the aims of this study and provided written consent.

Instrument

The Inventory of Interests in Chemistry Contexts (ICC) is the instrument used in the present study and it is based on the theoretical assumption of the domain, activity and context specific nature of interest (Fryer et al., 2016; Renninger & Hidi, 2011). Accordingly, each item from the ICC involves two parts in the chemistry domain: an activity part (chemistry learning) and an object part of interest (chemistry context). By indicating how much they like or dislike items, respondents reveal their preferences for shared properties of domain, activities and/or objects of interest (Liao, Armstrong, & Rounds, 2008).

The ICC consists of 50 items covering a wide range of possible contexts related to learning about secondary school chemistry. The items were designed in order to assess students' interests in issues involving the interaction between chemistry and society or the everyday life of the students (relevance). The students were asked to indicate their degree of interest in various chemistry contexts in a Likert-like scale ranging between 1 and 5 (with 1= not interested at all and 5 = interested very strongly). Some exemplary items of the instrument are the following: In the chemistry course, how much interested are you in learning about …? (a) preservation of foods; (b) batteries; (c) indoor air quality.

Statistical analysis

The internal structure of interest measure was examined using Exploratory Factor Analysis (EFA). This technique groups items based on their inter-item correlations; thus, items that students answered similarly were put in the same group (Fabrigar & Wegener, 2012). For Discipline Based Education Research fields, the ideas that are grouped together in the mind of the student are communicated via their responses and can be detected by EFA (Bretz & McClary, 2015). Principal components with a Varimax rotation were chosen as the factor extraction method. The reliability of the scales, i.e. the extracted factors, were analyzed by calculating Cronbach α's. Following EFA, paired samples t-tests were employed in order to examine the size variation of the identified chemistry contexts within specific student groups.

RESULTS

The correlation matrix for the variables (items 1 to 50) was computed. The Bartlett's test of sphericity had a value of 7920.980 with a significance level <0.001, indicating that correlations between items are significantly different from zero (Field, 2013). The Kaiser–Meyer–Olkin measure of sampling adequacy was computed equal to 0.910, also indicating the appropriateness of the factor model (Field, 2013). Principal component analysis resulted in ten factors with eigenvalues >1 which in combination explained 65.92 % of the variance. After examination of the scree-plot, and the number of items per factor a solution with five of the ten factors accounting for 53.93% of the variance was chosen. An examination of the items associated with each factor allowed the identification of five chemistry contexts: "Environmental Issues (EI)" (derived from 15 items), "Aesthetics, Arts, and Personal Care (AAPC)" (derived from 12 items), "Quality of Life (QL)" (derived from 9 items), "Hazards, Forensics and Weapons (HFW)" (derived from 7 items), and "Everyday Life (EL)" (derived from 5 items). The remaining two items had loadings which were smaller than 0.4 and they were thus excluded from further consideration.

Table 1. Descriptive Statistics and Internal Consistency for Five Variables - Scale Responses Range from 0% to 100%.

	Measure	EI	AAPC	QL	HFW	EL
Lower secondary school (N=121)	Mean	60.42	68.62	69.07	72.26	73.39
	(SD)	(18.18)	(21.14)	(20.95)	(17,66)	(18.15)
	Cronbach's α	0.89	0.91	0.89	0.73	0.72
Upper secondary school (N=131)	Mean	56.87	62.63	66.02	72.63	69.31
	(SD)	(18.45)	(21.87)	(18.15)	(17.62)	(16.84)
	Cronbach's α	0.92	0.93	0.87	0.77	0.72
Boys (N=122)	Mean	59.24	50.59	65.06	73.93	68.39
	(SD)	(18.93)	(17.36)	(19.99)	(17.51)	(18.02)
	Cronbach's α	0.91	0.87	0.88	0.76	0.71
Girls (N=130)	Mean	57.95	79.51	69.76	72.07	73.97
	(SD)	(17.88)	(14.98)	(18.95)	(17.74)	(16.74)
	Cronbach's α	0.91	0.87	0.89	0.76	0.73

Descriptive statistics and internal consistency estimates (Cronbach's alpha) for the students' scores (interest levels) in these five chemistry concepts are reported in Table 1. The internal consistency analysis for each scale reveals that Cronbach's alpha (α) values are acceptable (>0.70).

Table 2. Results of paired samples t-tests administered for whole samples. (Scale pairs with non-significant differences are shown in bold characters).

Via application of paired samples t-test, 9 non-significant differences were found between the following scale pairs: AAPC – QL, AAPC – HFW, QL – HFW, QL – EL, and HFW - EL for lower secondary students; QL - EL for upper secondary students; QL - EL for boys; QL - HFW and HFW - EL for girls (Table 2). Moreover, the paired samples t-test was conducted in order to examine for statistically significant differences between all possible chemistry contexts pairs for boys and girls within each specific school level. Five non-significant differences were found for the following scale pairs: QL – EL, and HFW - EL for lower secondary boys; QL – EL for upper secondary boys; QL - HFW, and QL – EL for lower secondary girls (Table 3). In addition, the non-significant difference between scales HFW and EL exhibited for the whole sample of girls was not shown for either for lower or upper secondary school girls.

DISCUSSION

Overall, the utilized instrument was shown to provide reliable and valid measures of students' interests in chemistry contexts over the secondary school years and, consequently, to be well suited to describe almost the entire period of chemical education in secondary schools with regard to these constructs. Data analysis allowed the identification of five main chemistry contexts related with the interests of Greek secondary school students. Paired-samples t-tests, applied within each specific school level and gender, showed that there exist statistically significant differences in the interest level between these contexts. More specifically, with respect to school level, lower secondary students were shown to exhibit the highest interest for the contexts El and HFW followed closely by AAPC and QL and subsequently by the context EI which scores the lowest. In upper secondary students, the top interest is shown to be HFW which exhibits a statistically significant difference relative to EL and QL which come in second place followed again by AAPC which is now a more distant third. The context EI displays again the lowest score.

However, the above described order of interests is significantly differentiated if the two genders are examined separately. The results are presented schematically in Figure 1. Thus, in the girls of both school levels, the context AAPC exhibits the highest interest (with the effect however being quite less pronounced for upper secondary girls) and EI the lowest (with the effect being more pronounced for upper secondary girls). On the other hand, in the boys of both school levels, the context AAPC exhibits the lowest interest, while it is the context HFW that scores in top position (with the effect being more pronounced for upper secondary boys). The girls' lowest interest (EI) is relatively low also for the boys (placed next to the boys' lowest interest). The boys' highest interest (HFW) is relatively high also for the girls (scoring next to the girls' highest score).

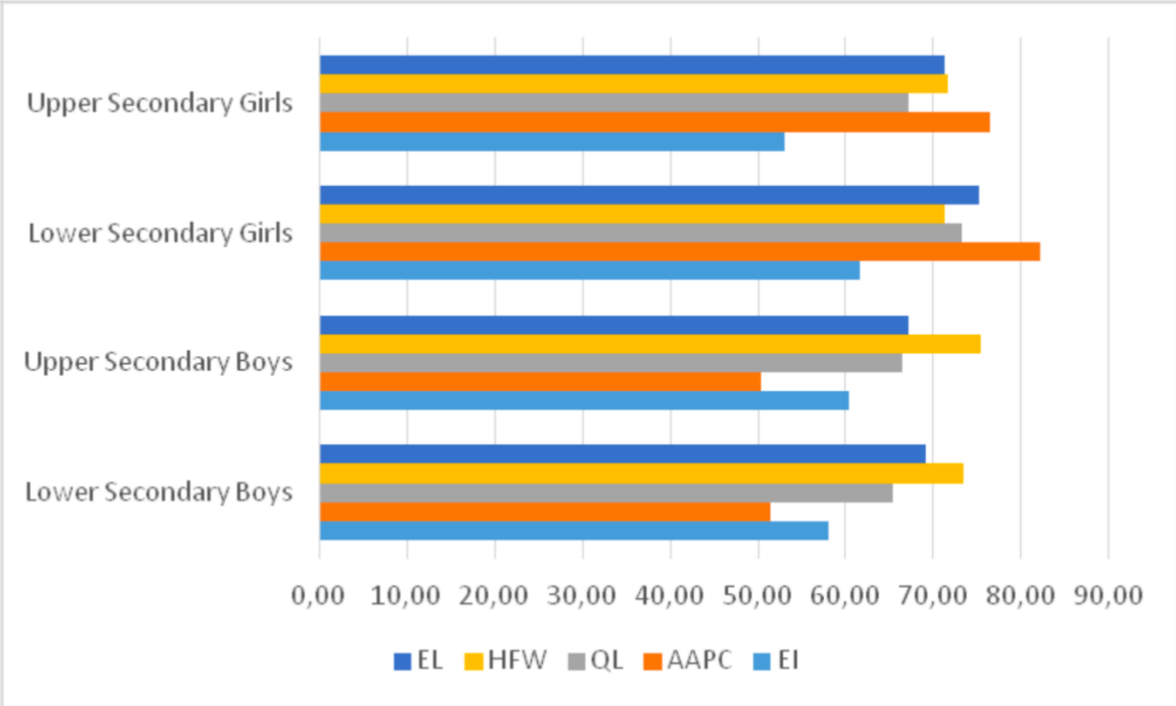

Figure 1. Mean scores of interests towards the five identified chemistry contexts exhibited within each gender for specific school levels (in a scale of 0% - 100%).

The above results may have significant implications for curriculum design in order to render school chemistry more effective in meeting students' interests. The tendency for girls and boys to be interested in different contexts cannot be overlooked. Although, relating subject matter to contemporary social issues may be especially beneficial for girls, chemistry topics in a more action-related context may be more beneficial for boys. Consequently, chemistry curricula ought to balance contexts like art and health care with others like hazards and forensics.

THE DIFFERENT TYPOLOGIES DESCRIBING THE INTEREST IN SCIENCE

Daniel Morin Ocampo[1], Eliziane da Silva Dávila[2], Luiz Caldeira Brant de Tolentino Neto[1]

[2]Farroupilha Federal Institute, São Vicente do Sul, Brazil,

It is essential understanding students' interests to help improving the teaching-learning process. Thus, investigations aimed at understanding how young people think and feel about Science and Technology have emerged. One of these initiatives lies on the project called Brazil Barometer, which is a 4-point Likert scale questionnaire comprising 96 questions that investigate the interest of young people in Science and Technology, among other things. The current study used data generated through the application of Brazil Barometer to 2,404 students in the age group 15 years in 2014; thus, these students were used as a representative sample of the Brazilian young population in this age group. Four (4) different typologies of Brazilian students were found based on the k-means clustering method: Reluctant, Enthusiast, Unselective Undecided, Selective Undecided. In addition, the interest of each typology was analyzed based on six different topics such as Health, Mystery, Scientific innovations, Agriculture, Science and Scientists, and Technology, which were determined based on the hierarchical clustering method. It was possible concluding that topics such as Mystery and Scientific innovations presented the greatest potential to boost students' intrinsic motivation, since they were the ones recording above average interest rates in all four typologies.

Keywords: Interest in Science; Intrinsic Motivation; Students' typology.

INTRODUCTION

Student demotivation is a common complaint among teachers, including Science teachers, who often attribute such demotivation to the mismatch between school speed and that of the digital world. This lack of interest in school contents is concerning because, as Pozo and Crespo (2009, p. 40) stated, "students are not interested in Science, they do not want to strive to study; therefore, since learning Science is an intellectual, complex and demanding task, they fail."

The motivation issue appears to be a key factor for the teaching-learning process and, sometimes, it goes unnoticed in debates about the subject. The literature points towards two motivational orientations focused on school learning: the *extrinsic* and *intrinsic* ones (Deci, Koestner & Ryan, 2001; Martinelli & Bartholomeu, 2007; Pozo & Crespo, 2009). Extrinsic motivation refers to performing tasks in response to external stimuli, i.e., students are motivated by the possibility of being rewarded (score, compliment, acknowledgement) or of avoiding punishment (failure, being grounded, humiliation). Thus, students are motivated because they aim at meeting orders given by, or the external pressure from, other people (Martinelli & Bartholomeu, 2007).

Intrinsic motivation is innate and concerns self-determination (Deci, Koestner & Ryan, 2001). Students driven by intrinsic motivation pursue challenges and novelties; thus, participating in tasks is their main reward. Consequently, prizes or external pressure are not necessary (Martinelli & Bartholomeu, 2007), since students lean because they like learning.

Although extrinsic motivation is recurrent in the classroom, studies available in the literature have reported that encouraging it can negatively affect intrinsic motivation (Deci, Koestner & Ryan, 2001). Moreover, extrinsic motivation systems depend on the maintenance of rewards and punishments, because students lose their reason for learning when rewards and punishments are withdrawn or lose meaning. According to Pozo and Crespo (2009), extrinsic motivation can generate undesirable results such as making students think that the studied content is irrelevant and show progressive lack of interest in the school subject.

There are few empirical tools and data available in the literature to help better understanding the triggers of intrinsic motivation (Martinelli & Bartholomeu, 2007). Thus, the current study adopted the hypothesis that students' interests in Science and Technology have the potential to boost their intrinsic motivation. Therefore, investigating the interests of young people would give us a tool to boost their intrinsic motivation.

In addition, there is a gap between students' interest and what is presented in Science curriculum (Amestoy, 2015; Swirski & Baram-Tsabari, 2014). The interest of young people is little, or not at all, explored at the time to plan school curricula, after all, as Ravitch (2011, p. 251) pointed out, "[...] contemporary reformers keep on searching for shortcuts and quick answers."

The aims of the current study were to elaborate Brazilian student typologies based on their interests in Science and Technology in order to generate data to be used in order to encourage students' education based on their intrinsic motivation, as well as to use students' interest to generate new interests, in a virtuous cycle of commitment to learning and knowledge.

History of studies about interest in Science

Young people's interest in Science and Technology is not a new subject of study: in 1984, the German Institute for Science Education hosted the first International Conference on Interest Research, which focused on students' interest in Science and Technology (Schreiner, 2006). The conference was so relevant that the topic to be approached in the next conference was decided right away, namely: the relation between interest and sex, which remains a recurring concern in studies conducted up to the present day.

The Science and Scientists (SAS) project was launched in 1996 based on an international partnership network generated in events such as the International Organization for Science and Technology Education Symposium (IOSTE). The study counted on the participation of 30 researchers from 21 countries and generated a questionnaire that, from 1996 to 1999, collected information from 9,350 children in the age group 13 years concerning their interest in, experiences with, and perceptions about, Science and what they learned on this field (Sjøberg, 2000).

Project ROSE (Santos-Gouw, 2013) - a new project that succeed SAS - began to be institutionally discussed in 2001. The aforementioned study was based on a questionnaire comprising 12 sections such as *My Opinions on Science and Technology*, *My Out-of-School Experiences* and *What I Want to Learn*. ROSE counted on the participation of more than 40 countries, including Brazil, whose applications were documented in the doctoral theses by Tolentino-Neto (2008) and Santos-Gouw (2013).

Some particularities about ROSE, such as the substantial number of questions and the lack of items by taking into consideration the regional context where the questionnaire was applied, were observed by researchers around the world. Hence, the project called Brazil Barometer emerged. This project is based on a 4-point Likert scale questionnaire comprising 96 questions, whose scores range from 1 - Disinterested to 4 - Very Interested; these questions approach different aspects of students' interest in, and position about, Science and Technology.

METHODOLOGY

The current study analyzed responses given to section "A" of the Barometer Brazil questionnaire, which was applied to 15-year-old students, at national representation level, in 2014. This section presents questions about students' level of interest in learning certain topics. The responses of 2,404 students were analyzed; 7 students were excluded from the sample based on pairwise comparison.

Our aim was to elaborate the typologies of Brazilian students based on the congruence of two different methodological stages, in which we made the option of using multivariate data analysis, more specifically, the cluster analysis.

The first methodological stage concerned the analysis of how the questions were grouped according to students' responses. The variables to be analyzed in this stage were the 24 questions - a sample comprising a few items to be grouped together. In this case, the literature (Hair, Black, Babin & Anderson, 2009, Ocampo & Tolentino-Neto, 2019) indicates that the hierarchical method is the most appropriate one, since it uses the nearest neighbor agglomeration algorithm and the square Euclidean distance.

The second methodological stage concerned how to group students based on their responses. The k-means was the herein adopted methodology (Hair, Black, Babin & Anderson, 2009, 2012; Ocampo & Tolentino-Neto, 2019), since it was more appropriate to analyze the massive amount of data (2,397 students) collected in the current study. Based on simulations and on our knowledge about the sample, we decided to work with the total of 4 clusters in the k-means method.

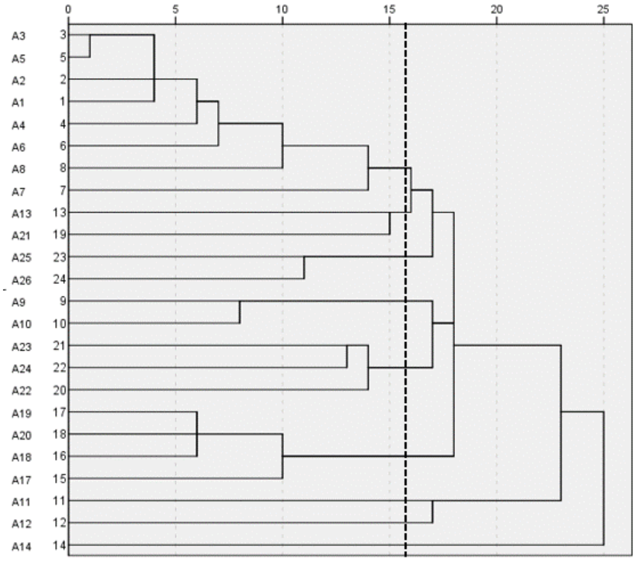
In our opinion, the combination between these two stages is what generated the students' typology. The next items of this manuscript present the results of, and the discussion about, these stages in separate and together.

CLUSTER OF QUESTIONS

The 24 Brazil Barometer questions analyzed in the current study can be empirically grouped based on topics. For example, item A2 "Cancer, what we know about it and how we treat it" can be classified as health-related topic. Thus, we hypothesized that students would respond to the questions according to their field of preference. Cluster analysis was herein adopted to find a statistical basis for this hypothesis.

The nearest-neighbor hierarchical clustering method was herein applied to generate the following dendrogram (Figure 1). We made the option for highlighting (a dotted line in the graph) clusters generated after 15 interactions, based on the good heterogeneity generated in each cluster.

Figure 1 Dendrogram depicting the clustering of questions based on the nearest-neighbor hierarchical clustering method.



Questions A11, A12 and A14 were not clustered into any other question after 15 interactions; consequently, we made the option of disregarding them in our analysis. Thus, the cluster analysis generated six clusters, which were classified based on topics (Table 1). These clusters were very similar to the ones generated by other researchers who worked with both the Barometer and ROSE projects (Schreiner, 2006; Tolentino-Neto, 2008; Chang, Yeung & Cheng, 2009; Santos-Gouw, 2013; Pinafo, 2016). Thus, the clusters generated in the current study were named by taking into consideration the legends used by these authors in their respective studies.

Table 1. Classification of the cluster of questions

Cluster	Questions
a – Health	A1,A2,A3, A4, A5, A6, A7, A8
b – Mystery	A13, A21
c – Scientific innovations	A25, A26
d – Agriculture	A9, A10
e – Science and scientists	A22, A23, A24
f – Technology	A17, A18, A19, A20

Note.Prepared by the authors of the current study, adapted from Schreiner (2006), Tolentino-Neto (2008); Chang, Yeung & Cheng (2009), Santos-Gouw (2013) and Pinafo (2016).

CLUSTER OF STUDENTS

Our first challenge in this stage lied on defining the number of clusters to be used, since the k-means method for clusters analysis requires determining the number of clusters *a priori*. Thus, we searched in the literature and found that Schreiner (2006), whose study adopted the instrument that inspired the development of the Barometer instrument, worked with five clusters of Norwegian students.

After conducting some simulations and data analyses, we noticed that two clusters always emerged: one cluster comprised students presenting above-average interest in Science and Technology, whereas the other one comprised students presenting below-average interest in the topic. Any number higher than two always generated intermediary clusters, which differed from each other based on discrepancies in one or more items, i.e., based on students' high or low interest in specific items. The number of clusters could have been increased by 2,397 so each cluster would represent a student. However, based on the herein obtained heterogeneity, we conclude that four clusters would be sufficient to enable sample segregation and definition.

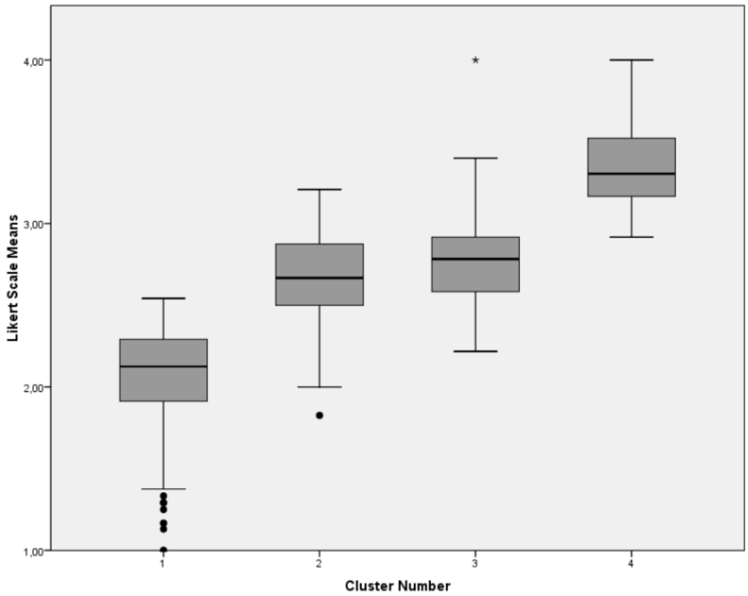
Table 2 Students' distribution per cluster

Cluster	Frequency	Percent (%)	Valid Percent (%)
1	530	22.0	22.1
2	574	23.9	23.9
3	678	28.2	28.3
4	615	25.6	25.7
Total	2,397	99.7	100.0

The number of students in each group did not differ much; there was 6.2% variation between clusters 1 and 3, which comprised the smallest and the largest number of students, respectively (Table 2). Other studies have found clusters with increased unequal distribution. Schreiner (2006) found approximately 13% variation between clusters comprising the largest and the smallest number of Norwegian students.

The clusters generated in the current study were organized according to the mean value attributed to students' responses: the first cluster encompassed students who presented the lowest interest in Science and Technology, whereas the fourth cluster comprised students who presented the highest interest in the topic (Figure 2).

Figure 2. Average and quartiles of interests per cluster



Schreiner (2006) divided Norwegian students in 5 clusters, which were differentiated based on three distinctive features. The first distinction was based on interest, which generated three typologies: *Reluctant*, *Undecided* and *Enthusiast*. The other distinction was based on the variance in students' responses, which generated two typologies: *Unselective* and *Selective*. Finally, the aforementioned researcher differed students based on what she called "Virtually sex-specific" (Schreiner, 2006, p. 128). In the end, Norwegian students were clustered as *Unselective Reluctant*, *Unselective Undecided*, *Unselective Enthusiast*, *Selective Boy* and *Selective Girl*.

Based on this study, we determined the first aspect distinguishing students' typologies: their interest in Science. We made the option of using the terms adopted by Schreiner (2006); thus, Cluster 1 was classified as Reluctant¸ Clusters 2 and 3 were classified as *Undecided*, and Cluster 4 was classified as *Enthusiast*.

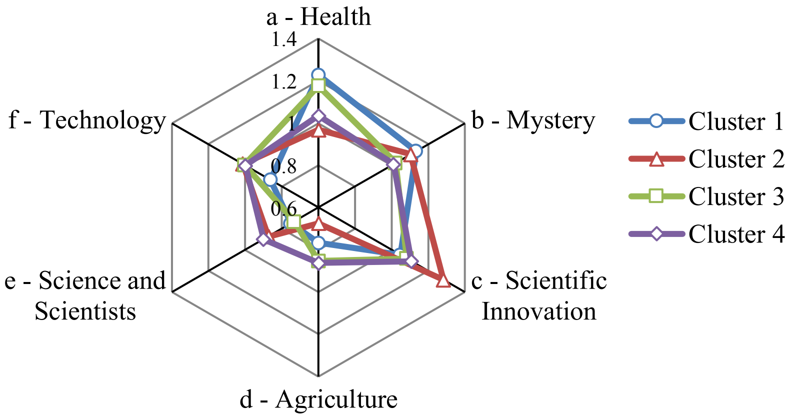
However, it is worth emphasizing that average interest alone was not enough to characterize students' typologies. It was necessary creating a second dimension to enable the elaboration of these typologies based on the fields of interest that most represented the students belonging to these clusters.

TYPOLOGY OF STUDENTS

We observed how members of each of the four clusters behaved towards the topics presented in Table 1 in order to characterize each students' typology. Thus, we herein elucidate these typologies based on students' interest in Science, as well as on the topics differentiating these clusters.

Initially, our concern was to distinguish the fields of interest of each cluster. However, since there were different average interest values, it would be difficult to effectively visualize differences between these fields. Thus, we made the option of weighing the interests in the fields based on the average interest of each cluster; this value was called $\bar{u}_p$ and it was calculated by dividing the interest of students belonging to each cluster in a certain field by the average interest of this cluster. Thus, it was possible overlapping and comparing these values, since each $\bar{u}_p > 1$ represented interest above the mean, whereas $\bar{u}_p < 1$ represented interest bellow the mean. These results are shown in Figure 3.

Figure 3. Comparison between weighted means of interest in the topics.



The center of the radar represents $\bar{u}_p$ = 0.6, whereas the extreme opposite represents $\bar{u}_p$ = 1.4. Each $\bar{u}_p > 1$ represents high interest of students belonging to this cluster in the topic.

The information that mostly stood out in Figure 3 concerned the high interest of students belonging to Cluster 2 in *Scientific innovations*. In addition, it was possible seeing that students in Clusters 2 and 4 had similar views about fields such as *Health*, *Science and scientists*, and *Technology*. Moreover, Cluster 2 stood out because its students presented the lowest interest in *Agriculture*.

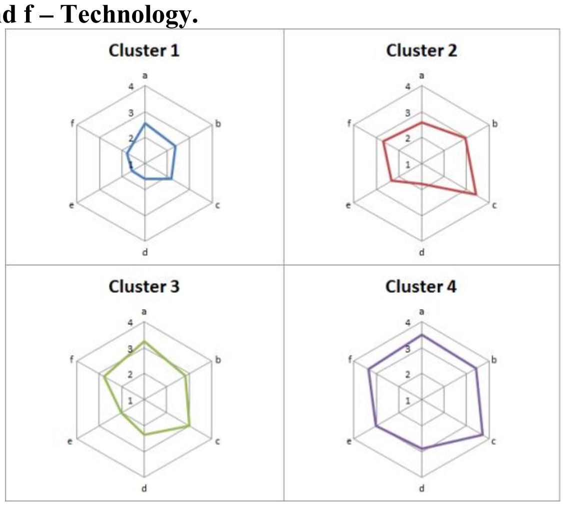
Health was the topic recording considerable interest in all clusters; only Cluster 2 presented $\bar{u}_p < 1$, although it was very close to 1. This outcome corroborates other studies such as the one conducted by Santos-Gouw (2013). However, students belonging to Clusters 1 and 3 showed more interest in the aforementioned topic than the ones belonging to Cluster 2 and 4 (Figure 3).

For illustration purposes, let us imagine a reality where most students belong to Clusters 1 and/or 3; in this case, the use of the topic *Health* in the classroom would have enormous potential, since it would sensitize students' intrinsic motivation. Similarly, if the reality in question does not count on students belonging to Cluster 1, the use of the topic *Technology* should be taken into consideration, since students belonging to the other clusters have great interest in it. Applying the questionnaire and characterizing/mapping the class is a great way for teachers to 'customize' their plans and bring examples and topics of interest to their students.

On the other hand, it is essential emphasizing that it is not the case to stop teaching topics students are not interested in. Teachers would be negligent, or irresponsible, if they failed to address - for example - photosynthesis, in case students did not express interest in botany or in environmental issues. The path to be covered is different, and we agree with Pozo and Crespo (2009, p. 43) who said that "[...] we should start from students' interests and preferences to generate new ones".

Thus, it is important identifying each cluster, which was the reason why we created typologies to name and characterize each of these groups. In order to do so, we took into consideration two aspects - the already mentioned terms based on average interest (*Reluctant*¸ *Undecided* and *Enthusiast*) and the field of greater interest of each cluster (Figure 4) - mainly to distinguish Clusters 2 and 3, which were both classified as *Undecided*. The center of the radar in Figure 4 represents value 1 (Disinterested), whereas the extreme opposite represents value 4 (Very Interested).

Figure 4. – Typologies based on fields: a - Health; b - Mystery; c - Scientific innovations; d - Agriculture; e - Science and scientists; and f – Technology.



The first typology concerned students belonging to Cluster 1. Although they had little interest in Science and Technology, the *Health* topic was attractive to them. Data indicated that the *Health* topic arouses an interest approximately 25% higher than the average. These students did not show interest in topics such as *Agriculture*, *Science and scientists*, and *Technology*. Thus, this cluster was given the *Reluctant* typology, based on the model by Schreiner (2006). *Reluctant* individuals correspond to approximately 22% of Brazilian adolescents in the age group 15 years.

On the other side of the spectrum, some students were very interested in Science. These students belonged to Cluster 4, which represents approximately 26% of the Brazilian population in the same age group. This typology was named *Enthusiast*, since, except for *Agriculture*, all other topics recorded average interest above 3 points, i.e., students belonging to this typology ranged from interested to very interested in almost all Science topics. In addition to the low interest in *Agriculture*, *Enthusiast* students showed high interest in *Scientific innovations*, the average (3.72) was very close to the maximum point. Presenting an optimistic and favorable attitude towards Science and Technology (Anderson, 2006) is characteristic of young people living in countries with low Human Development Index (HDI), which is the reality of a large number of Brazilian citizens; thus, it was not surprising that a significant number of students were given the *Enthusiast* typology.

The two aforementioned typologies comprise a large number of young individuals in Brazil. However, approximately 52% of students belong to Clusters 2 and 3, besides presenting interest close to the average in the 4-point Likert scale (2.5). These two clusters represent what

Schreiner (2006) called *Undecided* typology. Thus, we herein differentiated the two clusters based on the particularities of their interests.

Students belonging to Cluster 2 presented greater discrepancy between responses given to each Science and Technology field than the ones belonging to Cluster 3, as shown in Figure 1. There was 0.301 variance among fields in Cluster 2 and 0.197 in Cluster 3. Thus, students belonging to Cluster 2 were given the *Unselective Undecided* typology, whereas the ones belonging to Cluster 3 were given the *Selective Undecided* one, based on the criterion adopted by Schreiner (2006).

Selective Undecided individuals were very interested in *Scientific innovations* and did not appear to be interested in *Agriculture*. This information made us think about the representativeness of these young students in urban and rural schools, or even in regions presenting high or low population density. Our sample did not enable answering this question.

On the other hand, *Unselective Undecided* individuals were more interested in *Health* and less interested in *Science and scientists*. Previous studies have reported greater interest in *Health* among girls, not only in the Brazilian context (Pinafo, 2016) but also in other countries around the world such as Sweden, Finland, Spain and Ghana (Jidesjö, Oscarsson & Karlsson, 2009; Vázquez & Manassero, 2009; Anderson, 2006). Therefore, we investigated whether there was sex-related distinction in this typology: girls represented 60% of the *Unselective Undecided* students and approximately 44% of the *Selective Undecided* ones. This variation was not as significant as the one found in the aforementioned studies; thus, we did not dwell on this variable at data analysis time.

None of the typologies recorded in the current study showed as much gender discrepancy as the ones reported by Schreiner (2006), who recorded 97% boys in one cluster and 94% girls in another one. Consequently, we did not find it necessary distinguishing Brazilian students' typologies based on *Sex-Variable,* as it was done by the aforementioned researcher.

Thus, *Reluctant*, *Enthusiast*, *Unselective Undecided* and *Selective Undecided* were the typologies herein used to characterize Brazilian young students. Clearly, this is not a rule: generalizations in the education field are dangerous, mainly in significantly heterogeneous countries such as Brazil. On the other hand, these typologies can be used as guideline to develop strategies that take into consideration students' intrinsic motivation to boost Science education in Brazil.

FINAL CONSIDERATIONS

The present study aimed at generating typologies to represent Brazilian young people based on their interest in Science and Technology. Based on aspects quantified through the Brazil Barometer instrument, it was possible dividing them in four typologies named *Reluctant*, *Unselective Undecided*, *Selective Undecided* and *Enthusiast*.

It is essential understanding the existence and characteristics of these typologies in order to boost a teaching process that takes into account students' intrinsic motivations to learn Sciences. Thus, it is possible using students' interests to expand their knowledge about Science.

We concluded that individuals belonging to each of these four typologies have their own interests. *Reluctant* individuals presented greater interest in topics such as *Health*, *Mystery* and *Scientific innovations*. This outcome was similar to the one recorded for students belonging to the *Enthusiast* and *Unselective Undecided* typologies, who showed interest in *Scientific innovations* and *Health*, whereas the ones belonging to the *Selective Undecided* typology presented great interest in *Scientific innovations*.

Besides the individual interests of the herein presented typologies, it is essential investigating the fields arousing the interest of young people belonging to all typologies. Items associated with *Mystery* and *Scientific innovations* were the ones recording above-average interest in all typologies. Thus, we reiterate the potential of these two fields to boost students' intrinsic motivation to study Science, since the four herein investigated typologies shared this interest.

PERFORMANCE ANALYSIS OF STUDENTS REGARDING THE COMPLEXITY AND CONTENT DIMENSIONS OF ITEMS IN LEARNING OF PROGRAMMING LOGIC

Fernanda Regebe[1], Amanda Amantes[2]
[1]IFBA/UFBA, Camaçari-Bahia/Salvador-Bahia, Brazil
[2]UFBA, Salvador-Bahia, Brazil

This paper reports a study on the learning of Brazilian high school students with respect to contents of programming logic. In order to evaluate this learning two dimensions were considered: complexity dimension, which represents the difficulty of knowledge test items; and content dimension, which refers to contents related to logical reasoning and to mathematical skills. In terms of complexity, despite an increase in learning at all levels, the results indicated that the less complex questions were easier for the students, those of medium complexity were stable and those of greater complexity had an oscillating behaviour. Regarding the content dimension, the questions of pure mathematical knowledge were learned at a higher level, followed by those of programming structure. In the other hand, the hybrid questions, which combine two or more fields of knowledge, were learned the least. This corroborates the challenge of promoting interdisciplinary approaches which contemplate learning in this sense. We interpret the difficulties of achievement at hybrid domain as a process of building new knowledge and not only a direct transfer of concepts of one dimension to another.

Keywords: *Reasoning, Learning Progressions, Quantitative Methods*

INTRODUCTION

This study investigates how students learn concepts which demand logical reasoning in higher abstraction levels such as the scientific ones. The participants are students from an IT (Information Technology) Technical course of a Federal Technical School in northern Brazil. Programming logic is a discipline offered every first term in IT courses of technical and undergraduate levels. One of the main goals in this discipline is in promoting the ability of students to solve ordinary problems using logically structured instructions of computer programming languages. (Pereira Juúnior & Rapkiewicz, 2004). Some studies of learning disabilities in programming logic found difficulties of the students in understanding the problem to be solved, i. e., the understanding of what is asked to do, even before the difficulty of interpreting some kind of representation (Falkembach et al, 2003). Other studies found difficulties in: solving problems (Martins & Correia, 2003); in building the algorithm (Campos, 2009), in applying the algorithm control structures (Gomes, 2008); and in assimilating the abstractions involved in the teaching-learning process of programming fundamentals (Rodrigues, 2002). As IT courses usually have high rates of repetition and dropouts, we noted the importance of investigating issues related to the learning of abstract concepts. The present study focuses on learning from the perspective of cognitive development associated with hierarchical complexity of elements or attributes, which change in time (Fischer, 1980, Commons, 2008, Case, 1992, 1996). Cognitive development is explained by a series of skill structures called levels together with a set of transformation rules that relate these levels to each other. The levels designate skills of gradually increasing complexity, with a specific skill at one level built directly from specific skills at the preceding level (Fischer, 1980). In this way, learning is considered from the evolution of latent traits.

METHODS AND RESULTS

The learning of 71 students was evaluated over a school year. This evaluation was done through class observation by the researcher and the application of 9 exams. These exams were knowledge tests (measurement waves) created from a qualitative analysis of the material given by the IT course teachers (Regebe & Amantes, 2013, 2015). The tests were designed to evaluate the understanding of different contents related to mathematics and logical reasoning. Based on the categorical system TCH - Taxonomy of complexity of skills (Regebe & Amantes, 2013), the test items were intended to comply with the hierarchical complexity perspective (Fischer, 1980). All used material went through peer and sampled validation (Regebe & Amantes, 2015).

The analysis was performed from two perspectives: item complexity level which is related to the difficulty of the items; and content type which can be related to mathematical knowledge, logical reasoning or hybrid knowledge (the latter comprehend both types: mathematical content and logical reasoning). For the analysis of the complexity dimension, we measured the difficulty of the item in the Rasch scale (1960). This measure was provided by estimates considering the number of persons who answered the items correctly and the proficiency of these students. The items ended up being divided into 3 levels of complexity after the construction and analysis of the psychometric models where several types of tests were applied, such as exploratory analysis, confirmatory analysis and ANOVA (Regebe & Amantes, 2017).

Results suggested that learning rises at all levels, that is, as the difficulty index of the item decreases, the learning level increases. The Figure 2 shows that the level of complexity 1 had a downward trend as it became easier for students; the level of complexity 2 had a more or less stable trajectory; and the level of complexity 3 had a very oscillating behaviour, which is expected from more complex questions (Coelho, 2011).

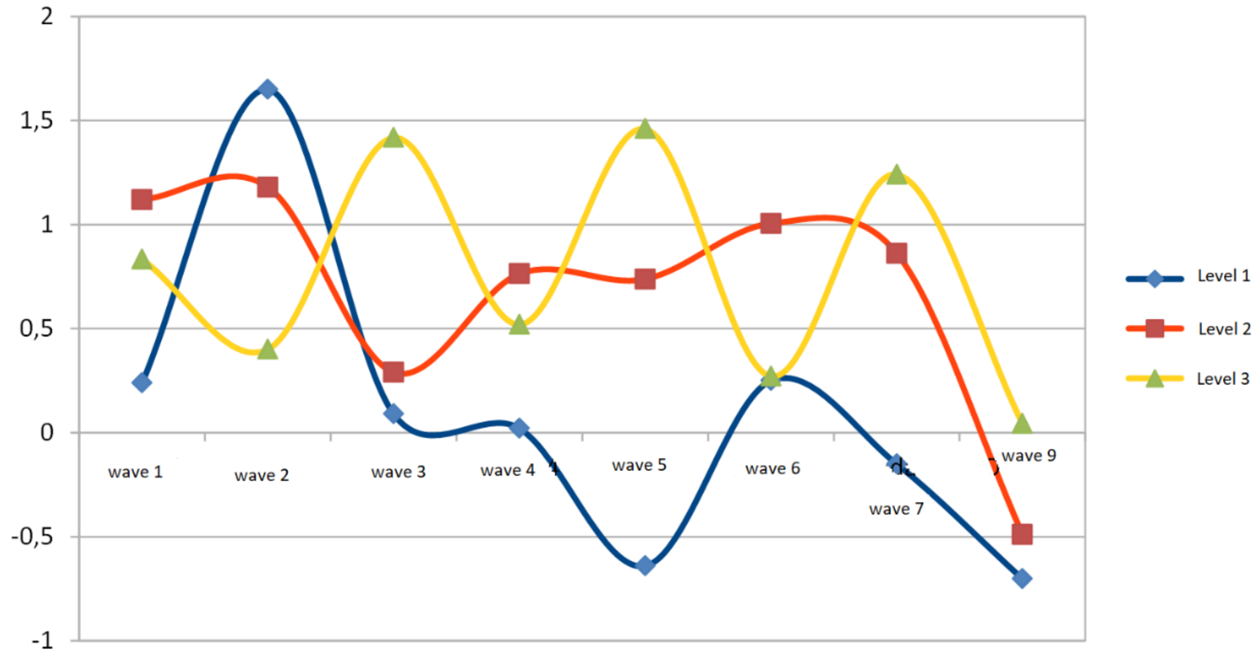

Figure 2. Trajectory of the difficulty index of the items, regarding complexity

We interpret that, according to the trajectory of the difficulty indexes in terms of levels of complexity, students learn more at the less complex level (blue line, complexity level 1). For the highest level of complexity (yellow line, complexity level 3), they end up not learning as much as the line does not follow a downward trend. For the intermediate level of complexity (red line, complexity level 2), the trajectory was more or less stable between waves 4 and 7, having a huge fall after wave 7. However, all levels of complexity presented a drop after wave 7, which may indicate some contextual aspect that has not been analysed yet.

For the content dimension analysis, we used the difficulty levels of items in the dimensions MK (mathematical knowledge), PS (programming structures) and HB (hybrid questions) during the measurement waves. We also used the item maps which show the difficulty indexes of the items and the proficiencies of the students on the same logit scale (Figure 3). This item map represents the result of 7th test applied to students. The item map also allows us to verify the evolution of student proficiency during the school year, through the relationship between increased proficiency and decreased difficulty level of items in their macro and micro contents. On the left side of the graph are estimates of the proficiency parameters of students who have completed the knowledge tests (mathematical content skills, programming logic, and hybrid content). Item estimates (item difficulty index) are represented on the right side of the graph. In this item map, the mathematical knowledge (MK) items are in blue, the programming structure items (PS) are in red, and hybrids (HB) are in green. Hybrid items are divided into three levels: N1, N2, and N3. Level N1 consists of recognizing and identifying the input, processing and output variables of the program, i. e., if the student has only been able to correctly identify and declare the input, processing and output variables, he or she only achieves the item of level heading N1 of the question of hierarchical level IV of our categorical system. Level N2 means that the student understood the problem, that is, if we can see a formula or outline of their understanding, the student achieves the N1 and N2 items. And finally, the

N3 level means that he was able to overcome the problem to the algorithmic language with all its nuances. If the student achieves this, he or she scores the N1, N2, and N3 level items, as this is a Guttman's partial score scale (Guttman, 1944).

Figure 3 - Items Map (Wave 7)

Results showed that students had less difficulty in items with MK content in almost all waves. The PS items were more difficult for the students than the former. In the other hand, the most difficult items were the hybrids (HB) which demands the implementation of an algorithm to solve a mathematical problem (Figure 4), that is, these are questions which request skills that combine different areas of knowledge to solve a problematic situation.

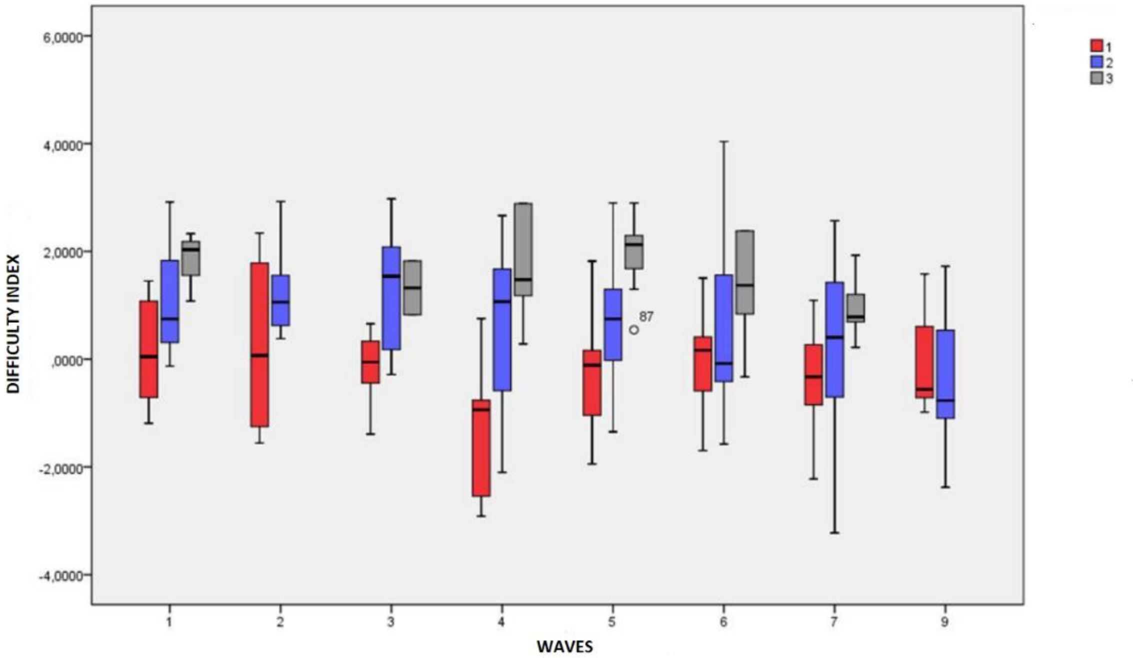

Figure 4. Medians in content dimension

In this way, it can be noted that, despite the items involving pure mathematical knowledge (MK) were considered easier by students, the same questions became much more difficult when requesting the implementation of algorithms. This finding corroborates with the results obtained by Amantes (2009) when investigating how technological and scientific knowledge is used to solve problems. In this present study, there is no direct transfer of knowledge from one area to another in order to develop algorithms, but rather a construction of new knowledge based on the specificities of the two domains (Fensham, 1994). Our findings pointed a difficulty to achieve higher complexity levels, indicating that there is necessary improvement to teaching strategies in order to provide a better way to develop students' abstract thinking. To accomplish this goal, it is also important to develop teaching approaches for improving students formal reasoning, once the hybrid questions were considered the most difficult ones. We also consider it is important to develop techniques for solving complex problems, such as the process of breaking a problem down into the smaller pieces necessary to solve it: "divide to conquer", but often the difficulties lie in understanding the problem as a whole and identifying its pieces. Understanding the mathematical problem and how to split it into easier ones to solve is a preceding step and without it the students cannot transpose the problem to an algorithm.

DISCUSSION

The analysis of student learning points to the increase in all levels of complexity and content, even though less complex questions have become easier for students, indicating that teaching strategies for the development of abstract thinking are necessary. In order to encourage the development of abstract and complex knowledge, it may be necessary to adopt approaches that strengthen students' formal reasoning. With regards to content, the hybrid questions were considered the most difficult. As an educational implication, this result draws particular attention to teaching strategies of programming logic subject. The algorithmic problems included in the hybrid questions required reasoning skills to transpose the problem, that is, that the students had enough proficiency in several mathematical contents, as raised by Gomes and Mendes (2006). Theses authors correlated the difficulties experienced by students to their background in mathematical knowledge. Therefore, the difficulty is more likely to be in transposing mathematical contents to build algorithms and in transferring knowledge from one area to another, that is, students may have trouble in in building new knowledge from the specificities of the two domains (Fensham, 1994). These finding calls attention to the difficulty in developing interdisciplinary approaches which could effectively enable the achievement of generalized knowledge.

Through our research we evaluated that an adoption of strategies that promote abstract thinking, logical/mathematical reasoning, interpretation and division of mathematical problems in the curriculum of mathematics discipline itself would be a great help to improve this situation. This would not only benefit the students' performance in the programming logic discipline, but throughout all the courses related to computer programming, programming skills is a prerequisite for many other subjects. The student's difficulties or success in the programming logic discipline extend throughout the course, leading to failures and dropouts. Focusing in these strategies would greatly increase the number of technology learners, while contributing to the generation of qualified jobs and country development.

DEVELOPMENT AND VALIDATION OF THE NEGATIVE APPRAISALS OF STUDYING SCHOOL SCIENCE (NASSS) SCALE

Radu Bogdan Toma[1], *Norman G. Lederman*[2], *Jesús Ángel Meneses Villagrá*[1]

[1]University of Burgos, Burgos, Spain.
[2]Illinois Institute of Technology, Chicago, USA.

Based on recent conceptualization of the cost construct from the expectancy-value model of achievement motivation, this study reports on the development of the Negative Appraisals for Studying School Science (NASSS) scale and initial psychometric evidences performed with elementary school students (N = 442) from the Spanish educational system. Results revealed a two-factor structure consistent with theoretical expectations and with strong internal consistency reliability and face, content and construct validity evidences. These findings provide sound theoretical and empirical evidence to consider NASSS as a valid and reliable instrument for the Spanish context.

Keywords: loss of valued alternatives, task effort, exploratory factor analysis.

INTRODUCTION

Despite the many curricula reforms, the leaky pipeline in science education seems to persist worldwide. More specifically, Spain has experienced a steady decline in students interested in studying science during secondary and tertiary education (MECD, 2016). On the other hand, persistence has been linked to achievement motivations and cost-related variables (Andersen & Ward, 2014). Since career aspirations and interest in science seem to be already established at 13 years old (Lindahl, 2007), and given that the promotion of positive attitudes towards science from early years is paramount for science education worldwide, it is crucial to advance the understanding of the variables affecting late elementary students interest for scientific studies and disciplines. Thus, the present study aims at developing and validating a short scale for the measurement of negative factors that hinders further participation in science education among Spanish-speaking elementary students, called the Negative Appraisals of Studying School Science (NASSS) scale. The availability of a valid and reliable instrument would enable future research on this important aspect, which may shed some light on this pattern of generalized disinterest in science. In turn, an increase in understanding of the negative aspects related to studying science may contribute to the effectiveness of educational interventions aimed at fostering scientific vocations.

BACKGROUND

Several studies highlighted concerns about the methodological quality of the attitudinal instruments published in science education research (i.e. Blalock et al, 2008; Gardner, 1975), revealing that many science attitudes instruments lack conceptual clarity and validity and reliability psychometric evidence. More recently, Toma (in press) performed a systematic review of 15 science attitude instruments published between 2004 and 2016, concluding that, overall, the quality of most recently published instruments remains a matter of concern; the author pointed that science attitude instruments were not rooted in any existing theoretical framework and that there as a deficient or inadequate analysis of the psychometric properties of the proposed instruments.

These findings question the validity and reliability of existing instruments and highlight the need to adopt more rigorous methodological designs for the development of instruments in science education research.

THEORETICAL UNDERPINNINGS

The expectancy-value theory of achievement motivation postulates that motivation, choice and persistence in a given activity or task are influenced by expectancies and task-values variables (Eccles, Wigfield, Harold, & Blumenfeld, 1993). While the expectancy construct refers to individual's beliefs about its own ability to successfully perform a specific activity, the task-value construct relates to the assessment that an individual attributes to that particular task or activity in terms of (a) intrinsic value (level of enjoyment related to a task), (b) attainment value (the importance of doing well on a given task that relates to own identity), (c) utility value (usefulness of a given task for future goals and plans), and (c) cost (negative factors related to a given task).

Recently, new studies further reported that cost dimension is better conceptualized as a separate construct from task-values and that the cost construct may be formed by others underlying factors, such as task effort cost, outside effort cost, loss of valued alternatives, and emotional cost (Flake, Barron, Hulleman, McCoach, & Welsh, 2015). Therefore, the NASSS scale is rooted in the understudied cost-construct from the EVT theory that may serve as a theoretical framework for understanding the factors influencing the development of students' interest and engagement in science courses.

An important caution needs to be raised. It is important to note that cost is different than self-efficacy and should not be confounded or treated as similar traits. While Bandura (1993) conceived self-efficacy as the beliefs that individuals have about their own ability to be successful at a given task (e.g. being able to understand science lessons), the cost construct includes internal beliefs about the salient negative aspects derived from the participation in a given task or activity, regardless of the ability to perform that task (i.e. having to study for long hours to understand science lessons).

For example, a student may be highly interested in the science subject and have high self-efficacy in the learning of the school science content. However, he/she may perceive that being successful in science requires for him/her too much effort (i.e. many hours of studying), the abandon of other activities to devote more time to study science, and the high changes of failing may be causing a lot of stress and anxiety. Despite the interest and ability to be successful in science, these perceived adverse factors related to science education could ultimately act like a barrier and affect his/her decision to engage in future science subjects and to pursue a science related career. Therefore, if the cost of studying school science is too high, or in other words, if students perceived too many adverse factors related to studying school science, students may be willing to abandon science studies.

METHODS

Sample

A total of 442 students (M_{age} = 10.3, *SD* = 1.18) enrolled in 3rd to 6th elementary school grades constituted the sample for this study. Participants were drawn from 21 elementary schools from the province of Burgos (Spain) by means of convenience sampling.

Procedure

The NASSS scale was developed using a three-stage procedure consistent with recent recommendations (AERA, APA, & NCME, 2014). In the first stage, an initial item pool was created by selecting items from existing cost scales. Items were translated from English to Spanish following cross-cultural adaptation procedures, which include translation into spanish and back-translation into the original language by two bilingual professors. In the second stage, selected items were subjected to theoretical analysis for content and face validity through a panel of experts composed of two university professors and six elementary school teachers, and through cognitive interviewing protocol with elementary students (*n* = 16) to assess item interpretation. In the last stage, large scale administration and psychometric analyses were performed. Construct validity was examined by subjecting items to exploratory factor analysis (EFA) using Principal Component Analysis (PCA) extraction with oblique-Promax rotation because factors were hypothesized to be related. Factors were retained following parallel analysis criteria and were further examined for convergent and discriminant validity using Pearson correlation within and between items included in each factor. Finally, internal consistency reliability was examined through Cronbach α, item-total correlation, and split-half reliability. Each one of these psychometric properties is defined in the next subsection.

Psychometric properties examined

Validity refers to the degree to which an instrument ""(…) measures the construct(s) it purports to measure" (Mokkink et al. 2010, p.743). One of the main validity indices is content and face validity, which examines if the content of a instrument adequately measures the construct of interest. More specifically, face validity examines what the test appears to be measuring based on subjective evaluations related to whether the test looks as thought to be measuring the target construct. Similarly, content validity evaluates the "(…) adequacy of content coverage and relevance for multi-item measures of a construct" (Polit, 2015, p.1750), but following a much more rigorous and systematic procedure.

Once the content and face validity are established, the instrument should be submitted to construct validity procedures to examine if the scores of the new instruments "(…) supports the inference that the construct has been appropriately represented" (Polit, 2015, p. 1750). Thus, construct validity is usually examined through factor analysis that reveal whether the proposed instrument captures the theoretically expected dimensionality. Likewise, it should be examined whether items of one construct are related to items with which conceptual convergence is expected (convergent validity), are not related to items with which conceptual convergence is not expected (discriminant validity).

Finally, the reliability of the extracted constructs should be examined. Reliability is defined as whether "(…) scores for people who have not changed are the same for repeated measurements, under several situations" (Polit & Yang, 2016, p. 25). One of the most common types of reliability is internal consistency, which examines if the items on a scale are part of the same underlying construct.

RESULTS

From the initial list of 19 items, the panel of experts reached agreement (above 75%) in including a total of 10 items measuring task effort, valued alternatives, and emotional negative appraisals. The cognitive interviews indicated that the emotional items were problematic, with most students showing difficulties in understanding some words included in these items. After eliminating emotional items including difficult words such as exhausting, frustrating, or anxious or stressful, six items remained for the large-scale administration.

Kaiser–Meyer–Olkin measure of sampling adequacy (KMO) was .795 and Bartlett's test of sphericity reached statistical significance ($p < .001$), which supports sampling adequacy for factor analysis. PCA with Promax rotation revealed a simple structure of two factors explaining a total of 65.16% of the variance, with items strongly loading on only one component and with no cross loadings between components above .40 (Table 1). The decision to retain two factors was further supported by parallel analysis which showed only two factors with actual eigenvalues exceeding the eigenvalues from a random generated sample of the same size (6 variables, 442 subjects). Thus, the first factor, named *Loss of valued alternatives*, measures the extent that students perceive that studying school science subject requires them to give up other valued activities, and the second factor, named *Task effort*, measures the effort students feel they must perform in order to be successful in school science.

Pearson correlation coefficient revealed medium to large-positive significant correlations ranging from .405 to .519 between items included the *Loss of valued alternatives* factor, and .345 to .519 for the *Task effort* factor items, which indicate convergent validity. The component correlation matrix revealed a medium-positive correlation between both factors (r = .457), which supports discriminant validity between factors.

Table 1. Pattern matrix of principal component analysis (PCA) with Promax rotation

Items	Factors extracted		
	1	2	h^2
6. I have to sacrifice a lot of free time to be good at science	**.937**	-.220	.739

3. I have to give up too much to do well in my science class	**.788**	.068	.674
4. I have to invest a lot of time to get good grades in science	**.557**	.299	.552
2. I am unable to put in the time needed to do well in my science class	-.282	**.887**	.638
5. Science class required too much effort	.190	**.713**	.668
1. My science classwork requires too much time	.189	**.696**	.640
% variance explained	47.9	17.29	3.91 (65.19)

Factor 1: Loss of valued alternatives; Factor 2: Task effort
h^2 refers to items communalities

Cronbach α for the entire scale was .778 (Factor 1 α = .715; Factor 2 α = .701). Split-half reliability was .724 for the *Loss of valued alternatives* factor and .743 for the *Task effort* factor, as reported by Spearman-Brown Coefficient. Finally, corrected item-total correlations ranged between .403 and .590. These indices suggest acceptable reliability for both factors.

CONCLUSIONS

The goal of this study was to develop and provide initial validation evidences for an instrument aimed at examining negative appraisals of studying school in Spanish elementary education students. Using a multistage translation approach and multiple psychometric evaluations, the NASSS scale reported strong validity (face, content, construct) and reliability evidences. Both constructs of the NASSS scale were consistent with recent conceptualization and existing cost instruments developed in the literature (Flake et al., 2015).

During the development and validation of the NASSS scale, it was intended to overcome the criticisms raised in science education research literature in relation to poorly validated instruments (see Blalock et al., 2008). Therefore, the NASSS was rooted in recent conceptualization of the cost construct from the EVT framework and the procedure used for selecting, adapting and assessing the items was robust and systematic, including back-translation, the use of both experts and students for examining the content and face validity, and the use of many more psychometric tests than most existing instruments in the literature to establish the validity and reliability of the proposed instrument. Consequently, the NASSS scale can be considered as a promising first step in the measurement of negative appraisals factors related to the study of school science in the Spanish context, which can allow future research about cost as an important factor in the development of student's interest toward school science and scientific-related disciplines.

EVALUATION OF LEARNING PROGRESSIONS ON CHEMICAL CONCEPTS IN SECONDARY SCHOOLS

Kübra Nur Celik[1], Maik Walpuski[1]
[1]University of Duisburg-Essen, Essen, Germany

Chemistry is characterized by a logical and hierarchical structure. The acquisition of new content knowledge is highly dependent on students' previous knowledge and how it is connected. If this knowledge is available, the new (hierarchically higher) knowledge can be integrated into existing knowledge in terms of cumulative learning (Duschl, Schweingruber & Shouse, 2007; Fischer, Glemnitz, Kauertz & Sumfleth, 2007). However, international (e.g. PISA, TIMSS) and national (IQB) studies report that students fall behind the desired knowledge developments. One possible assumption is that these students lose track in instruction and fail to catch up due to the deficits they acquired early on. Therefore, this study tries to map this hierarchical structure via a strand map and to empirically evaluate this map. The strand map considers the three chemical core concepts Structure of Matter, Chemical Reaction and Energy for the first two learning years (MSW NRW, 2011). Performance tests were developed and administered in a quasi-longitudinal and a true-longitudinal study to analyze the validity of the presupposed interdependencies of the core ideas. Different methods like the McNemar test for the single interdependencies and the Bayesian networks for the whole map were used for evaluation purposes. The results of this study contribute to the development of more precise diagnosis instruments for learning difficulties.

Keywords: Learning Progression, Conceptual Understanding, Secondary School

THEORETICAL FRAMEWORK

The results of international assessment studies such as PISA, in which German pupils' performance in the natural sciences fell short of expectations (Baumert et al., 2001), lead to discussions on initiating educational standards for science subjects. These were consequently introduced into the school system as general standards that define the middle performance level an average student is expected to reach (competence level III) (Klieme et al., 2007). The IQB national assessment study 2012 showed that many German students, especially in North Rhine-Westphalia, do not reach the educational standards for content knowledge in chemistry (Pant et al., 2013). About 69.7 % of the pupils who took part in this survey did not reach the first two competence levels and thus missed the minimum standards. Only 27.6 % reach competence level III and thus the standard, and only 2.7 % of pupils reach the last two higher competence levels (Pant et al., 2013, p. 216). The second IQB national assessment study of 2018 confirms the results for the competence area of content knowledge once again (Stanat, Schipolowski, Mahler, Weirich & Henschel, 2019). A possible reason for the students' lack of proficiency could be the cumulative structure of the subject chemistry (Fischer, Glemnitz, Kauertz, & Sumfleth, 2007). Early content knowledge deficits may hinder students to build a logical and hierarchical network where core ideas are cross-linked. In consequence, they cannot not catch up during further chemistry instruction but even increase their deficiencies, because low-achieving students cannot integrate new knowledge into existing knowledge structures. One approach to support them is to make the underlying structure of content knowledge explicit to them and to make sure, that "lower" ideas have been understood before "higher" ideas can be addressed. For this purpose, learning progressions are used to structure the content knowledge in strand maps – analogous to the "project 2061" of the *American Association for the Advancement of Science* (AAAS, 2007). Learning progressions are descriptions of possible pathways for the development of competences over time (e.g. Corcoran, Mosher, & Rogat, 2009; Duncan, & Hmelo-Silver, 2009). In preceding studies smaller learning progressions have already been described and evaluated, e.g. for different science subjects in the US (e.g. Alonzo, & Steedle, 2009; Stevens, Delgado, & Krajcik, 2010) or specifically the core concept of energy in physics (Neumann, Viering, Boone, & Fischer, 2013) as well as in the concept of chemical reactions in chemistry in the German context (Weber, 2018). Taking this into account, this study aims at mapping out a complete strand map for the first two years of chemistry education in Germany, and describing interdependencies between the core concepts *Structure of Matter*, *Chemical Reaction* and *Energy*. They can be assigned a structuring function with which chemical contents can be networked and systematically ordered (Demuth, Ralle & Parchmann, 2005).

RESEARCH QUESTION

In this study the following research question is investigated:

Are the presupposed interdependencies between the chemical core ideas valid?

PROCEDURE AND STUDY DESIGN

In a first step, a group of experts (school teachers and researchers) have developed a preliminary strand map which describes assumed links between the individual core ideas (Figure 1). Each core idea is supported by clarifications specifying knowledge students are expected to have about the targeted idea and boundaries describing knowledge students are not expected to have. In total, 57 core ideas were identified for the first two learning years and arranged in a logical and hierarchical strand map.

For the evaluation of these hypothetical interdependencies it was necessary to develop a test, which assesses students' knowledge about the core ideas. For this reason, in a second step, at least five items per core idea were developed in a multiple-choice single-select format. The items were administered to students from secondary schools (comprehensive schools and grammar schools in Germany) in a multi-matrix-design using an *unbalanced incomplete block design* (Giesbrecht & Gumbertz, 2004). The test items were arranged in test booklets in such a way that all items that belong to a core idea were administered together with the items of the core ideas that are directly related. The different test booklets were linked at least by the test items of two core ideas. However, some core ideas were cross-linked more frequently than others, which means that the tasks relating to these core ideas appear more often in the test booklets.

After the removal of items with construction errors a total of 326 items was administered to 787 students from the first two learning years in a quasi-longitudinal study. In addition, students from the third learning year were tested for increasing the variance. Data from this assessment (pilot study) was used to evaluate the test instrument.

In a last step, within the context of the main study the reworked test instrument (with 348 items) was administered to another sample of students at two measurement points to evaluate the proposed interdependencies between the core ideas. Here, a quasi-longitudinal study was chosen. Students from the first two learning years were tested two times in an interval of five months for a true longitudinal design. As control variables a cognitive ability test with a verbal and a non-verbal scale (Heller, & Perleth, 2000) was administered. The sample size for the main study was N = 1232 students for the first and N = 1187 students for the second measurement point.

RESULTS

All analyses regarding test quality were conducted using ConQuest® software, while group comparisons were calculated in SPSS. Due to a design error, 9 out of 348 items were excluded from the calculation, so the calculations were performed with 339 items. The fit statistics for the main study show that the item reliability (.919 and .929) and the EAP/PV reliability (.836 and .829) are satisfying (see Table 1).

Table 1. Results of the test quality.

Measurement point	Number of items	Item reliability	EAP/PV reliability	wMNSQ	t
1	339	.919	.836	.78 – 1.35	-3.5 – 3
2	339	.929	.829	.72 – 1.29	-3.9 – 2.8

The mean item difficulty for three chemical concepts C*hemical Reaction* ($t(69) = 11.271$, $p \leq .001$, $d = 1.355$), *Energy* ($t(67) = 11.809$, $p \leq .001$, $d = 1.436$) and *Structure of Matter* ($t(200) = 18.448$, $p \leq .001$, $d = 1.3$) for the first measurement point is significantly higher than for the second measurement point. This difference was expected and can be retraced to the fact that some of the content has been learned by the students in the meantime. Hence, the test is able to measure learning progress. There are no significant differences between the three chemical core concepts within each measurement point ($F(2,336) = 1.428$, $p = .241$, $\eta^2 = .008$; $F(2, 336) = 1.584$, $p = .207$, $\eta^2 = .009$) which means that the items for the three concepts are equally difficult.

Since there is no uniform procedure for testing the hypothetical dependencies between core ideas, two different methods with different focuses are combined here: The McNemar test and the Bayesian nets. The investigated dependencies are shown exemplarily for the section shown in Figure 1. The arrows drawn in mean that the core idea from which the arrow departs is the prerequisite for the acquisition of the core idea to which the arrow leads.

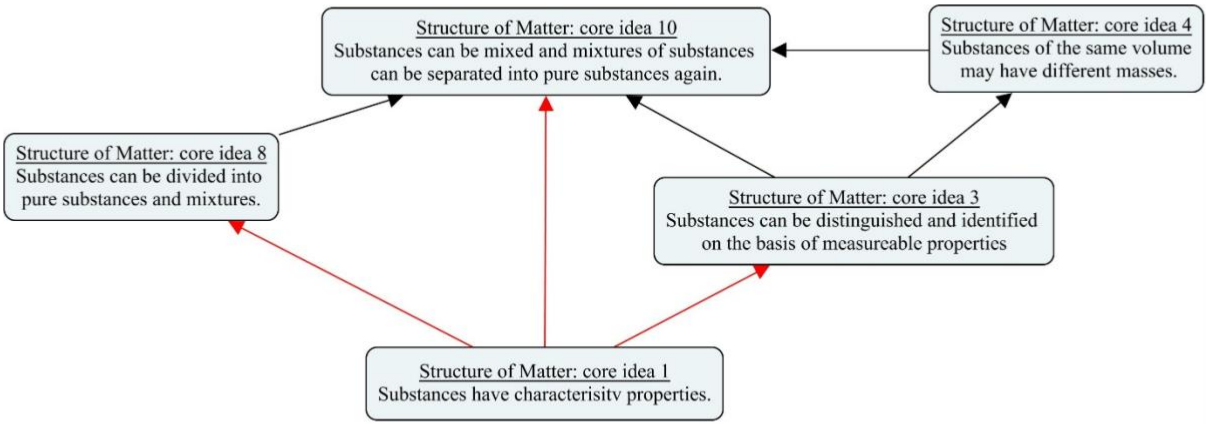

Figure 1. Excerpt from the strand map for the basic concept Structure of Matter of the first learning year.

Until now, the interdependencies have only been calculated for single core ideas. For the calculation of the McNemar test it was necessary to determine a cut off threshold to label a core idea as understood. Therefore, a binomial test was calculated to determine the guessing probability for a group of five items. Resulting from this, it has been decided that a minimum of four out of five items has to be answered correctly to make sure an idea is sufficiently understood (Bühl, 2016). The following example illustrates the calculation procedure for the McNemar test for one interdependency: For the assumption that core idea 3 is dependent on core idea 1 (Figure 1) the McNemar test (Field, 2013; Wirtz & Caspar, 2002) shows the consistency in the answers across both core ideas. For this test the three cases 0/0, 1/0 and 1/1 are expected, while the case 0/1 is unexpected (Table 2). For this test the last case (0/1) must have the lowest frequency to support the hypotheses that core idea 1 is the requirement of core idea 3. Over time decreasing numbers in the cell 0/0 are expected, while increasing numbers are expected for 1/0 and 1/1. In the example at hand, a marginal movement in this direction is noticeable. Here, the occupation of the cell 0/0 decreases while the cell 1/0 increases. For both measurement points the frequencies for the bold printed (expected) are higher than for the 0/1 cell (Table 2). However, the highest frequencies are in the 0/0 cell, which means that a lot of students have not acquired sufficient knowledge concerning both of the core ideas. For the dependencies marked in red in the figure, significant dependencies could be determined in each case. The black arrows, on the other hand, indicate that there is no significant dependency after the McNemar test. A total of 101 relationships were displayed with arrows in the strand map. Of these 38 relations are significantly dependent. Since there are only a few case numbers (N < 50) for some items of individual core ideas, the significance may be influenced. A minimum of 18 and a maximum of 243 case numbers are available for the core ideas.

Table 2. Cross table for the first (left) and second (right) measurement point.

		core idea 3		
		0	1	total
core idea 1	0	**68**	3	71
	1	**13**	**11**	24
total		81	14	95

		core idea 3		
		0	1	total
core idea 1	0	**63**	7	70
	1	**12**	**12**	24
total		75	19	94

0 = answered wrong   1 = answered correctly

The McNemar test was calculated not only for the analysis of the response behavior of two different core ideas within one measurement time (1 and 2), but also between two measurement times for the same core idea (Table 3). A similar pattern can be seen here in the results. Most pupils do not master the core ideas, despite the teaching that took place between the first and second point of measurement. Only a small proportion answered (partially) correctly the test items for the core ideas at both measurement points and consequently understood the core idea. While there these results confirm of the IQB national assessment study (Pant et al., 2013; Stanat et al. 2019), the low proficiency level is adverse for our analysis.

Table 3. Cross table for the core idea 1 (left) and core idea 3 (right) between two measurement points (mp).

		core idea 1 mp 2		
		0	1	total
core idea 1 mp 1	0	**64**	8	72
	1	**3**	**9**	12
total		67	17	84

		core idea 3 mp 2		
		0	1	total
core idea 3 mp 1	0	**63**	9	72
	1	**3**	**9**	12
total		66	18	84

The dependencies of larger sections of the strand map are checked with the Bayesian networks. The analyses were carried out with the Netica® software. This software calculates the conditional probabilities for the examined core ideas in a Conditional Probability Table (CPT) (Wei, 2014), which can be used to make statements about which core idea might have a greater influence on the understanding of another core idea. A CPT (Figure 4) was issued for the section shown in Figure 1, more precisely for core idea 10. The table on the right shows the percentages of students who master (state 1) or do not master (state 0) the core idea 10, depending on the other core ideas associated with the core idea 10. Here it becomes clear that core idea 1 has the greatest influence on core idea 10, because about 66.7 % of the pupils who understood core idea 10 also understood core idea 1, while about 33.3 % of these pupils did not understand this core idea. This finding is consistent with the McNemar test, which found that there is a dependency at least between core idea 1 and 10.

Table 4. Conditional Probability Table for core idea 10 (created with Netica®).

SDM7_K1	SDM7_K3	SDM7_K4	SDM7_K8	state0	state1
state0	state0	state0	state0	86.667	13.333
state0	state0	state0	state1	50	50
state0	state0	state1	state0	50	50
state0	state0	state1	state1	50	50
state0	state1	state0	state0	75	25
state0	state1	state0	state1	50	50
state0	state1	state1	state0	50	50
state0	state1	state1	state1	50	50
state1	state0	state0	state0	33.333	66.667
state1	state0	state0	state1	66.667	33.333
state1	state0	state1	state0	50	50
state1	state0	state1	state1	50	50
state1	state1	state0	state0	50	50
state1	state1	state0	state1	66.667	33.333
state1	state1	state1	state0	66.667	33.333
state1	state1	state1	state1	33.333	66.667

CONCLUSION AND OUTLOOK

Learning progressions offer the possibility to organize the core ideas in a strand map hypothetically and to empirically analyse the presented learning pathways. The investigated dependencies in the strand map could partly be confirmed, whereby there is a share that does not seem to be significantly dependent. From a content point of view, this is quite plausible in some places. For example, the separation of materials is dealt with in some lessons without any further elementary concepts being linked to these. The determination of the threshold value for the binomial test is set too strictly against the background of the test values found that - as international and national studies have shown - many pupils do not achieve the required competences and presumably leads to an underestimation of the actual dependencies or to no statements being made about many assumed relationships. For the discussion of the strand map with the teachers, the limit of the binomial test was therefore reduced (to three out of five items) and converted into a "traffic light system" that takes both analyses into account: If at least four items were solved, there is an empirically proven dependency between two core ideas whose relationship is marked green. If it is orange, there is probably a dependency (at least three correct answers). If less than three items were solved, no dependency is assumed, so that this dependency is shown in red.

These results should be interpreted with caution. Due to the study design, not all students were able to answer the same questions. Therefore, there are not many student responses to the items of some core ideas, so this may affect the analysis of dependencies.

ACKNOWLEDGEMENT

At this point I would like to thank all teachers involved in the project for the good cooperation. A further thank you goes to the schools, especially to all the pupils who took part in the project.

PROPOSAL OF THE USE OF SCIENTIFIC LITERACY INDICATORS TO ANALYSE A WRITTEN EVALUATION

Larissa Nascimento[1], Heloísa Flores[2], and Marcelo Motokane[2]
[1]University of São Paulo, São Paulo, Brazil,
[2]University of São Paulo, Ribeirão Preto, Brazil

Scientific Literacy is a process in which the students' learning occurs by experiencing the scientific culture. Furthermore, this is currently one of the science education goals. Through this method, students can acquire a critical awareness to make conscious decisions about life and society problems. To do so, we use an alternative didactic approach known as inquiry-based teaching. The inquiry performed during the classes must be evaluated in consistent ways, thus we propose the use of the Scientific Literacy Indicators to analyse written evaluations. It will reveal skills related to the scientific competencies that should be found within the Scientific Literacy process. These indicators are divided into 1) working with data obtained in the investigation, 2) structuring thought through logical and proportional reasoning and, 3) understanding the analysed situation and searching for connections in a given context. This study aimed to analyse a written evaluation applied in a didactic sequence about public health using Scientific Literacy Indicators. As a result, although there were found three questions containing most of the indicators, the other ones had a low variety of them. In conclusion, the Scientific Literacy Indicators were a good instrument to analyse the quality of written evaluations. Therefore, teachers must invest more time elaborating tests to achieve a greater amount of students with Scientific Literacy skills.

Keywords: Initial teacher education, evaluation, scientific competences.

INTRODUCTION

One of the goals of science education is the Scientific Literacy (SL). SL is an educational process that seeks to promote competencies and skills in students to understand science and its applications to social experiences (Bybee, 2012). It can insert students in scientific culture, making them capable of reading, understand and discuss science. Activities and classes that deliberatively seeks to promote SL in students can be guided by its axes: basic understanding of scientific terms, knowledge, and concepts; understanding the nature of science and its ethical and political factors surrounding the scientific practice; and, understanding the relationships between science, technology, society and environment (Sasseron & Carvalho, 2008). The same authors propose indicators that must be present in the DS to reveal scientific competencies through the process of SL. The indicators are divided based on scientific competencies: work with data obtained in an investigation, structuring and organization of thought, understanding of the analysed situation and searching for relation with scientific knowledge.

Health education is a subject that can include SL bringing a critical view about it during the classes. It can be defined as "a broad and varied set of strategies to influence both individuals and their social environments, to improve health behaviour and enhance health and quality of life" (Glanz, Rimer & Viswanath, 2008, p.10). William Griffiths (1972) stresses that health education is a concern of individuals, families, and institutions, such as the schools. He also says that this kind of education should give individuals some abilities. As a result, they begin to look at their environment paying attention to its real conditions which involve social conditions that hind them or facilitate optimal health. Similarly, Hurd (1998) emphasizes that the school curriculum should have practical activities in which students can solve problems, make investigations and develop field projects. Those activities show how science impacts our culture and citizenship and, as so, health issues must be included. Undoubtedly, school is a particularly relevant place where health education can be settled, and many educational approaches can be used to achieve this aim, such as inquiry-based learning.

Inquiry-based learning is an alternative teaching-learning approach that allows students to feel involved in their development and to recognize that they can use what they learn (Hurd, 1998). We can work these practices in didactic sequences (DS) that is a group of activities designed and organized for educational propose to reach a learning objective, additionally, it can also be a tool for data collection (Motokane, 2015). Furthermore, educational strategies such as we cited must have a consistent evaluation that upsurge elements previously acquired at the DS. This should be pointed out because the practice of evaluation is directly related to education democracy, in other words, the permanency of students in school is strongly and directly influenced by this practice (Luckesi, 2011). Black & William (1998) highlight essential characteristics of evaluation for it to be considered formative, and, consequently, democratic: it must be focused on the education of students to promote learning, in the process of decision-making of students, share of responsibility among professor and student, lastly, it must be focused on the form of transmission and in the moment of intervention and interaction.

Following these theoretical references, we formulated a DS about Public Health, Diseases, and Biotechnology which was applied in seventh-grade classes (12 and 13 years old) by scholarship recipients of a government program that promotes the insertion of undergraduate students in teaching initiation. The use of external contexts such as public health is a way to insert situations of student's daily life. In this study, we will use SL Indicators as an instrument to analyse a written evaluation applied during the DS and make a critical review of the professor's evaluative practice.

METHODS

The location and the participants of the study

The study was accomplished in a public elementary school located in a small town in the interior of the country. The DS and the written evaluation were applied to seventh-grade students from 12 to 13 years old. The DS was applied in two classrooms, and 45 students took the written evaluation.

The Didactic Sequence

The DS about Public Health, Diseases and Biotechnology was structured following the presupposes of inquiry-based teaching (Carvalho, 2013). Firstly, we surveyed to investigate students' prior knowledge. Secondly, the sequence had a contextualized problem that introduced the theme for students. Thirdly, support material and were used to systematize knowledge. In the DS the approached topics were: diseases caused by viruses, bacteria, worm and protozoan; endemic, epidemic, and pandemic diseases; and biotechnology (vaccine and fermentation). A brief description of each class follows:

Protozoan diseases

The DS was executed in 150 minutes, distributed in three classes of 50 minutes each. The class began with a conversation with the students about the topics: What is parasitism? What is a disease? What are public policies? This moment was important to raise the prior knowledge of students about these topics. The theme of protozoan diseases was approached using as a pedagogical resource the characters of the cartoon "The Powerpuff Girls". In this animation, one of the villains present in Townsville is the Amoeba Trio and they intend to contaminate the whole city. From these characters, several questions were asked of the students, based on a line of reasoning already pre-established, but which did not exclude the possibility of students questioning the subject matter. The questions involved the understanding of the life cycles, symptoms, form of contamination and prophylaxis of amoebas and another protozoan, focusing on the social and environmental characteristics related to the contamination by this group of organisms. At the end of this activity, students developed solutions to eliminate the Amoeba Trio from Townsville and help the Powerpuff Girls using arguments based on the knowledge worked in the class.

Diseases caused by a parasitic worm

The DS was executed in 150 minutes, distributed in three classes of 50 minutes each. The class began with the resumption of the topics covered in previous classes through a conceptual map formulated with the help of the students. Next, specimen of *Ascaris lumbricoides* and specimen of *Taenia solium* were shown. Students were able to see and ask about the morphological adaptations of worms to endoparasite life, always questioning the students about what they were observing. After observing the worms, an activity was proposed to the students to be performed in groups, based on the precepts theorized by Vygotsky, which approached the efficiency of the work done in this way. The students were organized into groups. For each group was given a story related to a disease caused by a parasitic worm and a drawing kit with a life cycle of the worm. Each group had a story about a disease that affected the population of a neighbourhood. After, each group made a poster with information about the disease, the life cycle of the worm and put the poster in the school's walls as an awareness. Many of the information needed to make the posters were already present in the story, except for prophylaxis. This should be proposed and justified by the students through the interpretation of history, it also was necessary to propose political measures to improve neighbourhood's wellbeing. This class was important to understand the consequences of political and social negligence related to health. The teachers acted as proposed by Carvalho (2013): a teacher-guide. After that, each group presented their work to the classroom and it was possible to discuss the information presented by each group, highlighting important information and reviewing misconceptions.

The epidemic, endemic and pandemic diseases

The DS was executed in 150 minutes, distributed in three classes of 50 minutes each. It had the objective to work the following concepts: endemic, epidemic and pandemic diseases, natural selection and adaptation. For this it was used a computer game named “Pandemic II”, free available on the internet, in which the player can control characteristics of a disease caused by a virus, a bacterium or parasite to kill all humankind. The students were instigated to think about strategies to contaminate the world, who was seeking a cure for the disease at the same time. Over the discussion, the students also remembered concepts previously worked in the classes, like diseases caused by viruses, bacteria and its characteristics including how it propagates, and prophylactic measures. It was possible to train scientific abilities like hypothesis testing and assessment, prediction, justification, explanation, logical and proportional reasoning, and information organization. The teacher was acting like a mediator between the knowledge of the content and the students in an epistemic way to rise and complement conceptions previously worked in class.

Biotechnology and microbiology

The DS was executed in 200 minutes, distributed in four classes of 50 minutes each. The objective of this sequence was students have contact with the scientific method, show benefits of microorganisms and talk about the work of a scientist. Initially, the students visited a bakery where they could see the process of making bread and the teacher complete the explanation bringing the concepts of fermentation and its uses by humankind. In the next class, they were able to familiarize themselves with the scientific method to learn how to make observations, elaborate questions, and hypotheses in a more systematized way. It was focused on methodologies to observe microorganisms and, for this, the students were initially instigated to ask questions about the existence and permanence of these beings in the classroom. Afterward, the students formulated hypotheses and saw the need to carry out experiments to validate them. The teacher presented instruments used in scientific research and how it was used most specifically in the field of microbiology, such as Petri dishes, pipettes, nutrient agar. The idea was to use those instruments to grow microorganisms and, therefore, to examine some hypotheses previously formulated. Petri dishes containing nutrient agar were opened in the courtyard and classroom for two minutes and they added in the middle of each plate a filter paper soaked with different substances that could or could not prevent the growth of microorganisms, such as mouthwash, sanitary water, water, and a control. After the experiment, we discussed the deficiencies and limitations of the used method and explained the existence of better and more accurate technological tools for the study of microorganisms. In this class, it was possible to find the following indicators of scientific literacy: hypothesis testing and assessment, prediction, explanation, logical and proportional reasoning, and information organization.

The evaluation

At the end of the DS, we applied an evaluation with three questions approaching the main themes. The first question was about the contamination and prevention of diseases, the second was about the vaccine and the third was about fermentation. Knowing that didactic innovations must be associated with innovative evaluation proposes, we use scientific literacy indicators to analyse this written evaluation to see if the applied evaluation were consistent with the investigative work done during the DS. The indicators are divided into three categories: 1) working with the data obtained through the serialization, organization, and classification of information, 2) structuring of thought through logical and proportional reasoning, and 3) understanding the analysed situation and searching for connections in a given context through the survey of hypotheses, hypothesis testing, justification, prediction and explanation (Sasseron & Carvalho, 2008). The written evaluations were digitalized and the responses of each student were analysed according to the scientific literacy indicator, separating the answers in categories.

RESULTS

The Investigative Didactic Sequence

By providing a context and a problem for the activities in the DS, it was possible to observe that most of the Scientific Literacy Indicators proposed by Sasseron (2008) appear in the classes. Table 1 resumes the scientific competencies observed in given classes.

Table 1. Scientific Literacy indicators in each class of the DS about Public Health, Diseases and Biotechnology. S: seriation of information; O: organization of information; C: classification of information; LR: logical reasoning; PR: proportional reasoning; HS: hypothesis survey; HT: hypothesis test; J: justification; P: prediction; E: explanation.

Topic	Indicators									
	Working with data			Structuring and organization of thought		Understanding the analysed situation				
	S	O	C	LR	PR	HS	HT	J	P	E
Viruses										
Worms										
Epidemic										
Microbiology										

The evaluation

We analysed 45 written evaluations seeking for the scientific literacy indicators. Table 2 systematizes the results found in this research, showing how many indicators were found in each question. The evaluation had three main questions and each question was divided in smaller questions, so in the table, we can see in the columns that the question 1 has, inside, questions A and B. The same happens in the questions 2 (A, B, C, D, and E) and 3 (B, C, and D).

Table 2. Scientific literacy indicators (lines) in each question (column) of the written evaluation.

	1A	1B	2A	2B	2C	2D	2E	3A	3B	3C	3D
Seriation of information	38	39	31	7	30	32	32	38	37	36	38
Organization of information	34	39	29	9	30	32	27	14	12	29	3
Classification of information	4	23	2	0	0	0	0	0	0	1	0
Logical reasoning	8	1	0	0	0	0	0	0	0	6	0
Proportional reasoning	0	2	0	0	0	0	0	0	0	1	0
Hypothesis survey	13	2	0	0	0	0	0	0	0	1	0
Hypothesis test	1	0	0	0	0	0	0	0	0	0	0
Justification	8	2	2	4	3	0	0	0	2	4	0
Prediction	10	9	0	0	4	0	0	2	4	23	0
Explanation	33	13	10	35	28	4	0	7	10	30	4

From the result presented in Table 1, it can be observed that the indicators "seriation of information" and "organization of information" (Sasseron & Carvalho, 2008) are present in all classes. On most of the evaluation questions, we can also see those indicators (Table 2). We can also see that questions 1A, 1B and 3C cover almost all SL indicators. However, eight of the eleven questions present a low variety of indicators in the analysed answers, being limited mostly by the serialization and organization of information. Figures 1 and 2 illustrate the difference between questions 1A and 2D, comparing the scientific literacy indicators found.

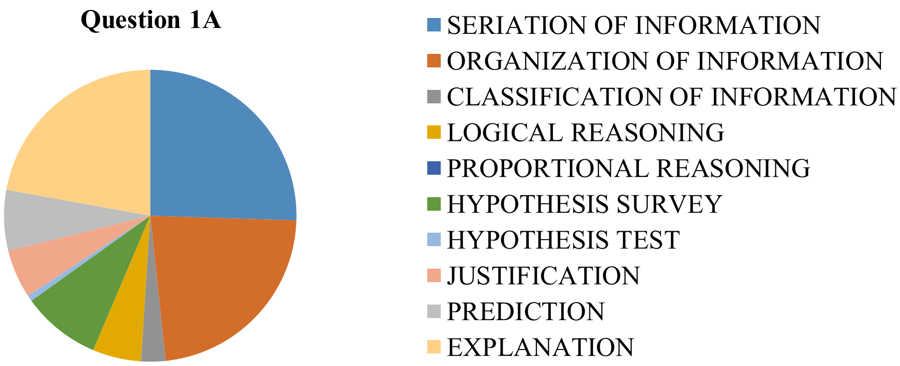

Figure 5. Indicators present in student's answers to question 1A.

Question 2D

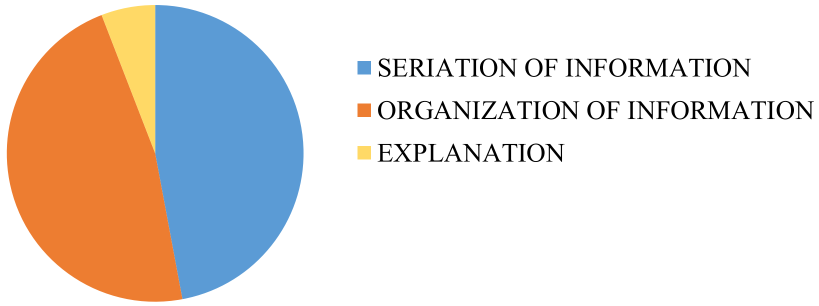

Figure 6. Indicators present in student's answers to the question 2D.

DISCUSSION AND CONCLUSION

The analysis of the written evaluations evidences a link between the type of question formulated by the teacher and the indicators of SL developed by the students in each question. Indeed, the type of question asked by the teacher in the written evaluation can influence the appearance or not of the SL indicators and, therefore, the questions is an important instrument that can unleash fundamental skills for SL. According to Machado & Sasseron (2012), the questions formulated by the teacher in classes should contain clear intentions and retake the purposes established in class planning. However, it was not possible to observe this in the applied evaluation. The questions were contextualized, but eight of the eleven questions did not present an investigative character, having a more traditional and memorization examination character. Those eight questions began with "what" or "which" and even though a few indicators appeared (serialization and organization of information), the majority of data used by students raised from the question itself and were content review and memorization of information. Only three questions had a bigger range of SL indicators. Those questions initiate with "how" and "why" and allowed students to structure data by having logical and proportional reasoning, as well as to explore the context of the proposed situation by formulating and testing hypotheses, justifying, predicting and explaining. Thus, we can see that in the applied written evaluation the questions did not stimulate students to reason and expose their point of view. Also, it does not bring the investigative character worked among the entire DS about Public Health, Diseases and Biotechnology and does not explore the problem in which the questions were inserted.

In fact, the evaluation can increase the quality of the learning (Luckesi, 2011), however, the present work brought examples of an inconsistent evaluation applied at the end of an DS potentially democratic. Over the DS the teachers possibly could improve cognitive and metacognitive resources in the students, but it couldn't be contemplated in the evaluation for its traditional character. Because of all the years spent in a traditional school with traditional curriculum, assessment and evaluations make the exit from this traditionalism very difficult to happen, since it is deep-seated in the students from the beginning of their school life (Nascimento, 2018). As a result, despite attempts to diversify didactic strategies, the evaluation followed the same traditional characteristic that teachers so much wanted to avoid.

From this work, we can see evidence of an alienating and uncritical educational system so efficient that even when teachers try to accomplish different actions they can fail. As a result, it is imperative that newly graduated teachers, and even older teachers, know theories of teaching-learning and evaluation within a democratic, dialogic and formative perspective. Also, it is substantial to emphasize the importance of the teacher as a researcher within the classroom, sensitive to feedback from students to always improve their pedagogical practice (Black & Wiliam, 1998). Indeed, the evaluation cannot be by memorization and aim to classifying students. On the contrary, the teacher as a reflective practitioner (Schön, 1987) always has to ask himself about the purpose of their evaluation: is it improving student's learning? Is it helping to overcome student's difficulties?

Thus, using the indicators of Scientific Literacy to analyse the final written evaluation, it is concluded that the questions do not stimulate the students to reason and to expose their point of view, not promoting the Scientific Literacy itself. Besides, this evaluation does not expose the investigative character worked during the entire Didactic Sequence on Public Health, Diseases and Biotechnology and does not explore the problem in which the questions are inserted. In fact, the evaluation is an important tool to achieve the knowledge constructed by the students in the DS. Therefore, a set of instructional practices that aim to subsidize the construction of successful learning is needed, using the evaluation in service of student learning and growth, like the formative evaluation. So teachers must invest more in the elaboration of questions and evaluation if they want to detect the skills and competencies internalized by students in the DS.

The SL indicators provided us a good tool to analyse the quality of written evaluations and the teacher's work. In conclusion, we see that the investment of teachers in the elaboration of questions that leads the students to think is very important. As a result, students can develop the skills necessary to promote Scientific Literacy.

ACKNOWLEDGEMENT

We thank CAPES for financing the project. This study would not be possible without the other fellows from the Pibid who assisted in the elaboration and application of DS on Public Health, Diseases and Biotechnology. We also thank the supervisor Gabriela Zanarotti for the confidence inside and outside the classroom and the coordinator of the project Marcelo Motokane for assistance and support.

EVALUATING DIVERGENT THINKING AMONG PARTICIPANTS OF A GERMAN SCIENCE COMPETITION

Swantje Müller[1], Verena Pietzner[1]
[1]Carl von Ossietzky University, Oldenburg, Germany

Creativity plays an important role in society, for it is needed for societal development. Discovering students' creative potential enables them to develop new technologies and ideas in the future. Sciences, especially chemistry, are pointing the way in many areas. Identifying a problem and finding its solution is part of the creative process and also closely related to divergent thinking. However, this has been poorly explored so far. In a study presented here, the divergent thinking abilities of students taking part in a German Student Science Competition called "Jugend forscht" have been tested using a validated test. First results regarding different performance depending on gender, parental academic background and previous participation in a competition among the participants in divergent thinking and problem discovery will be presented here.

Keywords: informal learning, problem solving, cognitive development

Introduction

Creativity plays an important role in many areas these days. This meaning not only comes into play in the creative subjects such as music and art, but also in science and technology; areas that advance a society in an increasingly complex world and are more important to our society today than ever before (Runco, 2004). Creativity refers to the ability to develop new ideas and solutions. Expressing them in a unique way (Abraham, 2016). Creative skills such as problem awareness and problem solving are needed to find solutions to political, economic, and social challenges, as well as to remain flexible in the development of new technologies.

The natural sciences and chemistry are pointing the way in many fields. However, creativity is rarely used or fostered in science education. Classical chemistry lessons, in which teachers set strict framework conditions for all phases of teaching and thus in particular for the path of knowledge, inhibit creative and innovative processes (Gärtner & Scharf, 2001). Kind and Kind (2007) assumed that elements of frontal teaching like "recipe" work is a teaching method that usually does not promote creativity, whereas it is still the method that is preferred by most teachers (Semmler & Pietzner, 2017). In doing so, the students are often already given a stringent solution by the teacher, which has to be worked on during the experimentation phase. The result is that for experiments, an important pillar of chemistry lessons, are carried out in a recipe-like way. This does not give young people the freedom to follow creatively their own ideas in the classroom (Starko, 2010). Free work phases, in which the students themselves can develop problems can also rarely be found in chemistry classes. Which means that an important aspect of problem solving cannot be addressed at all. Student-oriented school lessons, where students work independently on open-ended tasks, promote creative skills by giving the students the opportunity to develop, test and revise their own ideas therefore enhancing science learning (Kind & Kind, 2007; Semmler & Pietzner, 2017).

Unlike the formal school as a place of learning, non-formal learning environments such as Science Competitions make it possible for students to work on their projects in their afternoon hours with support, but still independently. The solution to the problem students' work on is not predetermined and can be designed by the participants themselves. Often there is not just one solution, but several. It has to be thought of in breadth, divergent. This divergent thinking is an important aspect of creativity that involves special significance and creative application in the natural sciences and leads to an improved life quality and scientific innovation (Achieng'Rabari et al., 2011). Finding a problem and its possible solutions is closely related with divergent thinking, which is a cognitive ability of a creative person (Runco & Okuda, 1988; Guilford, 1967). Problem solving skills as well as creative thinking skills are emphasised by after school programs (Wirt, 2011). Mund (2007) investigated the differences between participants in two different federal competitions; in science and music, and a comparison group of High School students regarding graphic creativity using a figural test. Here, the students taking part in *Jugend forscht* showed higher abilities. However, divergent thinking has not been evaluated. The aim of the study presented here is to close this gap and to investigate the divergent thinking abilities of students taking part in a German Student Science Competition called *Jugend forscht.* They were tested using a validated test. Initial results show gender differences among the participants in their aptitude for divergent thinking and problem discovery.

THEORETICAL BACKGROUND

Creativity is omnipresent, but in the search for a uniformly understood concept one searches in vain. Instead, one finds many different definitions and theoretical explanatory approaches (Urban, 2004). Since the beginning of modern creativity research which was initiated in the 1950s by psychologist J.P. Guilford. At the beginning of the 1970s, this trend spilled over to Europe. As a result, not only Guilford but also creativity researchers like Torrance, Wallach and Kogan or Urban tried to make creativity measurable (Urban, 2004). He defined creativity as an "*ability to create a new, unusual, and surprising product as the solution to a sensitively perceived or given problem whose implications are sensitively perceived*." (Urban, 2004, p.34). In so doing, Urban's Definition of Creativity not only encompasses the creative thinking process, but about the entire interaction process. He describes this interaction process in his "4P-E interaction" model. The four P's stand for Problem, Person, Process and Product; the E for environment. According to Urban (2004) divergent thinking and problem discovery are two out of six components of a creative person. In 1959, Guilford first defined divergent and convergent thinking: "*In divergent thinking operations we think in different directions, sometimes searching, sometimes seeking variety*." and "*in convergent thinking the information leads to one right answer or to a recognized best or conventional answer*." (Guilford, 1959, both p.470). Divergent thinking is one of the most important skills for creative thinking (Guilford & Hoepfner, 1976).

Runco and Okuda conclude that consequently "divergent thinking tests can be used to investigate problem finding, and they support the theory of problem discovery" (Runco & Okuda, 1988, p.219). Only if tasks were given, where the problem has to be discovered independently does "*the problem itself becomes a goal, necessitate problem finding*" (Starko, 2018, p.38). For Wakefield (1985), the pre-requisite for creative performance is the freedom to discover and solve problems. According to Urban (2004), divergent thinking is essential for the creative process and a prerequisite for fluent, flexible thinking, as well as a broad knowledge base and the ability to focus on the task. Urban (1995) further describes that divergent thinking does not lead to creative excellence alone but requires a special field mastery.

For decades, attempts have been made throughout Europe to increase the interest of students in natural sciences (Janštová et al., 2015). As a result, non-formal learning has emerged in education (Council of Europe, 2003). "*Science centres and non-formal student laboratories have emerged to provide additional value to school science education.*" (Affeldt et al., 2017, p.13). In these previously described non-formal learning settings, students have the opportunity to instigate and prepare their own projects for science competitions.

In Germany, in 1965 the most famous and still expanding Science Competition *Jugend forscht* was initiated to promote young scientists. It is promoted by the German Federal Government, as well as the German president, chancellor, and many large companies. In 2018, over 110 competitions took place per round on the three competition levels (Stiftung Jugend forscht e.V., 2019).There is a total of seven subject areas - biology, chemistry, geography and spatial sciences, mathematics/computer science, physics, technology and working world in which students can develop and present their project. Participants from age 10 to 14 belong to the junior category *Schüler experimentieren*, and the older ones from the age of 15 to 21 belong to the category *Jugend forscht*. After having successfully worked on their research project, mostly in non-formal learning places, students apply for the regional competition. The winners of this level take part in the federal contest (second level) and this is where the competition for the younger students ends. The winners of the senior federal level move on to take part in the national competition (third level).

When working on an own project, it is common to works not only on a stringent or convergent solution, but rather to think divergently. Whether this assumption holds true and how developed the participants' divergent thinking skills are has been little studied so far. This research gap could be closed with the help of two questions:

1.) How does divergent thinking of students taking part in a German Science Competition differ with respect to their gender, previous participation and academic background of the parents?
2.) How does divergent thinking and problem discovery differ with respect to the different competition levels (national and federal competition)?

Method

For collecting data, the divergent thinking questionnaire of Wallach and Kogan (1965) as well as the problem finding questionnaire of Wakefield (1985) were used, according to Runco and Okuda (1988). The divergent thinking questionnaire contains three standards, so called "presented-problem" items: *instances*, *alternate uses* and *similarities*. In the following, all the tasks of the present problems from the divergent thinking test are listed.

Instances: "Name all the round things you can think of."; "Name all the things you can think of that will make a noise."; "Name all the things you can think of that move on wheels."

Alternate uses: "Tell me all the different ways you could use a knife."; "Tell me all the different ways you could use a chair."

Similarities: "Tell me all the ways in which a potato and a carrot are alike."; "Tell me all the ways in which a cat and a mouse are alike."; "Tell me all the ways in which a radio and a telephone are alike."

Discovered problems were adapted from Wakefield (1985) for each of these items. The participants then had to define a problem and provide solutions for it, e.g. "Choose two objects that are alike, and then list your ideas of how the objects are similar."

The results were evaluated using the three criteria of fluency (scored number of distinct ideas as described in Runco (1986)), flexibility (the number of categories from which the ideas originated) and originality (Runco & Albert, 1985). All answers were categorised according to Torrance (1966), although for the evaluation of flexibility the Torrance list (1966) needed additional categories to aid analysis. This was validated by several group discussions with four experts.

The questionnaire was incorporated into a free App called Actionbound, which is supported by the German Federal Agency for Civic Education. This App collects data anonymously with a mobile phone with internet access. Depending on the type of task, data can either be entered in writing using the keyboard, or the multiple-choice task can be selected by clicking on it. This digital collection method enables fast data transfer. Due to the different procedure, a pilot study was performed in January and February 2018 at a comprehensive school. 29 students of different age participated in the study during their chemistry lesson (16 female, 12 males, 1 N/A). The results show that also with the different procedure compared to the original literature, valid results can be obtained.

In co-operation with the organisers and for the purposes of data collection a declaration of consent form for the underage participants was sent to the parents in advance. The procedure for the survey was in a leaflet and mentioned that the Actionbound app was required and therefore installed onto the participants' smartphone. During the competition the participants have been contacted directly, and the main author was always available to answer questions during the procedure. Based on Runco & Albert (1985), the participants were not given any time limits in this study, which resulted in some examinees completing the survey within 10 minutes, others after one hour. The latter were particularly ambitious and saving that after a few seconds another new answer came to mind, so they did not want to click on "Continue" in the online questionnaire and thus needed more time.

From the results of each task an average was formed representing the category result and used for evaluation. To assess the originality of an answer, all items named by students were listed according to Runco and Albert (1985). Every item that only occurred once received three points. Items which occurred less than 2,5 % had two points. Items which occurred between

2,51 % and 4,99 % were given one point, and all others received no points. An exception was made for the group from the national competition, where only 23 participants were interviewed. Here the point system was changed due to the low number of participants. Consequently, an item that occurred twice received two points, an item that occurred three times got one point, and all others got no points. Then the number of points for each student was calculated. For evaluating the discovered problems, only the creativity characteristics of the fluency and flexibility were applied. Originality was, according to Runco (1985), only evaluated in the presented it is not due to the individual discovered problems. The Whitney-Mann-U-test was used to investigate the differences between the gender, academic background and previous participation and presented and discovered problems were investigated. These were then compared to the presented and discovered problems that had also been investigated. The U-Test examines whether the central tendencies of two independent samples are different and is used if the requirements for an independent sample t-test are not met (Schwarz, 2019). If the sample sizes are less than 30, the exact significance is used, and since the number of participants in the study for the national competition was only 23 it was applied (Schwarz, 2019), providing valid results even for these small samples. All results were presented with an effect strength, which follows the division of Cohen (1992), so that a weak effect is represented by $r = 0.10$, a medium effect by $r = 0.30$ and a strong effect by $r = 0.50$.

Data was collected in the federal and national competitions ($n = 67$); for the federal competitions was collected between January and April 2018 in Hamburg, North Rhine-Westphalia, Lower Saxony and Schleswig-Holstein, for the national competition in Darmstadt on May 23, 2018.

DESCRIPTION OF THE SAMPLE

The participants in the study were students aged 15 - 21 years competing in the Science Competition *Jugend forscht*. In this survey, 44 students (12 female, 29 male and 3 N/A) took part in the federal competition and 23 students taking part in the national level of *Jugend forscht* (6 female and 17 male) participated, a total of 64 students. From the 42 participants in the federal competition, 26 have parents with an academic background: 16 do not. Of 23 participants in the national competition, 18 had parents with an academic background, whilst five sets of parents.

Results

Regarding the academic background and a possible previous participation in *Jugend forscht*, no differences have been found in the sample. Participants of the national competition show a higher performance in all criteria of both tests than participants of federal competition (see Table 1).

Whether the divergent thinking of girls in federal and national competition differ, should be examined hereinafter. Girls in the national competition outperform better in all criteria of both tests compared to girls of the federal with a strong effect (see Table 2). Also, differences between boys in federal and national competition are visible. Boys in national competition outperform better in originality (Mean Federal = 4.30, Mean National = 10.46, U = 76.000, Z = -3.881, p = 0.00, r = 0.572) and fluency (Mean Federal = 5.77, Mean National = 7.00, U = 142.500, Z = 2.368, 0.018, r = 0.439) of divergent thinking test compared to boys in federal competition. No differences are visible in problem discovery test.

Table 1: Differences between the participants of federal and national level.

Test	Criterion	Mean Federal Competition	Mean National Competition	Z	p	r
Divergent thinking (DT)	Originality	4.25	12.41	-4.986	< 0.0009	0.515
	Fluency	5.61	8.14	-2.991	0.003	0.365
	Flexibility	3.71	5.47	-3.606	< 0.0009	0.440
Problem discovery (PD)	Fluency	3.61	6.01	-2.148	0.032	0.262
	Flexibility	2.53	4.17	-2.620	0.009	0.320

Table 2: Differences among girls between federal and national competition

Test	Criterion	Mean Federal Competition	Mean National Competition	Z	p	r
DT	Originality	3.55	17.92	-3.278	< 0.0009	0.773
	Fluency	5.20	11.40	-3.092	0.001	0.729
	Flexibility	3.52	6.86	-3.097	0.001	0.730
PD	Fluency	3.08	7.50	-2.675	0.005	0.631
	Flexibility	2.22	4.89	-2.817	0.003	0.664

Regarding gender differences in on the federal and national level of *Jugend forscht,* girls in national competition show a higher performance in all criteria of divergent thinking test than boys with a strong effect (see Table 3). The results of the problem discovery test did not identify any significant gender differences in fluency and flexibility.

Table 3: Gender differences in national competition

Test	Criterion	Mean Value Girls	Mean Value Boys	Z	p	r
DT	Originality	17.92	10.46	-2.521	0.010	0.526
	Fluency	11.40	7.00	-2.591	0.008	0.540
	Flexibility	6.86	4.98	-2.031	0.044	0.424

In the federal competition, no significant differences between boys and girls in divergent thinking and problem discovery test could be measured.

Discussion and conclusion

This study has shown that a general difference between the competition levels regarding divergent thinking/problem discovery does exist. The participants showed a higher originality, fluency and flexibility in national competition compared to the results of the federal competition. The data contains some gender-dependent results; since no gender difference was found by Runco and Okuda (1988) among older participants (age 15 years and 11 months to 17 years and 7 months) and Wakefield (1985) among younger participants (age 10 years and 5 months to 11 years and 6 months), the question arises as to the background of this difference. Comparing the same gender in both levels of *Jugend forscht*, girls have greater divergent thinking in all three criteria compared to boys at national competition. Additionally, they also performed better in the problem discovery test than girls in federal competition. Boys show stronger divergent thinking in the national competition than boys in lower competition level. Unlike the girls, no connection between problem discoveries is measurable. It is noteworthy that girls with a pronounced skill for problem discovery reach the next competition level, while boys get ahead without a pronounced problem discovery sense which leads to further research questions like who chose the students taking part in a science competition and what are their selection criteria, as well as which priority has divergent thinking in this process.

The observed gender may have its origin in school, as often students were asked by their teachers if they would like to take part in *Jugend forscht*. The teachers' attribution of competences and ability of female students in science education and the question of whether girls in the classroom may need to be standing out with special achievements or special problem discovery skills to be supported by a teacher should be investigated. Since the beginning of their school career, science is perceived by girls as a male domain (Kennedy and Parks, 2000). Teachers influence students' interest the scientific interest of Chemistry and Physics Olympiad participants. Parents, regardless their profession, often have a positive impact on girls' interest in biology and often initiate it (Janštová et al., 2016). This may explain why most girls participated in biology in the national competition level of *Jugend forscht*, followed by chemistry and physics. It is an open question as to why teachers do not seem to have a more positive influence regarding the image of the other science subjects.

Further examination of whether teachers attribute the personal characteristics of a creative person to male stereotypes. According to Kämmerer (2000), characteristics of a creative person such as independence and belief in one's own abilities/positive self-assessment are ascribed to boys. A Portuguese study of national science competitions (NSC) showed that teachers pre-selected their best students to participate as they see a connection between performance in school and the results in the competitions (Descalço & Olivereira, 2018). However, good grades and a good relationship to the teacher is no guarantee of effective divergent thinking ability. These qualities of creative boys are at odds with the educational styles and socialisation of girls. In the process, girls are taught to be a good girl, otherwise they are "*considered bossy and worse*" (Wirt, 2011, p.59). It could be that girls are perceived by teachers more as "*troublemakers*" than as "*creative persons*". As Westby and Dawson (1995) found, the character traits of creative students' determination, independence and individualism are not consistent with the teacher's goals in traditional classroom.

A thesis that still needs to be reviewed posits is creative girls find their ways to *Jugend forscht* via out-of-school learning venues such as student laboratories. Here they can work freely on science projects in the afternoons without pre-conceived gender traits being at the forefront, as at school. These extra-curricular activities are encouraged and supported by the families. Whether families, especially those with an academic background, have more creative children was examined in this study. No connection between the *Jugend forscht* participants at either federal or national competition and the academic background of their parents could be measured.

Unexpectedly, and unlike originally thought, divergent thinking and problem discovery skills did not change during the problem-solving process of their projects changing; no difference could be measured between the participants who had previously taken part in the competition and those who took part the first time.

If the participants are influenced too much by a mentor with a knowledge advantage, the path to the product is convergent and the participation motivation is "extrinsic-reward", which is linked with extrinsic motivation. Rewards leads to obligation motivation that only compulsory tasks are solved, but that the person does not completely settle in a task and have an inner interest in solving the problem (Cooper & Jayatilaka, 2006). As a result, the actual spirit of research is satisfied, but the work and intrinsic motivation can be low. Extrinsic "motivation reduces individuals' freedom in that their behaviours tend to be confined to actions instrumental in gaining the rewards" and "typically reduces individual's creativity" (Cooper & Jayatilaka, 2006). Even though intrinsic motivation is a key factor for creativity, which is a "recognizable level of creativity to be produced" and is associated with best academic outcomes (Amabile, 1983, p. 367; Orvis et al., 2018). "As a result, individuals may be distracted from creativity-relevant aspects of the task and/or may exhibit functional fixedness or other forms of cognitive rigidity, with their efforts narrowly focused on the task as originally defined and on common algorithms that have worked well in the past" according to Cooper and Jayatilaka (2006, p. 153). Therefore, further studies should examine more closely the motivation of the participants taking part in a competition and where students are preparing. Additionally, other important questions would be what the supervisors influence on the students' work is, do the participants have the opportunity to playfully open and investigate the problem, or does the teacher/supervisor present a topic for the students work out.

In principle, it should be examined if participants had divergent thinking skills before their attendance at a *Jugend forscht e.V.* competition and to what extent the competition initiates divergent thinking. The latter question will be answered in a second study which examines non-formal learning places and out-of-school activities, where students are allowed to work freely on projects and partly prepare for *Jugend forscht*.

ACKNOWLEDGEMENT

We would like to thank Jugend forscht e.V. for the opportunity to carry out the study on their competitions.

AN EMPIRICAL STUDY ON LEARNING PROCESSES AND ACTIONS OF STUDENTS WHILE INTERACTING WITH EXHIBITS AT A SCIENCE CENTRE

Anastasia Striligka[1], Michael Komorek[1] and Dimitris Stavrou[2]
[1]University of Oldenburg, Oldenburg, Germany
[2]University of Crete, Rethymnon, Greece

Studies about informal learning environments like science centre show that pupils' interests in scientific topics can be aroused. However, current research only provides few indications on how pupils can develop subject-specific knowledge and competencies through self-directed interactions with exhibits. The aim of the presented study is to clarify how characteristics of the exhibits and the explanatory media lead to an understanding of the represented phenomena or hinder it. It is also of importance to take into consideration that although the learning processes are individual, the teachers as well as the staff of the science centre can affect these processes. Therefore, in cooperation with a Science Centre firstly the intentions of the centres' pedagogical leaders are empirically investigated. Secondly, certain exhibits are subjected to a subject-specific educational potential analysis. And thirdly, accompanying interviews and questionnaires are used to investigate pupils' processes of decoding and to interpret to what extent the exhibits induce subject-specific learning. Also, the perspective of teachers on pupil learning is examined. The preliminary results of the study will be presented.

Keywords: Informal learning, Non-formal Learning Environments, Primary School

INTRODUCTION

Studies about informal learning environments like science centres show that pupils' interests in scientific topics can be aroused at these environments (Scharfenberg & Bogner, 2014). However current research provides few indications on how pupils can develop subject-specific knowledge and competencies through self-directed interactions with exhibits. For example, previous studies have shown that common learning processes that are possible to occur during the interaction with exhibits are: a) remembering previous knowledge built on personal experience, b) establishing and recognising correlations between exhibits, c) asking questions and explaining (for example the function of the exhibit) (Hein, 1998; Falk & Dierking, 2000; Kelly, 2007). There were also proposals to operationalize the link between exhibition features and visitor activities. The four stages of Achiams praxeology (2013) that show the level of an users interaction with an exhibit are the following: (1) Task: The user is able to perceive the task provided by the exhibit. (2) Technique: The user can carry out or use a procedure in a given situation to solve the task. (3) Technology: The user can justify his action. He can also explain what and why is happening while interacting with the exhibit. (4) Theory: The user is able to justify himself with abstract concepts. However, to what extent the learning goals are achieved, in what way they differ from those at school, and how they can be described as inquiry-based learning remains to be further investigated.

Therefore, this presented study is aiming to investigate pupils' learning processes during their interactions with exhibits and to clarify how characteristics of the exhibits and the explanatory media lead to an understanding of the represented phenomena or hinder it. In order to get a deeper insights into the pupils' learning we took into consideration not only the pupils interactions with the exhibits but also what role teachers as well as the intentions the science centres' pedagogical leaders play in the learning process of the individuals during the visit at the science centre. It is of importance to take them into consideration, because although learning is individual for each pupil, the teachers as well as the staff of the science centre affect the learning process of the pupils (Griffin, 2012; Falk & Dierking, 2000).

Research questions

The study addresses the following questions:

(1) To what extend does learning of scientific content and what actions occur while interacting with the exhibits at a science centre visit?

(2) To what extent do the intentions of the science centres' leaders fit to the learning processes of the pupils?

(3) What are the teachers' views of their pupils' learning outcomes and the effective features of the exhibits?

RESEARCH DESIGN AND METHOD

The study is based on the Model of Educational Reconstruction (MER) (Duit, Gropengießer, Kattmann, Komorek & Parchmann, 2012). The aim of the model is to take equally into consideration science subject matter issues and learning needs and capabilities to improve the quality of teaching and learning. However, MER considers the general goals of science education to be 'given' by the curriculum. The situation in a out of school environment such a science center differs as the informal learning environment has no constraints imposed by a curriculum. MER must be, also, specified with an interpretation of visitors' interactions with the exhibits and the aim of the visit (Laherto,2013).

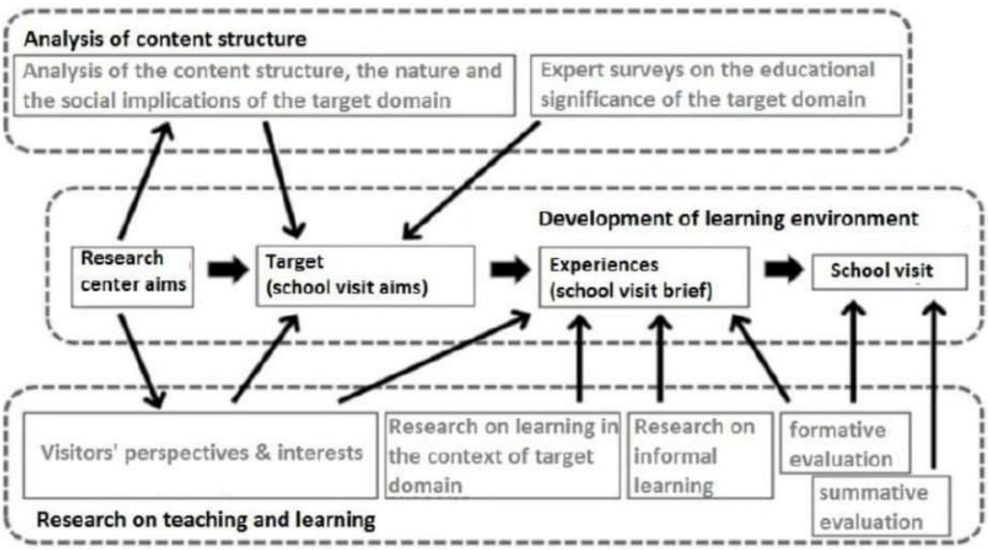

Figure 1: The suggested procedure for developing visits to non-formal learning environments based on MER (Laherto,2013)

Therefore, we apply the model to the situation where learning takes place by interacting with exhibits in a science centre: The exhibits have a scientific and an educational structure that need to be analysed. The results of these analyses have to be systematically related to the empirical results on the learning processes and the influences of the teachers and supervisors.

Research Context and Design

The empirical study is taking place in a science centre where 80 hands-on exhibits are provided to the public. Based on our educational analysis, we came to the conclusion that those exhibits provide different levels of interaction to the visitor. For example, some of them give the opportunity to change multiple variables to affect the phenomenon, while others only display the phenomenon at the push of a button. The exhibits are educationally analyzed to determine which actions and which learning processes are possible while interacting with them based on the "Praxeology" of Achiam, which scientific content of the exhibits could be conveyed to the pupils by interaction with them and what interaction they offer. We selected four exhibits (camera obscura, visible light, Bernoulli Effect, pulley system) with different offer of interaction to find out about the pupils' learning paths while interacting with them.

The views of the centres' pedagogical leaders were recorded during a structured guideline interviews in order to find out their views on what the four exhibits are aiming for and what kind of pupils' learning processes they expected. Examples: "What is the main goal of this particular exhibit?", "To what extend do you think that pupils will reach that goal?" Following, pupil visits at the science were attended and a random sample of pupils was participatory observed and interviewed in groups of two during their interactions with the hands-on exhibits, in order to investigate their actions and their learning paths. The aim is to interpret to what extent the exhibits induces subject-specific learning. Furthermore, questionnaires with open ended and multiple choice questions were administered before and after the school visit to pupils in order to find out which pupils' ideas emerge on the phenomenon of the selected exhibits and which the pupils' expectations of the visit to the science centre are. There were also teacher questionnaires with open and multiple-choice questions before and after the visit, based on categories by Cox-Peterson, Marsh, Kisiel & Melber (2003) and Griffin & Symington (1997). They are about the teachers' views on the learning outcomes they expect from the pupils' visits, and how the visit to the science centre could be integrated into the school curriculum (preparation, expected learning outcomes to be achieved by the visit, etc.). In this study–a random sample of 10 fourth grade pupils, were participatory observed and audio-recorded in groups of two. Additionally, 34 fourth grade pupils of two schools, 6 teachers and the supervisor of the science centre participated in the study.

RESULTS

In order to determine the actions and learning paths that occur while interacting with the exhibits we evaluated the empirically obtained data using qualitative content analysis (Mayring, 2015), and related the data to each other systematically through data triangulation (Flick, 2004). This is outlined in the following case study of the fourth-grade pupil Stefan. The pupil was interviewed and observed during his interaction with the “Visible Light” exhibit. At this exhibit there is the possibility to fold three colour filters (red, green, blue) and a prism one by one or simultaneously in front of a light source. The written task at the exhibit was: "Look at the spectrum of visible light with the prism, and the filters will only pass through a certain area." Stefan recognises all objects (lamp, button, colour filter, etc.) at the exhibit. He retrieves his prior knowledge of the exhibit and can justify and explain his actions. However, one also recognises his difficulty in distinguishing between the relevant and irrelevant variables of the exhibit. Although he placed the red and blue filters in front of the light source at the same time and could see that the light was largely absorbed by the filters, he remained in his initial opinion of his first questionnaire "the light should turn purple". His explanation for the phenomenon observed on the exhibit was that the filters are "too thick for any light to pass through". Therefore, he also replied at the questionnaire after the visit, that "the light is purple, if it goes first through a red and then through a blue filter". So Stefan stays with his initial opinion, that the phenomenon shown at this exhibit is colour addition instead of the actual phenomenon shown, that is colour subtraction.

This example is also reflected in the questionnaires of the pupils, where only 26% of the pupils answered before and after their interaction with the exhibit that little or no light goes through a blue and red filter (Figure 2).

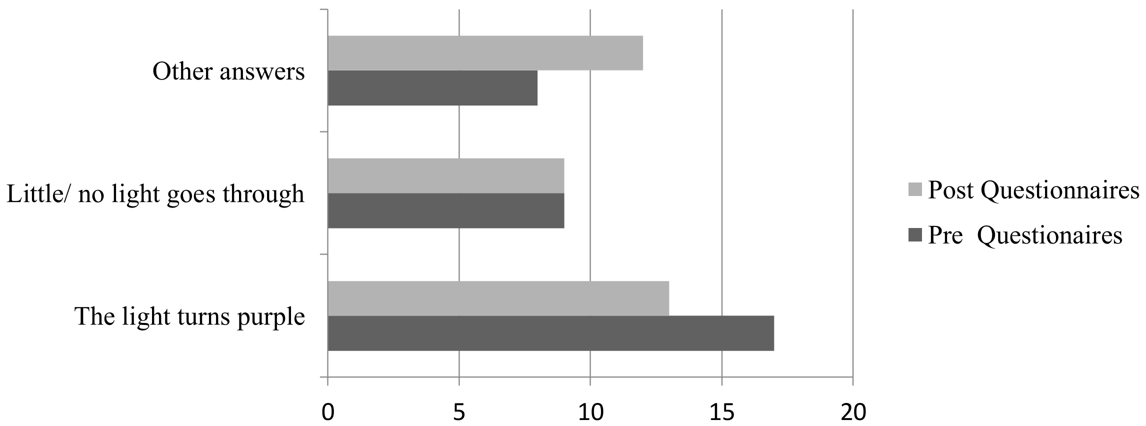

Figure 2: Answers to the question: "Describe what happens with the white light when it first goes through a red and then through a blue filter." (n=34)

The analysis of the pupils’ interviews during their interaction with the visible light exhibit with the Praxeology (Table 1), revealed that all pupils are able to perceive all the objects (filter, light source, etc.) and the task provided by the exhibit (Task). The pupils were also able to carry out the task in the science centres’ leaders intended way (Technique). However, they found some difficulty to explain what and why is happening while interacting with the exhibit and to justify themselves with abstract concepts (Technology, Theory).

For example, although eight out of ten pupils noticed that the white light was almost completely absorbed when it went through the red and blue filter of the exhibit, they remained to their prior idea that the light should turn purple. This happens because two of the pupils can’t give any explanations about the phenomenon they just observed, while six of them base their explanation on the fact that the light won't go through the filters because of the thickness of the exhibits' filters or because of the "larger distance the light has to go to reach both filters". Only one group of two pupils could explain that what happened at exhibit (Technology) but without the use of scientific terms.

Praxeology	□	~	X
(1) Task	5	0	0
(2) Technique	5	0	0
(3) Technology	1	3	1
(4) Theory	0	0	5

Table 1: Number of groups (2 pupils per group) and degree of accomplishment of Praxeology stages in the "visible light" exhibit. (n_{groups} = 5)
□ : fully accomplished ~: deficient accomplished X : unable to accomplish

As one can conclude from this example the intentions of the science centres' leaders do not fit one by one to the learning processes of the pupils. The data also showed that five of six teachers expected that their pupils had learned something new from the visit, although four of six noticed their pupils' difficulty to understand the different phenomena through the interaction with the exhibits, because of the lack of further guidance and explanations. Nevertheless, four of six teachers answered that there would not be any follow-up discussions about the visit in the classroom.

DISCUSSION

Responding to the first research question about the extent to which science content occurs when students interact with exhibits at a science centre, we conclude that interactive exhibits that at the centre appear to be unable to influence most pupils' perceptions without appropriate support. The results of this study show that when pupils visit the science centre, they are able to recognise the tasks and to carry out work procedures (Technique). They can also give explanations (technology) to their actions on the exhibits. These do not always agree with the desired explanations of the exhibition supervisor (Achiam, 2013). In addition, pupils have difficulties in justifying themselves with abstract concepts (Theory). This study also confirmed previous studies that the pupils, the teachers, and the centres leaders' views are not aligned (Griffin, 2012). Therefore, we suggest that further research is needed in order to bridge the gaps between the science centres' leaders intended use and learning processes of the exhibits from the pupils, the teachers views on their pupils learning during a school visit and the actual use and learning processes of the pupils while interacting with the exhibits.

ACKNOWLEDGEMENTS

This research is being carried out at the University of Oldenburg in Germany within the framework of the graduate program GINT (Geography, Informatics, Natural Sciences and Technology in non-formal learning areas) funded by the Land of Lower Saxony in Germany.

This research is also being part of the research project «Bridging the gap between school and out of school learning environments» within the framework of the IKYDA 2018-2020 (an exchange and cooperation program between the University of Crete and the Carl von Ossietzky University of Oldenburg, supported by the State Scholarships Foundation (IKY) and the German Academic Exchange Service (DAAD)).

PART 12: STRAND 12

Cultural, Social and Gender Issues in Science and Technology Education

Co-editors: *Lucy Avraamidou & Marisa Hernandez*

CONTENTS

STRAND 12: INTRODUCTION

CULTURAL, SOCIAL AND GENDER ISSUES IN SCIENCE AND TECHNOLOGY EDUCATION

Strand 12 examines cultural, social and gender issues in science and technology education. The seven papers included in the proceedings examine unique issues, as follows: a) Students' positioning and career aspirations in STEM professions; b) Students' gendered identities and views about science; c) Teachers' identities, practices and teacher education; and, d) Linguistic diversity in science classroom.

In the first paper with title Career orientation in the field of food chemistry for secondary school students, Alberding and Pietzner report on the findings of a study related to the preparation of German students for their post school life regarding their professional careers. For the purpose of their study, learning tasks for vocational orientation in the context of food chemistry were developed and evaluated. Important parameters for checking the quality of the learning tasks, which were tested in a specially developed student laboratory, are aspects of motivational and interest research, professional self-efficacy expectations and the motivational learning climate.

The second and third paper touch upon issues related to gender in science. Ampatzidis and Armeni examine gender gap in some science related occupations in areas such as physics and technology. In their paper titled "Gender and science: men and women in Greek Gymnasium science textbooks" the researchers examined the ways in gender is portrayed in science textbooks since it is argued that they may contribute to the sex role socialization of students; gender bias in science textbooks may influence the development of a view that science is a subject addressed more to boys than girls. Rodrigues, Roque and Signori report on the findings of a study that aimed to tackle the disparity of gender in science and research fields related to STEM. In order to verify students' conceptions of scientists, they used a pre- and post-evaluation with the use of the Draw-A-Scientist Test (DAST) with 50 middle-school girls who attended an extracurricular science course designed to support them in developing understandings about women in science.

The next three papers explore issues related to teacher identities with the use of different kinds of methodologies in different contexts. Sievert and LaFrance examine the underrepresentation of American Indian people in STEM and STEM education college degree programs and professions in the United States. In their paper titled "Identifying elements of effective programs for preparing American Indian secondary STEM teachers" they present a qualitative study designed to identify essential elements for effectively preparing American Indian secondary STEM teachers as a strategy for improving STEM outcomes for American Indian students. The research data for the study were collected through interviews with a range of education stakeholders.

Romero-Ariza and Quesada present results from a European project promoting context-based and inquiry-based learning approaches in their paper titled "Making use of contexts and inquiry to engage all students in STEM learning". Their study examined how teachers make use of contexts and inquiry to engage all students in their mathematics and science classrooms. Results from multiple case studies provide evidence of teachers from different schools and backgrounds articulating their beliefs, values and experiences to enact their teaching and to adapt to their particular group of students.

Kotwica and Pietzner examined "Chemistry teachers' knowledge about chemistry professions" in Germany. To do that, the researchers investigates how chemistry classes may contribute to career aspirations and career choices, focusing on getting information about chemistry teachers' regarding chemistry professions and how career education is implemented in their teaching and at their respective schools.

Greses Pérez-Jöhnk's work with title "Translanguaging in the science classroom: Learning engineering in multilingual contexts" is situated in California. Through event mapping of participants' video data, the study provides evidence of how students negotiate languages in science and engineering and their perceptions around notions of language boundaries in schools.

Lucy Avraamidou & Marisa Hernández

CAREER ORIENTATION IN THE FIELD OF FOOD CHEMISTRY FOR SECONDARY SCHOOL STUDENTS

Hennes Alberding[1], Verena Pietzner[1]
[1]University of Oldenburg, Oldenburg, Germany

One essential task for school in Germany is the preparation of its students for their post school life regarding their professional careers. Chemistry education on a secondary school level has the goal to empower students to infer scientific phenomena while keeping an eye on learners' achievements and development opportunities. Research on vocational orientation shows that chemical education did not succeed in opening a career orientation for young people, for the time being. This is the starting point of this study. Within this study learning tasks for vocational orientation in the context of food chemistry were developed and evaluated. Important parameters for checking the quality of the learning tasks, which were tested in a specially developed student laboratory, are aspects of motivational and interest research, professional self-efficacy expectations and the motivational learning climate. This article presents a first state and focuses on the motivational learning climate and the professional self-efficacy expectations of the students.

Keywords: Science Education, Self-Efficacy, Vocational Education

INTRODUCTION

The transition from school to working life represents a great challenge for young people, which starts well before graduation. The process of career choice is determined by many factors. Fundamentals of motivational and interest research as well as career research are among the most important areas of observation to clarify questions about career orientation. There are a variety of theories that describe the career orientation of people from various perspectives. A central theory is the RIASEC model of Holland (1997). The background to this basic idea is the clarification of the endogenous and exogenous characteristics of professional development, from orientation to professional implementation. First, according to Holland, six personality types can be mapped: realistic, investigative, artistic, social, enterprising and conventional. In these attributes, the personal abilities and skills can be incorporated. Depending on this, occupational groups that contain similar attributes are considered interesting perspectives. Holland thus describes an interaction between people and the environment that influences the career choice. It is important that a high fit between their personal and the environmental characteristics is achieved. The strongest three attributes are summarized to the so-called Holland code (Eder & Bergmann, 2015). By means of this typological approach, intersections between occupations and personalities can be identified and applied for career orientation. However, in order to broaden this aspect for scientific orientation, the IKON project completed the perspective of the natural sciences on the other attributes (Wentorf, Löffler, Parchmann, 2015). In addition, the extended model can be used to convey ideas about scientific fields of activity and the persons employed in it. It becomes clear that activities of chemistry-related occupations include not only analytical traits but also creative or social aspects. An integration of this characteristic can thus be realized for teaching, for example through learning tasks (Dierks et al., 2014).

In the centre of the process of vocational orientation is the adolescent individuum. The process can also be described as finding its professional identity. Based on the developmental psychology approach of Erikson and Super and the transition theoretic approach according to Bußhoff, Egloff developed the cooperation model (Egloff, 1998). In addition to the theories of the before mentioned authors Egloff considers the core idea that young people can and do find support from different persons to deal with the question of their professional career. These cooperation partners should accompany the transition of young people to vocational training, into working life or into a secondary school and support them in a role-specific manner. They represent the persons who co-develop the identity in the course of adolescence and persons as well as institutions who serve as competent contact persons in vocational training.

Further attention in career orientation is based on the importance of the self-efficacy that can be described as subjective conviction to self-manage a situation and achieve certain goals, which in turn affect the further life-course (Bandura, 1994). The objective of a successful career choice can only be achieved if there is a match between the action-outcome expectation and one’s self-efficacy (Wirth, 2019).

Career education in chemistry lessons

The educational decisions of the political decision-makers at state and federal level emphasize the importance of school-based vocational orientation as a school-related as well as subject-specific task (Kultusministerkonferenz [KMK], 2019). The ROSE study shows that teaching chemistry fails in opening interesting career prospects for learners (Krause et al., 2014). Science education therefore must contribute to career orientation and to show the students corresponding occupational areas (Parchmann et al., 2014). This raises the question for many teachers how to integrate vocational orientation in subject-specific education. According to Parchmann et al. (2014) many teachers combine this demand with excursions or elective lessons. Beyond these temporal limited insights into career orientation, chemistry education is rather based on teaching strictly chemical content. This procedure is based on the perception that career orientation is an additional task that has to be done alongside the curricular given content; as a consequence, this additional task is often dropped (Parchmann et al.,2014). However, several examples exist that career orientation in fact can be integrated (Parchmann & Lühken, 2014). In order to give the students as many vocational orientations as possible, it is necessary to talk and teach about (also non-academic) occupations of scientific industry in chemistry lessons. In this context, it is important to not only point out theoretical content of these occupational fields, but also in practical or informative learning approaches (Bertels, 2015). One way of practical orientation is to link learning tasks with professional focus, but appropriate materials are lacking. Therefore, learning tasks need to be developed that enable the teachers to include career orientation in multiple ways. Learning tasks with a job-oriented focus should, in addition to the acquisition of knowledge as well as specialised and social competences, primarily address the educational needs of the students. These needs must be professional and adapted to the students (Sokolowski & Pietzner, 2015).

The school lab on food chemistry professions

Foods are used for human nutrition and are derived from plant or animal organisms. Major components are proteins, carbohydrates and fats, which play a key role in the functionality of the organisms. All these substances can be viewed from a chemical perspective, for example digestion, the supply of energy in the cells or the conversion to water and carbon dioxide. Within food many chemical reactions take place that can lead to spoilage. On the other hand, chemical processes are used to produce foods such as making bread, wine, beer and cheese. The third area is food control, where chemical reactions are used to maintain food safety and, for example, uncover food fraud. For many people the terms "food" and "chemistry" have little or no relationship. All in all, the school lab has the objective of integrating existing experiments as they in part are done in school already with knowledge about food chemistry professions, so that the students also gain specialist knowledge. The materials developed in the school laboratory should create a first step to enable young people to better link these two terms. In addition, food chemistry is of great societal relevance, which can help to make students aware of the societal relevance of chemistry in general.

The chemical processes related to food described here are used or monitored by various professions. However, studies show that many of these occupations are unknown among adolescents (Haase, 2017). In order to convey the relevance of professions in food chemistry in chemistry classes, five different professions were selected and used in a school lab. All of the chosen professions can be learned within a vocational training that requires a graduation from lower secondary school after grade ten. The five professions are chemical lab assistant, distiller, chemical technical assistant, food technical assistant, and dairy industry lab assistant. Table 1 gives an overview how the different experiments intersect with the professions. The assigned tasks have been derived from the training requirements of the respective professions and the school curricula applicable to the state of Lower Saxony.

Table 1: Assignment of experiments to the respective occupations; CLA: chemical lab assistant, DIST: distiller, CTA: chemical technical assistant, FTA: food technical assistant, DILA: dairy industry las assistant; X: regular connection, (X): extended connection

Experiment	CLA	DIST	CTA	FTA	DILA
Analysis of raw milk	(x)		x	(x)	
Examine of dairy products on lactose	(x)		x	(x)	
Acidity of milk	(x)		x	(x)	
Maturity of apples		x			
Density of spirits	(x)	x		(x)	(x)
Content of salmiac in liquorice	(x)			(x)	x
Sensory food analysis		(x)	(x)	x	(x)
Food analysis of honey		(x)		(x)	x
TLC of vanillin/ethylvanillin	x		(x)	(x)	(x)
Qualitative analysis of vanillin sugar	(x)			x	
Determination of nitrate in lettuce	x			(x)	(x)

Learning tasks in the school lab

The school lab is scheduled to run for about five hours. Before and after the lab work, a seminar phase will be held to welcome the students, to discuss topics, to provide general information about experimentation and safety, and to accompany observations and phenomena in a professional manner. The students receive a lab journal containing information about the professions presented in the lab, worksheets for the experiments as well as general information on career orientation. The students experiment in groups of two or three at the workplaces prepared for them.

Students select experiments that are of interest to the individual small groups. Each experiment is connected to a professional context in which the experiment reflects a typical task. However, these activities are not just for just one profession, but can also be linked to other occupations. The students should immerse themselves into the course of action of the professions presented. For this, the tasks are designed to be action oriented. They note their observation and work on the subtasks of the experiments, which always require an interpretation (and explanation) of the observations. For example, decisions drawn from the experimental outcome must be formulated; e.g. if the milk tested is still suitable for making cheese. After the experimental phase, the results of the groups are discussed in the seminar. There students present their observations and which conclusion they derive from them. The also may describe how they came to this conclusion.

The lab script that every student gets for the work begins with a general job-oriented information section. Here, essential information on career orientation is deposited, including QR codes that refer to the internet pages of "http://www.berufe.net" as well as the Federal Employment Agency. In addition, the chemical background of the experiments is presented. Since enzymatic reactions often play a role in the context of food, but also is very difficult to understand for students of grade 7 to 10, this topic has been made as tangible as possible, because a complete waiver of biochemical processes would not have met the intention of the lab. Wherever it appears necessary and sensible for the students, the specialist knowledge is simplified, and the context of professional orientation is increasingly brought to the fore.

Each of the professions then is presented by means of an overview. In this overview, a variety of information such as educational content, training duration or activities are conveyed. The core elements of the lab script are the test protocols with the instructions. For each analysis, a page is provided where students can write down their observations. After noting their observation, the students can evaluate them with the help of a given analysis instruction and then give a recommendation regarding the examined food, food quality or characteristic. The students hereby get into the role of one of the chosen food chemistry professions and give a professional recommendation based on their own findings. An important reflection task of the following seminar is that there are recurring tasks in chemical analysis. Thus, an arc is to be closed that shows the young people that the knowledge they acquire in class is not useless knowledge, but rather serves as the basis for a professional work in many professions.

To investigate the success of the school lab, we focused on the professional self-efficacy, the students' assessment of various affective aspects of teaching as well as gender differences. Here, the results regarding the learning climate as well as selected results regarding gender differences will be presented.

METHOD

In this study, the data is collected via a fully standardized questionnaire that was developed, piloted and then used in a pre/post/follow-up design. Whilst the pre and post-test were admitted right before and after the school laboratory, the follow-up test was filled out by the students four to five months after the visit. The questionnaire comprises questions regarding the students' status of their personal career aspirations, their professional self-efficacy (Abele et al., 2000), the scientific interest (Engeln, 2004; Pawek, 2009), the self-assessment of the academic interests (Pawek, 2009) and finally questions regarding the motivational climate (Bolte, 2004). The learning climate questionnaire consists of 7 dimensions: satisfaction, comprehensibility, chemical relevance of the topic, societal relevance of the topic, participation opportunities, participation of the class and own participation. The focus of the learning climate is to present the societal significance of chemistry to students because vocational orientation can also show the societal relevance of chemistry. Therefore, investigating the learning climate of general chemistry lessons in the pre-test and of the school lab in the post and follow-up test provide information to what extend the school lab meets the goal of pointing out the societal relevance of chemistry. Most of the questions were scaled in a five-level Likert scale, the ones about the already experienced career orientation have been open questions. In total, 3 classes with 67 students took part in validating both the questionnaire as well as the materials used in the school lab. Afterwards, questionnaire and materials have been revised. To ensure the reliability of the research instrument, a group discussion was held with lecturers, PhD students and a professor about the method, the data collected and their analysis (Steinke, 2004). With the follow up test admitted four to five months after the school lab the medium-term effects have been evaluated. Data was analysed using SPSS 25. Besides the frequency distribution, the Wilcoxon sign-rank test and the Friedman test were used for evaluation. To evaluate the significance of the results, the effect size according to Cohen is calculated (Schwarz & Bruderer Enzler, 2019). As a valid level of significance for the evaluation, $\alpha = 0.05$ is chosen.

RESULTS

So far, a total of 498 students filled out the questionnaires. The students have been between 12 and 16 years old and attend grades seven to ten of the middle level of various German school types (see Table 2).

Before the lab visit, many of the students have no or only rudimentary knowledge and ideas about food chemistry professions, and less than five percent of the students would choose a chemical profession. This value increases slightly to just under 12 percent directly after the lab visit but drops to seven percent at the time of follow-up. Based on the task profiles, less than ten percent of the students recognise the five professions presented here as a food chemistry profession. After visiting the school lab, the value rises to over 71 percent and remains at 64 percent in the follow up. Therefore, a gain in knowledge can be seen.

Table 2: Student sample that participated in the school lab and already filled out all three questionnaires

Age	Male	Female	∑
12	18	18	36
13	53	73	126
14	17	15	32
15	50	80	130
16	91	83	174
∑	**229**	**269**	**498**

In order to assess the development of the motivational learning climate, the three paired samples were evaluated with the Friedman test. As can be seen in table 3, there are differences in all seven dimensions. The satisfaction increases significantly and then decreases significantly. Subjectively, the students are less satisfied in the general lessons than in the school lab. However, the school lab receives less approval in the reflection after five months. However, the rating is still significantly higher compared with the general lessons. In addition to satisfaction, the results in terms of the comprehensibility are of a similar structure, but the students do not rate the lab as more comprehensible in the follow-up test compared to the pre-test.

Table 3: Median rank of the learning climate dimensions; significant differences are marked with an *, highly significant results with an **

Dimension	Pre	Post	Follow Up
Satisfaction	1.52 Post**/Follow Up**	2.35 Pre**/Follow Up**	2.13 Pre**/Post**
Comprehensibility	1.83 Post*/Follow Up	2.22 Pre*/Follow Up*	1.95 Pre/Post*
Chemical relevance	2.53 Post**/Follow Up**	1.78 Pre**/Follow Up	1.69 Pre**/Post
Societal relevance	1.72 Post**/Follow Up**	2.36 Pre**/Follow Up**	1.92 Pre**/Post**
Participation opportunities	1.72 Post**/Follow Up**	2.10 Pre**/Follow Up	2.16 Pre**/Post

Participation of the class	1.42 Post**/Follow Up**	2.48 Pre**/Follow Up**	2.10 Pre**/Post**
Own participation	1.98 Post**/Follow Up*	2.24 Pre**/Follow Up**	1.79 Pre*/Post**

The chemical relevance of the school lab is rated significantly lower than of the general chemistry lessons. For the students, chemistry is a world of formulas and equations. The school lab shows the students that other factors such as application-related problem solving also play an important role in chemistry. This effect is also visible in the follow-up test. The food chemistry context also changed the recognition of societal relevance, so that the students evaluate this dimension significantly higher in both post and follow-up test. Regarding the three dimensions dealing with participation, there was significant growth in all of them. Working and experimenting in the laboratory differs significantly from the general chemistry class. The school lab is characterized by a high level of initiative; the students have no time pressure and experience that doing experiments is a casual way to acquire information about the presented professions.

Looking at differences between girls and boys the girls rate the comprehensibility of general chemistry lessons significantly lower than boys ($U = 24990,00$; $z = -1,994$; $p = 0,046$). No further differences between the two groups can be detected.

Further analysis was done to investigate the different ratings of the learning climate between general chemistry lessons (see Table 4). Both groups rate the learning environment in the school laboratory as more satisfied than the regular lessons in school. The median values in the post-test of the girls are higher, therefore it can be assumed that the girls were more interested in the learning tasks than the boys. The dimension of comprehensibility also shows a higher growth for girls than for boys.

Table 4: Gender-specific median rank results of learning climate dimensions 1-4

Dimension		Pre	Post	Follow Up
Satisfaction	male	1.61 Post**/Follow Up**	2.35 Pre**/Follow Up	2.14 Pre**/Post
	female	1.44 Post**/Follow Up**	2.44 Pre**/Follow Up**	2.12 Pre**/Post**
Comprehen-sibility	male	1.93 Post/Follow Up	2.15 Pre/Follow Up	1.92 Pre/Post
	female	1.73 Post**/Follow Up*	2.28 Pre**/Follow Up*	1.99 Pre*/Post*
Chemical relevance	male	2.53 Post**/Follow Up**	1.74 Pre**/Follow Up	1.72 Pre*/Post
	female	2.52 Post**/Follow Up**	1.82 Pre**/Follow Up	1.66 Pre*/Post

Societal relevance	male	1.78 Post**/Follow Up	2.25 Pre**/Follow Up**	1.97 Pre/Post**
	female	1.68 Post**/Follow Up	2.44 Pre**/Follow Up**	1.88 Pre/Post**

The rating of the chemical relevance decreases significantly in both groups, and this effect is also visible in the follow up-test. Looking at the societal relevance, the results are vice versa. The girls were also better able to leave the chemical relevance behind and saw the social aspect more clearly than the boys. However, the follow-up test shows no significant difference to the per-test. Therefore, the positive effect of the school lab regarding the societal relevance cannot be maintained.

Overall, the students rated the general lessons much more subject-specific, whereas the school lab was able to point out the societal aspects of chemistry. Both groups also report that the school lab is more motivating than general chemistry lessons. However, Table 4 also shows that the positive effects cannot be maintained in all dimensions. The values of the follow-up test for social relevance in both groups as well as the intelligibility among the boys approximate those of the pre-test again.

Conclusions

In addition to teaching knowledge, schools also have the task of promoting students' personal development, their abilities and their skillset. For this, complex school and extra-curricular offers for personal development should be offered. These are important aspects for career orientation and at long last a successful career choice. Chemistry education, as part of the overall school concept, should take up this development. This study supports the problem identified by Haase (2017) that adolescents have little or no ideas about chemical training occupations. School does not succeed in providing sufficient information about STEM professions. This study thus reflects the results of Krause, Stuckey, & Eilks, (2014). One method to change this problem is the conception of job-oriented learning tasks in chemical teaching. With learning tasks that provide both chemistry knowledge and professional orientation in class, students not only succeed in realizing the relevance of chemistry, but also are able to see the link between chemistry and the social world they live in.

Learning tasks are developed and tested as part of the presented student laboratory on professions related to food. Initial results show that the school lab has brought about a change in the self-perception of the participating students. However, clarity is not yet recognizable to the current state of research. The learning climate shows clearly differences between the three evaluation tests. The students rate the learning environment as well as the learning tasks more positively in comparison with their experience in general chemistry lessons. At the same time, the recognition of societal relevance increases with the learning tasks in the school lab. Results from Sokolowski & Pietzner (2015) also show the significantly higher assessment of social relevance for tasks relating chemistry and career orientation. These changes cannot be kept completely over time. This leads to the conclusion that action and process-oriented learning tasks dealing with food chemistry professions can positively influence the learning climate in chemistry education. However, these special learning tasks need to be used frequently in chemistry class, otherwise the positive effects cannot be maintained. This shows that the tasks have the potential to combine subject-specific and professional information in the classroom.

The primary purpose of the learning tasks is to show the students the importance of chemistry in social perception to support their career choices. With the newly designed tasks the students experience a change of perspective. Both the boys and the girls support these statements on the quality of the learning tasks. Furthermore, the students' horizon is broadened by their work in the school laboratory at the university. This data will be further analysed regarding professional self-efficacy as well as motivational and interest-oriented values. Currently there are hardly any data that allow a statement as to the extent to which occupational teaching tasks in chemistry lessons can promote the motivational learning climate and interests in food chemistry professions. This shows the exploratory nature of this study. Furthermore, the motivation and interest of students in the use of professional learning tasks in science teaching is examined. So that a better statement of the change of perspective can take place in the context of food chemistry.

GENDER AND SCIENCE: MEN AND WOMEN IN GREEK GYMNASIUM SCIENCE TEXTBOOKS

Georgios Ampatzidis and Anastasia Armeni
University of Patras, Patras, Greece

Although the gender gap in science related occupations has been considerably reduced during the last 40 years, women still seem to be underrepresented in areas such as physics and technology. Several reasons have been suggested to explain the lack of interest of female students for science classes such as (a) the formation of sex-segregated groups of students especially in early school years, (b) parental attitudes and behaviour and (c) textbooks. Focusing on the latter, it has been argued that the way gender is portrayed in science textbooks may contribute to the sex role socialization of students; gender bias in science textbooks may influence the development of a view that science is a subject addressed more to boys than girls. This article focuses on the frequency of appearance of men/women and male scientists/female scientists in the illustrations of science textbooks of the Greek Gymnasium (students aged 12-15 years old). The analysis of 7 science textbooks shows that men and male scientists appear more frequently than women and female scientists respectively in the illustrations of physics, biology and chemistry textbooks. Relevant limitations and possible implications are discussed.

Keywords: Gender Issues, Curriculum, Science Education

INTRODUCTION

Although the gender gap in science related occupation has been considerably reduced during the last 40 years – for example, the number of women employed in science fields in US has increased significantly between 1980 and 2000 (Ceci & Williams, 2007) (Jones et al., 2000) – women still seem to be underrepresented in areas such as physics and technology (Frome et al., 2006) (Wang & Degol, 2017). Several strategies have been suggested in order to achieve a greater participation of women in science and technology (Brotman & Moore, 2008) (Scantlebury & Baker, 2007); however, it seems that girls generally start to lose interest in science at the age of 9-14, and few women choose to follow a relevant career (Vincent-Ruz & Schunn, 2017).

Several reasons have been suggested to explain the lack of interest of female students for science classes. Adamson et al. (1998) suggest that gender differences towards science are already evident in early school years and they claim that sex-segregated groups of students in elementary school contribute 'to the divergence of boys' and girls' approach to science by maintaining sex-stereotypic values and attitudes, including the masculine image of science' (Adamson et al., 1998, p. 855). Parental attitudes and behaviour seem also to influence children's attitudes towards science. Investigating children's and their parents' attitudes towards science, Andre et al., (1999) report that the parents participated rated boys' science skills higher than girls' and they claimed science to be more important to theirs sons than their daughters. In another study, Crowley et al. (2016) report that when visiting a science museum, parents explained the exhibits to their sons three times more often than their daughters. Since this difference was evident even when children were as young as 1 year old, the authors note that parents may contribute to creating sex-specific attitudes towards science learning.

Moreover, it seems that textbooks largely influence the gender differences observed in classroom when it comes to science learning. Textbooks are a source of social and cultural information on the ideas and attitudes that prevail within a society (Gouvias & Alexopoulos, 2018; Regueiro, 2000). The way gender is portrayed in science textbooks is believed to contribute to the sex role socialization of students; gender bias in science textbooks may influence the development of a view that science is a subject addressed more to boys than girls (Elgar, 2004). Researching English and Caribbean science textbooks, Whiteley (1996) argues that men appearing more frequent than women in textbooks' illustrations can lead to small numbers of girls choosing to follow studies in physics. Similar conclusions are reached by Elgar (2004), who report a gender imbalance in text and illustrations of textbooks of Brunei in favour of men, Potter & Rosser (1992), who underline the higher frequency of males depicted in illustrations of American biology textbooks, and Bazler & Simonis (1991), who claim that, although there are changes towards gender fairness in illustrations of American chemistry textbooks in years, in most textbooks men still dominate.

Considering the above, we decided to investigate gender representation in science textbooks. In this article we focus on the illustration of the Gymnasium science textbooks and the research questions formulated are the following:

1. How many men and how many women appear in the illustrations of the Gymnasium science textbooks?

2. How many male and how many female scientists appear in the illustrations of the Gymnasium science textbooks?

METHODS

For this study, we investigated the 7 textbooks of physics, chemistry and biology used in Greek Gymnasium (students aged 12-15 years old) during the school year 2018-2019:

- Physics with experiments (Kalkanis et al., 2013)
- Physics for the 2nd grade of Gymnasium (Antoniou et al., 2013a)
- Physics for the 3rd grade of Gymnasium (Antoniou et al., 2013b)
- Chemistry for the 2nd grade of Gymnasium (Avramiotis et al., 2013)
- Chemistry for the 3rd grade of Gymnasium (Theodoropoulos et al., 2013)
- Biology for the 1st grade of Gymnasium (Mavrikaki et al., 2017a)
- Biology for the 2nd and 3rd grade of Gymnasium (Mavrikaki et al., 2017b)

Initially, all humans who appeared in illustrations were identified and counted according to the following rules:

– For a series of illustrations where the same humans appear more than once (e.g. a human's movement shown in a series of consecutive illustrations) the depicted humans are counted only once.
– When an illustration is repeated in a textbook (e.g. at the end of every section) the humans depicted are counted only once.
– Only humans who are at the forefront of each illustration are counted. Humans who are part of the background or a watermark are not taken into account.
– When only parts of a human body are depicted they are not taken into account.

The identification and counting of humans were made by the two authors independently. In the few cases where there was a disagreement (e.g. whether a depicted human was in the foreground or background of an illustration) the humans involved in the disagreement were not counted.

The two authors classified independently all humans as men, women, and unknown gender (e.g. abstract figures). In the few cases where there was a disagreement, the humans involved in the disagreement were classified as unknown gender.

Moreover, the two authors went independently once more through all the humans identified, as explained above, and counted all the male and female scientists whose name was mentioned in illustration's caption or the adjacent paragraphs. In the few cases where there was a disagreement, humans who were involved in the disagreement were not classified as male or female scientists.

RESULTS

In all textbooks, men depicted are more than women: the difference ranges from 87 men / 17 women (physics for the 2nd grade of Gymnasium) to 52 men / 43 women (biology for the 2nd and 3rd grade of Gymnasium). Overall, men account for 66% of the humans depicted, while the percentage of women is 26% (Figure 1).

With regard to the number of male and female scientists, the difference is even more profound: in a total of 49 scientists shown in illustrations of science textbooks investigated, there are only three female scientists. The biggest number of scientists appear in illustrations of the physics for the 3rd grade of Gymnasium textbook (24) while in two textbooks (physics for the 1st grade of Gymnasium, and biology for 1st grade of Gymnasium) there are no illustrations of named scientists at all (Figure 2).

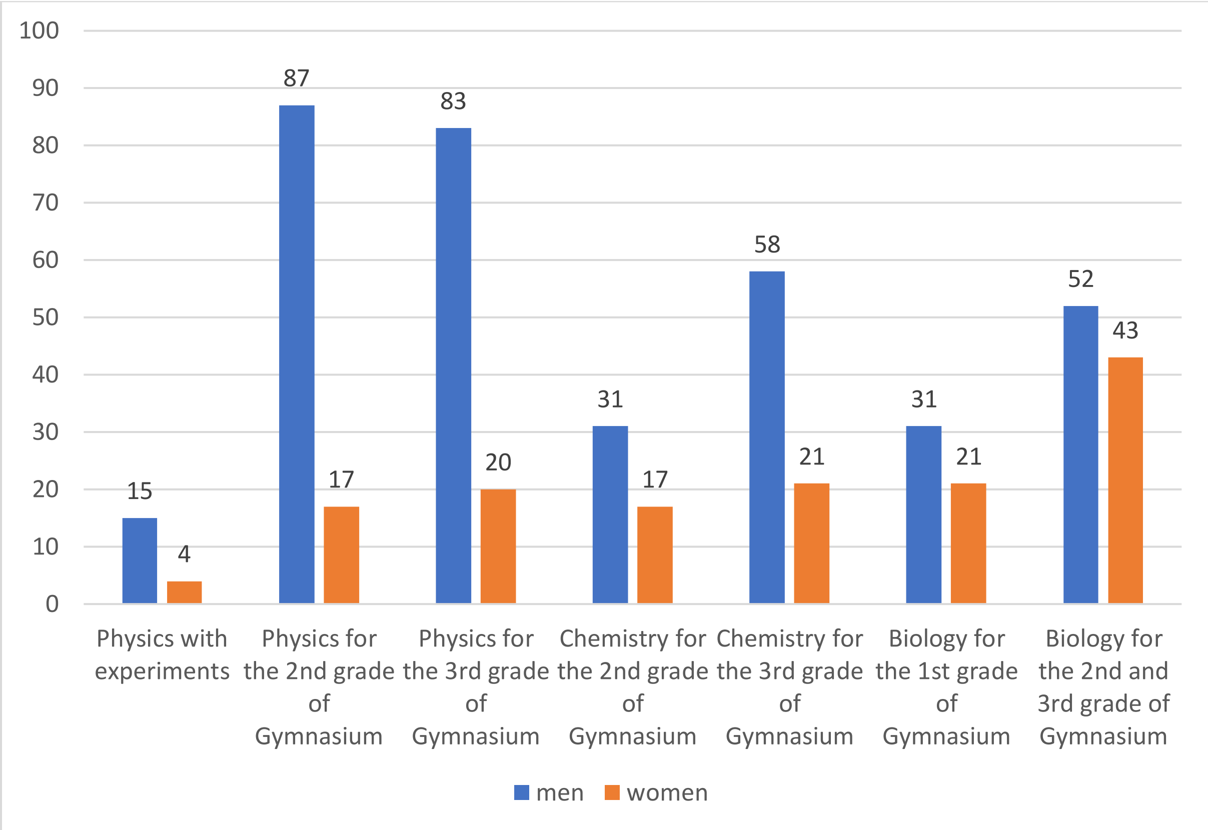

Figure 1. Frequency of men/women's appearance in illustrations of Gymnasium science textbooks.

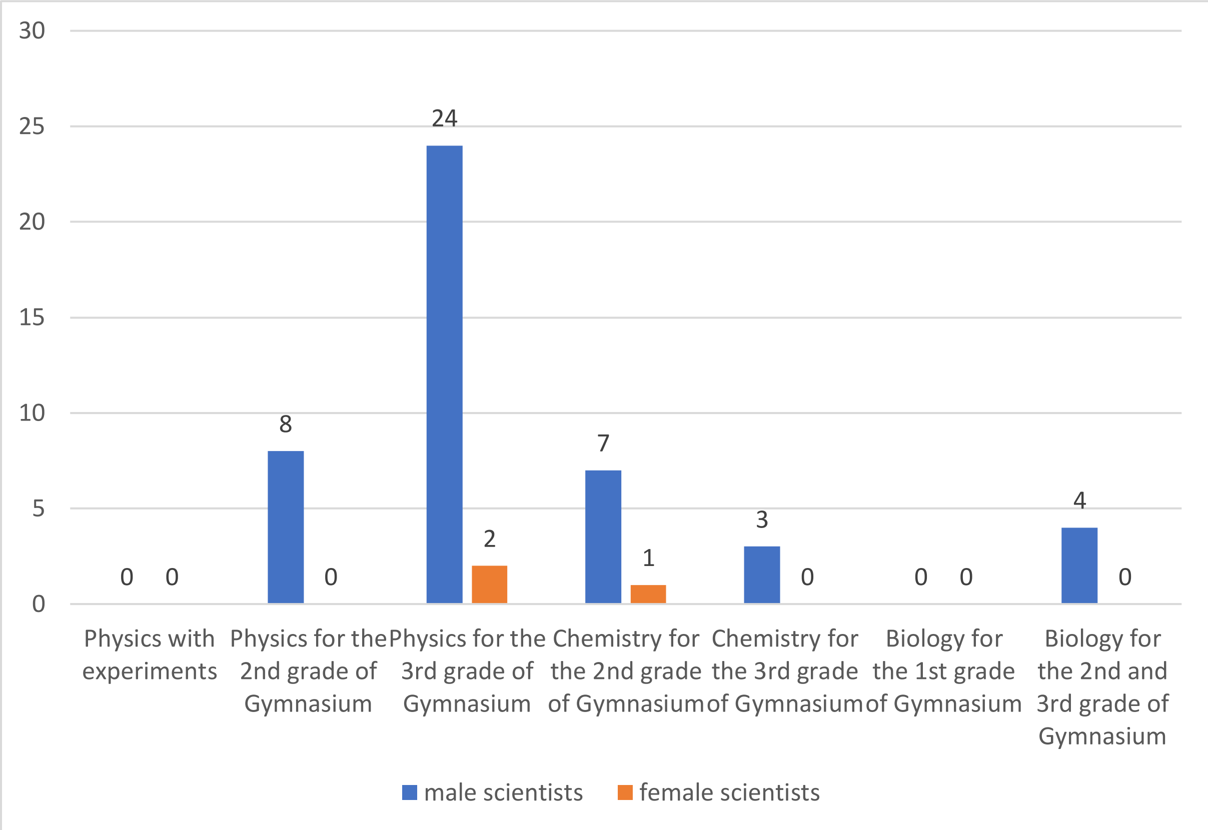

Figure 2. Frequency of male/female scientists' appearance in illustrations of Gymnasium science textbooks.

DISCUSSION

Men appear dominant in the illustrations of science textbooks used in the Greek Gymnasium. Whether appearing static (e.g. anatomy illustrations) or moving (e.g. a human throwing a ball), the human figures included in the illustrations are more likely to be men. A similar picture is formed concerning the proportion of male and female scientists. In a total of 49 scientists, only three illustrations depict female scientists, two of them depicting the same person (Marie Curie).

The dominance of male figures in science textbooks' illustrations may convey the message that males are the norm, the standard regarding science (Brickhouse et al., 2000). On the other hand, the dominance of male scientists in science textbooks' illustrations may convey the message that either the history of science has been written by men or only male scientists worth recognition (Potter & Rosser, 1992). A view that science is addressed more to boys than girls may lead female students to lose interest in science subjects and avoid a future career in science (Elgar, 2004).

Textbooks embody specific constructions of reality, which illuminate certain aspects of possible knowledge (Elgar, 2004; Gupta & Yin, 1990). However, we should acknowledge that their power to influence students' attitudes towards science comes with certain limitations. For instance, we should keep in mind that the way any written text is read depends on each reader's response to that text (Sunderland et al., 2000). Moreover, the way each learner responds to any given text included in a textbook may be related to the way that text is mediated by the teacher and peer students. Focusing on the role of teachers, Sunderland et al. (2000) note that teachers have three options when dealing with gender-biased texts: ignoring, subverting or endorsing the gendered messages.

Considering (a) the role of textbooks in shaping students attitudes towards science subjects, and (b) the under-representation of women and female scientists in the illustration of the Gymnasium science textbooks, we plan to extend our research by moving to the text of the same textbooks and investigating them in search of gendered messages. Finally, we argue it would be interesting to explore the reasons why, although male figures are in all cases more than female figures, the ratio of men to women differs considerably among the textbooks we explored for our research.

MIDDLE SCHOOL GIRLS IN A SCIENTIFIC CONTEXT AND THEIR CONCEPTION ABOUT SCIENTISTS: WHAT CAN BE LEARNED?

Maria Inês R. Rodrigues[1], Diana R. R. Roque[1] and Camila N. Signori[2]
[1]Federal University of ABC, Santo André, Brazil,
[2]University of São Paulo, São Paulo, Brazil

There is a disparity of gender in Science, about 70% of academic students and researchers in the world are men, mainly in research fields related to STEM: Science, Technology, Engineering and Mathematics. In order to verify the students conceptions of scientists, we've used the instrument Draw-A-Scientist Test (DAST), which is a tool to assess stereotypical imagery of scientists. The DAST was administered during the extracurricular science course "Meninas com Ciência", promoted for 50 middle school girls in two stages: One before the beginning of the course and another at the end. The aim of the course was to broaden students' views on the participation of women in the sciences. The course was entirely organized by women teachers and scientists. This exploratory study of the DAST analysis indicated that after the end of the course the number of girls who drew a female scientist significantly increased and, in contrast, the number of drawings of men scientists decreased. In addition, participants added professions of their own choosing in the second DAST application.

Keywords: *Gender Issues, Scientific Literacy, Science Education*

INTRODUCTION

There is concern about what students in elementary and middle school think about what science is and how and by whom it is developed.

We had already used DAST in 2018 in a context of science education, where boys and girls drew a scientist in their daily work. On that occasion, we found the same results as Chambers (1983), that is, for every 3 drawings, one was the figure of a female scientist, the other two being men. This has already pointed out to us an increase in the participation of women, possibly for several reasons such as - media, films, teachers, female scientists.

But that increase is still insufficient, as Chambers' research took place 30 years ago.

The strategy we are developing in Brazil is to implement projects that aim to bring girls closer to science and try to break the gender paradigm that has been established in this field.

How is this accomplished?

This proposal is not innovative, as England has done this for over twenty years with projects such as Girl in Science (SONNERT, 1995). But not that they had an effect, as the author points out.

Our proposal, in this course, is to attract girls aged between 11 and 14 years old, exactly attending EF II (middle school), so that in this way, they are sensitized even before entering high school, pre-university age, time to select their own profession.

The authors of this work have already participated in 3 versions of this course, since 2017. The positive results (frequency of girls during the course, motivation and enthusiasm during participation in activities, testimony from family members reporting the girls' excitement) motivated these initial proposals new projects.

The authors of this work have already participated in 3 versions of this course, since 2017. The positive results (frequency of girls during the course, motivation and enthusiasm during participation in activities, testimony from family members reporting the girls' excitement)

Our research carried out a survey on the conceptions of the girls participating in the Girls with Science course, which took place in 2018 at USP. The methodology we used was DAST (CHAMBERS, 1983). It is a projective method of surveying students' conceptions of a scientist, through a free drawing, based on the proposal - Draw a scientist in your daily life.

THEORETICAL BACKGROUND

Reason for women's participation in STEM area

The data has shown that there is a disparity between the number of women and men in the scientific area that involves Physics, Chemistry, Mathematics and Technology. Blickenstaff (2005) pointed out at least three arguments for women to be present, in greater numbers, in these related areas.

The first one is that every person should have an equal opportunity to study and work in the subject he or she chooses. The second one tell us that as long as women are underrepresented in STEM**,** a substantial number of talented women are choosing other subject areas in which to study and work. These might be women who could make important contributions to science or engineering if given a chance.The last one is that Scientific and technical endeavors can only be improved by having a greater diversity of perspectives in the search for knowledge and solutions to human problems. As scientists expand their knowledge of the world, the ability to look at questions and answers from different perspectives will help to make scientific explanations more robust and broad.

Conceptions of scientist by drawings

The fact that students usually have the fixed stereotype in their minds of scientists been predominantly male may be a barrier to girls' entry into science. Between the 1960s and 1970s, studies were carried out, in the United States and Canada, which involved the analysis of drawings made by children in the initial grades of elementary school. These drawings illustrate the figure of male scientists wearing mostly aprons, goggles, beards; working in a closed laboratory and surrounded by equipment and glassware. During this period, only 28 children performed drawings illustrating female scientists, which corresponds to 0.6% of the 3000 sample designs (Chambers, 1983).

Although the results presented on these researches were relevant, there was not yet neither an adequate methodology for the data collection nor for the analysis of the drawings. It was Chambers (1983) who developed a projective technique called the Draw-A-Scientist-Test (DAST) in order to investigate, among elementary school students, what the image each had in mind when the subject involved the subject who exercises the profession of scientist. In addition, the author verified other factors that could influence the way of thinking of the children, verified through the drawings. Thus, through the analysis of the results obtained, it was possible to evaluate patterns in the drawings made by these children, as well as their relation with socioeconomic factors, among others.

According to Miller et al. (2018), from the 1960s until the present time, a progressive change of this scenario has been noticed in the United States, that is, the drawings have been presenting a greater number of female scientists. This may be a result of the increase in the number of female representation in scientific circles, as well as television commercials, programs and children's magazines. Because of these notes, Miller et al (2018) noted a shift in this scenario from the use of DAST in research contexts similar to those of the 1960s: about one in three designs represents a female scientist.

RESEARCH GOALS AND QUESTIONS

The goal of our study was to explore the girl's conceptions of a scientist, to answer the following research questions:

1. How can the DAST (Chambers, 1983)* evaluate the potential of a course aimed at bringing girls closer to science?
2. May the results pointed out for DAST* indicate that girls approach to science context?
3. Are there other interesting features?

We had as hypotheses that the course, *Girls in Science* would be a motivator for the girls to approach the sciences.

* DAST - Draw a Scientist Test (Chambers, 1983)

METHODOLOGY

The present research was carried out in the second semester of 2018, during the extracurricular science course "Meninas com Ciência" (Girls with Science), which took place in the city of São Paulo, Brazil, for the first time. This is a differentiated situation, since the course is aimed only at girls with the intention of showing the role of a female scientist in different areas of activity, expanding the horizons of girls attending middle school and humanizing the figure of a scientist.

More than 12,000 girls have applied for the course, which had the limited number of vacancies of only 50. By means of a lottery, 25 girls from public schools and 25 from private schools participated in five weekly meetings, where prominent female scientists in each of the scientific areas, such as Oceanography; Astrobiology; Physics; Education; Astronomy; Paleontology; Geology; Zoology;

Microbiology; Pharmacology; Electrical engineering; Neurosciences; presented workshops, lectures, research experiments, in order to raise awareness about the role played by women in scientific areas.

Thus, the 50 participants were asked to perform the DAST on the first day of class of the course, even before any other activity, without any of them having had contact with the researchers and their lectures. After five meetings, the participants were invited to retake the DAST, so that we could confirm how much the activities, in which they participated, could increase their awareness about the participation of women in the scientific environment.

Participants should draw a free drawing according to the following proposal: They should draw - as they imagined - a scientist in his or her daily life. The methodology we used was DAST (CHAMBERS, 1983). It is a projective method of surveying students' conceptions of a scientist.

RESULTS

In this section we will present the data, which are images of scientists drawn by the participating girls in Girls with Science course. Thus, we use DAST in both situations: before the course and after. The differences are very interesting, because in addition to showing the image that each of the girls had before the course, the first of the photos, also showed that the course may influenced their future professional choices.

Figure 1. At first, the student illustrated a male scientist, and after the end of the five day course, she drew a woman scientist, wearing a T-shirt with a print indicating a degree course (Biology) and a University (Federal University of São Carlos).

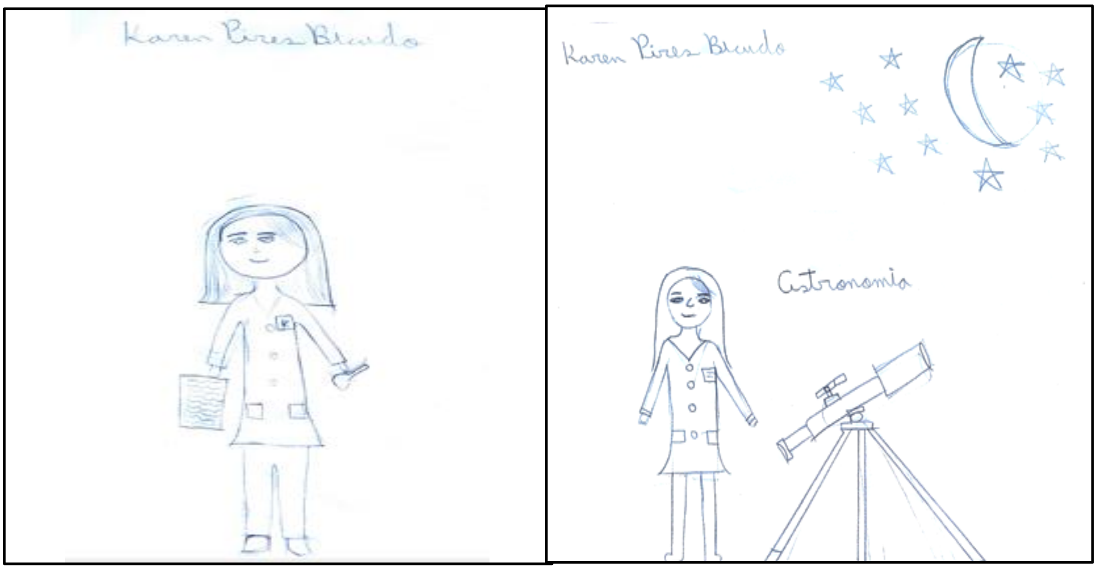

Figure 2. The first picture is a drawing made on the first day of the course. The second one is the image of a scientist after the end of the course.

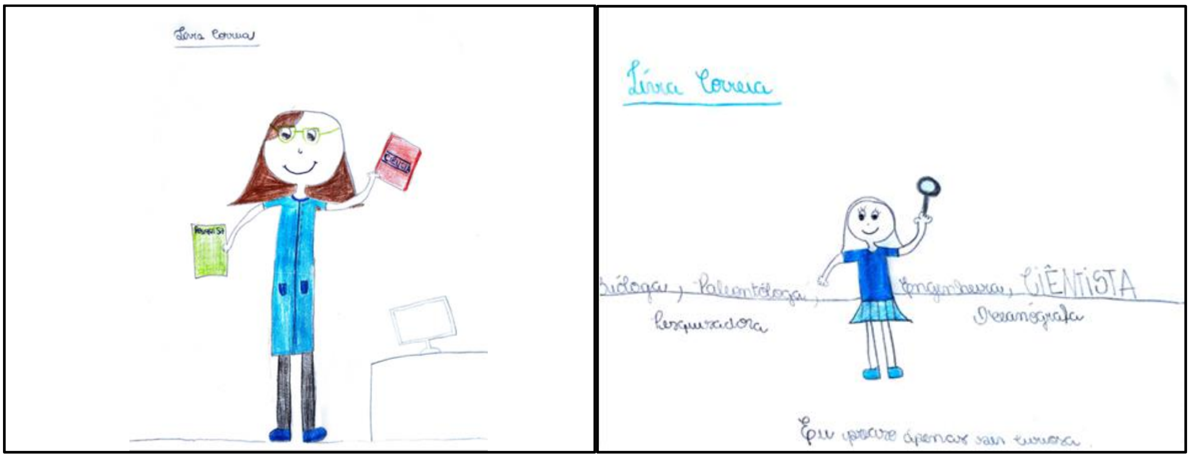

Figure 3. In the first situation, the student drew a girl with science books and a book on "research". In the second situation, she drew a woman with a magnifying lens in her hands and with some areas like Biologist, paleontologist, engineer, scientist, researcher written on the background. And, at the end, she wrote "I just need to be curious".

Analyses of drawings

The table below presents the results found in the drawings made by the participants of the Girls with Science course. As highlighted above, we applied the DAST methodology on two occasions, one before the course started and the other at the end of the course.

Initially, before the course, we had the lack of two girls, resulting in 48 drawings, of which 39 participants represented the figure of a woman as a scientist; 6 drawings represented men as scientists and 3 of the total were indefinite.

After the closing of the course, we had the participation of the total of girls, that is, 50 drawings, of which 45 were figures representing women; 2 represented men and 3 representing indefinite figures.

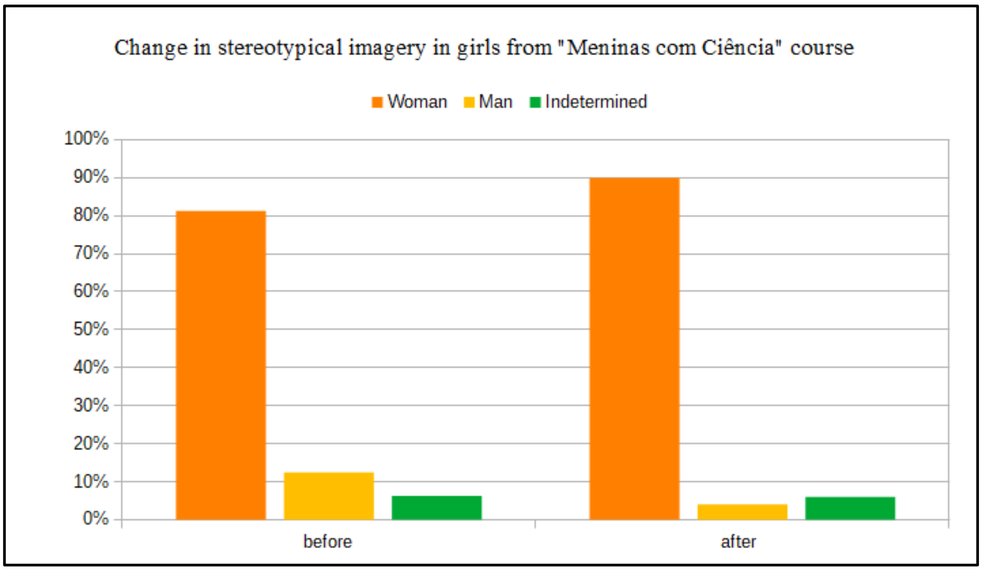

Figure 4. Change in stereotypical imagery in girls from "Meninas com Ciência" course

Table 1. The percentage result of our data

	Before	After
Women	39 (81,5%)	45* (90%)
Men	6 (12,5%)	2 (4,0%)
Undefined	3 (6,0%)	3 (6,0%)
TOTAL	48	50

DISCUSSION AND CONCLUSIONS

Our objective was to verify the conceptions of the girls participating in the Girls with Science course, regarding the gender of the scientists. Our results showed that after the end of the course, with the active and exciting participation of both girls and female researchers, there was a significant increase in the number of drawings referring to the figure of female scientists. But in addition, the participating girls added to their designs wishes for professions involving science, including those that involve the themes present during the course. This shows the possibility of using DAST as well to evaluate the course's potential to encourage choice for a science-oriented profession. It stands out the presence of laboratory instruments, notebooks, books, glasses continue.

IDENTIFYING ELEMENTS OF EFFECTIVE PROGRAMS FOR PREPARING AMERICAN INDIAN SECONDARY STEM TEACHERS

Regina Sievert, Ed D[1] and Joan LaFrance, Ph D[2]
[1]Salish Kootenai College, Pablo, MT, USA
[2]Mekinak Consulting, Seattle, WA, USA

American Indian people continue to be underrepresented in STEM and STEM education college degree programs and professions in the United States. Increasing the number of American Indian STEM teachers working with students at the pre-college level is believed to be an important strategy for improving STEM outcomes for American Indian students. This qualitative study was designed to identify essential elements for effectively preparing American Indian secondary STEM teachers. Data were gathered through a two pronged approach: Interviews with a range of education stakeholders on the topic of American Indian STEM teacher preparation and a literature review of studies of American Indian education teacher preparation. Interview participants included American Indian secondary STEM teachers and teacher candidates, education faculty and administrators at colleges and universities that serve significant number of American Indian students, and administrators at secondary schools with high American Indian enrollment. A thematic analysis was conducted on interviewees' responses and relevant publications to identify factors identified as important to the development of effective American Indian secondary STEM teachers. A variety of specific themes emerged falling into three categories: supportive relationships, cultural responsiveness, and reflective practitioners. Implications for teacher preparation programs and recommendations for improving American Indian students' experiences in secondary STEM teacher preparation programs as well as recommendations for future research are offered.

Keywords: Indigenous STEM teacher, American Indian teacher preparation, Indigenous teacher preparation

OVERVIEW OF THE STUDY

American Indian people are underrepresented in science, technology, engineering and math (STEM) caeers and in the attainment of STEM college degrees. In 2015, American Indians and Alaska Natives (AI/AN) combined comprised 0.9% of American citizens of college age (18-24 years of age) but earned only 0.6% of STEM Bachelor's degrees, 0.5% of STEM Master's degrees, and 0.4% of all STEM doctorates awarded at U.S. colleges and universities (National Science Foundation, 2017). This underrepresentation deprives American Indian tribes, the United States, and the world of valuable STEM professionals and contributes to social inequities for American Indian people in the United States. Many American Indian tribes employ STEM professionals in fields like natural resource management, health sciences, accounting, and information technology, positions that could be filled by their own tribal members if they held STEM degrees. Employing one's community members in STEM positions contributes to the local economy, the quality of life for tribal peoples, and the tribe's sovereignty.

Closer examination of multiple measures of achievement suggests that the disproportionately low levels of representation of American Indians in STEM has its roots in the precollege years. For example, AI/AN consistently attain significantly lower scores than White students in math and science on the National Assessment of Educational Progress (NAEP) and on college entrance exams. AI/AN are lower than nearly every other ethnic group on rates of completion of core academic courses and advanced coursework, completion of advanced placement exams, and high school graduation rates. AI/AN have by far the highest percentage of high school drop outs and unemployment than any other ethnic group in the United States (United States Department of Education, 2018).

Employing American Indian secondary science and math educators in schools serving high numbers of American Indians students is believed to be a key strategy for reducing the achievement gap for American Indians in STEM (e.g., Archibald & La Rochelle, 2018; Belgarde, Mitchell & Arquero, 2002; Frances, Torrez & Krebs, 2018; Morcom, Freeman, & Davis, 2017; Oloo & Kiramba, 2019; Vinlove, 2018). Teachers who share Indigenous students' cultural backgrounds are thought to relate more effectively to students, serve as role models for Indigenous students, validate students' cultures, and provide socio-emotional support that fosters Indigenous students' success in college. Unfortunately, these are also professions in which American Indians are sorely underrepresented. According to the 2011-2012 *School and Staffing Survey*, only 0.5% of K-12 teachers in the United States identified as American Indian/Alaska Native, most of whom were teaching at the K-5 level, while over 1% of K-12 students are American Indian (United States Department of Education, 2012). The dearth of American Indian secondary STEM teachers is the central issue driving this study. The overarching research question for the study is as follows: What are the elements of teacher preparation programs that are essential to developing highly prepared American Indian secondary STEM teachers?

METHODS

Qualitative data about the essential elements and challenges encountered in preparing American Indian STEM teachers were gathered through literature review and interviews of educational stakeholders and then subjected to thematic analysis. The literature review included publications identified using keywords such as "Indigenous teacher preparation", "American Indian teacher preparation", "Native STEM teacher preparation", and combinations of these terms. Twenty-three articles that focused on American Indian, Alaska Native, and Canada's First Nations people were included in the literature review. Elements of teacher preparation programs from each were compiled in a spreadsheet, exposing emerging themes.

Interview participants were comprised of American Indian secondary science inservice and preservice teachers, secondary administrators at schools with high American Indian student enrollment, and STEM Education and STEM faculty and administrators in colleges and universities that serve significant numbers of American Indian students. Twenty interviews were conducted using structured interview protocols developed by the two authors of this paper and customized for each stakeholder group. Interviews were conducted both in person and via phone, depending on the interviewee's availability. Interviews were recorded and transcribed, whenever possible. Participants were selected from secondary schools and colleges and universities mainly in the northwestern United States, generally located near or on American Indian reservations. Faculty, administrators, students, and graduates from tribal colleges as well as mainstream universities were included in the interviews.

RESULTS

This is an ongoing study that initially focused on Montana institutions and was expanded in the last year to include additional institutions in the northwestern United States. A variety of specific themes emerged in the analyses of the literature and were affirmed by the interview data. These data will undergo further analyses as the study continues. It is anticipated that some themes will be refined and additional themes may emerge.

Three categories of elements emerged from the literature review as important to programs designed for developing Indigenous secondary STEM teachers. The categories and the most frequent items within each are listed below.

1. Relationships provide guidance and socio-emotional support
   - Caring and supportive faculty, advisors, and mentors are key
   - Students complete their program as a cohort
   - Tribal elders and community members are integral program partners
   - Consideration and involvement of families in program activities is important
2. Cultural elements ground programs in the norms, epistemology and ontology of local Indigenous people
   - Indigenous values
   - Place-based content and contexts
   - Indigenous knowledge
   - Local Indigenous language
   - Examining Indigenous history, contemporary Indigenous issues (e.g., sovereignty), history of Indigenous education
   - Working with elders and other community members
3. Developing reflective and critical practitioners
   - Grappling with social justice issues
   - Examining and expanding beyond mainstream practices and Eurocentric paradigms
   - Customizing practice to support Indigenous students

The twenty interviews conducted, which included all the aforementioned stakeholder groups, produced some variation in their responses. As a group, though, the interviews affirmed the categories found in the literature review.

DISCUSSION AND CONCLUSIONS

This study uncovered a number of practices that are believed to increase the effectiveness of teacher preparation programs for American Indian secondary STEM teachers. Some of the identified practices describe changes in curriculum while others focus on more customized and deliberate efforts to adopt cultural accommodations to better provide socio-emotional support for American Indian students.

Relationality

The theme of relationships in the study's findings is not surprising, given that this is a central value of tribal communities in the United States. Family and community relationships foreground all aspects of life in Indigenous communities, including students' academic journeys. Interviewees in all categories identified caring relationships between students, faculty, and staff as the second most important factor supporting Indigenous students' success in their degree programs, citing their importance in providing guidance, boosting motivation, and fostering persistence during difficult times. This factor's importance was affirmed in the literature review.

Moving through the degree as a cohort was also frequently identified in interviews and was again affirmed in the literature review. Cohorts were described as providing socio-emotional as well as academic support for students. Students described cohort-based study groups and sharing child care and transportation, for example, as significant to their academic success and emotional wellness as they progressed through their degree programs.

Partnering with elders and other community members in the design and delivery of programs was also cited with high frequency in interviews across stakeholder groups and in the literature review. The integral inclusion of multiple mentors such as elders and other cultural experts is a practice common in tribal cultures that bolsters the cultural content and authentic nature of learning experiences, validates students' cultures, and acknowledges the importance of these knowledge-keepers in Indigenous communities.

Relationship-related responsibilities hold an importance that may supersede Indigenous students' academic goals and extend beyond their immediate families to their extended families, friends, mentors, and the tribal community as a whole. Priority for relationships is manifested every day in the lives of students at tribal colleges in the choices they make related to class attendance versus attending relation-based events like caring for infirmed relatives, providing child care, and attending wakes. Student interviewees commonly noted their appreciation for faculty members who accommodated their needs to attend to relationship-related responsibilities by offering extended assignment deadlines, alternative assignments, or flexible content delivery. Faculty members and college administrators interviewed likewise affirmed the importance of such accommodations in supporting Indigenous students' success.

Cultural Grounding

Likewise, the theme of cultural grounding is not unexpected since including cultural content, pedagogy, and values in instruction allows students to "see" themselves in the curriculum and therefore better engages them, supports cultural validation, and facilitates connection of new ideas to existing schema, thereby supporting student success. Interviewees and the research literature identified the inclusion of place-based cultural content in the curriculum more than any other factor as important in secondary STEM education degree programs. Indigenous knowledge and content grounded in culturally relevant issues were specific examples highlighted in interviews as favored content. Experiential learning experiences, working with multiple mentors and especially tribal elders, and visits to culturally important sites were common examples interviewees mentioned as significant to student success. In the values realm, humor, caring attitudes, flexibility, individual choice, trust, and respect from faculty and staff were highlighted as positive attributes that support student success.

Reflective Practitioners

Developing reflective and critical practitioners, the third category, is the ultimate step toward transforming Indigenous teachers' ideas about teaching and learning. By encouraging preservice teachers' deep examination of the dominant Eurocentric teaching paradigm and of the power dynamics and politics in education, Indigenous teachers are fostered in throwing off indoctrination earned through generations of marginalization and their experiences in pre-college schooling, to expand their teaching philosophies to prioritize Indigenous perspectives, and customize their teaching to better support Indigenous learners. Critical analysis of the history of Indigenous people in the United States and particularly the history of Indigenous education were cited as specific topics crucial to developing reflective, empowered Indigenous practitioners.

Implications for Teacher Preparation Programs

Teacher licensure in the United States is under state control and the design of teacher preparation programs is further influenced by entities such as regional accrediting bodies, schools of education at individual colleges and universities, local K-12 schools, and the local communities served. Given the multi-layered system that bounds teacher education and the breadth and depth of items identified in this study's findings, it is clear that real change in teacher education to increase the representation of Indigenous people in secondary STEM education will only be realized if it occurs system-wide through substantive collaborative efforts, partnering schools of education, STEM and STEM education faculty, secondary schools, tribal communities, and ultimately state education agencies and accrediting bodies. Such collaborations require significant investments of time and effort to build trusting, enduring relationships that enable deep conversations with the power to transform teacher preparation. Respect, reciprocity, and recognition of the value and validity of each partner's contribution to the partnership are keys to success in these partnerships. Schools of education are the likely initiators of the work to create change. Engagement with tribal entities such as tribal education departments, tribal governments, tribal school teachers and administrators, tribal elders, and parents of Indigenous students is imperative and should observe tribal protocols.

Substantive integration of culturaly relevant content and adoption of preferred instructional practices and cultural accommodations require deep knowledge of tribal cultures. Many faculty members are not prepared for this work, necessitating substantive professional development in these realms in order to effect meaningful change. Schools of education may want to invite cultural experts to work with STEM and education faculty members, to build instructors' understanding of cultural norms, tribal history, Indigenous epistemologies, and Indigenous STEM and how to integrate them into their instruction and interactions with students. Faculty members will also require time to develop their courses to improve their cultural content and instructional methods. Tribal colleges already use the practices suggested in this study and have proven themselves useful resources for assisting mainstream colleges in making these transformations. Tribes are increasingly active in leading educational change for their people as well. Both will be crucial partners in this transformative work that challenges the status quo. Political will, commitment, willingness to cross cultural borders, and courage on the part of all stakeholders will be essential in realizing true transformation in teacher preparation programs for American Indian secondary STEM teachers.

MAKING USE OF CONTEXTS AND INQUIRY TO ENGAGE ALL STUDENTS IN STEM LEARNING

Marta Romero-Ariza[1], Ana M. Abril[1] and Antonio Quesada[1]
[1]Departament of Didactics of Sciences, University of Jaén, Jaén, Spain

Scientific and technological advances along with current societal changes are posing new challenges to education, raising questions about what is relevant to be learnt in the 21st century and which means are appropriate to bring about the desired learning goals. Science teachers need to find new ways to engage students in meaningful and transferable learning, taking into consideration diversity in skills, motivations, academic-achievement and cultural background and to advance their potential as future professionals and citizens. Context-based and inquiry-based learning offer interesting opportunities to meet these goals. Within a European project promoting these two educational approaches, this paper looks at how teachers make use of contexts and inquiry to engage all students in their mathematics and science classrooms. Results from multiple case studies show rich pictures of teachers from different schools and backgrounds articulating their beliefs, values and experiences to enact the context-based and inquiry-based teaching and to adapt to their particular group of students. We discuss which criteria underlying the selection of meaningful and authentic learning contexts in any case and how teachers design, plan and implement inquiry approaches. Lesson plans and classroom observations show differences in the level of structure of the activities, the amount of guidance and support required from the teacher and how they perceived their role in inquiry-based approaches to address diversity.

Keywords: Inquiry-based learning, context-based learning, teacher professional development.

INTRODUCTION

STEM (Science Technology Engineering and Mathematics) education is essential to prepare future scientists and engineers but also to equip non-scientists citizens with the knowledge, skills, values and dispositions to understand the world around them and make informed and responsible decisions in a world deeply influenced by science and technology.

Inquiry-Based Learning (IBL) has been widely supported and highly recommend by several policy documents and experts' report as an appropriate methodology to improve STEM education and has been defined as "one that engages students in authentic, problem-based learning activities, where there may not be one correct answer, experimental procedures and hands on activities, including searching for information, self-regulated learning sequences and discursive argumentation and communication with peers in a process of talking science" (European Commission, 2015, p. 68). The study conducted by Scogin et al. (2018) shows that IBL is among the practices and characteristics of successful science programs in those schools that best support achievement in diverse classrooms.

A critical analysis of research evidence shows that the role of teachers in IBL is essential to foster students' reasoning and that a major emphasis should be placed on the cognitive processes conducive to meaningful learning (Romero-Ariza, 2017). Teachers support these processes through the use of questions that draw students' attention on key aspects and stimulate their critical thinking, empowering them to develop evidence-based explanations.

Along with teaching methods, learning contexts also have a significant impact on students' motivation and engagement and the quality of learning that takes place. Context is defined as the interactive everything in which learning is situated (Finkelstein, 2005). The notion of context has inspired a classical line of work in science education and has recently gained new attention in an attempt to design meaningful, functional and motivating scenarios for STEM learning (Sevian, Dori & Parchmann, 2018).

Given the key role of STEM education in todays' societies and considering the value of inquiry and context-based approaches, this work intends to have a look at how teachers implement those key elements in classrooms with students' diversity after a specific teacher professional development course. The course was specifically designed to support teachers to engage diverse students in active inquiry through meaningful and motivating contexts for STEM learning.

METHOD

A multiple case study methodology was used to get a rich picture of how teachers may use contexts and inquiry to engage students in STEM learning. The scientific rigor of the study is supported by low-inference statements (quotations), the triangulation of information from diverse sources and the involvement of different researchers (Creswell & Plano Clark, 2011). Categories were established in an inductive way to reflect the main themes arising. The content analysis was conducted through iterative cycles to ensure reliability and agreement. The outcomes and interpretation coming from one source of information were triangulated with those coming from the others to ensure consistency.

RESULTS AND DISCUSSION

Lesson plans, classroom observations, reflective notes and students' responses show that in the three case studies, teachers succeeded in developing contexts for STEM learning that engage all students. The categories arising for the analysis of contexts were *authenticity*, *students' ownership* and *utility*.

Table 1. Examples of extracts coded under the categories for the analysis of contexts.

Extract	Category	Source
" it engaged all students, no matter their cultural background because it was connected to something real and close to them"	Authenticity	Interview Teacher A
"….one student suggested the task when I asked what would you like to learn… and I thought why not"	Ownership	Interview teacher B
"…it allowed students to solve a particular problem, in this case, the high level of noise at school…we better live and work without noise"	Utility	Reflective notes Teacher C

The learning contexts used by teachers differed in the criteria used for their selection. In the first case, the teacher designed a task called 'much more than honey" inspired by recent news reporting on the disappearance of *the blue bee* and the importance of bees and their products for the human being (authentic events). According to the teacher's word the task "engaged all students, no matter their cultural background" because it was connected to "something real and close to them" (teacher A).

In the second case, the teacher took a student's suggestion about making slime in the classroom and used it as a context to learn about the properties of matter, mixtures and proportions, encouraging students to inquiry about how to make a 'safe' slime. He highlighted students' motivation and sense of ownership: "I chose the context because it came out in a previous lesson and I thought why not…and I cannot be more satisfied with the experience, with the outcomes and with my students' faces…" (teacher B).

In the third case, the teacher encouraged students to build their own robot to assess noise. When explaining the selection of the context the teacher emphasized its authenticity and utility for the community, stating that "learning will take place when addressing and searching solutions for a problem: the high level of noise at school" (teacher C).

In two of the case studies students developed real products (authenticity) as a result of the process: a robot to assess noise at school and a safe slime. Both products might be considered of special interest or utility from students' perspective (to improve the situation in their community in one case, and to produce a playful staff in the other). However, in the project entitled 'much more than honey' students conducted a sequence of activities to understand the value of bees and the materials and substances they produced, but they did not develop a final product of special interest or utility. However, in the three cases, students reported high levels of interest and engagement in learning and felt valued and appreciated by the teacher and others in the classroom. Results were especially remarkable in a classroom with many low-achievers: "…students felt valued and I could see their self-esteem increased…the experience made them find their space in the school" (teacher B).

In addition, the three teachers designed inquiry tasks, but they significantly varied in the way teaching and learning was planned and finally enacted. Some of the categories appearing when analysing how inquiry might be used to address diversity were *collaborative inquiry, peer learning, teacher prompts, challenges and specific teaching techniques*.

Table 2. Examples of extracts coded under the categories for the analysis of inquiry enactment.

Extract	Category	Source
"I use small challenges they have to address in teams so they can support each other. I want them to make sense together"	Peer learning	Interview Teacher A
"Students were set in groups to address the task collaboratively"	Collaborative inquiry	Observation notes, researcher B
"I really like when her mate saw her mistake and how he made her notice…This is what I want, I want them to support each other, to learn together…"	Peer learning	Interview Teacher A
"…my intervention was crucial for them not to drop off, to gain self-confidence and to believe in the project, in their project…"	Teacher prompts	Reflective notes Teacher B
"The main difficulties were related to the use of new concepts and the application of complex skills: developing a 3D prototype, programming with Bitbloq and Arduino and using appinventor to create an app"	Challenges	Reflective notes Teacher C
"Then I used a strategy we saw in the PD course: setting experts commissions with delegates from the different working groups to get experience in any of the three big challenges. Then they transferred their expertise to their own groups"	Specific teaching techniques	Reflective notes Teacher C

Concerning how inquiry was planned, enacted by students and guided by the teacher, we also found differences in the three case studies. The inquiry about bees was designed as a sequence of carefully planned activities that allowed students to develop key ideas progressively. Activities came with guiding questions aimed at stimulating students' thinking and enabling them to interrelate those key ideas in order to make the whole picture. The classroom observation showed that the initial design was very scaffolded and students were able to successfully conduct the task with minimal guidance from the teacher. The teacher mainly focussed on controlling time to respect the initial lesson plan and to pose stimulating questions to draw attention on the key issues. Though students had autonomy to organise their group work and to decide upon the best way to address any activity, the teacher exhibited a high control of the class at any moment.

The task about '*making-slime'* was introduced as an open task with minimal guidelines and students required the teacher support very often: "…my intervention was crucial for them not to drop off, to gain self-confidence and to believe in the project, in their project…" and "due to perseverance and encouragement …finally all the groups reached their goal" (teacher B).

The case study about noise level in the school was initially designed as an open project where students had to make decisions about how to design and build their own robot. It required new knowledge and complex skills from students and in the interview the teacher recognised feeling a bit frustrated for not being able to support any working group at the same time. However, she decided implementing a technique learnt in the course and set student's 'commission of experts' to facilitate collaborative learning and peer-support.

Finally, the study shows positive effects on the classroom atmosphere and the way students interact with peers and the teacher. Table 3 shows some examples.

Table 3. Examples of extracts showing positive effects and increase in students' self-esteem and sense of inclusion.

Extract	Category	Source
"…It has changed the way the group communicates and interacts and my relationship with them, enhancing empathy and complicity…	Positive interactions	Reflective notes Teacher B
"…the implementation of the task in the classroom has been an inflection point in the story of my classroom, a demarking point between before and after.	Students' identity	Reflective notes Teacher B
"…students felt valued and I could see their self-esteem increased…the experience made them find their space in the school…"	Students' self-esteem	Reflective notes Teacher B
"What was most impacting from the course was to realise that science education was no longer a field for the most smart or capable. The first thing I got from the course is, as you demonstrated repeatedly with examples, that it is absolutely possible to teach STEM in a diverse classroom, achieving very good objectives for all"	Inclusion	Interview Teacher B

The study provides interesting evidence about the positive effect of the pedagogical approach on students' identity and self-esteem and all learners' capacity to engage in the STEM classrooms in a meaningful way.

CONCLUSIONS

The three case studies discussed above allowed us to illustrate different ways in which teachers can make use of contexts and inquiry to enhance all students' engagement in STEM learning, suggesting the importance of providing teachers with opportunities to transfer what they learn in professional development courses to their teaching practice.

CHEMISTRY TEACHERS' KNOWLEDGE ABOUT CHEMISTRY PROFESSIONS

Anna Kotwica[1], Verena Pietzner[1]
[1]University of Oldenburg, Oldenburg, Germany

In the field of chemistry, school is rather influential regarding students' career aspirations because chemistry-related professions are much less visible in everyday life than other professions. Schools need to provide information about respective professions to enable the students to take a career decision on a proper knowledge base. In Germany, only few students have chemistry related career aspirations, even though the field of employment has a broad range, starting from classical chemistry professions like lab technician or new professions like specialist in wastewater technology. Therefore, it is necessary to know more about the situations at schools to better understand the background of the students' lack of interest to follow a respective career. Thus, it is necessary to investigate how chemistry classes may contribute to career aspirations and career choices. Within the context of our study, the focus lies on getting information about chemistry teachers' regarding chemistry professions and how career education is implemented in their teaching and at their respective schools.

Keywords: Career Education, Teacher-Professionalism, Teacher Professional Development

INTRODUCTION

Schudy (2002) summarizes the term career orientation by assigning four different meanings to it. He distinguishes subjective career orientation, career orientation of the educational content and teaching methods, career orientation in the sense of career choice preparation and career orientation in the sense of work-related general education. The subjective career orientation refers to the individual. Career orientation of educational contents and teaching methods should take account of new requirements of the economy. This should be implemented through the selection of important contents and appropriate methods in the school. By doing this, career orientation in the sense of career choice preparation is addressed at the same time. School activities are designed to help students in this process so that they can ultimately make a rational career decision at the end of schooling. Career orientation in the sense of work-related general education means that general skills are taught in the school, which enable the students to act in as much as possible areas of work. As important soft skills for being successful in a profession, he names judgment, solidarity, self-determination and social competence.

To support students in their career choice, various programs have been developed and integrated into the school system. However, most are focused on general aspects of employability like assessing the students' general skills or how to write an appropriate application. However, school also has the responsibility to guide students with respect to subject-oriented career competencies and support them to develop a vocational identity (Winters, Meijers, Kuijpers, & Baert, 2009).

Besides school students can get in contact with various professions in everyday life. The parents and other adult relatives as well as their friends' parents have a profession and talk about their work; taking part in everyday life also gives an insight in a lot of professions: sellers, doctor's assistants, car mechanics etc. The ten mostly chosen professions in the field of training professions are professions that are visible in everyday life (Bundesinstitut für Berufsbildung [BIBB], 2017). In contrast to this, chemistry training professions are more or less hidden – only the results of their work are visible: safe food, dairy products, kitchenware, cell phones, OLEDs and much more. Whereas chemistry professions that require a study programme at a university, for example a chemist, are known by some students, training professions are mostly unknown, unless someone in the students' family has a respective profession (Haase, 2017). In Germany, there are school types of lower secondary education that do not lead to the Abitur, a graduation that enables the students to enter University. Therefore, a chemistry related career education is of great importance especially at these schools because their students will likely never have the chance to work in the professions they know. Therefore, students interested in chemistry might think that chemistry can never be a basis for their professional life, and it is not possible to get interested in a profession you do not know about. This situation could be changed if teachers would be enabled to provide a proper career orientation in class that is closely related to chemistry.

Holland (1997) describes career choice as an expression of personality. He classifies six idealized personality types, which are characterized by specific abilities, professional preferences, values, life goals, problem-solving styles and self-concepts. Their characterizations are represented by the acronym RIASEC: realistic, investigative, artistic, social, enterprising, conventional. Each person's personality has a focus on one of these six types, the so-called primary type. However, a comprehensive description of a person is only possible by two other predominant types, the secondary and tertiary type. They are weaker than the primary type, but much stronger than the remaining three feature descriptions (Weinrach & Srebalus, 1994). The three types form the Holland Code. Such a code can be created for every profession but also for a person. For example, the profession Distiller has the Holland Code IRE. A match in Holland Codes between profession and person does not automatically guarantee an ideal job for this person but can help to narrow down the wide field of possible professions to a smaller selection.

In addition to the theory of Holland, the developmental psychology approach of Gottfredson (2005) is important for an appropriate career educational at school. According to this theory, the professional self-concept is influenced by factors like sex, status, or personal interests. This self-concept is compared by the individual with his or her professional concept. Above all, this professional concept determines the choice of occupation. A correspondence of self-concept and occupation leads to an individual considering of a profession as desirable. Both the self-concept and the professional concept develop in a long-term process that consists of four phases shown in table 1.

Table 1: The four stages of career orientation according to Gottfredson (2005)

	Stage 1: Size and Power	*Stage 2: Sex roles*	*Stage 3: Social valuation*	*Phase 4: Internal, unique self*
Grade	Preschool	Primary school	Middle school	High school and later
Mental process	Intuitive	Concrete	Less abstract	Abstract
New element of the perception	Big vs. small	Male roles vs. female roles	High prestige vs. low prestige	Personal interest, values, competences

of self and others				

One model that has been developed especially for career orientation at school is the cooperation model of Egloff (1998, pp. 106). The central aspect of the model is therefore the exploration of the professional and working world. The different collaborating partners of the students, e.g. parents, the school, the federal work agency as well as companies in the area of the school, should promote the transition of young people to vocational training or to a suitable upper secondary school and therefore into working life and support them in a role-specific manner.

Cohen, Patterson, Kovank and Chowning (2013) analysed the role of science teachers in promoting the students' interest in STEM careers and identified four factors that teachers need to take into consideration: Awareness (students develop an understanding and appreciation of STEM careers), Relevance (seeing the relevance of the subject matter in their lives), Engagement (engaging with the subject matter and STEM careers) and Self-efficacy (feeling comfortable using the tools of science). Wyss (2013) could show that the usage of videos can foster students' career interests in STEM fields, and Curry, Belser, & Binns (2013) suggest integrating career education in chemistry augmenting the existing classroom resources like providing additional learning material for the students focusing on careers in chemical industry. They stress that career exploration can be easily integrated in the classroom, for in the classroom, the same activities are dealt with as in the varied chemistry professions.

Dreer (2013, p. 145) has identified teachers' subject-related competences that are important for the implementation of career orientation in subject-specific education. They should know about suitable didactic principles of valuable learning opportunities for vocational orientation and based on this being able to design lessons to foster vocational, subject-related competences. Furthermore, they need to know relevant learning content and learning objectives for career education as well as suitable teaching material. This includes in particular the knowledge about different professions. Finally, teachers need to know how to design extra-curricular activities to promote career relevant and subject-related competences by individual preparation and evaluation of extra-curricular activities, for example by teaching students how to write an internship report. Based on these required competences, the following aspects can be derived for chemistry teachers:

- Teachers need to understand vocational orientation as a task of chemistry education at school.
- They need to know about
  - chemical occupations, their fields of application and main activities.
  - different working methods in the chemical industry.
  - characteristics of different chemical occupations
  - educational methods, like open lessons, action-oriented lessons, project lessons or problem-solving lessons, that contribute to career orientation.
- Teachers should have an own insight in the world of chemistry professions and the chemical industry.
- Teachers should be able to design chemistry lessons that foster key competences like autonomy, power to act, and team work.

However, there are currently only a few conversations about chemistry professions in the classroom (Mittenddorff, den Brok, & Beijaard, 2011). All means to foster career education in chemistry classes need to be planned and done by the teacher. Therefore, it is the teacher who is somehow a prerequisite for a suitable career orientation. It is known that only a few students in Germany want to work in STEM-related professions (Kjærnsli & Lie, 2011). To better understand the results of the different studies dealing with career orientation in chemistry classes, it is necessary to take a closer look at the teachers' knowledge about and views on chemistry professions. The following research questions were relevant for evaluation:

1. How important are the natural sciences within the general career education at school?
2. Do chemistry teachers implement career education in chemistry class?
3. To what extent has career education (methodologically or content-related) already been integrated into the chemistry classroom by the teachers?

METHOD

To investigate the research questions, the expert interview method was used, whereas an expert is described as follows: "'*Expert' describes the specific role of the interviewee as a source of specialized knowledge of the social issues to be explored*" (Gläser & Laudel, 2010, p. 12). They have a diverse experience-based knowledge that is usually not directly available but can be accessed in expert interviews. Meuser and Nagel (2009) distinguish between the operational knowledge and the contextual knowledge of the experts. Business knowledge often includes the process knowledge of the experts, which includes a certain amount of self-reflection about one's own actions. Contextual knowledge, on the other hand, means knowledge about the field of action in which the expert is located.

According to Bogner and Menz (2002), three types of expert interviews exist: the explorative, the systematizing and the theory-generating expert interviews. A new field of research can be developed by generating hypotheses and thereby identifying important thematic aspects. Following the systematizing approach, expert interviews serve can help to structure a topic in order to generate a network of knowledge that describes the frame of the topic. In this study, the explorative approach is pursued because little is known about the extent to which chemistry teachers integrate professional orientation into their teaching. Based on the interviews, a framework for implementing chemistry-related vocational orientation in class will be developed. Since the literature about this topic is limited and a qualitative approach was chosen, the results of the survey are not generalizable, but convey the first tendencies that are emerging in the subject of vocational orientation in chemistry lessons.

To answer the research questions, a semi-structured interview was developed and validated by intense discussion with a group of experts (Steinke, 2004, p. 187) as well as doing test interviews with two volunteers. The interview covered four different areas: First, the teachers should describe their individual view on career education. In the second part, they were asked give information about the concept of career education at their respective schools and, in more detail, what role science subjects have. Afterwards, they described their experiences, attitudes and ideas about the implementation of career education in chemistry class. Finally, questions about gender issues were discussed.

The interview guide was tested in a pilot study for clarity and informative value. Subsequently, the interview was transcribed and looked at whether research-relevant aspects are included. Since there were no difficulties in understanding during the interview and that relevant aspects related to the framework conditions for vocational orientation in chemistry lessons were included, no changes had to be made.

Contact with the chemistry teachers was made via the teacher professional development centre of the University of Oldenburg that has a full list of all schools in Lower Saxony and by e-mail to schools in the region of the university. Thus, it should be ensured that all chemistry teachers in Lower Saxony receive the project information and as many teachers as possible agree to participate in the interview study. The e-mail was accompanied by an information letter about the project, in which the teachers received a project overview and the objectives of the study were briefly explained.

For the main study, the interviews were recorded on tape and transcribed with the consent of the participants. The evaluation of the interviews was carried out with the method of qualitative content analysis according to Mayring (2014). For this, the interviews have been transcripted and the teachers' statements have been categorised. The categories were inductively derived from the interviews and have been validated by a consensual validation. The categories are: beginning of vocational orientation, responsibility for organization, offers for vocational orientation, the role of school social workers, and inclusion of the parents.

RESULTS

In total, eleven teachers (five females, six males) have been interviewed. In average, they have been teaching for 15.6 years. Six of them learned a profession before they became chemistry teachers; all the professions have a close relation to science (oecotrophologist, agricultural engineer, chemical lab technician, Master of Science in Chemistry and Biology, respectively). The interviews took between 20 and 70 minutes. All teachers work at a secondary school types that do not lead to Abitur and that traditionally focus much more on career orientation than teachers working at a Gymnasium. These schools offer different profiles in grade 9 and 10 that enables the students to focus on language, economy, technology or health and social affairs.

Table 2: Description of the sample of interviewed teachers

			Professional Biography	
Participant	*Sex*	*Years of teaching experience*	*Teacher Study Program*	*Previous Career*
B1	Female	7	No	Oecotrophologist, Microbiological Assistant, M. Sc. Biology
B2	Female	5	Yes	
B3	Female	8	No	Agricultural Engineer
B4	Female	24	Yes	
B5	Female	19	Yes	
B6	Male	23	Yes	Chemical Lab Technician
B7	Male	11	Yes	Commercial Apprenticeship, M. Sc. Biology

B8	Male	37	Yes	Chemical Lab Technician
B9	Male	7	No	M. Sc. Chemistry
B10	Male	3	Yes	
B11	Male	28	Yes	

Ten participants addressed chemical professions in the classroom, but big differences could be identified. Teachers who have previously worked in another profession tell their students about their experiences. In addition, they can name various professions and precisely describe their activities. Three teachers were able to comprehensively describe some typical activities, three other teachers cannot describe activities, but still name them. The remaining five teachers named two or one activities but did not describe them in detail.

Occupational orientation in chemistry classes is most taught by doing factory tours or working on a project like cosmetics or food chemistry. Two teachers still have contact with their former companies. Another teacher is currently planning to cooperate with a local chemical company. Apart from that, the teachers named project weeks as a possible contribution of science subjects to career orientation. In total, the relevance of science classes for career orientation was rated as low by ten teachers. The inclusion of career orientation in regular chemistry lessons was not usually included in lesson planning. In fact, the chemistry teachers tend to point out the professions by chance when they spontaneously see connections to the content to be taught.

When asked for possible different interests of boys and girls with respect to career aspirations, six teachers described differences which they noticed during their teaching. They claim that boys and girls try to live up to the classic role classification anchored in society. Girls would be seeking careers in the field of health or social affairs and would have no interest in technology or science, boys orientate themselves the opposite way. However, girls would place their occupational decision on a broader basis and would be more targeted than boys. Three teachers pointed out that there are still old stereotypes at school, with one teacher who considers it critical to break them up.

DISCUSSION AND CONCLUSIONS

The results show that teachers are only able to give their students some career orientation in the field of chemistry if they have learned a respective profession themselves, or at least they are far better able to do so. But even if they have learned a chemistry profession, career orientation is taking place accidently within the regular chemistry classes, with teachers focusing mainly on teaching chemistry-related content. Therefore, career orientation is currently no teaching goal for the teachers that needs to be considered. They see more possibilities to include career orientation within extracurricular activities like factory visits or more special activities like project weeks to give the students an insight into chemistry professions. This result closely relates to the circumstance that most of the teachers in this study have only little knowledge about chemistry professions. Although they can name a few occupations, only few teachers can provide information on the typical activities of these occupations. Therefore, all teachers in this study do not meet the four factors for suitable career orientation according to Cohen et al. (2013). However, the small number of participants in the study must be considered, and it would be useful to verify the results by a questionnaire study.

The results suggest that teachers need much more knowledge about chemical professions to incorporate career orientation in the classroom. This is of relevance because few adolescents in Germany have science-related career expectations and do not know chemistry professions from their daily life.

Usually, chemistry professions are much less visible in society than other professions, and therefore students depend on information from school. Chemistry classes could provide a way to introduce chemistry professions and to bring the students closer to the multi-faced professional world of chemistry. Because many typical activities of chemical professions are already part of the school, it is easy to provide a suitable career orientation easily (Curry, Belser, & Binns, 2013). Therefore, career orientation needs to be implemented into teacher education, considering both the study programmes as well as professional development courses.

Teachers also reported that gender stereotypes still exist for career orientation. Even gender equity is an important big issue in society, girls and boys still tend to follow "male" or "female" professions. This result shows once more the relevance of the theory of Gottfredson that the career choice is mainly influenced by the own gender and other factors are of secondary importance (Gottfredson, 2005). Therefore, it will need much more effort from society, beginning in Kindergarten, to overcome a gender-focused career choice.

At school, teachers can incorporate vocational orientation into their lessons with a small amount of measures that do not require to change their teaching fundamentally. To integrate information about chemistry professions, teachers need to have some basic knowledge about chemistry professions. Valid information can be found in the WWW from different stakeholders like the Federal Agency for Work or the Federal Employers Association Chemistry e.V. Based on this, they could develop teaching materials that put the students in a context that shows the relation between the experiment and a profession. This can also easily be done for topics that are part of the core curriculum for Chemistry, and teachers do not need to teach any additional topics for implementing career orientation. For example, instead of just doing an acid-base titration the teachers could design a context of a lab technician who has, as part of a goods receiving inspection, to check the acidity of a delivery of hydrochloric acid. This is just one example of a combination of chemistry-related content and the inclusion of a chemistry profession. At the University of Oldenburg school labs were developed and evaluated that show even more possibilities where chemistry professions were combined with typical tasks the workers have to do in their jobs. In addition, teachers could invite people into chemistry classes to do a chemical job, report on their activities and their professional environment.

In summary, not only previous research but also this study shows a still existing outdated role understanding by the student. Therefore, it is still a big challenge to foster science career interests of female students. But this means that career education has to be incorporated more and better in science education in schools. With the overall goal to motivate more students for science career it is necessary to break up outdated but still existing role understandings and ends with implementing more career orientation not only in extracurricular activities but in each science subject. This is possible in ways which previously have been described but have to be extended to a much larger group of teachers. Therefore, it is worth thinking about changing the course of study in teacher training courses at University and enhance the chemistry teachers' knowledge about chemistry professions.

TRANSLANGUAGING IN THE SCIENCE CLASSROOM: LEARNING ENGINEERING IN MULTILINGUAL CONTEXTS

Greses Pérez-Jöhnk
Stanford University, Stanford, USA

Demographic shifts due to immigration in the United States have increased the number of multilingual learners in schools. While this population trends continue, schools have recently implemented frameworks for elementary and secondary science education that incorporate engineering and the language demands associated with the field into the science education. These changes pose new challenges and opportunities for culturally and linguistically diverse (CLD) students. CLD students are now expected to engage in the language-intensive practices of engineering while developing basic literacy in English. However, research on immigrant communities in the United States often assumes a homogenous experience in learning settings while omitting the complexity within these communities. Contemporary research has yet to understand the relationship between language practices and engineering learning within the elementary science classroom. Drawing both on the literature of language in science education and translanguaging, this study investigates how students negotiate language in science and engineering and their perceptions around notions of language boundaries in schools. Through event mapping of participants' video data, this paper seeks to understand language negotiation in three different linguistic contexts during an engineering program at a university in Northern California. The results suggest that participants negotiated linguistic resources and meaning during the engineering lesson in four ways: rejection, loan, leasing, and ownership. Students' responses during the course also suggest that they perceived schools as spaces where language boundaries are reinforced. Learners expressed that educational institutions consider their capacity to transgress language boundaries as a negative behaviour. In summary, this study unpacks the intricacy of language value by showing the way pedagogical conditions provide affordances for language use in specialized learning environments.

Keywords: bilingualism, STEM, language in Science Education

INTRODUCTION

Language is important for science learning, especially for students who are speakers of non-dominant varieties. The number of speakers of languages other than English in schools has increased considerably in the United States in recent decades mainly due to factors such as immigration. As a result of these changes in national demographic trends, cultural and linguistic diversity has become a central force that shape education in the United States (Vogel, Ascenzi-Moreno, & García, 2018). A culturally and linguistically diverse student (CLD) is a learner whose ways of speaking, being and knowing in the world differ from those of the dominant society. According to recent Census data, culturally and linguistically diverse (CLD) learners will soon become the majority of students in U.S. public schools (U.S. Census data, 2015). These diverse learners perform poorly on academic achievement, exhibiting the lowest scores on performance and graduating at the lowest rates of all students (Darling-Hammond, 2015). Scholars have offered alternatives to ameliorate this issue. These alternatives range from focusing on the linguistic register of classroom-based science as a resource for learning (Halliday & Martin, 1993; Fang & Schleppegrell, 2008), supporting students engagement in the ways of talking and engaging in the scientific enterprise (Lemke, 1990; Engle & Conant, 2002; Osborne, 2012) to addressing the learning needs in content and language of traditionally marginalized students (Lee, Buxton, Lewis, & LeRoy, 2006; Brown, 2006; Lee, Quinn & Valdés, 2013). Most researchers investigating this dilemma frame language barriers in science education as an important component to the failure of schools to serve students. However, few researchers in the area of science education and language focus their work on understanding the role of language barriers for CLD students (c.f. Lee, 2005). The applied linguistics research on language practices in the context of science could contribute to the literature on language in science education by reimagining ways to negotiate language use and linguistic resources in learning environments (Bravo and Garcia 2004; Poza, 2016). To this end, educational research could look at the divisions of languages, which are socially imposed, in relationship with science learning. Both factors are important elements to consider in understanding how marginalized students access, interact with, and engage with, conceptual understanding of science and engineering. This work in progress seeks to provide empirical data to the question of how do students negotiate language when learning engineering in science learning environments.

THEORETICAL FRAMEWORK

The efforts to establish what students need to know and be able to do in science can be trace back to the 1800s with the Committee of Ten and recently to the integration of engineering in the science education frameworks. Two major perspectives emerged from these reforms: the cognitive-centred and the sociocultural-centred perspective (Brown, Reveles & Kelly, 2005). The cognitive centred perspective, based on earlier definitions of scientific literacy (Hurd, 1998; Thomas & Durant, 1987), focuses on developing scientific knowledge for extrinsic purposes, such as college and career readiness. Sociocultural approaches consider the relevance of literacy to a particular task within a meaningful social context (Jenkins, 1994; Kelly & Brown, 2003) or within the fundamental sense of literacy (Norris & Philips, 2003). The sociocultural perspective holds a view of language as a variable resource where forms emerge in use. From the sociocultural tradition emerge the theory and pedagogy of translanguaging. Inspired by Bakhtin (1934), Garcia (2009) define translanguaging as "the deployment of a speaker's full linguistic repertoire without regard for watchful adherence to the socially and politically defined boundaries of named languages." According to the author students build on their full linguistic repertoire to make meaning and use their semiotic resources to know, act and be. An important idea in translanguaging is the notion of language boundaries or imaginary division between languages (e.g. Spanish and English as different systems) connected to nation-state and political borders.

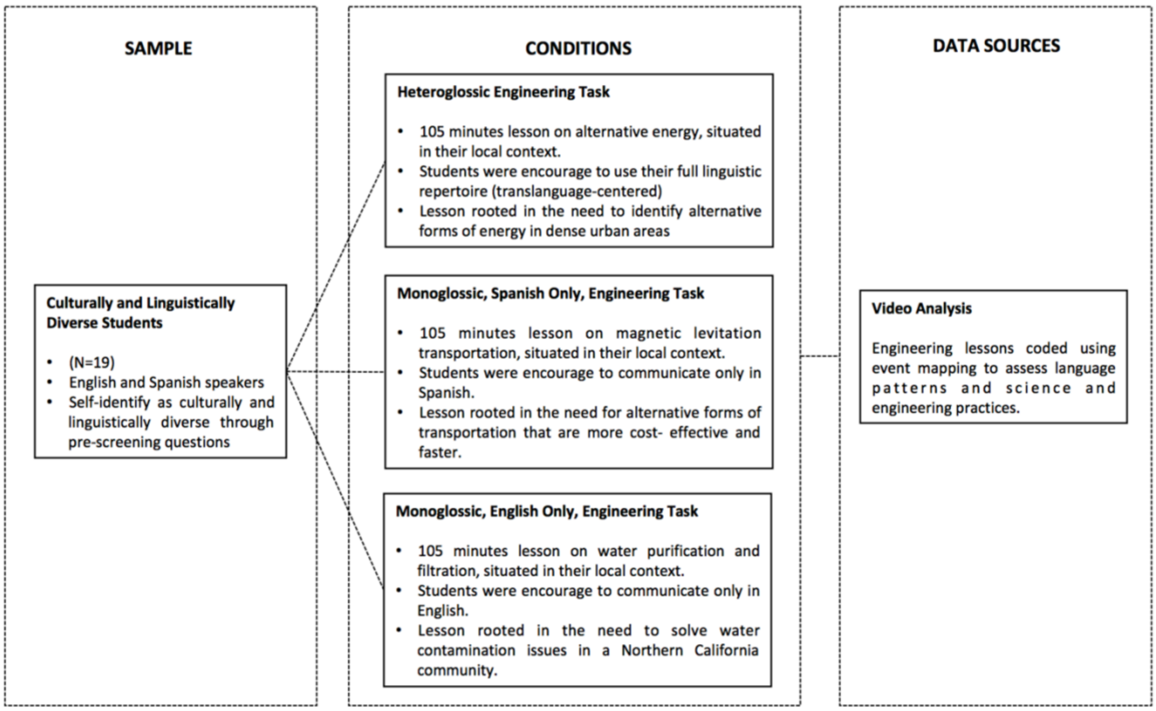
METHOD

In this qualitative study, nineteen elementary and middle school students, aged 7 to 13 years, participated. The manuscript explores how students negotiate language during their participation on a summer science program with a focus on engineering design in different language contexts. All participants identified as Hispanics, except for two of them who identified as African American and Latinx-Asian. Participants experienced three different linguistic contexts in the following order: translingual context, Spanish-only and English-only (see Figure 1). In the translanguaging context or heteroglossic engineering task, students were encouraged to engage in mixing the languages (both

English and Spanish) when designing a windmill for a community in Northern California. In the Spanish-only and English-only lesson or monoglossic engineering tasks, students were expected to interact in Spanish or English. Learners designed a magnetic levitation train and a water purification system respectively. Adult facilitators model the language practices associated with the lesson for students. We provided the instructional materials in accordance with the language context. All students participated in all three settings, enabling comparisons of their affordances. The research team recorded program to captured students negotiation of language when engaging in engineering tasks in the science classroom. Through event mapping analysis of video data of participants (Brown & Spang, 2007), this preliminary work explores the connections between language negotiation and the linguistic context during an engineering program. Specifically, this work investigates the following questions:

1. What do culturally and linguistically diverse students do with language when engaging in science talk and social talk?
2. What are students' perceptions on how schools impose language boundaries in science?

Figure 1. Study Design Summary



RESULTS

When coding the students' video and audio during the engineering tasks in the different linguistic contexts, the author noted an intriguing pattern of language negotiations where students deployed linguistic resources based on the situation.

To answer the question of what do culturally and linguistically diverse students do with language in science talk, the researcher draw on the video and audio recording of participants to identify language patterns. After participating in the engineering tasks with various language expectations, students negotiated linguistic resources and meaning in four ways: *rejection, loan*, *leasing, and ownership.* In a linguistic rejection, the student refuses to use a linguistic element that may not be congruent with their linguistic system. The linguistic leasing is characterized by the situations where the speaker performs a linguistic construct, but does not continue its use during the utterance or after unless is prompted. In the linguistic loan, the speaker tentatively accepts an utterance. In the last one, linguistic ownership, the learner comes to the conversation with a sense of *como es la lengua*. The speaker reaches ownership in a linguistic element when they feel more comfortable expressing their ideas using those resources for an intended audience and context.

The researcher provided preliminary data about students' perceptions on normative views of language in school-based science. For this purpose, the researcher two analyse video and audio episodes and conducted a small qualitative analysis of these two illustrative cases in the sample to suggest a mechanism for understanding the different language patterns identified for research question one. During the program, especially in the translingual lesson, students offer rationales for their language practices. In their comments, they described the monoglossic and monolingual norms of schools that restrict their language repertoire when learning science. Learners explained how notions of language in the classroom equate the use of their full repertoire with violent behaviours. In one of the instances, the student suggest that speaking English in the science class, which it is taught in Spanish at the dual language school where the students attends, was equated with being mean to other children. The data suggests that ideologies of language that reinforce monoglossic and monolingual norms in schools may be restricting students' experiences in learning science and engineering.

CONTRIBUTION TO THE ESERA COMMUNITY

In alignment with the conference theme "The beauty and pleasure of understanding: engaging with contemporary challenges through science education", the empirical paper presented here addresses current topics and challenges in line to the learning of science and engineering and an intrinsic link between science education and social domains. For instance, our finding that notions of language boundaries in schools influence students' experiences in the science classroom implies that there is an opportunity for educators to reimagine equitable and inclusive learning environments in science and engineering. Broadening our views of what knowledge and ways of talking are valued in science open doors for populations traditionally marginalized in the specialized fields of science and engineering.

PART 13: STRAND 13

Pre-service Science Teacher Education

Co-editors: *Maria Evagorou & María Ruth Jimenez Liso*

CONTENTS

STRAND 13: INTRODUCTION

PRE-SERVICE SCIENCE TEACHER EDUCATION

While we are preparing this introduction, the coronavirus disease (COVID-19) is spreading, and the world is facing a situation that raises many questions and a lot of uncertainties. Almost all aspects of our daily lives have been affected in some way, amongst them education. One of the questions we have been considering as science educators during the pandemic has to do with whether we have been preparing science teachers to navigate a complex situation as the one we are currently facing. Do we provide our pre-service teachers with the necessary skills, practices and behaviors? Do we support them to prepare their own students to think critically and understand the uncertainties of science? Doubts about the effectiveness of current teacher training have been raised for a long time. More than a decade ago, the internationally influential report Teachers Matters. Attracting, Developing and Retaining Effective Teachers of the OECD (2005) placed teachers as the backbone of the education system and recognized the growing concern of all countries about the scarce links between teacher training and school needs, questioning whether the teachers have the knowledge and skills necessary to respond to such school needs. We conclude, from the large number of submissions in Strand 13 (180 submissions), that as a science education community we are concerned about preparing our future teachers and narrowing the gap between research and teaching practice.

As part of the ESERA 2019 conference, we invited researchers to submit under Strand 13 studies related to professional knowledge of teachers, pre-service teacher preparation, instructional methods in pre-service teacher education, programs and policy, field experience, relation of theory with practice, and issues related to pre-service teacher education reform. 180 papers were reviewed for the 13th biennial conference held in Bologna in August 2019, and we would like to thank all reviewers for their time and effort. This volume of the e-proceedings brings together 28 submissions from different countries representing four of the continents: Europe, Africa, Asia and America, highlighting in that way the international nature of the conference. The papers in this strand illustrate the trends in pre-service science teacher (PSTs) education across the world currently, and focus on a variety of issues and science disciplines. The topics range from studies on PSTs as learners engaging in argumentation, modeling and inquiry; PSTs as thinkers, as designers and as reflective practitioners.

The majority of studies in this strand are especially linked to analyzing the PSTs' scientific practices of inquiry, modeling and argumentation, and this is probably linked to earlier critics of science teacher training programs as being too abstract and theoretical, out of context and removed from the reality of their future classrooms (Bryan & Abell, 1999; Darling-Hammond, 2005), as well as on recent emphasis on scientific practices and scientific competences (OECD, 2018; Osborne, 2014). Furthermore, submissions in Strand 13 focused on PCK, emphasizing on few aspects depending on the different roles of the PSTs: teachers as learners, teachers as thinkers, teachers as reflective practitioners, and teachers as designers (Silm, et. al., 2017). Finally, in the selected studies there is an evolution from the traditional research line on PSTs conceptions to assess relevance, competencies and other issues that contribute to their PCK development.

We anticipate that this collective volume will become the basis of conversations discussing the changes and challenges in pre-service science teacher education, and that the interest in Strand 13 will continue to grow and will evolve following the changes brought by the pandemic.

PRE-SERVICE ELEMENTARY SCIENCE TEACHERS' VIEWS ABOUT SCIENTIFIC INQUIRY. A PILOT STUDY

Mª Marta Alarcón-Orozco[1], Isabel Mª. Cruz-Lorite[2], Antonio-Joaquín Franco-Mariscal[2]and Ángel Blanco-López[2]

[1] Department of Science Education, María Inmaculada Teacher Training Centre, University of Málaga, Málaga, Spain

[2] Department of Science Education, Faculty of Science Education, University of Málaga, Málaga, Spain

Inquiry is a scientific practice that allows, from researchable questions, the development of logic and critical thinking, and so is the need to consider alternative explanations. These characteristics make it especially suitable for science teaching-learning processes, as it has been recognized in different international reports. This paper is a pilot study carried out with 53 Spanish Pre-service Elementary Science Teachers (PSESTs) in Spain, which tries to know their ideas about the need to start a research from a question and the differences between research and experiment. For this purpose, the first dimension of the international questionnaire Views About Scientific Inquiry (VASI) was used, formulated as "scientific investigations all begin with a question and do not necessarily test a hypothesis". One of the contributions of this work is the breakdown of the categorization of responses proposed by Lederman et al. (2014) into five levels instead of three, to adapt it to the evaluation of the PSESTs. The main result obtained is that the vast majority of PSESTs does not distinguish between research and experiment and does not recognize that a research is based on a researchable question. On the other hand, no statistically significant differences have been found in the demographic variables considered: sex and previous scientific training. These results indicate the need to develop a specific training programme for PSEST's in this sense.

Keywords: Initial teacher education (Pre service), diagnostic tools, science inquiry

INTRODUCTION

The inquiry, understood as the various ways in which scientists study the natural world and propose explanations based on the evidence derived from their work (NRC, 1996, p.23), is an inherent activity of scientific practice. In this respect, the investigative approach in the teaching-learning processes of science, according to Caamaño (2012, p. 84) allows students to work in a similar way, to the fact that scientists solve problems by allowing them to familiarize themselves with scientific work and acquire a procedural understanding of science. Nevertheless, Couso (2014) considers that, from this point of view, taking the inquiry to the science classroom highlights, the importance of making students understand the nature of science from their participation in scientific practices as authentic as possible.

In Europe, since the publication of Science Education Now (Rocard, 2007), numerous pedagogical proposals have emerged focusing on inquiry-based science teaching. According to NRC (2000, p. 1) "… yet the activities and thinking processes used by scientists are not always familiar to the educator seeking to introduce inquiry into the classroom", therefore, there is a need to train pre-school and primary school teachers in inquiry skills. In this way Mosquera, Puig & Blanco (2018, p. 9) point out "the identification of questions and concepts that guide scientific research, its design and implementation, formulation of scientific explanations, recognition and analysis of explanations and alternative models, as well as the communication and defense of a scientific argument".

Thus, the purpose of this study is to implement inquiry as a teaching-learning strategy for science in the Preservice Elementary Science Teachers (PSESTs) training. Lee and Shea (2016) have shown how the understanding of inquiry-based teaching of the PSESTs increases after a training programme, being this program a key step in developing their confidence and effectiveness in science teaching. The aim of this paper is to evaluate the scientific research views of the PSESTs as a starting point to develop an inquiry-based training programme.

METHODS

The sample of this study consisted of 53 PSESTs from the Maria Inmaculada Teacher Training Centre at the University of Malaga (Malaga, Spain). 52.8% were women and 47.1% were men. 85% had not taken a baccalaureate in science, so their last contact with formal training in science had been 5 years earlier.

The data collection instrument was the international and validated VASI (Views About Scientific Inquiry) questionnaire (Lederman et al., 2014), which was translated and adapted into Spanish. The VASI questionnaire is conceived by the authors as a powerful tool to evaluate students' conceptions of essential aspects of scientific inquiry, in line with the vision established in the next generation science standards (Lederman et al. 2014, p. 65). These conceptions refer to 8 dimensions:

> "(1) scientific investigations all begin with a question and do not necessarily test a hypothesis; (2) there is no single set of steps followed in all investigations (i.e. there is no single scientific method); (3) inquiry procedures are guided by the question asked; (4) all scientists performing the same procedures may not get the same results; (5) inquiry procedures can influence results; (6) research conclusions must be consistent with the data collected; (7) scientific data are not the same as scientific evidence; and that (8) explanations are developed from a combination of collected data and what is already known." (Lederman et al., 2014, p. 68).

Initially this questionnaire was used to assess the vision of scientific research by students with at least 6th grade (middle school) reading and writing ability, but can be appropriately applied to college level students too (Lederman et al., 2019).

The objective of this paper is to test the first dimension of the VASI questionnaire in Spain with PSESTs and analyze the first results. This dimension is assessed in the VASI questionnaire with items 1.a), 1.b) and 2). The statements of these items are included in Table 1.

Table 1. Statements of items 1.a), 1.b) y 2) of the VASI questionnaire (Lederman et al., 2014).

A person interested in birds looked at hundreds of different types of birds who eat different types of food. He noticed that birds who eat similar types of food, tended to have similar shaped beaks. For example, birds that eat hard-shelled nuts have short, strong beaks, and birds that eat insects have long, slim beaks. He wondered if the shape of a bird's beak was related to the type of food the bird eats and he began to collect data to answer that question. He concluded that there is a relationship between beak shape and the type of food birds eat.

1.a) Do you consider this person's investigation to be scientific? Please explain why or why not.

1.b) Do you consider this person's investigation to be an experiment? Please explain why or why not.

2. Two students are asked if scientific investigations must always begin with a scientific question. One of the students says "yes" while the other says "no". Whom do you agree with and why?

The aim of item 1.a) is to identify whether or not the experience described was an investigation justifying why, while item 1.b) sought to know whether or not the same experience was an experiment. Item 2 demanded to reason on whether or not scientific research should be based on a question.

These items are open and demand an explanation from the students, hence the importance of building an appropriate rubric. The answers were categorized by authors' consensus, based on the categories proposed by Lederman et al. (2014) and adding more levels (called "our levels" in Table 2) to adequately address the range of answers offered by the PSESTs. The criteria used to sequence the performance levels of the answers were: a) to assess the presence or absence of an explanation and b) to assess the degree to which the explanations provided were closer to the most accepted ideas on the aspect asked.

The statistical treatment of the data obtained was performed with the SPSS 21.0 programme. The mean and median were calculated for each of the items analyzed and the variables studied, sex and scientific backing. The existence of statistically significant differences according to sex and the existence, or not, of previous scientific training was studied using the non parametric Mann-Whitney U test.

RESULTS

Table 2 shows the system of categories used, their relationship with the categories of Lederman et al. (2014) and the percentages of responses recorded. For each of the levels used in this study the criteria for categorizing the responses of the PSESTs are indicated and illustrated with an example of them.

88.6% of the PSESTs (levels 2, 3 and 4) considered in item 1.a) that the experience described was an investigation, and being 26.4% at the most appropriate level when indicating, in addition, two or more important aspects of the investigation.

For item 1.b), 67.9% of the responses were at levels 0 and 1, the most inadequate levels, showing that PSESTs confuse research with experiment. Only 13.2% were able to relate an experiment with variable control.

Table 2. Relationship between items, concordance of evaluation rubrics, examples and results obtained.

Item	Rubrics: Lederman et al. (2014) level	Our level	Criterion	Example	(%)
1.a) Do you consider this person's investigation to be scientific? Please explain why or why not.	Naïve	0	Yes or no without explanation.	Yes.	5.7
		1	No with explanation.	No, because he has conducted scientific experiments to validate his hypothesis.	5.7
	Transitional	2	Yes with some vague or imprecise explanation of the research aspects.	Yes, because research has a basis.	26.4
	Informed	3	Yes, indicating an important research aspect	Yes, because one investigates something with analysis and tests.	35.8
		4	Yes, indicating two or more important research aspects.	Yes, because for a period of time he has been observing and taking data to reach the conclusion that there is a relationship between the types of peaks and the type of feeding they have.	26.4
1.b) Do you consider this person's investigation to be an experiment? Please explain why or why not.	Naïve	0	Yes or no without explanation	Yes.	11.3
		1	Yes or no with some vague and imprecise explanation.	Yes, for he experiments with birds.	56.6
	Transitional	2	No, indicating that observation/data collection are different things from an experiment.	No, since he has only collected information.	18.9
	Informed	3	No, relating an experiment with variable control (intervenes, modifies, etc.) or with an alteration of reality	No, whereas it has not included factors that alter or modify the object of study.	13.2
2. Two students are asked if scientific investigations must always begin with a scientific question. One of the students says "yes" while the other says "no". Whom do you agree with and why?	Naïve	0	Yes or no without explanation	Yes.	11.3
		1	No with explanation.	Yes, since everything must start from something.	62.3
	Transitional	2	Yes, with some vague or imprecise explanation about the research questions.	There is no level example 2.	0.0
		3	Yes, mentioning some important research aspects.	Yes, because in order to investigate something you have to start from a question and get more information.	13.2
	Informed	4	Yes and give a meaning to the research question.	I agree with the boy who says yes, since for me all research starts from a concern and starts looking for a reason to some internal question of the individual.	13.2

Regarding item 2, 73.6% were in the least adequate levels (0 and 1). At the most appropriate level, which gives meaning to the research question, only 13.2% of the PSESTs were at this last one.

Table 3 shows the results for the variables studied. No statistically significant differences were found for the variables sex (Z = -1.637; p = 0.102) and previous scientific training (Z = -1.019; p = 0.308) in any of the three items.

Table 3. Results for items 1.a, 1.b. and 2, mean, median and Mann Whitney U test, depending on the variables studied.

Item	**Sex**				**Scientific backing**			
	Mean / Median		**Mann Whitney U Test**		**Mean / Median**		**Mann Whitney U Test**	
	Women (N=28)	**Men (N=25)**	**Z**	**p-value**	**Scientific (N=11)**	**Non-scientific (N=42)**	**Z**	**p-value**
1.a)	2.50 / 3	2.96 / 3	-1.637	0.102	2.45 / 3	2.79 / 3	-1.019	0.308
1.b)	1.29 / 1	1.40 / 1	-0.406	0.685	0.91 / 1	1.45 / 1	-1.817	0.069
2.	1.61 / 1	1.48 / 1	-0.103	0.918	1.36 / 1	1.60 / 1	-0.417	0.677

CONCLUSIONS

The results obtained are in accordance with those found by Lederman et al. (2019) for Spanish students at the end of primary school. According to the authors "the Spanish students hold a naïve understanding for all the aspect of scientific inquiry" (p. 30) and attribute this situation to the teaching methods and content in which scientific inquiry is lacking as relevant scientific curriculum content. They also point out, among others things, the lack of explicit and reflective teaching and the lack of effective teaching approaches to the teaching of scientific research.

The results obtained shows that it is necessary to address with the PSESTs an explicit treatment on research aspects, oriented to differentiate between a research and an experiment and to recognize that research requires to start from a question formulated in a clear and precise way, and so is the sense that this question has for the research.

These and other aspects will be attempted by designing a training program for PSESTs.

PRE-SERVICE SCIENCE TEACHERS' CONCEPTIONS ON SCIENTIFIC INQUIRY: A PRACTICAL EXPERIENCE

Soraya Hamed[1], Juan Jimenez[2]
[1]University of Seville, Seville, Spain
[2]Illinois Institute of Technology, Chicago, Illinois

Abstract: The following study presents the analysis of the conceptions of 40 future teachers when they are presented with a practical case related to the thermal properties of materials. This case is proposed as an experimental activity in which students must develop and reflect on the strategies of scientific research processes. For this, they are induced to explain: 1. The hypothesis from which they start to respond to the predetermined problem, 2. The experimental design to address it, 3. The results and 4. The conclusions obtained. The results indicate the existence of two tendencies, a majority related to common-sense thinking and another more counter-intuitive and scientific to explain natural phenomena.

Keywords: Practical Work in Science, Experiential Learning, Scientific Inquiry; Pre-service Teacher Education

CONTEXT, OBJECTIVE AND THEORETICAL FRAMEWORK

The current reforms in scientific education emphasize the importance of developing an informed understanding of science, its nature and the processes that generate it (that is, scientific research) as fundamental elements for reaching scientific literacy (AAAS, 1993; National Research Council [NRC], 1996; Rocard et al., 2007). Therefore, understanding its nature and the methods that generate it are essential for making appropriate scientific decisions in the social and personal sphere (Lederman, Lederman, & Antink, 2013). These authors suggest the relevance of the Nature of Science (NOS) and Scientific Research also known as Scientific Inquiry (SI) as elements that are related and interact in an important way. Focusing on scientific research, it is known that students and science teachers do not have sophisticated knowledge about science and its practices (Schwartz et al., 2002; Lederman & Lederman, 2004; Lederman, Lederman, & Antink, 2013). One of the reasons is due to the distorted vision that they have about it (Lederman, 2007). The reasons can be diverse e.g., the information provided by the media, the education received, among others. In addition, there are very few studies that systematically evaluate conceptions about this component (Capps, Crawford, & Costas, 2012).

Scientific research is related to scientific processes. In other words, the steps associated with the collection, analysis, and establishment of conclusions in response to one or more problems, but extends beyond the mere fact of developing procedural skills, such as observing, inferring, classify, predict, question, interpret, and analyze data. It also refers to the combination of these processes with scientific knowledge, scientific reasoning and critical thinking to build science (Crawford, 2014). In other words, developing a meta-knowledge about the nature of science and the processes that generate it requires understanding, explicitly and critically, the logic and relationship between the two constructs (Millar, 2004; Schwartz, Lederman, & Crawford, 2004; Lederman, Lederman, Kim, & Ko, 2012).

Our great challenge as researchers and trainers of future Primary Education science teachers is to ensure that learning of a more optimal and functional knowledge about the nature of science and scientific research occurs through non-communicative strategies. We intend, in particular, to facilitate research-based learning, promoting the immersion of students in scientific processes in a cooperative manner. We think that influencing the conceptions of teachers in their initial training is key to achieve it.

The present study was developed in the context of a teacher training course to learn how to teach science, whose educational reference is school teaching research (Porlan et al., 2010, Rivero et al., 2017) and is based on research of fundamental professional problems such as, what is science, what is its nature, how scientific knowledge is built, what science to teach, how to do it, and so on. In this line, we have selected one activity that has been used and described by some authors to study the thermal properties of certain materials (Ariza, Aguirre, Quesada, Abril, & García, 2016a). In our particular case, we intend to examine the conceptions that future science teachers have to develop appropriate training strategies and adjusted to the characteristics of these conceptions. To that end, we have considered curricular reforms and current research as a frame of reference (Rocard et al., 2007; Lederman et al., 2014; Schwartz et al., 2014; Ariza et al., 2016a).

METHODS

The study took place during the academic year 2017-18 in a cohort corresponding to the 2nd year of Primary Education Degree in the subject of Experimental Science Didactics at the University of Seville, Spain. Participants were a group of 40 students whose average age is in their 20s, although the range is between 18 and 37 years old. The majority of students are females (62.5% of the cohort). They were grouped into working groups of three and five participants each in order to be able to address the case. At the moment in which this content topic was developed, students have already completed others related courses based on content knowledge (Fundamentals I and II of Natural Sciences, and Fundamentals of Matter Sciences) and with some courses addressing pedagogical knowledge (General Teaching, Basic Sociological Processes in Education and Educational Psychology), although they have not yet completed Teaching Practices or practicum sessions at schools.

For the study, a qualitative research design was carried out framed in a descriptive and interpretative paradigm (Creswell, 2013) to examine the understanding of future science teachers of the University of Seville. In relation to the data collection and data analysis, the following instrument was used and presented to the students as a case study: After an air accident we made an emergency landing in the Sahara desert and the flight attendants told us that the plane carried some very valuable and important medicines that we have to protect at all costs while we wait for the rescue. For this, we have wool cloths and metal pots. How do you think we can get the medicines to stay as cold as possible? Wrapping them with wool? Putting them in the pots? Using something else? Once the case was exposed, students should try to explain to the rest of the classmates the hypotheses suggested by this case. The information was collected as a personal report of the activity. Next, they had to design the procedures that they consider necessary to verify their hypotheses. Materials were available for the students in order to carry out investigations that allow them to test their hypotheses. Afterward, they have to explain the detail of the results and conclusions obtained before and after the discussion to their classmates. In total, we have 40 personal reports on the experience.

With respect to the analysis of information, we identified and classified units of information relevant to the construction of propositions that summarize, in an organized manner, the aspects investigated; Hypothesis (H), Experimental Design, (D) Results and Conclusions (C). The categorization has been made according to the degree of complexity of the answers. That is, the minimum value of 1 would correspond to a level of formulation of knowledge more naive or less sophisticated and the value 4, the level of greater complexity or reference. In this line we have for the category "Hypothesis" the levels H1, H2, H3, and H4; for the category "Experimental design" (D) we have the levels D1, D2, D3, and D4 and for the category "Results-Conclusions" we have the levels C1, C2, C3, and C4. Levels 2 and 3 correspond to intermediate or transitional values between extreme levels 1 and 4. Finally, the categories have been validated through triangulation processes among several researchers. Two researchers have performed the analysis of the responses separately so that at least 80% agreement is reached. In addition, to manage this task, we have helped with the ATLAS.ti, V.8 program.

RESULTS

After the analysis of data, the results by categories are the followings:

Hypothesis (H)

Regarding this aspect, we detected a group of future teachers (12.5%) who consider metal as the most suitable material for preserving the medications (H1). They justify their choice without arguing it or with naive arguments and based on every day and sensory perceptions. Some examples:

> [If we put the medications] inside the metal pot, the medications will be kept (Student 15, Hypothesis level 1, E15.H1).
>
> [If we put the medications] inside metal, [then] the cold will be preserved because the wool produces heat (E39.H1).

On the other hand, 52.5% of the students believe that the combination of the metal plus wool would allow them to be better preserved the medications (H2). Some of them reveal tautological reasoning to defend their choice. In other cases, they think that both materials behave similarly and together they are enhanced, acting as a kind of barrier to heat; or they believe that the final effect of both materials is similar, although for different reasons: wool insulates from heat and metal retains cold.

> [If we put the medicines] inside the metal saucepan, we wrap it in wool and close it with polystyrene foam, [then] the ice will last longer, so they will be better preserved (E5.H2).
>
> [If we put the medicines] in the metal pot wrapped with wool [then] when protected from the heat they do not melt and are preserved (E27.H2).
>
> [If we put the medicines] in wool and in the shaded saucepan [then] the medicines will remain cold because the wool does not allow heat to pass and the saucepan is a cold container, so it keeps the cold (E7.H2).

Finally, we identify 35% of the students who choose wool as the most suitable material, contributing arguments of science (wool is an insulating material, or wool is insulating, and metal is conductive, recognized the latter only by a student of this group) (H3):

> I think the best way to keep medications cold is to insulate them with wool because it is a very good thermal insulator since we are in the desert (E8.H3).
>
> Wrapped in wool, then the medicine will be better preserved than in the container. If the medicines are wrapped in wool, a non-conductive material, the ice will be better preserved than if it were in direct contact with the metal, conductive surface. (E32.H3)

Experimental design (D)

Regarding the experimental design, we identified a large group of students (57.3%) that carried out a unique experience to obtain tests. Among them, we identify those who carry out an experimental design in an inconsistent or independent way from the starting hypothesis (10 %) and another group of students, majority, who do experience incoherence or dependent on it (47.3 %). We have defined the first case as Design level 1 (D1) and, the second, level 2 (D2). Let's see some examples:

> Hypothesis: they are better preserved medically in the saucepan, which keeps the cold]: Design: We have taken the ice, we have put it in the metal saucepan, we have wrapped it in wool and polystyrene foam so that it does not escape. Burying it in moist soil could benefit the one that does not melt the ice (Student 3. Level 1 design, D1.)
>
> [Hypothesis: they are better preserved with both the dipper and the wool]: Design: To preserve the medications well we have thought about taking the metal saucepan and introducing the ice in the saucepan and closing it. When closing it, we took a wool coil and wrapped the wool dipper (E14.D2.)

On the other hand, we detect another group (37.5 %) that performs two or more experiences, trying to develop some control of variables, but in whole or in part inconsistent or independent of their hypothesis –D3-. Let's see an example:

> [Hypothesis: you have to use wool, which is insulating]: Design: In principle, we have decided to make two proposals: 1. Wrap the ice cube in wool and leave it in the open air. 2. Wrap the ice in wool and, in turn, put it in the aluminum dipper (E4.D3.)

And 5% of students design two or more experiences consistent with their hypotheses for obtaining results (D4):

[Hypothesis: you have to use the wool that is insulating. Design: To test the hypothesis, we make two checks: first, we wrap the ice in wool and, secondly, we put the ice in a metal saucepan (E1.D4.)

[Hypothesis: you have to use the wool that is insulating] Design: We take a piece of ice and put it in the metal dipper. The other piece is wrapped in wool. We also put a piece on the outside and another wrapped in wool and, in turn, inside the saucepan. After a few minutes, we see which piece of ice keeps the temperature the most (E2.D4.)

Results and Conclusions (C)

Regarding this category, 32.5 % of the students express their conclusions in an inconsistent/independent manner of the results they have obtained.

[Hypothesis: the combination of the two materials. Design: ice inside the dipper and the dipper wrapped in wool]. Results and Conclusions: the ice has melted after a while. We accept the hypothesis because it is conserved for a long time, but with difficulty because it melts for a long period. (Student 3, E3. Level 1, C1 conclusions)

[Hypothesis: wool must be used, which is insulating. Design: Ice inside the saucepan and wrapped all in wool]. Results and Conclusions: After 25-30 min we have returned the saucepan and we have observed that the ice remained, although they had melted a little, so we believe that at the time they would end up melting completely. Our theory has worked partially since wool has not been a good insulator (E24.C1)

On the other hand, 47.5% do develop conclusions that are more or less consistent or dependent on the results obtained (C2). However, the conclusions are made based only partially on the initial assumptions or the results obtained:

Hypothesis: You have to use wool, which is insulating. Design: Two experiences: ice wrapped in wool and ice wrapped in wool and introduced in the saucepan]. Results and Conclusions: In the end, we have verified that the wool-wrapped medicines are better preserved than those with wool in the aluminum saucepan. This occurs because wool is a very good insulator (E4.C2).

Finally, 20% of students develop conclusions consistent with the experiences and results obtained (C3). Let's see some examples:

[Hypothesis: You have to use wool, which is insulating. Design: Two experiences: ice wrapped in wool and ice introduced in the saucepan]. Results and Conclusions: The ice wrapped in wool does not melt, however, the ice in the metal saucepan does. We approve that wool is a thermal insulator and metal is not. (E1.C3)

[Hypothesis: You have to use wool, which is insulating. Design: Four experiences: ice wrapped in wool, ice introduced in the saucepan, ice in the air, ice wrapped in wool and introduced in the saucepan]. Results and Conclusions: Those who were wrapped in wool have maintained their temperature more than those who were not. Wool is a good thermal insulator; it helps the body maintain its temperature. Metal, on the other hand, is a conductor of energy, so the temperature varies, increases. (E2.C3)

CONCLUSIONS

It seems, then, that there is a majority group of future teachers who present common sense thought in front of another group that presents a counter-intuitive and scientific thought (Yu & Cole, 2014). Putting them in a position to carry out an investigation allowed to reveal these different levels of thinking and their review by the students themselves, which allowed them to make a solid, although the gradual, approach to the knowledge of reference about the characteristics of scientific research.

We are aware of the complexity of constructing and explaining in a grounded way the nature of this meta-knowledge as suggested by current reforms and paradigms (Millar, 2004; Schwartz, Lederman & Crawford, 2004; Rocard et al., 2007; Lederman, et al., 2012). Teachers will not be able to develop effective and coherent classroom practices with socio-constructivist and research perspectives if they do not have a sophisticated vision and in relation to the epistemological and procedural aspects of scientific research (Schwartz, Lederman and Crawford, 2004; Antink- Meyer, et al., 2016).

The findings suggest that more studies be carried out to analyze the conceptions of science professors when they pursue professional development and teacher research programs, including the understanding of scientific research as a teaching and learning objective and their connection with those strategies that allow improving this knowledge (Capps, Crawford and Constas, 2012).

The purpose of this study has been to examine and improve the conceptions of participating science teachers as a first step to improve teacher training. In a way that allows us to obtain reference data to develop appropriate training strategies and adjusted to the characteristics of said knowledge.

THE INTEGRATION OF EXPERIMENT DURING IMPLEMENTATION OF INQUIRY-BASED TEACHING

Ioanna Stavrou, Constantina Stefanidou, Kyriakos Kyriakou, Violeta Galanopoulou & Constantine Skordoulis

National and Kapodistrian University of Athens

This study investigates whether pre-service primary teachers can integrate experimental activities into inquiry-based teaching scenarios. Our sample consists of 110 pre-service teachers' teaching scenarios for Electromagnetism; they were collected in the context of an Introductory Didactics of Science Laboratory course in which participants experienced inquiry-based teaching and learning. A Thematic Analysis of the data shows that most pre-service teachers can set teaching objectives in their scenarios which are achievable through experiments. Furthermore, participants can integrate appropriate experimental activities into their scenarios – worksheets, in the context of inquiry-based teaching. Moreover, they suggest experiments in the interpretation and discussion phases. The difficulties faced mostly relate to hypothesis generation. In several scenarios, there is no hypothesis expressed, while in other scenarios only a general question, unrelated to either the research question or the teaching objectives, is expressed in the place of a hypothesis.

Keywords: inquiry-based teaching

INTRODUCTION

Science education has the goal of contributing to scientific literacy, a goal directly related not only to the content of the lessons learned in science classrooms, but also to the didactic methods. The implementation of inquiry-based teaching and learning is considered crucial to improve science education at the international level (Abd-el-Khalick et al., 2004; Dorier & Garcia, 2013; Rocard et al., 2007).Inquiry-based teaching and learning is a method which prioritizes students' questions, ideas and analysis. However, there is a lack of agreement on the meaning of inquiry in the field of science education (Barrow, 2006; Minner et al., 2010)). In a broad sense, the term refers to teaching which follows the procedures involved in the scientific inquiry and the investigation of an open question or problem.

The present study follows the theoretical scheme proposed by Pedaste et al. (2015), which identifies and summarizes the core features of inquiry-based learning by means of a systematic literature and includes the following phases: *orientation, conceptualization, investigation, conclusion and discussion*. Some of these phases are divided into sub-phases; the *conceptualization* phase is divided into two sub-phases: *questioning and hypothesis generation*; the *investigation* phase is divided into three sub-phases: *exploration* and *experimentation* leading to *data interpretation*.

An extensive analysis of the conditions and constraints which might favor or hinder the implementation of inquiry-based learning has been conducted (Dorier & Garcia, 2013). The literature revealed that in most countries, pre-service primary school teachers must be offered sufficient support if they are to overcome their general disinclination towards science and deepen their knowledge so they are in a position to use inquiry-based teaching flexibly in class (Davis et al., 2006; Kim& Tan, 2011; Tseng et al., 2013). A key factor for the successful implementation of inquiry-based learning approaches in science classrooms is the teachers' education (Crawford, 2007; Yoon & Young, 2011; Capps et al. 2013; Tseng, et al., 2013).The literature also supports the assertion that it is not science teacher education alone that makes an inquiry-oriented teacher (Trna, et al., 2012). One of the critical factors influencing a pre-service teacher's intentions and abilities to teach science as inquiry, is their complex set of personal beliefs about teaching and about science (Crawford, 2007: Battacharyya et al., 2009; Kim & Tan 2011; Lebak, 2015). Moreover, pre-service teachers have a lack of knowledge on science process skills and for that reason they often fail when attempting to build a learning sequence based on inquiry (Kim & Tan, 2011; Chabalengula et al., 2012; Binns & Popp, 2013; Capps & Crawford, 2013; Montero-Pau et al., 2017). Thus, a pre-service teacher predisposed to inquiry-oriented teaching will benefit most from science teacher education: learning orientations, past experiences in schools, and experience in teaching and doing science appear to support the critical aspects of an inquiry-oriented science teacher education program (Eick & Reed, 2002; Davis et al., 2006; Kim & Tan, 2011; Binns & Popp, 2013; Garcia – Carmona et al., 2016; Montero – Pau et al., 2017). In this line, in the context of science teacher education programs, there is a need to design inquiry-based activities that will reactivate pre-service teachers' interest in these disciplines.

This is the issue under consideration in this study, which aims to investigate the extent to which pre-service primary teachers are able to design structured, inquiry-based lessons and materials, and specifically, the extent to which they integrate experimentation activities into structured, inquiry-based scenarios, in the context of their science education program. The present study is part of a broader research investigating pre-service teachers' ability to implement inquiry-based teaching in relation to the content knowledge (electromagnetism, mechanics, etc).

RESEARCH METHODOLOGY

Fieldwork was carried out in Athens, at the Department of Primary Education of the National and Kapodistrian University of Athens during the spring semester of 2017-2018.

The Sample

The sample consisted of 110 pre-service teachers' teaching scenarios of Electromagnetism, developed in the context of an Introductory Didactics of Science Laboratory Course (IDSLC). Participants were selected due to convenient access. Learners were divided into five classes of 22 persons whose members worked in pairs. The IDSLC comprised of four independent two-hour laboratory exercises once a week: 1) teaching NoS, 2) electromagnetism, 3) photosynthesis and 4) heat. Pre-service teachers had inquiry-based learning experiences during the four laboratory exercises. In particular, the aim of the second laboratory exercise was pre-service teachers to experimentally determine the relationship between electricity and magnetism and conceptualize the working principles of electric motors and electromagnets. As part of their final assessment, participants were asked to develop four inquiry-based teaching scenarios, including a lesson plan and the related work sheets, that corresponded to the content knowledge of the four laboratory exercises.

Data Analysis

Our data, the teaching scenarios, were analyzed by means of Thematic Analysis, a process which identifies the important issues in the context of qualitative data analysis. It differs from Content Analysis (Vaismoradi, Turunen & Bondas, 2013) in that the results are presented qualitatively with no reference to quantitative data (Guest, 2012 p.11; Maguire & Delahunt, 2017). Thematic Analysis was chosen as it allows for more flexible data analysis and can thus identify relations among the qualitative data elements that derive from the multiple level analysis, irrespective of the sample volume (Nowell, Moules, & Norris, 2017).

Considering that the main aim of this study is to investigate the integration of experimentation in various phases of the inquiry-based Electromagnetism teaching scenarios, the determining and categorizing was performed in the sense of the cross-sectional reference of the main Theme, which is the experimental activities, in the various phases of the inquiry-based teaching scenario.

Therefore, the Themes are formulated as follows:

1st Theme: Experimental activities – Research question / Teaching objectives; this refers to whether the teaching objectives could be achieved through the proposed experimental activities.

2nd Theme: Experimental activities –Hypothesis; this refers to whether a formulated hypothesis could be experimentally tested.

3rd Theme: Experimental activities – Teaching objectives; this refers to whether, and to what extent, the proposed experimental activities play a role in the achievement of the teaching objectives, either implicitly or explicitly. Such analysis enables further investigation of the relationship between the proposed experimental activities and the implicit or explicit objectives.

4th Theme: Experimental activities –Interpretation of results; this refers to whether, and to what extent, experimental activities were suggested during the result interpretation and discussion phases.

Considering the important role experimentation plays in inquiry-based learning approaches within science education, further research into how the experiments are presented in the worksheets – scenarios designed by pre-service teachers has been conducted. Importance was given to whether actual experimental activities were suggested, or experimental activities were limited to images, software or video. Finally, an attempt was made to interrelate the results from certain Themes.

RESULTS

1st Theme :Experimental activities related to Research question / Teaching objectives: most pre-service teachers could set at least one teaching objective related to proposed experimental activities. One of the most popular topics that pre-service teachers set as teaching objective in their scenarios, was the construction and explanation of the generator, while the construction and explanation of electromotor was less popular.

2nd Theme: Experimental activities related to Hypothesis: in most teaching scenarios, no hypothesis was formulated before experimentation. For example, a pre-service teacher (PST 58) in his scenario asked students to make the experiment in order to determine what happens when a compass approaches a wire with electric current, without asking them to make an initial hypothesis on the phenomenon under consideration. There were a considerable number of scenarios in which the formulated hypothesis was strongly related to the research question and the experimental activities that followed. In a very few scenarios, instead of a hypothesis, a question was set which related to neither the research question nor the teaching objectives and was supposed to aid orientation. For example, a pre-service teacher (PST 45) included in his scenario the question "why we use the compound word electromagnetism instead of the two separate words electricity and magnetism". This is a question that may help motivate students to think about the topic under discussion, but it is not a hypothesis.
3rd Theme: Experimental activities related to Teaching objectives: most of the teaching scenarios included experimental activities in the context of inquiry implementation. Such activities were proposed by pre-service teachers with a view to their contributing to structured inquiry and the achievement of the objectives. For example, most pre-service teachers proposed the experimental set up of an electromotor in order to teach how electrical energy is converted to mechanical energy.
4th Theme: Experimental activities related to Interpretation of results: some pre-service teachers included in their scenarios experimental activities into the results interpretation phase, mainly suggesting videotaped experiments. Most of these scenarios were related either to the electric motor or to the electromagnet.

CONCLUSIONS

Teaching science by inquiry in primary education has been one of the biggest challenges in science education for many years. One of the main obstacles is the education of pre-service teachers. This study sets out to investigate the extent to which pre-service primary teachers are able to design structured inquiry-based teaching scenarios and, specifically, the extent to which they integrate experimentation activities into the context of their science education program. The initial findings show that the majority of the pre-service teachers could both set teaching objectives achievable through experimental activities and propose well-targeted experimental activities in order to guide "their students" through the scenario to achieve their learning objectives. Some pre-service teachers proposed the use of videotaped experiments in the result interpretation phase, too.
Regarding their difficulties, the analysis of the scenarios revealed that the majority of pre-service teachers faced difficulties during the hypothesis formulation phase (Kim &. Tan, 2011). Some of them did not include a hypothesis phase in their scenario posing a general question. It seems that pre-service teachers do not value the hypothesis formulation phase as important in the context of inquiry-based teaching and learning procedure. While they give emphasis on experimental activities, they do not find hypothesis as conceptual preparation of the experimental procedure. They find experiment important "per se", an idea that is not in line with the nature of scientific investigation. In addition, in some teaching scenarios difficulties arose with the implementation of experimental activities which were incompletely presented. Some pre-service teachers had difficulties in determining the variables, so they failed to

articulate the experimental process clearly in the students' sheets. Such difficulties show pre-service teachers' limited level of knowledge on science process skills (Lee & Shea, 2016; Montero-Pau et al., 2017).

Finally, in the overwhelming majority of the pre-service teachers' scenarios most the inquiry-based teaching phases were included whereas in some of them the phases were incomplete and in some others the phases were not clearly distinguished.

Further research in the field could shed light to pre-service teachers' ability to implement inquiry-based teaching in relation to the content knowledge: Does the specific subject, eg electromagnetism, heat, photosynthesis, etc affect pre-service students' ability in implementing inquiry-based teaching? Are there topics that pre-service teachers prefer implementing inquiry-based teaching to others and what are their specific characteristics?

Although most pre-service students managed to keep almost all the phases of the inquiry, this does not guarantee that the teaching scenario is inquiry-based. The reason for that is that the authentic development of scientific research is more complicated than implementing the steps. Overall, our results provide evidence that pre-service primary teachers need more training in science process skills.

PRESCHOOL TEACHER STUDENTS VIEWS'S INFLUENCE ON THEIR INTENTION TO USE TAUHGT INQUIRY METHODS

Anastasios Zoupidis[1], *Vasileios Tselfes*[2] *and Petros Kariotoglou*[1]
[1]University of Western Macedonia, Florina, Greece
[2] National and Kapodistrian University of Athens, Greece

In this research we investigated preschool teacher students' views that could possibly influence their intention to use inquiry methods, which they have been taught during a one-semester laboratory-type course, concerning concepts of science and their teaching methods. During this inquiry-based course, the teacher students (N=17) participated in several experiments concerning phenomena that are usually negotiated in the frame of preschool education, e.g., floating – sinking, magnets, air properties, etc. Moreover, the teacher students were explicitly taught the reasoning of the Control of Variables Strategy (CVS), as one of the course's goals was to provide understanding of aspects of the inquiry method. According to Ajzen & Fishbein's theory, our hypothesis was that teacher students' intention to use this taught method (CVS) in their classes as preschool teachers, depends also on teacher students' views about specific categories of social factors: (a) personal gains and losses, (b) important people that would approve or disapprove, and (c) personal features that would help or impede them. A six-task questionnaire was used to investigate teacher students' intention to use CVS method in their classes, at their first teaching year, focusing on the three aforementioned categories of social factors. Data were analyzed initially through a bottom-up approach, taking into account the answers of the teacher students, and afterwards using a K-means Cluster Analysis. The results have revealed three independent teaching professional profiles.

Keywords: teacher preparation, social interaction, inquiry-based teaching

INTRODUCTION

Current guidelines for effective instruction in science education suggest teaching both with and about the procedure scientists follow in their experimentation and scientific practices such as the Control of Variables Strategy (CVS), a method for designing and implementing fair experiments in order to test a variable's influence on a phenomenon (Chen & Klahr, 1999). Moreover, students of all ages confront difficulties with scientific reasoning pertained to CVS, such as hesitancy to make inferences from data, failure to realize that the value of a variable must be changed to test its impact and failure to recognize the need of controlling the rest of the variables (Boudreaux, Shaffer, Heron & McDermott, 2008; NRC, 2012).

There is evidence that explicit teaching of experimentation reasoning of the CVS method is necessary for a holistic understanding of the method (Lorch et al., 2010; Zoupidis, Strangas & Kariotoglou, 2017). Educating teachers such a way focuses on the expectation that they could spontaneously include such teaching approaches, when they will get started on their own teaching implementations. However, this expectation seems to be degraded when it is about teaching science content, because of preschool teachers' broader hesitant stance with regards to science and its instruction (Andersson, Gullberg, Danielsson, Scantlebury, & Hussénius, 2019).

One of the most influential and popular conceptual frameworks for the study of human action is the theory of planned behavior (Ajzen & Fishbein, 2001; Ajzen, 2002). According to the planned behavior theory, human behavior is guided by three kinds of considerations: (a) beliefs about the likely consequences or other attributes of the behavior (personal gains or losses), (b) beliefs about the normative expectations of other people (important people that would approve or disapprove), and (c) beliefs about the presence of factors that may further or hinder performance of the behavior (personal features that would help or impede them from doing so). The first consideration, attitude beliefs, produces a favorable or unfavorable attitude towards the behavior. The second consideration, normative beliefs, result in perceived social pressure and the third consideration, control beliefs, give rise to the perceived ease or difficulty of performing the behavior (Ajzen, 2002). In combination, all three considerations lead to the formation of a behavioral intention, which is expected to be carried out when the opportunity arises.

RATIONALE

Following the trends described in introduction, preschool education teacher students in the focal University usually follow a science laboratory lesson, during which the teacher students have the opportunity to design and implement several experiments concerning phenomena that are usually negotiated in the frame of preschool education, e.g., floating – sinking, magnets, air properties, etc. In parallel, the teacher students are explicitly taught aspects of the experimentation reasoning, such as the CVS method. The results of this approach concerning the understanding of the method have been proved to be positive (Zoupidis, Strangas & Kariotoglou, 2017).

Following though Ajzen & Fishbein's (2001) (A-F) framework, we hypothesized that the intention of the preschool teacher students to use the taught CVS method when they design and implement teaching scenarios for science education issues is influenced by social factors such as personal gains and losses (attitude beliefs), important people that would approve or disapprove (normative beliefs), and personal features that would help or impede them (control beliefs), from using the CVS method. In short, we think that the question, if and how preschool teacher students would use CVS method in their classes, is still an open question and that an answer to this question, even in a primary level, would be convenient in the sense that it could influence our teaching practices (Andersson & Gullberg, 2014).

METHOD

This research has been realized during a university, laboratory-type and inquiry-based course in the frame of the preschool science education. The participants were seventeen second grade teacher students. During the course, the teacher students participated in several inquiry-based experiments concerning phenomena that are usually negotiated in the frame of preschool education, e.g., floating – sinking, magnets, air properties, etc., investigating, among other issues, the variables that could influence those phenomena. Moreover, the teacher students were explicitly taught the reasoning of the Control of Variables Strategy (CVS), as one of the course's goals was to provide understanding of aspects of the inquiry method. For instance, the teacher students had the opportunity to deal with both unconfounded and confounded experiments and to justify their choices during the activities (Figures 1 and 2).

- We sink an object into the water. A colleague claims that « the shape influences floating or sinking of an object, that is cylinder-spape objects sink and sphere-shape objects float». The following four experiments were realized.

	Experiment 1		*Experiment 2*		*Experiment 3*		*Experiment 4*	
Variable	Test1	Test2	Test1	Test2	Test1	Test2	Test1	Test2
Weight	10 g	10 g	10 g	10 g	10 g	100 g	10 g	10 g
Material	foam	iron	foam	foam	foam	iron	foam	iron
Shape	sphere	sphere	sphere	rod	sphere	rod	sphere	rod

Which of the above experiments you think is or are fair to test this claim?
Please justify your answer:

....

....

Why did you exclude the rest of the experiments?

....

....

....

Figure 1. The teacher students are prompted to characterise experiments (fair or unfair) and justify their choices.

« You have in front of you two magnets (bar magnet and horseshoe magnet).
Weigh them on the electronic balance.
The large magnet weighs ....
The small magnet weighs ....
Approach them now to the heap of the clips. Which one attracts more clips? »

Please, propose a change in order the experiment to become fair.

....

....

....

Execute the experiment.

Figure 2. The teacher students are prompted to find the error in the experiment and propose a change in order that the experiment becomes fair.

A six-task questionnaire was used to investigate teacher students' intention to use CVS method in their classes, at their first teaching year, focusing on the three aforementioned categories of social factors. Specifically, attitude beliefs were investigated asking the teacher students about what their personal gains and losses would be if they used the CVS method in their classes, the first year that they would teach. Respectively, teacher students' normative beliefs were investigated asking them the reasons that specific for them important third people would approve or disapprove their teaching choices. Last but not least, teacher students' control beliefs were investigated, asking them to provide their personal features that could help or impede them from successfully implementing such a teaching approach.

Data analysis followed a bottom-up approach (Strauss & Corbin, 1994) taking into account teacher students' answers, so that categories of teacher students' beliefs would be revealed. Afterwards, data were analyzed using K-means Cluster Analysis, scale 1,0 (1: the category is present, 0: the category is absent), which was implemented to partition the teacher students into clusters that present behavioral intention similarity.

RESULTS

The categories of teacher students' beliefs that were revealed from the bottom-up analysis of their answers to the six-task questionnaire are presented in Table 1.

Table 1. The categories of teacher students' beliefs in the three relatively differentiated clusters.

	Cluster1 (17 teacher students)
1. Personal gains	a. Understanding of science, b. Enhance teaching skills, c. Pleasant / efficient classroom climate, d. Satisfaction for helping children
2. Personal losses	a. Time to make them understand, b. Loosing self-confidence lead to frustration or/and discouragement
3. Important thirds approve due to	a. Children's improvement (Parents), b. Understanding of method's importance (Colleagues), c. Emphasis on my strengths and abilities (Relatives), d. My professional development (Relatives)
4. Important thirds disapprove due to	a. Dangerous and excessive method for this age range, b. Not understand method's importance (Colleagues)
5. Personal features that help	a. Patience and perseverance, b. Being methodical, c. Critical thinking / research glance
6. Personal features that impede	a. Classroom management skills, b. Self-management skills

Cluster Analysis was implemented to the data that revealed from the qualitative analysis of the teacher students' answers. The teacher students were partitioned into three relatively differentiated clusters (Table 2). So, according A-F analysis framework, three teaching professional profiles, each corresponding to one of the three clusters, have been revealed.

Table 2. The categories of teacher students' beliefs in the three relatively differentiated clusters.

	Cluster1 (6 teacher students)	Cluster2 (5 teacher students)	Cluster3 (6 teacher students)
1. Personal gains	1a, 1b*	1b, 1c	1a, 1d
2. Personal losses	-	2a	2b
3. Important thirds approve	3a, 3b	3a, 3b	3c, 3d
4. Important thirds disapprove	-	4a	4b
5. Personal features that help	5a	5a, 5b, 5c	5a
6. Personal features that impede	6a	6b	6b

*categories from Table 1

Specifically, six out of seventeen teacher students (cluster1) advocate that the use of the CVS method helps both the teacher and the children to understand science. It also enhances teachers' teaching skills. The method offers recognition from important thirds due to children's improvement and teacher's knowledge and succeeds only through patience and perseverance until the children understand. On the other hand, it has a risk in terms of classroom management.

Five out of seventeen teacher students (cluster2) advocate that CVS method can provide pleasant and efficient classroom climate and also enhances teachers' teaching skills. The method offers recognition from important thirds due to children's improvement and teacher's knowledge. It succeeds through patience and perseverance, being methodic, but also through critical thinking and research glance on the part of the teacher. On the other hand, it takes time to make the children understand, has a risk in terms of self-management issues and could be accused from important thirds that do not know the method for involving the children in dangerous and excessive activities.

Finally, six out of seventeen teacher students (cluster3) advocate that the use of the CVS method helps both the teacher and the children to understand science and provides satisfaction for helping children. The method offers recognition from important thirds due to teacher's abilities and professional development. It succeeds only through patience and perseverance until the children understand. On the other hand, issues of losing self-confidence could appear or important thirds that do not know the method could disapprove the teacher.

DISCUSSION AND IMPLICATIONS

The aim of this research was to investigate teacher students' intention to use CVS method in their classes, at their first teaching year. So, there is a need to connect teacher students' beliefs about social factors (attitude, normative and control beliefs) to their beliefs concerning the use of the CVS method, which they have been taught during the laboratory course. To realize this connection, we use the following analysis framework: (a) their beliefs about their personal gains and losses reveal the direction that teacher students appreciate that the method can get them, (b) the content of important thirds attitude towards the use of the method reveals the positive results or the possible resistance that will show up as a consequence of the use of the method, and (c) from their beliefs about personal features that could further or hinder the use of the method we can recognize the aspects of the method that teacher students appreciate as crucial to its success.

The results have revealed three independent teaching professional profiles. Teacher students that belong in the first profile approach the innovative method as it could simply be implemented in a traditional teaching environment like any other method, without challenging the class. Teacher students belonging in the second profile appreciate the method, recognize and very possibly would strive to provoke traditional teaching environment implementing the method. Finally, teacher students that belong in the third profile perceive the method within a framework that they have the total responsibility of its successful implementation. Each teacher students profile provides important information that could lead to useful teaching implications.

Specifically, the teaching implications that arise from the above analysis are that apart from understanding the CVS method, teacher students should also be helped: a) to distinguish this method from other traditional ones, emphasizing its procedural character, b) to take the risk of sacrificing teaching time in order to succeed introducing such an innovative method, and c) to consent that passing to their students responsibilities to implement the innovation would be pleasant and fruitful for the teaching and learning procedure.

PRE-SERVICE SCIENCE TEACHERS' PERCEPTIONS OF HOW THEY LEARN TO FACILITATE INQUIRY-BASED PRACTICAL WORK

Maria Tsakeni[1]
[1]University of the Free State, QwaQwa, South Africa

This paper reports on the results of a needs analysis stage of a larger design-based research project on how pre-service teachers learn to facilitate inquiry-based practical work (IBPW) in science classrooms. Using a case study of one university in South Africa, a questionnaire with close-ended question items was completed by 31 final year pre-service science teachers in the postgraduate certificate in education (PGCE) and bachelor of education (BEd) intermediate phase programmes. The concept of opportunities to learn (OTL) was used to guide the experiences measured by the questionnaire. Descriptive statistics, the Mann-Whitney U test and Pearson correlation coefficient were used to analyse the quantitative data. The findings indicated that the pre-service teachers from both programmes brought similar experiences of OTL from school. The PGCE pre-service teachers perceived that the OTL on how to facilitate IBPW were significantly enhanced during tertiary education experiences. However, the intermediate phase pre-service teachers did not perceive that the tertiary education experiences significantly enhanced the OTL how to facilitate IBPW. The study indicates nine positively correlated experiences that present OTL how to facilitate IBPW. A recommendation to increase and diversify OTL how to facilitate IBPW experiences is made.

Keywords: inquiry-based science, pre-service teacher training, practical work in science

INTRODUCTION AND BACKGROUND

There have been widespread adoptions of inquiry-based science teaching by most national science curricula. Crawford (1999) defines inquiry as a process of looking for answers to questions posed using methods similar to the ones used by scientists. Some of the national science curricula that have adopted inquiry-based science include the National Science Education Standards in the US (National Research Council, 1996) and the Curriculum and Assessment Policy Statement (CAPS) for natural sciences and technology as well as CAPS for physical sciences in South Africa (Department of Basic Education, 2011a, 2011b; Ramnarain, 2014). The reform drive is an attempt to address and reverse effects of traditional teaching practices such as rote learning of science (Gaigher, Lederman & Lederman, 2014). Based on the widespread adoptions of inquiry-based science teaching in most national curricula, Tatar (2012) makes an extrapolation that one of the aims of science teacher education is to prepare pre-service teachers for the teaching of science through inquiry. Inquiry-based science teaching is commonly implemented through practical work (Leon, 2015). Millar (2004) points out that practical work facilitated through more open-ended and investigative type approaches develops the learners' tacit knowledge about scientific inquiry.

Research reports on the implementation of inquiry through practical work reflect a practice fraught with challenges (Barrow, 2006; Lunetta, Hofstein & Clough, 2010). Crawford (1999) contends that facilitating inquiry for learners may be challenging even to the most expert of teachers. Sporea and Sporea (2013) and Kidman (2015) contend that not all teachers have been trained in the use of inquiry-based science teaching. Facilitating inquiry through practical work is a specialised teacher task that calls for proper training (Hofstein, 2004). The training may be provided to teachers during initial teacher training programmes. Accordingly, there is a growing body of research that advocates for the inclusion of inquiry-based science teaching modules in the programmes for pre-service teachers (Nivalainen, Asikainen, & Hirvonen, 2013; van den Herrick, Luis & van den Berg, 2013; Kidman, 2015; Koller, Olufsen, Stojanovska, & Petrusevski, 2015; Finlayson, Maciejowska, Ctrnactova, 2015; Lee & Shea, 2016).

Teachers have been observed to possess differing understandings of inquiry-based science teaching (Barrow, 2006; Leon, 2015). Leon (2015) concluded that teachers associate inquiry-based science teaching with only some of its characteristics. Similarly, some pre-service teachers' understanding of inquiry-based science has been found to be erroneous and incomplete. In a study conducted by Saribas and Ceyhan (2015), pre-service teachers understood the scientific method as a step-by-step process meant to verify facts oblivious to the notion that it can also be an iterative and inquiry-based process. Finlayson *et al.* (2015) and Kidman (2015) recommend that pre-service teachers should experience inquiry themselves as students and get an opportunity to try out the approach with learners.

Crawford (1999) posits that it is realistic to expect pre-service teachers to begin to design and implement inquiry-based instruction. Accordingly, pre-service science teachers should be prepared so that they can facilitate inquiry through practical work. Meaningful inquiry starts by being inquisitive about the natural world around us and developing questions that culminate in authentic investigations (Chin & Brown, 2002). This study was conducted against a backdrop of a 'recurriculation' process at one university in South Africa. It was the first stage of a larger design-based research project, which according to Reeves (2000) entails the analysis of practical problems by researchers and practitioners (needs analysis). Accordingly, the purpose of the study was to investigate the pre-service science teachers' experiences of how they learn to facilitate inquiry-based practical work through. Hence, the main research question of the study is, *what are the pre-service science teachers' perceptions of they learn to facilitate inquiry-based practical work?*

LITERATURE REVIEW

It will be unfair to expect teachers who have not experienced inquiry-based instruction through practical work to be able to implement it during their practice only because science curricula expect them to do so. McBride, Bhatti, Hannan and Feinburg (2004) propose that the best way to teach inquiry strategies is by engaging the pre-service teachers in inquiry science activities. Inquiry in science is driven by significant questions that should be answered through methods used by scientists such as experimentation (Crawford, 1999). Facilitating the development of questioning skills in students initiates them to engage in learning through inquiry (Chin *et al.,* 2002). Through inquiry, students can be involved in investigations and do the following, (1) confirm expectations or challenge currently accepted scientific concepts, (2) resolve unexpected puzzles and develop more insights on the currently accepted scientific concepts and (3) provide differing explanations for particular scientific phenomena and fill knowledge gaps (Chin *et al.,* 2002; McBride *et al.,* 2004).

Akuma and Callaghan (2019, p. 65) describe inquiry-based practical work as a type of practical work whereby students

> …collaboratively manipulate a combination of hands-on and/or computer-based science education equipment and materials, or existing data sets, to better understand the natural world as they engage in scientific practices through structured, directed, or open inquiry.

Although, the primary duty of science teachers is not to be professional scientists, they should be able to facilitate and implement inquiry-based practical work. The study by Chabalengula, Mumba and Mbewe (2012) on 91 elementary pre-service science teachers revealed that the participants had a limited conceptual understanding of science process skills, which according to Anderson (2002), form an important part of scientific inquiry. The science process skills include measuring, observing, inferring, classifying, controlling variables, formulating hypothesis, experimenting, interpreting data and communicating (Chabalengula *et al.,* 2012). The limited conceptual understanding of the science process may hinder efforts by teachers to facilitate inquiry-based practical work for learners.

The National Science Foundation (2003) posits that experiences such as open inquiry experiments enhance the quality of undergraduate science education. Students engage actively in the pursuit of knowledge by engaging in scientific inquiry projects that involve experimentation (Crawford, 1999). Besides developing practical skills associated with laboratory work, students develop skills in conducting scientific literature searches; read, interpret and extract information relevant to the project; operate instruments and operate laboratory techniques that are not usually available in the laboratories; interact professionally with other students and professors and communicate results orally and in writing (*ibid*). Widely engaging students in open inquiry experiments at undergraduate level is a way of providing equitable access to research opportunities for all students (National Science Foundation, 2003). Students from multicultural backgrounds in terms of race, gender, class and so forth will have access to the scientific inquiry activities. This is significant for South Africa in its protracted efforts to tackle issues of accessibility and equity by correcting imbalances created by a pre-independence education system defined by race (Selod & Zenou, 2003).

In the wake of critical skills shortages in the country, recruiting students by kindling their interest towards areas that experience the shortages is crucial. Science teachers can play a significant role in recruiting students to study fields in the scarce skills category. Harlen (2010) points out that one of the goals of science education is to develop in students, scientific capabilities and attitudes such as those espoused in scientific inquiry. The National Science Foundation (2003) points out that sustaining and diversifying the technical workforce requires significant creativity and investment in educational infrastructure. Furthermore, the focus should expand from merely developing a technical workforce but also students who are able to pursue research in the science fields (*ibid*). Accordingly, there is a need to train science teachers who are able to advance and support that vision.

Conceptual framework

The study used the opportunities to learn (OTL) concept to investigate the pre-service science teachers' experiences of IBPW. The concept of OTL is based on the notion that what students learn is related to the time they spend learning it (Cogan & Schmidt, 2015). Accordingly, the close-ended questionnaire was developed to measure the IBPW experiences in school science, tertiary science and methods courses. These experiences were regarded as opportunities to learn. Chin *et al.* (2002) posit that inquiry activities are question-driven. Therefore, the generation of questions by students is critical for the IBPW instruction model. Students may have autonomy over part or the whole inquiry process from problem conception, posing questions, hypothesising, designing experiments, gathering and analysing data, drawing conclusions and communication of results (Kipnis & Hofstein, 2008). McBride *et al.* (2004) posit that students should be taught inquiry in the context of real life. For science classroom contexts, Llewelyn (2013) suggests a process by which teachers and pre-service teachers can facilitate the generation of questions for inquiry. The pre-service teachers can facilitate question generation by doing the following, (i) introducing the topic, (ii) assessing prior knowledge, (iii) providing exploration, (iv) raising and recording questions, and, (v) sorting and revising questions.

METHOD

Using a case study of one university, quantitative data were collected by means of a questionnaire with close-ended items from 31 pre-service science teachers. The study was a needs analysis part of a larger design-based study to develop a conceptual framework to prepare pre-service science teachers who can successfully implement IBPW in the classroom. The needs analysis aimed to investigate the pre-service science teachers' experiences of IBPW by establishing opportunities to learn it. The convenient sample of participants consisted of 13 out of 18 PGCE pre-service science teachers at campus A of the university and all 10 PGCE pre-service teachers at campus B. The PGCE pre-service teachers specialised in secondary school life and physical sciences (Grades 10-12). Eight out of the 12 Bachelor of Education (BEd) intermediate phase (Grades 4-6) natural sciences pre-service teachers also participated in this study. The intermediate phase teachers were from campus A since campus B was not offering the programme at the time of the study. The questionnaire had 33 close-ended items that were reduced to nine categories of OTL which were (1) practical work experiences in school-PWS (2) inquiry experiences in school-IES, (3) practical work experiences during teacher training-PWT, (4) inquiry experiences during teacher training-IET, (5) open inquiry experiences at tertiary-OIE, (6) interest in practical work-IPW, (7) use of laboratory work as an instructional strategy-ULS, (8) use of laboratory work as an instructional strategy-ULS and (9) ensuring laboratory safety-ELS. A 6-point Likert scale was used to give a measure of the perception on each of the question items. The 6 points were as follows: 0 "never been true", 1 "not true", 2 "somewhat true", 3 "moderately true", 4 "true" and 5 "very true". A reliability test was run using the Cronbach's alpha coefficient for the 33 question items. A Cronbach's alpha score of 0.907 was obtained.

Data analysis

In order to answer the main research question the four objectives were formulated for the study. The study aimed to,

(i) calculate the means and standard deviations for each of the nine categories,

(ii) compare the distribution of the categories between PGCE pre-service teachers of campus A and campus B using the Mann-Whitney U test,

(iii) compare the distribution of categories between the PGCE pre-service teachers and the intermediate phase pre-service teachers using Mann-Whitney U test for independent samples, and

(iv) determine the correlation among the categories using the Pearson correlation coefficients.

Accordingly, means, standard deviations, the Mann- Whitney U tests and the Pearson correlation coefficient were used to analyse the data.

RESULTS

The table below shows the means (M) and the standard deviations (SD) for each of the categories for campus A and Campus B PGCE groups. The means and standard deviations of the categories for both campuses together were also calculated.

Table 1. Summary of category means for the PGCE groups

Campus		FI	OIE	PWS	IES	PWT	IET	ULS	ELS	IPW
A	Mean	**3.9**	**4.1**	**2.9**	3.2	3.4	3.2	**4.3**	**4.9**	**4.3**
	SD	**0.9**	**1.2**	**2.1**	1.7	1.5	1.3	1.2	**0.3**	1.1
B	Mean	**3.9**	**4.3**	3.5	3.4	4.1	4.1	**4.5**	**5.0**	**4.6**
	SD	**1.0**	**0.7**	1.7	1.4	1.4	0.8	**0.5**	**0.0**	0.6
A & B	Mean	**3.9**	**4.2**	**3.2**	**3.3**	3.7	3.6	**4.4**	**4.95**	**4.4**
	SD	**0.9**	**1.0**	**1.9**	**1.6**	1.5	1.2	**0.9**	**0.2**	**0.9**

Key: FI- facilitating inquiry; **OIE**- open inquiry experiences at tertiary; **PWS**- practical work experiences in school; **IES**- inquiry experiences in school; **PWT**- practical work experiences at tertiary; **IET**- inquiry experiences at tertiary; **ULS**- use of laboratory work as an instructional strategy; **ELS**- ensuring laboratory safety; **IPW**- interest in practical work

According to the results in Table 1 the PGCE pre-service teachers perceived that five of the category experiences presented them with opportunities to learn IBPW the most by responding with "true" and "very true" on the Likert scale. The categories were (i) facilitating inquiry- FI with M= 3.9, (ii) the open inquiry experiences at tertiary- OIE with M= 4.2, (iii) use of laboratory strategies- ULS with M= 4.4, (iv) interest in practical work with M= 4.4 and (v) ensuring laboratory safety with M= 4.95. The standard deviations for the five categories range from SD= 0.2 to SD= 1.0 implying that most of the responses were fairly close to the mean. Although the perceptions of the PGCE pre-service teachers were above the average mean (M= 2.5) in all the nine categories, they considered the school experiences to present them with lowest levels of learning opportunities. These experiences were (i) practical work at school- PWS and (ii) inquiry experiences at school- IES. The opportunities to learn at tertiary level had the highest scores.

In order to establish whether or not the distribution of the categories across campus A and campus B was the same or not, a Mann-Whitney U was run to compare the means for each category and the results are displayed in Table 2 below.

Table 2. Distribution of categories Mann-Whitney U test across the PGCE groups

	FI	PWS	OIE	IES	PWT	IET	ULS	ELS	IPW
Mann-Whitney U	63.0	63.0	60.5	63.0	44.0	41.0	58.0	60.0	55.5
Z	-0.1	-0.1	-0.3	-0.1	-1.3	-1.5	-0.5	-0.9	-0.6
Asymp. Sig. (2-tailed)	**0.9**	**0.9**	**0.8**	**0.9**	**0.2**	**0.1**	**0.6**	**0.4**	**0.5**
a. Grouping Variable: Campus									

The test assumes that the distribution is the same in both groups if the level of significance is more than 0.05. The levels of significance range from P= 0.1 to P= 0.9 for all nine categories and are greater than 0.05. Therefore it was assumed that the distribution of the nine categories was not different for the two campuses. This information was important to establish because the needs analysis results would be applied to both campuses.

In Table 3 the intermediate phase pre-service teachers considered two of the tertiary experiences to have presented them with the most learning opportunities for IBPW. These categories were (i) ensuring laboratory safety with M= 4.1 and (ii) interest in practical work with M= 3.9. However, the standard deviations ranged from SD= 1.2 to SD= 1.8 suggesting that some of the responses fell a bit further from the mean.

Table 3. Summary of category means and standard deviation for the PGCE groups

Campus		FI	OIE	PWS	IES	PWT	IET	ULS	ELS	IPW
A	Mean	**2.1**	3.1	2.7	2.8	**2.3**	2.8	3.4	**4.1**	**3.9**
	SD	**1.6**	1.4	1.9	1.7	**1.7**	1.3	1.6	**1.8**	**1.2**

Key: FI- facilitating inquiry; **OIE**- open inquiry experiences at tertiary; **PWS**- practical work experiences in school; **IES**- inquiry experiences in school; **PWT**- practical work experiences at tertiary; **IET**- inquiry experiences at tertiary; **ULS**- use of laboratory work as an instructional strategy; **ELS**- ensuring laboratory safety; **IPW**- interest in practical work

The intermediate phase pre-service teachers considered the two categories, facilitating inquiry-FI with M= 2.1 and practical work experiences at tertiary- PWT with M= 2.3 to have presented them with the least learning opportunities. These categories were scored as "somewhat true" on the Likert scale and were below the average M= 2.5. The SD values ranged from 1.2 to 1.9 which suggested that some of the responses fell a bit further from the mean.

In order to determine whether the distribution of the nine categories was the same in the PGCE pre-service teachers and the intermediate phase a Mann- Whitney U test for independent samples was run and the results are in Table 4. The test worked with a null hypothesis, H_0, that assumes that the distribution of categories were the same across the programmes.

Table 4. Hypothesis test summary (Independent-samples Mann-Whitney U test)

	H_0	Sig.	Decision
1	The distribution of **ULS** is the same across categories of programme	.132	Retain H_0
2	The distribution of **FI** is the same across categories of programme	**.006**	Reject H_0
3	The distribution of **PWS** is the same across categories of programme	.464	Retain H_0
4	The distribution of **IES** is the same across categories of programme	.437	Retain H_0
5	The distribution of **PWT** is the same across categories of programme	.067	Retain H_0
6	The distribution of **IET** is the same across categories of programme	.110	Retain H_0
7	The distribution of **OIE** is the same across categories of programme	**.043**	Reject H_0
8	The distribution of **ELS** is the same across categories of programme	.386	Retain H_0
9	The distribution of **IPW** is the same across categories of programme	.386	Retain H_0

The results showed that the distribution of the two categories, (i) facilitating inquiry- FI and (ii) open inquiry experiences at tertiary- OIE was not the same across the two programmes with levels of significance P= 0.006 and P= 0.043 respectively. These categories presented fewer OTL for the intermediate phase pre-service teachers than the PGCE pre-service teachers.

The Pearson' correlation coefficients calculated at the level of significance P= 0.05 showed a positive correlation among the nine categories in Table 5. The positive correlation seems to suggest that the increase in experiences of OTL defined by each of the categories positively impacted the other experiences of OTL in IBPW.

Table 5. Inter-item correlation among the nine categories

	PWS	IES	PWT	IET	OIE	ULS	FI	ELS	IPW
PWS	1.0	**0.8**	0.5	0.5	0.5	0.4	0.3	0.3	0.6
IES	**0.8**	1.0	0.6	0.6	0.6	0.6	0.5	**0.2**	0.7
PWT	0.5	0.6	1.0	0.6	0.7	0.7	0.6	0.4	0.6
IET	0.5	0.6	0.6	1.0	0.5	0.6	0.5	0.3	0.6
OIE	0.5	0.6	0.7	0.5	1.0	**0.9**	0.6	0.3	**0.8**
ULS	0.4	0.6	0.7	0.6	**0.9**	1.0	0.7	0.4	**0.8**
FI	0.3	0.5	0.6	0.5	0.6	0.7	1.0	0.5	0.5
ELS	0.3	**0.2**	0.4	0.3	0.3	0.4	0.5	1.0	0.4
IPW	0.6	0.7	0.6	0.6	**0.8**	**0.8**	0.5	0.4	1.0

However, it can be noted that the correlation between the categories inquiry experiences at school-IES and ensuring laboratory safety-ELS was the weakest. The strongest correlations were between practical work at school-PWS and inquiry experiences at school-IES; open inquiry experiences at tertiary-OIE and use of laboratory strategy-ULS; interest in practical work- IPW and open inquiry experiences at tertiary- OIE; and finally, interest in practical work- IPW and use of laboratory strategy- ULS.

DISCUSSION AND CONCLUSION

The study set out to investigate pre-service science teachers' perceptions of how they learn to facilitate IBPW. The study was part of a needs analysis stage of a larger design-based study on how a teacher training programme can prepare pre-service science teachers to facilitate IBPW. The results showed that pre-service teachers experience OTL of how to facilitate IBPW during their years in school and at tertiary. These OTL include practical work activities and inquiry experiences at school. They also experience OTL at tertiary when they further engage in practical work and open inquiry activities. McBride *et al*. (2004) affirm that engaging pre-service teachers in inquiry activities helps them to learn how to teach using inquiry strategies.The pre-service teachers perceived that they also experienced OTL when they facilitated inquiry for learners, used laboratory strategies, ensured laboratory safety and had an interest in practical work activities. What is important to note is that the pre-service teachers in this study did not come to the teacher training programme as blank slates in terms of experiences that might translate to knowledge about IBPW. The PGCE pre-service teachers perceived the tertiary experiences of facilitating inquiry to learners, open inquiry, use of laboratory strategies and ensuring laboratory safety and interest in practical work to have presented them with more OTL than experiences accumulated in school. Koller *et al.* (2015) point out the marked differences between practical work facilities in tertiary institutions and those found in schools. The marked differences may also extend to OTL. However, the intermediate phase pre-service teachers did not perceive the OTL experienced at tertiary as significantly more than those experienced at school. The intermediate phase teachers considered facilitating inquiry to learners as the experience that presented them with least OTL. This result may suggest that they were not exposed to the OTL of facilitating inquiry significantly. Cogan and Schmidt (2015) explain that OTL are experienced when time is spent learning something. The limited OTL may be the reason why Leon (2015) and Saribas and Ceyhan (2015) indicate that some pre-service teachers demonstrate incomplete conceptions and misconceptions about inquiry-based practical work

The Pearson correlation coefficient showed that the OTL experiences for IBPW were positively correlated suggesting that experiences accumulated previously impacted on future experiences. Hence, a recommendation is made in this study to increase and diversify the pre-service science teachers' OTL how to facilitate IBPW.

The results of the study have implications for the larger design-based project by taking note of the following, (i) the PGCE pre-service teachers in campus A and B experienced similar OTL for IBPW, (ii) the intermediate phase teachers experienced less OTL through facilitating inquiry for learners and practical work at tertiary, and, (iii) the intermediate phase pre-service teachers experienced less OTL at tertiary even though their school experiences were similar to those experienced by PGCE pre-service teachers. A follow-up qualitative study will be conducted to explore how the pre-service teachers experience OTL for IBPW in the teacher-training programme as a way of validating their perceptions in this study.

ACKNOWLEDGEMENT

This study is part of project funded by the NRF Thuthuka of South Africa.

MODELLING IN STEM: THE TALE OF TWO COUNTRIES IN CENTRAL ASIA

Kathy L. Malone[1], Ozkan Yilmaz[2], Janet Helmer[1], Arman Assanbayev[1] and Gulnara Namyssova[1]
[1]Nazarbayev University, Nur-Sultan, Kazakhstan
[2]Erzincan University, Erzincan, Turkey

International testing in STEM, such as PISA, has demonstrated that students across the world have difficulty with scientific reasoning but especially in Kazakhstan and Turkey. One suggestion to improve students' reasoning skills is to teach using more authentic science methods. The authentic science practice of science modelling has shown promise towards improving student gains in conception and reasoning skills. In order to accomplish this, secondary teachers need to be prepared to teach using these authentic science practices such as science modelling. A decade ago published studies demonstrated the existence of teacher confusion about models and modeling and led to reform suggestions for pre and in-service science educators. But, do we know if science educators are doing a better job? Kazakhstan has been undergoing massive curriculum changes, which includes a nationwide teacher professional development plan. Turkey has been working towards STEM education improvements for a number of years. Are these initiatives having an effect on teacher perceptions? This study's goal is to explore Kazakhstani and Turkish in-service teachers' perceptions about the authentic science practice of scientific modelling. An interview protocol was used with 22 STEM secondary teachers. Open coding was used to analyze the interviews. When teacher perceptions were compared across countries the preliminary findings show that in these two countries major confusion exists,. Coding revealed that the most common model representation used in both countries was that of physical models. The use of demonstrations, the teaching of a process and step by step inquiry labs were considered forms of modeling. However, Turkish teachers' codes were more focused than that of the Kazakhstani teachers possibly due to a longer period of professional development opportunities. This work in progress has led to tentative science education suggestions for Central Asia.

Keywords: Models in Science, Teaching Practices, Teacher Professional Development

SCIENCE MODELLING IN STEM

The Programme for International Student Assessment (PISA) studies suggest that there is a need for students in Kazakhstan, Turkey and other countries to not only acquire but practice higher order thinking skills in classrooms (Mullis, Martin, Goh, & Cotter, 2016; OECD, 2016). In Kazakhstan, students score well on TIMMS but very low on PISA. This is ascribed "to the unfinished agenda of raising student learning achievement beyond basic literacy and numeracy" (World Bank, 2012). Turkish students have been performing below the OECD average and these scores have been consistent since 2006 (OECD, 2015).

Science Models and Modelling In Practice

The use of science modelling encourages students to design experiments, interpret the data, use the data to construct science models with multiple representations (e.g., pictorial, graphical, verbal, computer, and mathematical), make predictions and draw conclusions about scientific phenomena. These multiple representations that make up a science model allow students to see how each representation leads to similar predictions and can make the model more meaningful to them. See Figure 1 for a diagram of a science model and its multiple representations. Thus, using it in science classrooms should help to improve this situation. Past studies have shown that the implementation of modelling practices has produced improved student conceptual gains, usage of multiple representations, scientific reasoning skills and model-based reasoning (e.g., Liang, Fulmer, Majerich, Clevenstine, Howanski, 2012; Malone, Schuchardt, Sabree, 2019; Miller & Kastens, 2017).

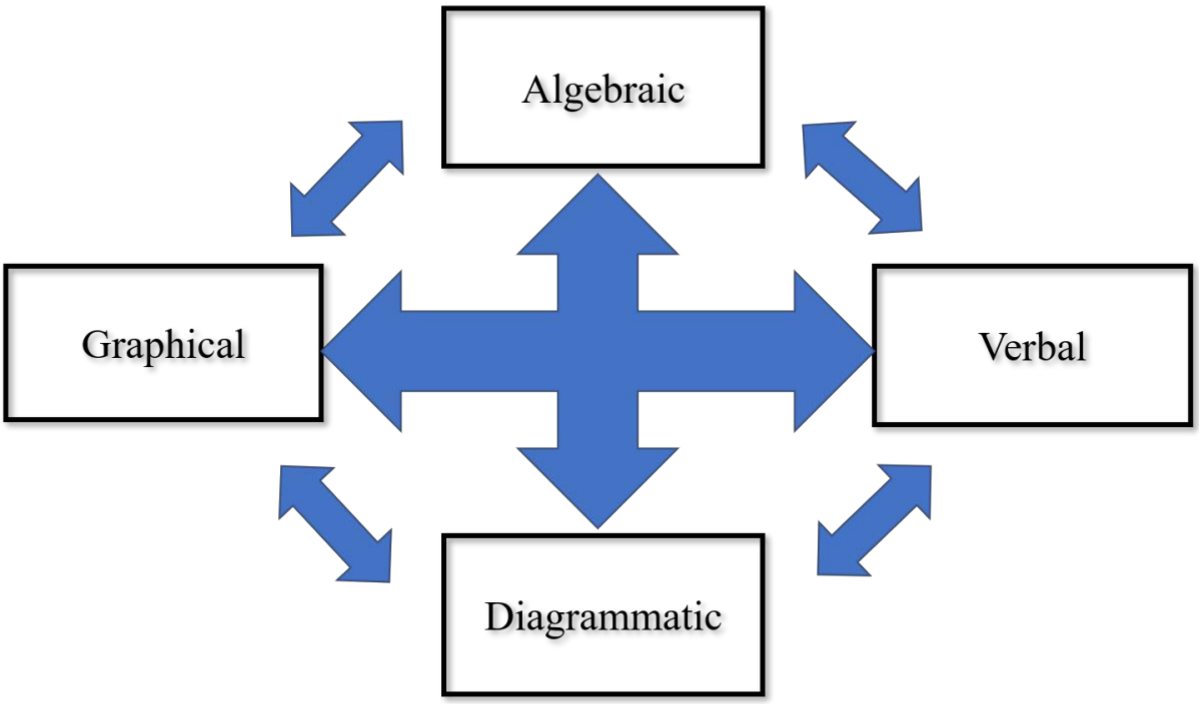

Figure 1. Science Models with connected representations. Adapted from Stammen, Malone & Irving, 2018.

Scientific Modelling is a cycle that is practiced by professional scientists (Gilbert & Justi, 2016; Hestenes, 2010). The cycle is used when developing models as well as using models to study new scientific phenomena. The cycle allows for students or scientists to develop experiments that will allow them to determine the nature of a physical phenomenon that is being studied. The empirical data collected can be used to develop a science model consisting of multiple representations as seen in Figure 1. The cycle continues by having the students then use the model to see how well it corresponds or makes predictive the physical phenomenon originally being studied. The development of this scientific model is a part of scientific modelling. Scientific modelling also consists of then using the developed science models to predict and study other scientific phenomenon of interest. When data is obtained that is different from the model predictions than the student or scientist must either refine their model to account for these differences or start the process again in order to develop a new model. This modelling cycle is portrayed in Figure 2.

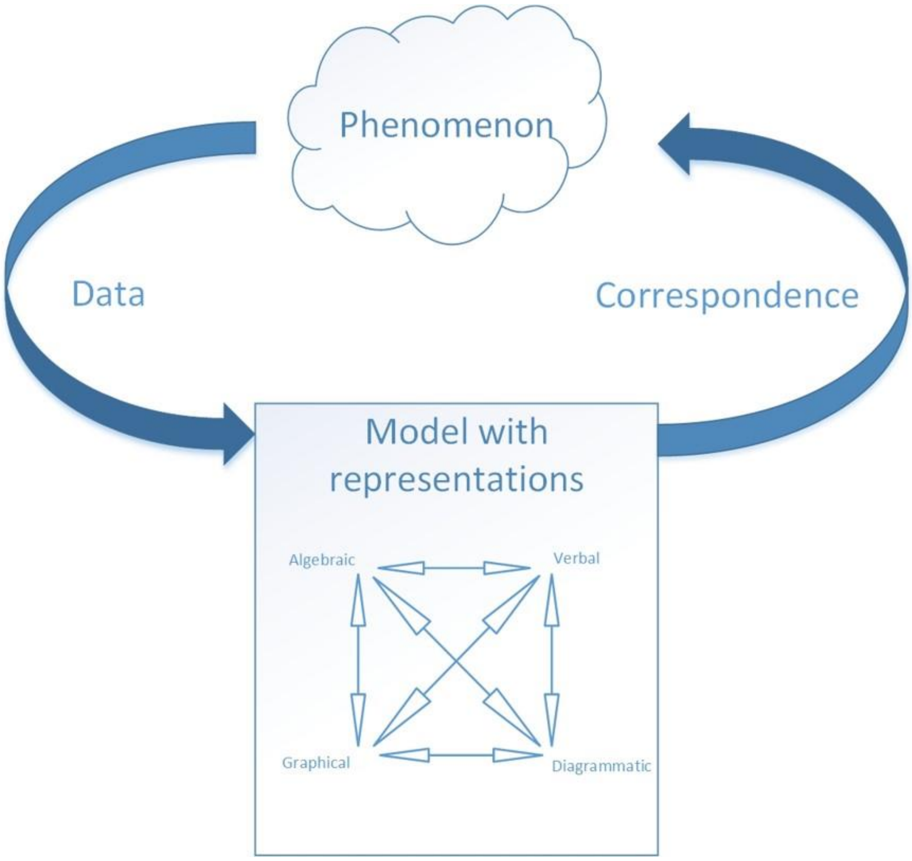

Figure 2. The Scientific Modelling Cycle. Adapted from Malone, Schuchardt & Sabree, 2019)

Teacher Perceptions about Models and Modelling

In the early 2000's research on in-service teachers' perceptions about models and modelling demonstrated that in multiple countries knowledge of and about the use of this type of authentic practice was extremely lacking (e.g., Henze, Van Drield & Verloop, 2007; Justi, & Gilbert, 2003). Thus, the recommendation was that pre-service science education courses and professional development (PD) worldwide should educate teachers on this in order to impact usage of the practice in classrooms. In order to encourage the use of science modelling, educational policies need to be more focused on incorporating science models and scientific modeling into pre-service university education as part of the instruction during every lesson. More specifically, pre-service teachers at the universities should be required to use science models and scientific modeling during their pre-service education. Through modelling such approaches at the pre-service level it was thought that the role of models and scientific modeling in classroom activities would be enhanced. Thus, these trained pre-service teachers would in turn serve as the vehicle to deliver solutions to understanding and exploring the phenomenon. Thus, if the original recommendations in the early 2000's had been implemented we should observe teachers worldwide who not only understand the nature of science models and science modelling but actively utilize it in their own classrooms as part of their daily practice.

However, the international testing results bring into question whether this situation has improved any over the years? Recent work in United States (US) and Germany with biology teachers has revealed that teachers responses are still similar to those found a decade prior (Krell & Kruger, 2016; Ware, Malone, Irving & Mollohan, 2017). However, models and modelling may be seen to be too difficult to put into practice in biology classrooms but easier and more practical to use in other subjects which consist of more visual elements for students such as in physics. Thus, interviewing teachers from multiple STEM disciplines might allow for a different picture to emerge.

Educational Reform and Authentic Practices in Kazakhstan and Turkey

In Kazakhstan curriculum reform efforts include professional development for teachers across the country to improve their abilities to teach using 21st century reasoning skills along with an increased focus on STEM education nationwide (Bridges, 2014; OECD, 2014). Turkey has been introducing a reformed curriculum since 2005 which supports modelling in science (Şentürk & Aydogmus, 2017). To examine the results of these efforts on teacher competencies in scientific modelling this exploratory study was conducted with the following guiding question:

What kind of teacher competencies in scientific modelling exist in Turkey and Kazakhstan?

Only by discovering the STEM competencies in these countries can changes be made to pre-service STEM teacher education and in-service professional development.

METHODS

Research Design

A qualitative semi-structured interview approach was selected in order to obtain an in depth understanding of teachers' perceptions of models and modelling. The participants, in-service schoolteachers who teach science disciplines, were selected for the study in two countries. The 22 teachers participating in the study were asked to discuss their understanding of models and modelling, how these terms compare and to give specific examples of their use in their classrooms.

Participants

In terms of gender of participants and the level of education there was a difference between the two countries. The participants from Turkey were mostly female with a 69% to 31% female to male ratio. The participants from Kazakhstan were the reverse with a 60% to 40% male to female ratio. The level of education or graduate education level of in-service teachers showed that 31 % of the teachers from Turkey had a graduate education in comparison to only 20% of the Kazakhstani teachers. Thus, participants from Turkey and Kazakhstan have significant differences in educational level with a greater number of teachers from Turkey having graduate degrees in education while their Kazakhstani counterparts possessed mostly undergraduate degrees. However, while the participants from each country were not closely matched according to educational level, they were evenly matched according to years of teaching experience with the teachers from both countries having taught on average for 9 years. Thus, the majority of the teachers graduated from a pre-service teacher education within the past 10 years. This means that the majority of the participants were relatively new to teaching and were pre-service teachers well after the studies completed by Justi and Gilbert (2003).

Data Analysis

The interviews were conducted in Russian, Kazakh and Turkish. The interviews were transcribed and translated into English for coding purposes. Two interviews were initially coded by two researchers and a code book emerged. The convergencies in two researchers' answers have been taken as the core themes and those themes were used to group and interpret the data from the rest of the interviews. Thus, nine major converging themes were jointly created to code for the use and understanding of scientific models. Eight major themes emerged for the coding of scientific modelling. All of the codes were included in a codebook. The codebook included the name of theme or code as well as a few exemplars for each code. The finalized codebook was then used to code the rest of the interviews.

After all the interviews were coded an interrater check was conducted using 10% of the transcripts or two randomly selected interview transcripts. The Cohen's Kappa score for these transcripts was determined to be 0.83. This indicator or convergence in interpretation of field data among two researchers is considered as significant since the correlation can vary between 0 and 1. The range of scores from 0.81 to 1.00 is considered to have "almost perfect agreement" (McHugh, 2012, p. 279). Thus, the coded transcripts is considered excellent for comparative analysis.

RESULTS

Figure 3 outlines the 9 sub-codes that describe what teachers in this study considered a scientific model. The scientific models codes that emerged based on teacher comments focused mostly on specific model representations. For example, teachers would discuss the physical representations of a particular model such as the crystal lattice model as a 'physical model'. They did not seem to clearly recognize that scientific models consist of multiple representations such as physical, pictorial and mathematical (refer to Figure 1). The idea of a physical model was most commonly referred to by interview participants regardless of nationality (i.e., 87% vs 60%, Turkey and Kazakhstan, respectively).

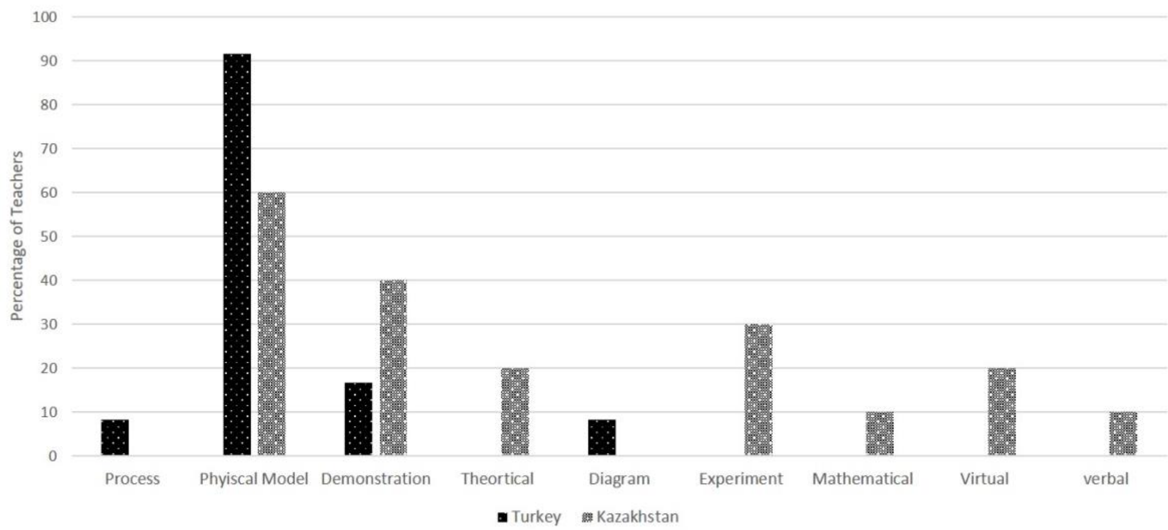

Figure 3. Scientific Model Coding Themes by country

When the transcripts were reviewed in terms of scientific modelling, seven separate codes were discovered (see Figure 4). An eighth code called, scientific modelling, was a predetermined code based upon how scientific modelling is defined in the research community. None of the teacher participants, no matter nationality, had a concise, well-defined understanding of modelling thus that code was not utilized (refer to Figure 4). Many of the codes and their descriptions overlap between the concept of science models and modelling. Thus, the majority of the teachers did not distinguish the difference between models and modelling thus interpreting the terms as synonymous. It seemed that teachers were not making the observation that a model is a noun and modelling is a verb but "seeing" these two science terms as identical in usage and definition. None of the teachers from either nationality spoke about modeling in terms of a cycle as shown in Figure 2.

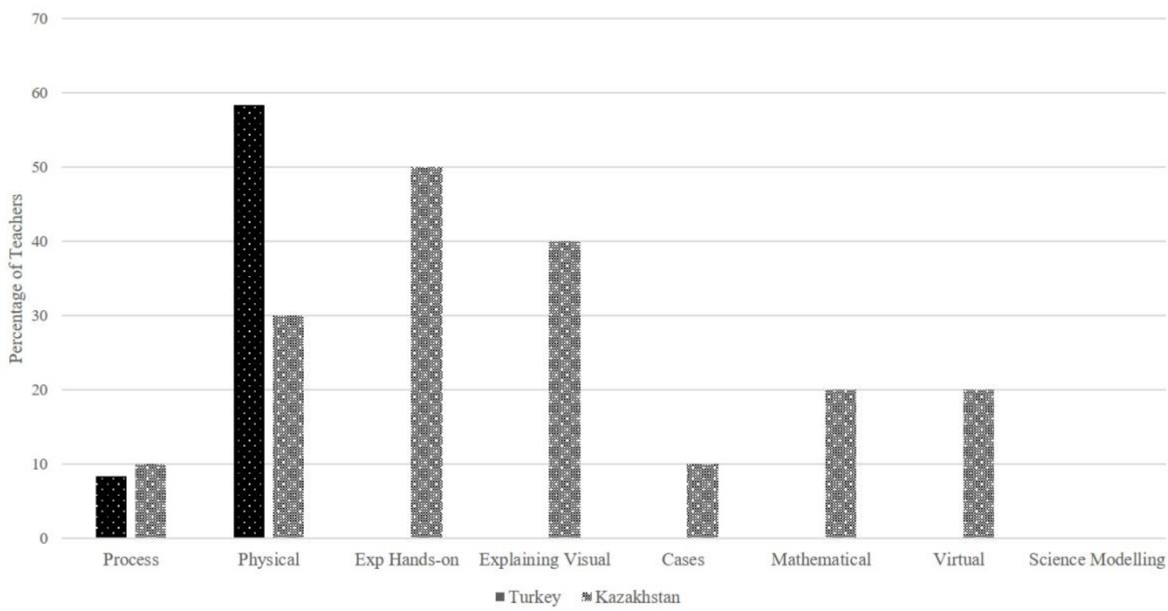

Figure 4. Scientific Modelling Coding Themes by country

Another finding worth mentioning is that both Turkish and Kazakhstani teachers did not seem to have chances to upgrade their skills in teaching their disciplines during their teaching careers via targeted professional development. This can be seen in the transcripts when teachers are asked about their attendance at workshops that focused on scientific modelling. None of the teachers in either country had participated in workshops focused on science models and modelling.

DISCUSSION AND CONCLUSIONS

The results of this exploratory study demonstrate that the in-service science teachers in this study do not have a clear understanding of the authentic practice of using science models and scientific modelling in science classrooms. There is no conception that the multiple representations in a model are linked thus supporting and enriching student understanding. The data suggest that while many teachers may use one or more multiple representations in their classes, they seem to consider them as separate entities. In addition, it is unclear whether teachers use them in a predictive sense during modelling activities. In other words, this study seems to point out that the in-service teachers of Kazakhstan and Turkey do not use scientific modeling in its true sense.

According to this study, another difference in understanding of science models could be connected with the gender. By way of illustration, the Turkish in-service STEM teachers, predominantly females conceptualized both science models and modeling as a physical entity and a process. While their Kazakhstani counterparts, who were predominantly male also did not seem to have a conceptual understanding of the differences between science models and modelling but intellectualized them in a different fashion. The Kazakhstani teachers also thought of models as physical entities but did not consider it a process. The male Kazakhstani teachers considered a science model to be either a demonstration or an experiment. As this study posits, males have different attitudes towards the new phenomenon than females and they seem to conceptualize modelling as more hands-on and experimental in nature. In addition, only the Kazakhstani teachers identified modelling as being connected to mathematical representations. This means it is possible that Kazakh teachers may use more experiments that require predictions or the gathering of some initial data. However, further evaluation and data needs to be explored in the future to determine if there really is a difference in its use in the classroom. The inability to apply modeling for predictions can lead to insufficient application of science models in the classroom with in-service teachers underestimating the importance of various representations or science models during modelling activities. This means that teachers could be neglecting to use a range of possible science models with their students in both of these two selected countries. Thus, the idea that a scientific model consists of multiple representations does not seem to be an understanding shared by in-service teachers, whether they are located in Turkey or Kazakhstan.

These misconceptions of scientific models and scientific modelling that are shared by teachers seems to point to a failure ultimately in both countries in terms of science education at the university level. Changes in science education methods courses as well as general science courses at the university level in both countries are not supporting teachers in reaching an understanding of the authentic practice of scientific modelling. Curricular updates need to be made at the university level that allow pre-service science to embed using science models and modelling in both general science and science methods courses.

Another suggestion to improve students' reasoning skills is to further promote the application of modeling by in-service teachers in both Turkey and Kazakhstan. In-service teachers need to have additional support via targeted PD to shift their practice towards the use of scientific modelling in their classes, so it becomes a natural part of their teaching practice. The models should be diverse including not only physical or demonstration ones but also those consisting of multiple representations. Moreover, there could be solutions such as the requirement for the in-service teachers of the selected countries to allocate a special time slot for the use of scientific modeling during lessons as an integral part of the study and instruction. In other words, the policies should require incorporating science models and scientific modeling as an integral part of each lesson in the preparation of in-service teachers at the university levels. Such initiatives could be articulated in the policy documents both at the country and institutional levels then they could underpin the whole learning process of students. Raising the awareness about science models and scientific modeling through PD to teachers complemented with the policy initiatives could be a solution to improving students' reasoning skills in the selected countries.

THE ROLE OF REPRESENTATIONS IN CHEMISTRY TEACHING: AN EXPERIENCE WITH PRE-SERVICE TEACHERS

Ana Luiza de Quadros[1], Daniela Martins Buccini Pena[2] and Maria Luiza S. T. Botelho[2]

[1]Department of Chemistry, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.

[2]School of Education, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.

Meaning making in Science classes has been related to multimodal representations and multimodality. The communication of many science phenomena demands a complex combination of verbal language with images, formulas, symbols, gestures etc. In this sense, the orchestration of multiple representations and different forms of communication is an important aspect of the teacher's performance and of the meaning making process. The main purpose of this paper is to analyze the understanding of teachers in training relative to the role of representation in Science/Chemistry teaching. A limited understanding was perceived, which evolves with the use of an approach based on the multimodal representations.

Keywords: pre-service teacher, representation, multimodal representation.

INTRODUCTION

According to studies conducted by Halliday (1978; 1985) on Systemic Functional Grammar (SFG), language is a system of meanings, with which an individual interactively codes and decodes expressions, developing communicative competence.

Kress and van Leeuwen (1996) expanded Halliday's studies (1978; 1985) by incorporating imaging and developed 'The Grammar of Visual Design.' Other modes of communication were incorporated into research involving language, creating the concept of multimodality. So, efficient communication involves going beyond the interpretation of language and its meanings, requiring other modes of representation and communication (Jewitt, 2006; 2008; 2009; Kress, 2009; 2010; Norris, 2004) and leading to the development of a 'Multimodality' field (Adami, 2016).

Since communication is multimodal by nature, it is necessary to specify what semiotic modes are and which of them are used to communicate something. According to Kress (2010) and Jewitt (2008), mode is defined as a communication channel that a culture recognizes. A ball-and-stick model, for example, is an important mode of communication for chemists. However, for an individual with little knowledge of chemistry, it may be just a toy or something unimportant. This ball-and-stick model only acts as a semiotic mode in a context where it is culturally recognized.

Kress (2010) states semiotic modes often used in the classroom refer to words, images, colors, shapes, typographic features, proxemics, gestures, prosody, sounds, music, speech, among others that depend on the context. Norris (2004) classifies these modes as audio (speech, music, sound, sound effects, etc.), visual (look, impression, image, etc.), action (gestures, posture, movement, facial expression, contact, handling of objects/models, screen projection, etc.), and environmental modes (proxemics, layout, etc.).

However, these modes must be brought together, organized, and planned to be useful for those who want to produce meanings according to what they are communicating, a process reported by Kress (2010) as 'multimodal orchestration'. Based on that, using different modes is not enough, they should be correlated to produce meanings and for learning.

Multimodality is associated with communication and representations. Considering science teaching/learning or, more specifically, chemistry, communication and modes of representation are critical, as it involves an understanding of chemical 'entities' that cannot be seen, for instance, atoms, electrons, ions, molecules and other submicroscopic entities that constitute the group of entities used to explain the formation of matter, its properties and transformation process.

One of the approaches for science teaching in the classroom is based on multimodality and the wide use of representations, called 'multimodal representations,' which will be discussed below.

Multimodal representations

Representations have been widely used for thinking about and communicating concepts and explanations in the field of natural sciences. This study is focused on how these representations are used, and not on the representations themselves.

Lemke (1998, p. 87) suggests that "to do science, to talk science, to read and write science, it is necessary to juggle and combine in canonical ways verbal discourse, mathematical expression, graphical-visual representations, and motor operations in the natural world." Lemke (1998, p. 89) adds that scientists "combine, interconnect, and integrate verbal text with mathematical expressions, quantitative graphs, information tables, abstract diagrams, maps, drawings, photographs, and a host of unique specialized visual genres seen nowhere else". Latour (1986) argues that this reasoning practice using visualization and inscription, involving material and symbolic instruments, was crucial for understanding scientific origins and some special characteristics. According to him, it attracted the interest of science educators in the role of representations in science teaching and learning.

Kozma (2003, p. 205), when analyzing the work of chemistry experts, noted that, regarding their research, they made different representations based on the characteristics of the material, and when negotiating/sharing understandings, they manipulated these representations, correlating them. Then, Kozma (2003) argued that students could develop this ability to build representations and communicate them in a suitable way to the teacher, constructing and correlating different representations. When investigating the use of representations with students, Kozma and Russell (2005, p. 129-130) argued that students learn science effectively when they participate in activities "in which representations are used in the formulation and evaluation of conjectures, examples, applications, hypotheses, evidence, conclusions, and arguments."

Tytler (2003) argues that students have to deal with two aspects present in scientific discourse: representations and multimodality. The perception of science built from multimodal and representational reasoning associated with active involvement of students in class and respect for the individual learning needs and preferences of students becomes the basis of the approach based on multimodal representations. Therefore, this approach is focused on the negotiation process for understanding representations. Quadros and Giordan (2019) analyzed the class of a teacher who used the representation proposed by the students to begin the studies of chemistry present in a given phenomenon.

Prain and Tytler (2013) argue that representational competence plays a crucial role in learning science and that developing this competence implies student involvement in the interpretation and construction of relations of an object, its representation and meaning. For these authors, representation becomes a sign for the student when it means something (an idea or explanation) in relation to the object of study. For students to understand or explain concepts in science, they must use their cognitive and representational resources and then learn new concepts while learning how to represent them. With the approach of multimodal representations, learning scientific concepts involves switching between representational modes (verbal, written, visual and mathematical), coordinating them to generate consistent explanations.

For Prain, Tytler, Hubber and Waldrip (2013), quality learning involves building and coordinating representations to solve problems and develop explanations. Therefore, learning is a more active process. Knowledge is built through representational practices involving generation/proposition, refining/negotiation, justification and judgment of explanations, processes and methods in science. Throughout this process, students will be challenged to represent and argue around representations in an attempt to place the student's representations closer to canonical representations.

Therefore, multimodal representations involve the integration of methods to communicate ideas related to science through different representations. As an approach in science classes, students are involved in proposition, justification/negotiation, reformulation of representations.

METHODOLOGY

The classes analyzed in this study took place in an optional course offered to students from the Chemistry teacher training course (didactic-pedagogical classes) at the Universidade Federal de Minas Gerais, Brazil, in the second semester of 2018. Twelve students from the fifth to the eighth semester of the training course participated in this optional course.

From an experiment involving the presence of air in a syringe, the students (teachers in training) were asked to represent the air particles at three different moments: with syringe plunger in the normal position, with syringe pushed in, and syringe pushed out, keeping the air outlet closed in these last two cases (Figure 1). The air particles were under normal pressure in the first moment, higher pressure in the second, and lower pressure in the third.

A B C

Figure 1 - Experiment with a syringe at three different moments. A) plunger in normal position; B) plunger pushed in, and C) plunger pushed out.

Once the students produced the three representations (five pairs and two individual students), the course teacher invited them to draw such representations on the board. After the seven groups of representations were drawn on the board, they discussed about these representations for 28 minutes and 30 seconds. The class was fully videotaped and, for this study, the discussion about representations built by the students was analyzed to identify possible contributions of this discussion for the understanding of the role of representation in science classes.

The episode was transcribed to facilitate the analysis. This analysis considered the multiple representations and multimodality involved in the construction of meanings, and the analysis categories were defined according to resulting data.

RESULTS AND DISCUSSION

With the experiment involving the presence of air in a syringe, the students were invited to represent the air particles at three moments (Figure 1). After the students produced the three representations, the teacher asked them to draw these representations on the board. Figure 2 shows a picture of the board with the representations drawn by the students.

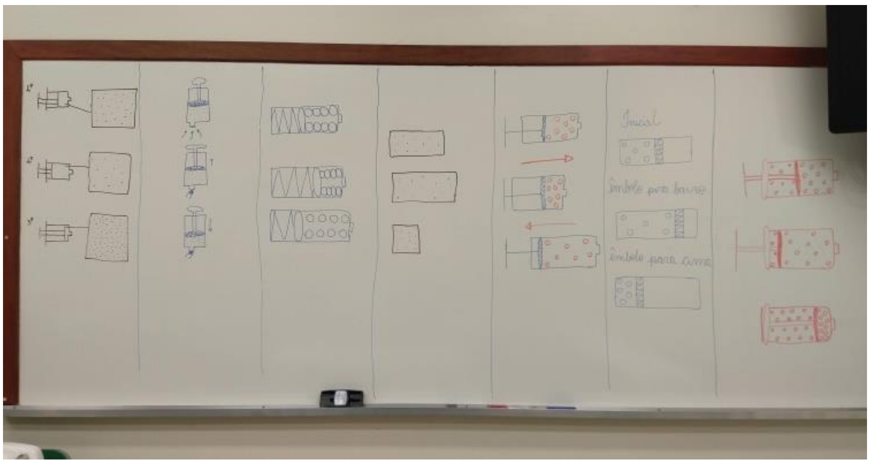

Figure 2 – Picture of the board with the representations drawn by the students.

The representations had similar features among them, but also many different aspects. The first group to the left showed a zoomed-in section of the syringe while the fourth group had a box without many details; all other groups represented the internal part of the syringe. Air particles were represented as both dots and balls. Some used arrows to indicate the force exerted on the syringe and one had notes with the drawing. After the students explained their representations, the teacher made questions that were essential to help understand them in their aspects of particle size, amount of particles drawn and distance between them, as explained below.

Particle size

In four of the seven groups, the particles were drawn as a small ball, with an empty space inside each one. The teacher questioned these shapes and several justifications were produced, most of them reporting easy visualization. With the teacher's persistence, student Patricia said: '... it's just a representation, it's not the particle itself!' The teacher insisted on the use of the ball and asked the students to put themselves in the place of a student who does not know chemistry and is still learning, and reminded them that alternative conceptions can also be constructed in school, as they had already studied.

Then the discussion involved possible alternative conceptions that could be built if they represented the particles as small balls, or empty spaces inside them. The students agreed that dots would be the best way to represent air particles to avoid alternative conceptions.

For Prain and Waldrip (2010), the act of representing is an important skill for an individual to become scientifically literate, and not just a peripheral resource. When Patricia said it was just a representation and not the particle itself, she seems to use the representation as a peripheral resource. For the authors of this study, the act of representing is a method to organize our own ideas and, therefore, it helps learning as it builds meanings. Tang, Delgado and Moge (2014) also consider representations as artifacts that symbolize an idea or concept in science and, for this reason, they are an integral part of the language of science. In teacher training, the need to value the role of representation in the construction of meanings is already evident in the beginning of this discussion.

Amount of air particles

Considering all representations drawn on the board, only Milena's drawing clearly used the zoom resource to represent air particles (Figure 6); the other students represented the internal part of the syringe (Figure 7). The teacher highlighted this difference and asked them to explain why this difference happened between their representations. The following dialogue took place.

Table 1 – Dialog involving types of representations

Narrator	Transcription of speech
Teacher	*What is the advantage of yours when comparing them to Milena's?*
Pedro	*I liked it because of the zoom.*
Juliana	*But it shows only a small part.*
Natália	*In fact, it does not have only 12 particles in a syringe.*
Teacher	*How many air particles do you think a syringe can have?*

Natália, when comparing her representation with the representation highlighted by the teacher (Milena's), realizes the number of particles drawn on the board does not match their knowledge of chemistry. This discussion was more consensual when compared to the others, since the students agreed with Milena's proposal. Tytler et al. (2013) discuss about explanatory representations, that is, representations that help understand a phenomenon. These students were aware that a space like that inside a syringe could contain thousands of particles. But, when they represented the particles, they drew a very limited number of particles, not paying attention to this mistake. The teacher had to question these representations so Natália could express her understanding, which seemed to be the understanding of all other students.

Figure 6 – Representation with zoom in section of the syringe

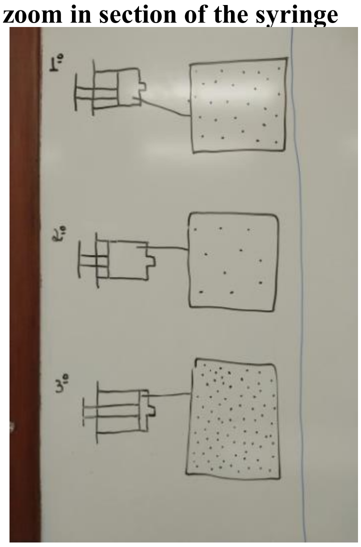

Figure 7 – Representation of internal part of the syringe

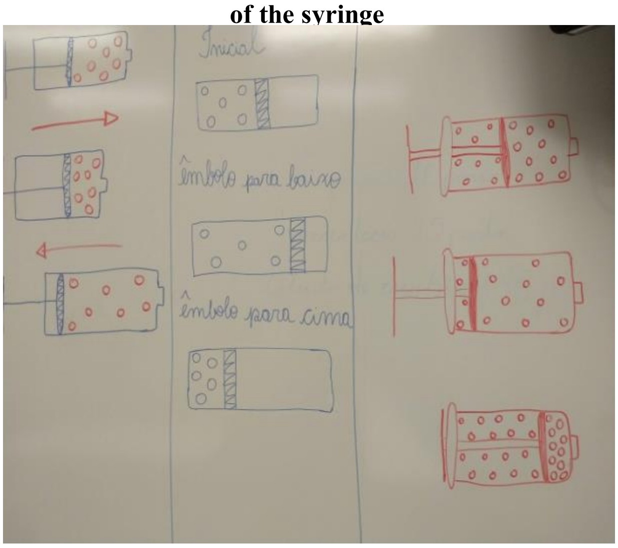

Distance between air particles

The representations showed different spacing between air particles, even in the same group. The particles were subjected to different pressure, but all three cases referred to gas. Since the students did not notice any problem regarding the distance between the particles in the representations they had drawn on the board, the teacher talked about a subject that apparently was not part of the lesson: representations of different physical states of the matter. The teacher drew on the board three boxes and identified them as zoom-in substances in the solid, liquid and gas states, respectively. She asked the students to represent the particles in these three states. Augusto went to the board and drew the representations, ensuring proper distance between the particles – the particles in the gas box were far from each other, and those in the solid box were much closer to each other (Figure 3).

gas

liquid

solid

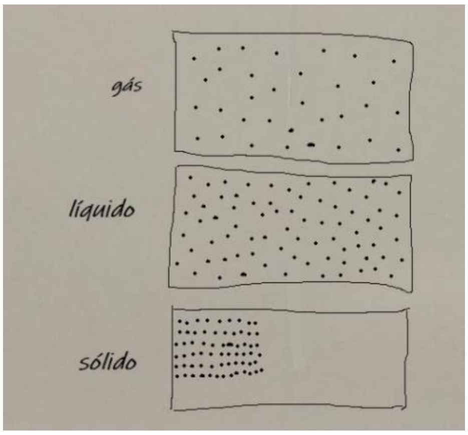

Figure 3 – Representations of states of matter drawn by one student

In the case of solid state representation, the student did not use the whole box, stating that all space would be occupied in the same way, with particles organized in lines. The teacher asked the support from the other students in the analysis of the drawing made by Augusto. Apparently no one disagreed with the drawing. However, the teacher's silence promoted another discussion.

The presence of lines was justified by the fact that, in the solid state, the particles are more organized. As a strategy to show the limitation of these representations and advance in the discussions, the teacher asked everyone to stand up and pretend they were particles of a substance in the gas state. One student started to move around the room, followed by the others, who also started to walk randomly around the room. The movement of vibration was also used by one student. The teacher highlighted the challenge of inserting movement in a static representation like a drawing, and argued that embodied representation favors the understanding of movement. Two students, when in contact, questioned if such closeness is possible, and another student answered that 'the particles are always in contact, not always producing a reaction.'

After that, the teacher asked the students to pretend they were particles of a liquid substance, and the group immediately gathered to one side of the room, moving in a more limited area. As there was no question regarding this representation, the teacher then asked the students to pretend they were solid particles. They were closer to one another, but leaving an empty space in the center of the group. When questioned about the meaning of that space, they moved and assumed a more standardized distance between them. Some of them kept doing the vibratory movement. The teacher then asked if they were sure that it was the most suitable representation of solid particles, which was confirmed by all students.

The next task consisted in comparing the embodied representations made by the students to the drawings on the board. The fact that the movement cannot be represented in the drawing was emphasized by most students and some suggestions were made but not materialized in the drawing. The teacher highlighted the solid state representation by saying: 'Here (pointing to the drawing on the board – Figure 8), the particles are lined up, but you didn't get in line when you represented the solid state in the corner (pointing to the corner of the room). You assumed more random positions.' The students understood the inconsistency between the two representations and said the drawing should be different. The teacher asked one student to go to the board and reformulate the drawing.

gas

liquid

solid

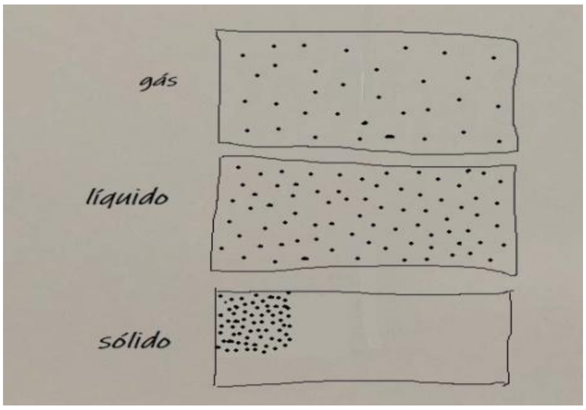

Figure 4 – Representations of states of matter drawn on the board after embodied representation

For being two representations of the same phenomenon, they are expected to be similar. Prain and Tytler (2013) point out the importance of students to have multiple opportunities to represent and reconfigure their understandings through discussion with their peers and the teacher. By using a different representation from what they had initially drawn on the board, the students ended up changing the representation, placing the particles that represented the solid state more randomly. Then, the authors agree with Prain and Tytler (2013), considering that, by providing students with an opportunity to represent the same phenomenon using different semiotic modes – first the drawing on the board and then their own bodies – the students compared the representations and reformulated the drawing on the board.

Once a consensus was created for the representations of solid particle, the teacher asked the students to observe the distance between air particles represented in the first activity, that is, the representation of air present in the syringe at three different moments. Milena, who correctly used the zoom resource, laughed at her own representation and said: ‘This is not gas!’ She went to the board and drew the particles again, keeping proper distance between them, that is, keeping the distance of particles in the gas state, but with a small difference between them due to higher or lower pressure to which they were subjected.

FINAL CONSIDERATIONS

To ensure a meaning to the representations, the students had the opportunity to construct, justify, negotiate and reformulate their own representations, placing them closer to canonical representations. Although they were teachers in training, there was no consistent understanding of the role of representation in chemistry teaching.

Regarding the distance between gas particles subjected to different pressures, representations through drawings on the board were not enough. When using embodied representations, the students understood the incoherence in the distribution of particles representing the solid state. Then, they were able to advance their knowledge by returning to the initial representation of the phenomenon that occurred inside the syringe and reformulating their representations. This way they placed their representations closer to canonical representations. Multimodality and multimodal representation were, therefore, essential for the construction of meanings.

Based on the initial speeches present in the discussion of episode 2, these teachers in training did not use representation as a form of knowledge construction. After the activities of classes 1 and 2, the teacher used the meaning of representations in chemistry teaching, exploring the possibility of creating alternative conceptions and using representation to help organize ideas and, therefore, construct knowledge. Understanding the role of representation proved to be essential for teachers, and in this sense, this topic should be widely explored in science teacher education courses. Students from teacher education courses who will soon become chemistry teachers, need to recognize the role of representations in conceptual learning.

ACKNOWLEDGEMENT

The authors would like to thank Fapemig and CAPES for their support.

PRE-SERVICE TEACHERS' EXPLANATIONS OF PHYSICAL PHENOMENA USING A SELF-CONSTRUCTED PARTICLE MODEL OF MATTER

Arnau Amat, Isabel Jiménez[1]
[1]Universitat de Vic – Universitat Central de Catalunya, Vic, Spain

This paper analyses pre-service teachers' explanations of physical phenomena and their ability to improve them using a self-constructed particle model of matter. The investigation was conducted in an undergraduate double degree teachers' course where student teachers were introduced to a model-based learning and teaching approach. Data was collected from the written material produced by students explaining different experiments in two moments of a lesson. Explanations were analyzed in order to understand the characteristics of the model of matter being used to produce such explanations and the characteristics of the explanation itself. Results suggest that student teachers did not have a consistent model to explain physical phenomena but a context-dependent model, and they improved the sophistication of their explanations during the instruction.

Keywords: Teacher Professional Development, Explanation Construction, Modeling-based learning.

INTRODUCTION

This study compares prior and after instruction pre-service teachers' explanations using a self-constructed particle model of matter as a tool to gain access to the development of their abilities related to causal explanations for natural phenomena. The study is framed in a pre-service science teaching course of a primary and kindergarten teaching double degree which main goal is to change students' views of science and science teaching, while being immersed in a Model Based Learning approach. During the course, students were engaged in modelling practices regarding the kinetic theory of matter over a four-week lesson period, in order to: (i) offer a new learning experience useful to work on their teaching views; (ii) work on their content knowledge, which is important as the vast majority of them gave up studying science subjects at the age of 16.

THEORETHICAL FRAMEWORK

Current research in science education emphasizes engaging students in the scientific practices in order to learn core scientific ideas (Oh & Oh, 2011). Although scientific activity involves many different practices (i.e. posing investigable questions, argumentation, analysing data, etc.), all of them must be developed in an intricate way in order to achieve the broad purpose of the scientific endeavour: developing evidence-based, explanatory models of natural phenomena to make sense of the world (Passmore et al., 2014). Thus, constructing scientific explanations for natural phenomena appears to be a key scientific practice ~~and~~ providing students with the competence to construct explanations scientifically resulting in their learning new ways of thinking about science education (National Research Council, 2007).

Characterizing scientific explanations and their nature has been at the centre of philosophical attention and debate throughout history and five major philosophical models of scientific explanations have been identified as relevant to research and practice in science education (Braaten & Windschitl, 2011). However, for the purposes of this study, we focus on causal (also referred to as mechanistic) explanations (Braaten & Windschitl, 2011; Russ et al. 2008), being understood as explicit applications of theory that go beyond description to reveal the causal relationship or model the mechanism for a specific situation or phenomenon (Braaten & Windschitl, 2011).

Even though mechanistic reasoning seems to arise quite intuitively when trying to explain certain natural phenomena (Russ et al., 2008), research underlines the persistence of difficulties in constructing proper scientific explanations, even after years of instruction (McNeill et al. 2006). To foster students' competence in constructing scientific explanation calls, therefore, for explicit guidance (McNeill et al. 2006; Braaten & Windschitl, 2011).

The kinetic theory of matter (particle theory) is used by scientist to give mechanistic explanations about a vast array of biological, chemical and physical phenomena. Several studies explore how students of different ages use particle models to give an account of natural phenomena (Harrison & Treagust, 2002). However, little is known about how pre-service teachers construct such knowledge to further support students in this sort of practice.

To address this issue, the present study analyses pre-service teachers' explanations of physical phenomena and their ability to use a self-constructed particle model of matter to build them.

METHOD

Data was gathered from 23 student teachers' written explanations of physical phenomena in two moments: (i) prior to instruction, when student teachers had to work in small groups following the Prediction-Observation- Explanation structure in relation to six experiments regarding air pressure, condensation or solutions; (ii) after four weeks of instruction where student teachers engaged in modelling practices (thus constructing, evaluating, reviewing and using models) to learn about the kinetic theory of matter. In this moment, working in the same groups, student teachers were encouraged to revisit some of their initial explanations and to explain some of the same phenomena. The explanations given were analysed in terms of: (i) characteristics of explanations and the mechanistic reasoning within them (based on Russ et al approach (2008), see table 1) and; (ii) characteristics of the subjacent model being used (based on Harrison & Treagust, 2002, see table 2).

Table 1. Categories within analysis of explanations (based on Russ et al., 2008)

Type	Description
Type A	Entities; the organization, activities, and properties of the entities which are needed to explain the phenomenon identified and which are appropriate to explain the observed phenomenon. Chaining occurs.
Type B.1	The components identified are adequate to explain the observed phenomenon, but not all components are identified. Chaining occurs.
Type B.2	The components identified are adequate to explain the observed phenomenon, but not all components are identified. Chaining does not occur.

Type C.1	The components identified are not adequate to explain the observed phenomenon. Chaining occurs.
Type C.2	The components identified are not adequate to explain the observed phenomenon. Chaining does not occur.
Type D	Non-explanation, a description of an observation.

Table 2. Categories within subjacent models (based on Harrison & Treagust, 2002)

Type	Description
Type 0. No model	No model is being used
Type 1. Macroscopic	The phenomenon is described using a macroscopic model of matter
Type 2. Non-kinetic particulate model	The model being used considers microscopic particles, but they do not have any sort of movement
Type 3. Partial kinetic particulate model	The model being used considers microscopic particles, but they have any sort of movement

RESULTS

In this paper, results come from the detailed analysis of two experiments. These experiments have been chosen because they describe the most common situations found in the complete results.

In the first experiment, students were required to place a drop of dye into three beakers containing the same amount of water at different temperatures. Students had to explain why an increase in temperature causes an increase of liquid solubility. The aim was to focus on the relationship between temperature and the movement of molecules in a liquid, thus relating the observed phenomena to the molecular-kinetic theory and neglecting other theories (i.e. thermodynamics) that could also be used to explain it.

Prior to instruction, the subjacent models used to explain this phenomenon were, as shown in Fig. 1, the non-kinetic particulate model (33% in grey, type 2) and the kinetic particulate model (39%, in yellow, type 3). However, it is also worthwhile to notice that, in 28% of the initial accounts no kind of matter representation was used (in blue colour, type 0 in fig. 1).

Regarding the sophistication of the explanations, and as it is also shown in figure 1, 33% of the students made a mere description of what was happening (type D). For example, student 1 wrote: "*In warm water the drop of dye dissolves faster*". Furthermore, 32% of the students gave unchained explanations (types B.2 and C.2) for the phenomena. There was not a single explanation Type A in this stage.

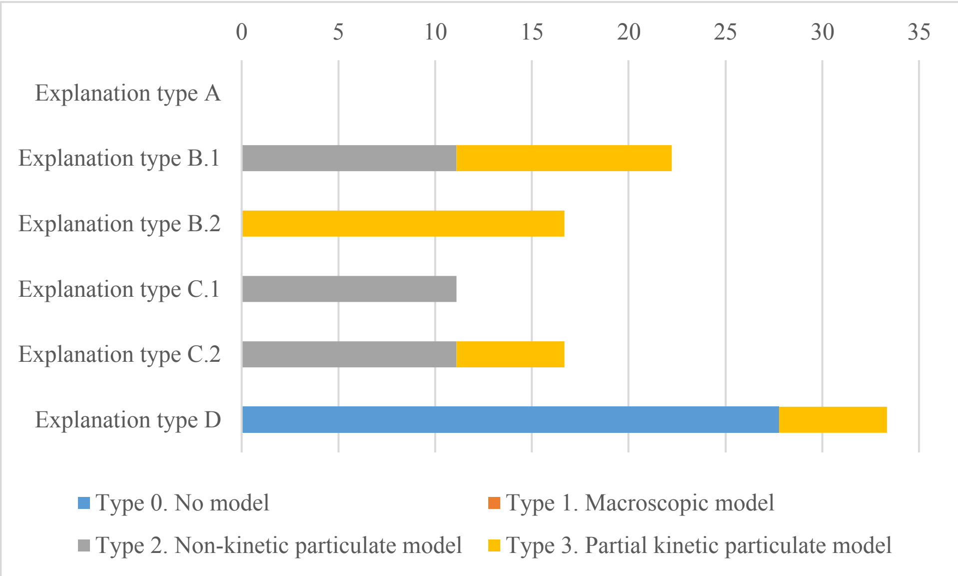

Figure 1. Results of initial explanations in the first experiment

Through instruction, student teachers not only improved their representations of matter, but also their explanations of the phenomenon became more sophisticated. As it can be seen in Fig. 2, the vast majority of students used the kinetic particulate model (58%, type 3 in yellow) and the non-kinetic particulate model (32% type 2 in grey). Regarding their explanations, it is possible to see that mere descriptions (type D, fig.2) were only given by 5% of the student teachers. Unchained events explanation, types B.2 and C.2 in fig. 2, decreased to 0% and the most sophisticated ways of explaining (type A explanations, fig. 2) represented 21% of the sample.

For instance, and in order to show a sophisticated way of explaining (Type A) in which chaining occurs and the components of the explanations are adequate to explain the phenomenon, we see that student 2 wrote: "*The drop of dye descends more vertically in the* *cold water, because in warm temperatures, dye and water particles move faster and, therefore, the drop of dye dissolves better in the warm water*".

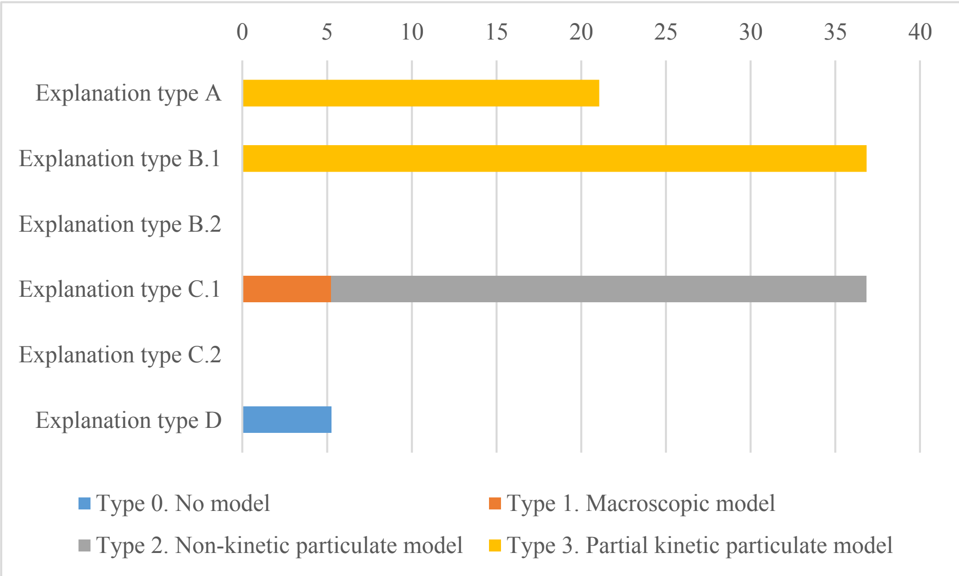

Figure 2. Results of final explanations of the first experiment

The second experiment referred to the effects of air pressure. In this case, students had to explain why a tied balloon expands after pumping the air out using a vacuum apparatus.

At initial stages and as shown in Fig. 3, students used a macroscopic model (52%, orange, type 1) and a non-kinetic particular model (29%, grey colour, type 2). As far as the sophistication of explanations is concerned, we can see that 19% of them were classified as mere descriptions (type D explanations). Moreover, 38% of the students produced unchained explanations, types B.2 and C.2. There was not a single explanation Type A in this stage.

In order to show how they use a macroscopic model we can see, for example, how student 3 wrote: *"The air inside the balloon wants to take up the maximum space, but is stopped by the balloon's elastic wall, which is deformed, and the balloon blows up. The particles inside the balloon push up to take up space"*. This example is also useful to show how students were able to chain events, even though the components of the explanation were not adequate to explain the phenomenon.

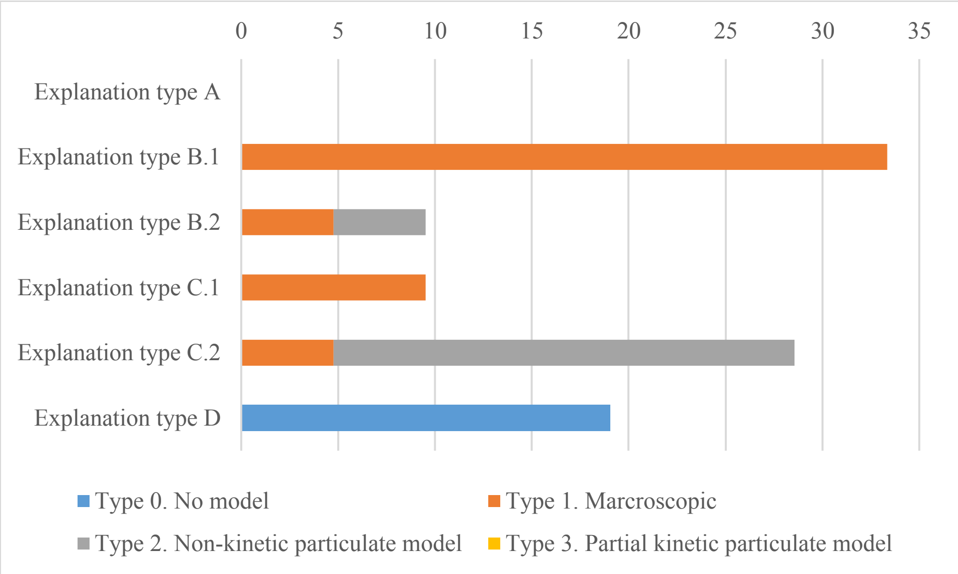

Figure 3. Results of initial explanations in the second experiment

After instruction, as is shown in Fig. 4, 26% of students continued using a macroscopic model (type 1, orange). However, most of them used particulate models: non-kinetic particulate model (60%, grey, type 2) and kinetic particulate model (9%, yellow, type 3). Explanations also increased in sophistication. Mere descriptions (type D) only represented the 13% during the final stage, while chained explanations types A, B.1 and C.1 increased from 42% to 82%, through instruction.

The following example shows a sophisticated explanation using a non-kinetic particulate model. In this case, student 4 wrote: "*First of all, the particles of air inside the vacuum apparatus take up a space that the particles inside the balloon are not able to take up. The air particles outside the balloon push against the balloon, the air particles inside the balloon push outwards. When we pump the air out, in other words, when the vacuum is made, the pressure exerted by the particles outside the balloon disappeared. So, the pressure exerted by the air particles inside the balloon has no opposition. The air particles inside the balloon take up this space, and the volume of the balloon increases*". Even though this explanation could not be considered scientifically adequate due to the macroscopic model used by students, from the point of view of the structure of the explanation, the components and the chaining of the events could be considered fully adequate.

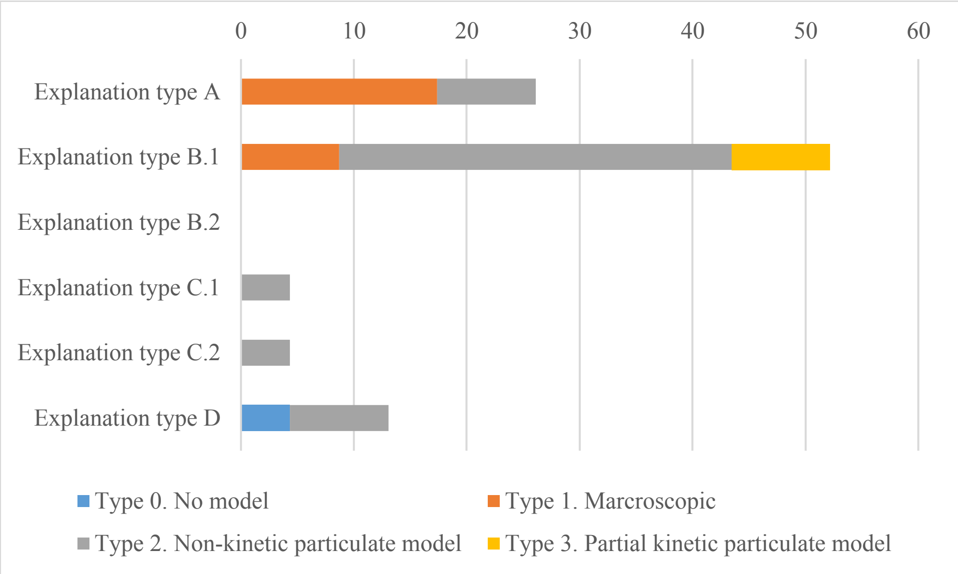

Figure 4. Results of final explanations in the second experiment

CONCLUSIONS

Mechanistic reasoning is fundamental for predicting and explaining the behaviour of many natural phenomena and, accordingly, is necessary for the knowledge construction in science (Nersessian, 2008). Models are also central to the process of understanding, doing and communicating about science, being used as tools to make predictions and construct explanations for how and why natural phenomena occur (Passmore et al., 2017). This study contributes to think about the relation between construction of models and its use to give explanations about natural phenomena.

Overall, the results suggest a lack of consistency using a self-constructed model of matter while explaining different phenomena. For example, some students would use a particulate model to explain why an increase in temperature causes an increase of liquid solubility while using a macroscopic model to explain why a balloon expands in a vacuum apparatus. In this sense, using one model or another seems to be context dependent.

Furthermore, it is possible to conclude that instruction increases the sophistication of causal explanations mainly facilitating chaining reasoning strategies. These results are in consonance with other studies that show that, although the potential of reasoning about causes and effects emerges very early, its mastery is not an all-or-nothing accomplishment and, therefore requires for explicit guidance (McNeill et al. 2006; Braaten & Windschitl, 2011).

Finally, results show that causal explanations given by students are not always consistent with those accepted by scientists as the components of the explanation differs from those considered in scientific explanations. According to theories on responsive teaching in science classrooms (Hammer et al., 2005), these results may have important implications for undergraduate classes. Pre-service teachers in this study were engaged in modelling practices to learn concepts within science while learning about the kinds of epistemic activity that constitutes science. Therefore, the recognition of productive explanations beyond their scientific correctness, could help pre-service teachers to recognise them.

Teaching science is a crucial issue in early childhood and primary school, as it greatly influences the future attitude of pupils (and, thus, of future citizens) towards scientific knowledge. However, an effective training in teaching science cannot rely solely on isolated, well-curated courses. In this paper, we describe a widescale proposal of innovation for the academic scientific curriculum of pre-service pre-primary and primary teachers. Our aim is to improve scientific knowledge of students, as well as their related teaching skills. The major foci of our proposal are: (i) making a "scientific environment" available, i.e. a term fully devoted to science during the five years of the academic curriculum; (ii) planning interdisciplinary lab classes connected to a central topic of keynote importance (which was chosen to be water); (iii) allowing students to actively work on the topic through hands-on activities. The combination of these factors is expected to circumvent many flaws in the traditional academic teaching of science, which are exaggerated in the context of the education of pre-service teachers, who actually did not select a scientific course for their academic career. In a nutshell, a stimulating scientific context and more engaging, cutting-edge classes will hopefully turn motivated students into effective teachers of tomorrow.

Keywords: Primary School, Teacher Preparation, Interdisciplinarity

INTRODUCTION

Because of the quick changes of our world, the development of STEM (Science, Technology, Engineering, and Mathematics) knowledge and skills to deal with complex issues and wicked problems is becoming more and more important since the beginning of the educational path. As stated in the Netherland report (Adams et al., 2018), "Science [STEM] education, which cuts across the persistent divide of natural sciences and social science, is potentially uniquely positioned to support new generations' understanding and engagement and address the social, economic and environmental dimensions of these global challenges."

Although recent educational reforms emphasize the importance of teaching STEM from the lower educational level, it still remains a difficult domain. Indeed, many elementary teachers feel less knowledgeable about STEM content and less comfortable teaching STEM than other subjects.

One of the most accurate statistics on science learning from the United States clearly pinpoints flaws in science teaching: roughly 60% of students enrolling in a STEM field leave for non-STEM courses or drop out. The percentage can reach 80% for women and for some minority groups (President's Council of Advisors on Science and Technology, 2012). This issue is amplificated in university courses for pre-service pre-primary and primary school teachers, who did not enrol in STEM university courses at all and should anyway follow science courses. Recently, in the US, STEM education has been placed in the spotlight because of mediocre achievement in these disciplines (NCES, 2009; OECD, 2013). Indeed, across US, many teacher education programmes are now becoming more focused on ways to improve pre-service teachers' preparation for teaching and integrating STEM disciplines (Lederman & Lederman, 2013).

Many claims have risen in recent years in favour of two long-known, but not long-applied ways of teaching, notwithstanding a large amount of skepticism (Waldrop, 2015; Wieman & Gilbert, 2015b). First, active teaching methodologies are persistently found to be more effective and more engaging (e.g., Šorgo, 2010; Freeman et al., 2014; Waldrop, 2015; Wieman & Gilbert, 2015a, 2015b); moreover, the importance of interdisciplinarity is repeatedly underlined (Huber & Hutchings, 2004; Huber, Hutchings, Gale, Miller, & Bree, 2007; Woods, 2007; Šorgo, 2010). Again, the multidisciplinary, relevant, and experiential character of place-based education is said to increase students' engagement, understanding, and academic achievement (Semken & Freeman, 2008). Many universities are fostering opportunities for integrative learnings (Association of American Colleges and Universities, 2002), but these experiences still involve limited numbers of students (Huber & Hutchings, 2004).

Integrate learning across contexts and time is one of the greatest challenges in education (Huber & Hutchings, 2004): accordingly, the integrative learning approach should be a "campus-wide concern" (Huber et al., 2007). The idea that teaching STEM needs to be grounded on inter-multi-disciplinary knowledge organization poses challenges to teacher preparation and teaching practices. As stated by Woods (2007), inter-multi-disciplinary learning is expected to effectively improve knowledge and skills if three mandatory elements are kept: the interdisciplinary collaboration needs to be set up some months before the lab classes; the lab classes must offer a real opportunity for interdisciplinary collaboration; time and space for reflection and assessment should be envisaged (Woods 2007; Wieman & Gilbert, 2015b).

Given this literature background, the Single Cycle Degree of Primary Teacher Education at the University of Bologna, proposed an institutional and educational reform concerning the scientific disciplines, with the specific aim of engaging more and more the students towards science and improving scientific knowledge of students, as well as their related teaching skills.

This paper aims at presenting the architecture and the main features of a new scientific inter-multi-disciplinary laboratory designed to combine active learning and inter-multi-disciplinarity for pre-service pre-primary and primary teachers. The lab classes devised by our group for pre-service teachers were conceived as a first step towards the scenario we introduced above, with active teaching and learning interwoven in an inter-multi-disciplinary framework spanning over biology, chemistry, ecology, and physics as well as crossing boundaries between STEM and humanities in order to address more complex societal issues. In this paper, we describe the architecture of the lab, followed by a preliminary analysis of students' reactions to the inputs of this innovative inter-multi-disciplinary lab.

THE ARCHITECTURE

The institutional and educational context

The context of our study is the Single Cycle Degree of Primary Teacher Education of the University of Bologna (Italy), aiming to the training of future primary and pre-primary teachers. The access to the degree course is restricted and every year a cohort of about 300 students is enrolled.

According with the institutional reform started in the 2016/2017 academic year, from the 2018/2019 a.y., all the third-year courses carried out during the second term are totally devoted to science and science education, which sets up the interdisciplinary collaboration (following Woods, 2007). This institutional choice followed up a process of reflection at institutional level that took into account both the results within the literature, concerning the difficulties illustrated in the framework above (e.g., OECD, 2013), as well as the data collected in the previous years from student evaluation questionnaires concerning the degree course and its structure.

Specifically, three scientific courses have been assembled in the same term: Elements of Biology, Elements of Chemistry and Ecology, Elements of Physics and Physics Teaching. All courses span over the foundations of the discipline and its teaching/learning methods, where the educational reconstruction of the basic concepts together with educational reflections and phenomenological experiences are used to elaborate the acquired knowledge and to turn it into teaching knowledge.

The institutional reform concerns not only the organisation of the scientific courses, but also the laboratory courses related to them. Indeed, along with the theoretical disciplinary courses, the program foresees disciplinary laboratories, which are strictly interconnected with the topics addressed in the courses. Each student can choose to attend the laboratory courses of one discipline among Biology, Chemistry and Ecology, or Physics: the specific purpose of the disciplinary laboratory is to elaborate on some of the course's topics, observing and carrying out scientific experiments, that can be easily reproduced in early childhood and primary schools. Together with the disciplinary laboratory, all the students are required to attend an inter-multi-disciplinary laboratory, spanning over Biology, Chemistry and Ecology, and Physics. This innovative laboratory has been designed and introduced to achieve several purposes: (i) investigating a topic underlying all the aforementioned scientific disciplines; (ii) discovering that a topic can be studied in detail and better understood if it is analysed under different perspectives, each related to a different discipline; (iii) highlighting the ethic and social impact of science and technology, that cannot be neglected. Moreover, an inter- and trans-disciplinary approach allows to face natural and anthropic phenomena, along with problems associated to everyday life, which are not easily understandable with a purely disciplinary approach.

The choice of introducing a mandatory inter-multi-disciplinary laboratory for all the students represented a real innovation within the degree courses and it represented a real experimental context that needed to be shaped from the very beginning.

In order to answer this need, a group of experts was established for designing such new and innovative lab. The group was comprised by researchers in the specific disciplinary domains, researchers in science education, a researcher in methodology of educational research (who is also the Director of Single Cycle Degree of Primary Teacher Education) together with school teachers.

The group of experts met up for one year and cared about the whole process: from the reflection on the existing literature on the topic to the design of the course, from the preparation of all the materials (e.g., slide, worksheet, home tasks, evaluation questionnaire) to the setting up of the experimental equipment. The lab was hosted in a science centre in Bologna (Opificio Golinelli), that provided adequate spaces and structures in order to realise the lab.

The first implementation of the inter-multi-disciplinary lab was carried out on May and July 2019 and was repeated 9 times with 9 different groups of students, for a total amount of 238 students. The teachers of the lab were two of the experts of the designing group, with the occasional co-participation of other experts of the group.

The inter-multi-disciplinary lab

As introduced before, the inter-multi-disciplinary laboratory aims at investigating a topic under different frameworks, each one related to a different discipline, in order to obtain an overall picture by integrating all its different aspects. Water was considered to be a suitable theme since it is a very transdisciplinary topic from a scientific standpoint, but also an open-ended multifaceted social issue.

Each implementation consists of a full-day lab class of 8 hours. Briefly, the trail of the laboratory begins with a phenomenological analysis of the behaviour of different objects put in water to build a macroscopic physical model that can explain this phenomenon. Then, a microscopic chemical model is introduced to explain other peculiar properties of water, highlighting some of their ecological consequences. Finally, the relation between these properties of water and the origin and adaptations of life is explored.

The first part of the laboratory follows a classical physical approach. The students start from observation of phenomenological evidence. Then, through a group discussion, students start to compare ideas and preconceptions about the features of a floating object, formulating hypotheses and designing experiments to verify their validity. A free exploration phase immediately follows: using a wide range of common objects and materials, including ice, students can test the validity of their hypotheses in large and medium-sized water tanks. In this way, they recognize that mass and volume individually do not justify the property of an object to float. The new concept of density must be built at this point, allowing the macroscopic explanation of the phenomenon of flotation.

In the second part of this laboratory, a microscopic chemical model is introduced: water molecule and hydrogen bridge bonds. This microscopic structure can explain many other water anomalies: the presence of all the three aggregation states under commonly encountered temperatures and pressures conditions, the high surface tension, the phenomenon of capillarity, the high solvent power. For each of these peculiarities, students carry out laboratory activities in small groups, like chromatography on paper, solubility tests, preparation of crystals. Also, the ecological consequences of these characteristics are highlighted: the relevance of ice floating on water for life development and maintenance on Earth, the role of capillarity in vascular plants, the karst environments.

Finally, biological consequences of water properties are investigated. Water high solvent power has played a crucial role in the processes that led to the origin of life on our planet. This peculiarity is also a decisive key for all metabolic reactions occurring in a single cell. As a take-home message from this section of the lab, students are faced with the idea that life was in its origin and still is an essentially aquatic phenomenon. Students experience and elaborate on the disparity of aquatic animals and their different forms of adaptation through (i) placing various animals in a salty water ecospace and (ii) observing the diverse microorganisms present in a single drop of steady water.

METHODS AND DATA ANALYSIS

Materials and Methods

Interdisciplinary laboratory classes were carried out in May and July 2019 for a total of 238 students. Teachers were two of the authors, namely CB (4 classes) and FP (5 classes). After the laboratory, students were assigned to hand a three-page report about the didactic value of the experience, discussing its strengths and weaknesses from the teacher's point of view, and eventual improving feedbacks as well. The assignment was mandatory for the students and they were graded by lab teachers with −1, 0, or +1 (on a 30 scale). The obtained grade contributed to the final mark of their semester examination. The assignment is reported in Table 1, while the assessment criteria are shown in Table 2.

Table 1. The assignment of the reports used for text mining

	Item
1	Strength of the approach presented in the lab (both methodology and contents)
2	Weaknesses and suggested improvements
3	Inter- and trans-disciplinary links
4	Suitability and plasticity for pre-primary school
5	Suggested connection with local resources (field trips, museums, natural parks,…)

Table 2. Assessment criteria

	Item
1	Mastering of disciplinary contents and of inter- and trans-disciplinary connections
2	Logic of the adaptation to the pre-primary school and of the use of local resources
3	Soundness of the use of the disciplinary lexicon and jargon
4	Originality of the proposals

At the conclusion of the semester, a total of 226 reports have been handed in and assessed. Overall, 164 out of 226 reports (72.57%) were scored +1.

Custom bash scripts were written to convert all reports in plain text files, which were cleaned and filtered using the package tm (Feinerer et al., 2008) of the software R (R Core Team, 2019). Stemming was carried out with the R package SnowballC (Bouchet-Valat, 2019). Words between 4 and 20 characters were retained if present in at least 20 texts and at most 222; empty words ("to be", "to can", "many", "some", "through", "when", "first", "second", "moreover", "allow", "during", "therefore", "to do", "point", "strength", "relative", and "weakness") among the most used terms were manually removed. Associations between words were looked for, setting 0.40 as the threshold level to retain an association.

Differences in text composition might be due to the two different hosts of the lab classes. In order to investigate this issue, we used the Principal Component Analysis (PCA) on the final term matrix. Given the sparsity of the matrix, it was not possible to use the log-transformed frequencies and, for the sake of clarity, only the 34 top-occurring terms were investigated, provided that results using all terms are not different. The PCA biplot was depicted using the R package ggbiplot (available at https://github.com/vqv/ggbiplot).

Results

The initial term matrix was comprised by 6,824 vocabulary items for a total of 1,542,224 words after cleaning typos, removing punctuation and filtering out Italian stop words. Expectedly, the most used word is "water" (3,542 occurrences), followed by "child", "active", "lab", and "school" (2,519, 1,725, 1,430, and 1,350 occurrences, respectively). Generally speaking, our corpus is in good agreement with the Zipf's law ($r = -0.98$, $R^2 = 0.95$, $P = 0$) and 183 vocabulary items account for half the corpus.

After removal of empty words and of poorly informative words present in more than 222 texts ("water", "child", "lab", and "school"), we obtained a matrix with 880 terms with a maximum length of 16 characters. The sparsity of the matrix was 72.97% (53,760 non-sparse entries). The words which were found in more texts were "active", "experiment" (216 texts each), "childhood", "to use" (215 texts each), and "possible" (214 texts). Similarly, the five most used words in terms of total occurrence are "active", "experiment", "to use", "possible", and "to observe": all top-occurring words (i.e., those words with more than 400 occurrences) are shown in Figure 1.

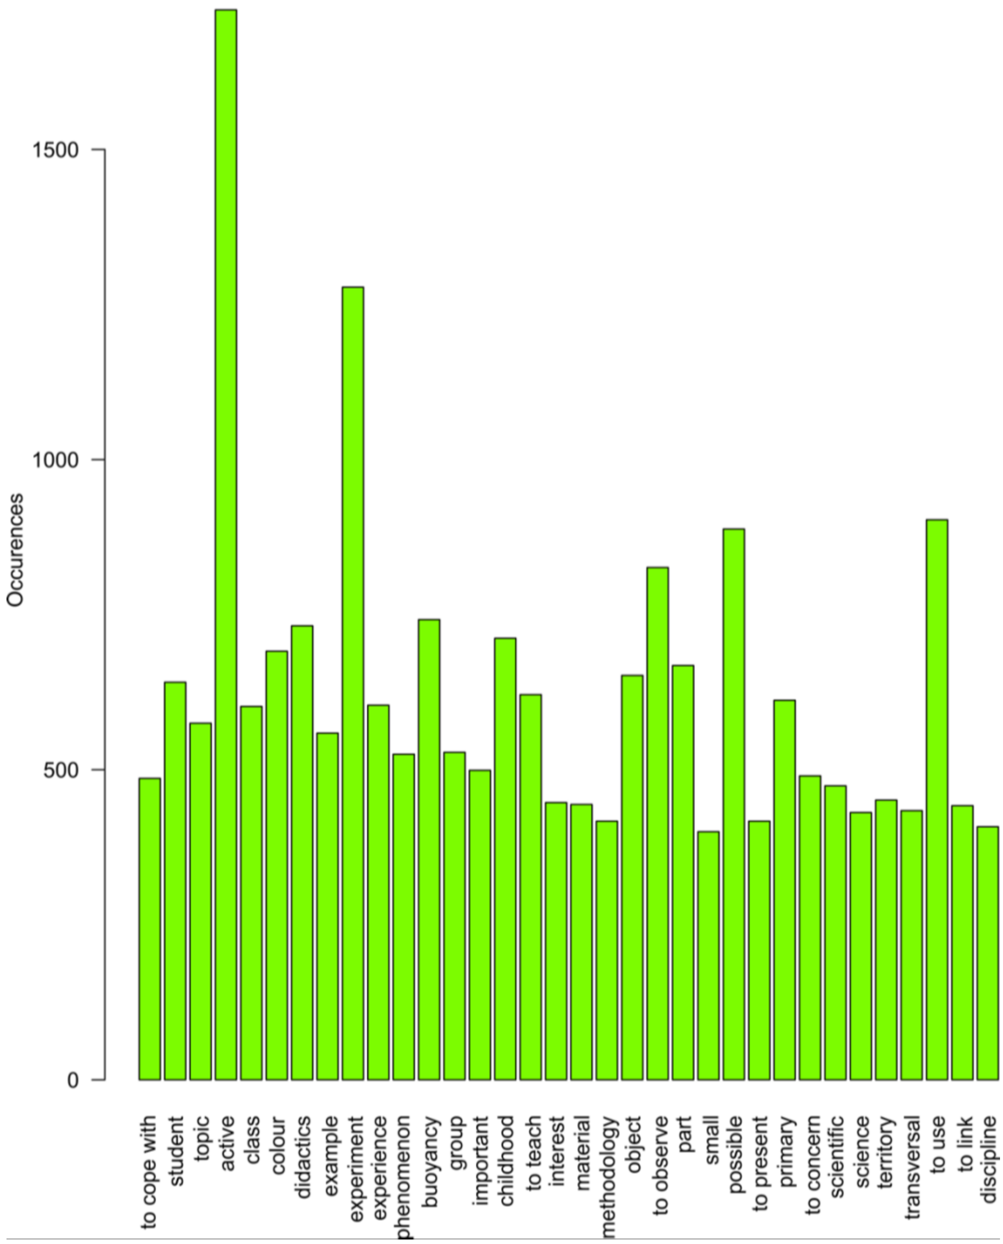

Figure 1. Top-occurring words. Word with at least 400 occurrences are shown.

Intermediate to moderately high levels of associations were evidenced within the corpus, in that only two term pairs scored an association level greater than 0.60; interestingly, both are connected to the flotation experience: "object"/ "to float" (0.69) and "object"/ "to sink" (0.65). Many pairs are connected to concrete, hands-on experience that were carried out during the lab (e.g., "object"/"to float", "colour"/"glass"); other pairs are connected to the scientific approach (e.g., "phenomenon"/"to observe") as well as to science teaching and learning (e.g., "to teach"/"to ask"). Notably, "methodology" and "content" are associated with an association level equal to 0.57, which means that an effective, multifaceted figure of science teaching and learning has been achieved by most students. Interestingly, all the three disciplines which are involved in the present lab are connected with the term "to present" to a similar extent (0.44 for "chemistry", 0.42 for "physics", and 0.40 for "biology"). The term "to teach" is more common in the corpus, with 621 occurrences in 186 texts against 417 occurrences in 162 texts for "to present"; recall that it shares the same stem with "teacher", the latter is probably the most used meaning of this stem, while the need of a fascinating way to deliver (to "present") science to pupils is retrieved from our corpus.

The first two principal components evidenced by the PCA approach jointly explain the 31.07% variance in the use of words in the filtered corpus (Fig. 2). There is apparently no structure in the corpus, i.e. no sub-groupings or cluster are evident. Interestingly, this holds for the lab hosts as well: the 95% ellipse computed on texts written by students who carried out the lab class with CB is perfectly superimposed with that computed on texts written by those who carried out it with FP. This suggests that the lab architecture and its outcome in terms of knowledge and effectiveness in science teaching and learning are largely independent from the actual host of the lab, which indicates that the inter-multi-disciplinary lab is robust to personal teaching idiosyncrasies of single lab teachers.

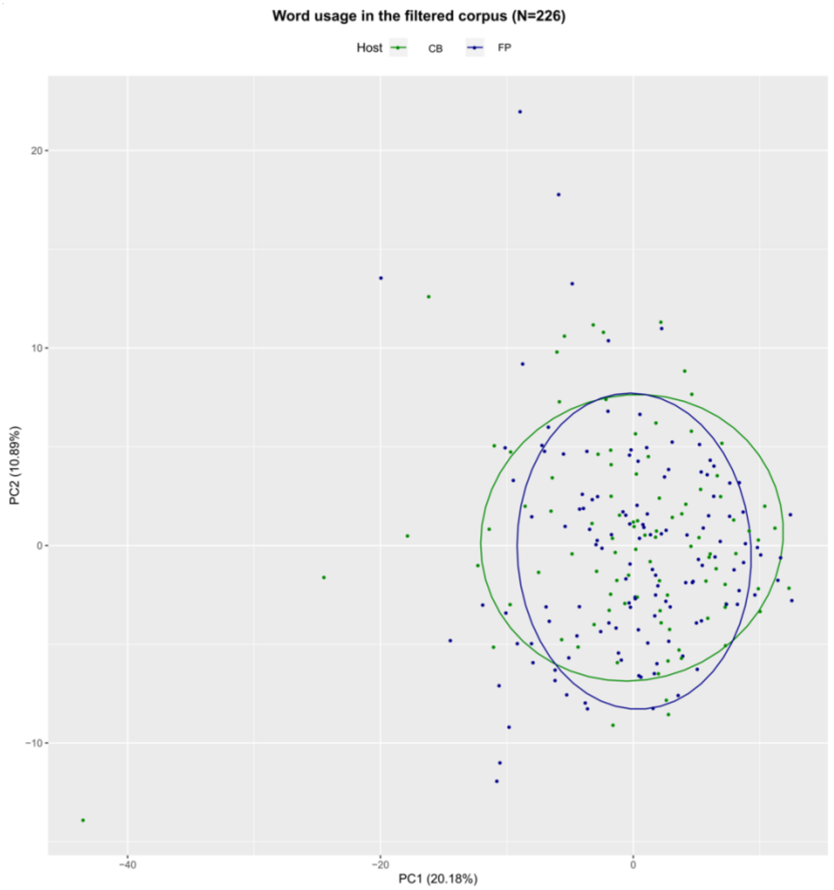

Figure 2. Word usage in the filtered corpus. Only the 34 top-occurring words shown in Fig. 1 are used.

DISCUSSION AND PERSPECTIVES

The inter-multi-disciplinary lab described in this paper is an experimental implementation of the current leading framework about STEM teaching and learning: active teaching methodologies (Šorgo, 2010; Freeman et al., 2014; Waldrop, 2015; Wieman & Gilbert, 2015a, 2015b); interdisciplinarity (Huber & Hutchings, 2004; Woods, 2007; Šorgo, 2010), even at a whole-curriculum scale (Huber et al., 2007); long-lasting interdisciplinary collaboration that does not run out with the lab class (Woods 2007); reflection and assessment opportunities (Wieman & Gilbert, 2015b).

The set up of a term which is explicitly devoted to natural sciences (biology, chemistry, ecology, and physics) is a precise line of the graduation degree board, and it represented a powerful introduction towards an effective interdisciplinary learning and thinking as well (Huber et al., 2007; Woods, 2007). The three courses are held together, and links and overlaps are highlighted, with special reference to the biology-chemistry, biology-ecology, and chemistry-physics boundaries. Within this framework, it seemed natural for students the hands-on experience to be focused on a topic, such as water, and not on single disciplines.

Therefore, the full-day lab class is naturally intended to play a pivotal role in the three courses and in the scientific education of pre-service pre-primary and primary teachers itself. Still, the aim of the lab would have not been pursued without a proper and sound opportunity of (self-)assessment (Woods, 2007; Wieman & Gilbert, 2015b), and this is the point of the brief reports that were requested to students: offering an opportunity of processing on the experience, a process which would have not been spontaneous in many cases.

The inter-multi-disciplinary lab has been put into practice with students for the first time in the a.y. 2018-2019. Thus, aim of the present paper is not a thorough evaluation of its effectiveness, rather a discussion of preliminary results about students' reaction to the novelty, reporting about the first impact on students' engagement and improvement in scientific knowledge related to the lab itself and independently from the lab teachers. Interestingly, the lab appears to be relatively robust with respect to the host, at least considering the word usage of the students' reports (Fig. 2). Conversely, observation and experiment are two faces of the scientific method, and these words and their relatives were retrieved among the most used in the students' reports (Fig. 1), meaning that the architecture of the lab class hit the students' attention more than the actual host.

Concerning the disciplinary contents, some misconceptions were found in the reports: e.g., the use of the word "heavy" associated to "object", while the concept of "dense" has been demonstrated to be preferable. Moreover, some experiences of the lab are more common in students' reports with respect to others – this is the case, for example, of flotation and capillarity. However, the main purposes of the lab class appear to have been fulfilled: (i) the association of "methodology" and "content" suggests a pursuit of an effective STEM teaching, resulting in active learning sequences, and (ii) the present lab class constitutes a possibility of integration of different scientific realms.

Notably, words and ideas connected to biology and ecology are more sparse and less common with respect to chemistry and physics. Whether this indicates a minor interest of students towards these disciplines or a greater difficulty to integrate these concepts within a written report is beyond the scope of the present paper. Our results suggest the validity and effectiveness of the inter-multidisciplinary approach in STEM education; a rigorous and thorough evaluation and characterization of the inter-multi-disciplinary lab deserves careful investigation in the following cohorts, in order to obtain an affordable amount of information.

ACKNOWLEDGEMENT

We are deeply grateful to Professor Ira Vannini, Director of Single Cycle Degree of Primary

Teacher Education, whose invaluable support was essential for the introduction of the innovative curriculum which is described in the present paper. We also wish to thank the Marino Golinelli Foundation, that provided spaces, materials and assistance for the lab.

INITIAL SKILLS IN DRAWING OF THE PRE-SERVICE BIOLOGY TEACHERS

Jan Petr and Lukáš Rokos
University of South Bohemia in České Budějovice, Faculty of Education,
České Budějovice, Czech Republic

Observations of biological objects accompanied by their description are natural parts of biology and biology teaching and learning. According to Dempsey & Betz (2001) the drawing is an excellent way to describe an object and it helps to develop change from simple mental models to focus on the identity of specific object. Whilst biologists use drawings in their studies, labs or field research, these drawings have different purpose in the school science. Many research studies support an idea that drawing is the key element in science education. It enables visualization in scientific thinking, helps to organize students' knowledge, students are more motivated and their understanding and communication competencies are better developed etc. These reasons speak in favour of the use of biological drawing in education. This article deals with the problems of use drawing in teacher training. Initial drawing skills of pre-service primary biology teachers were investigated in this empirical study. Fifty-seven pre-service teachers were asked for making the sketches of selected biological specimens (tick, woodlouse, spider, feather, fish scale) using the microscope and stereomicroscope. Research questions: (1) Are standard rules of biological drawing used by future teachers at the beginning of their studies?; (2) Are students able to visualize typical attributes of specimens?; (3) Are there any typical mistakes in drawings or some attributes preferred in drawing?, and (4) Are there any misconceptions in biological knowledge recognizable from the sketches? Sketches of the pre-service teachers were analysed using the coding tool with respect to the RQs. The tool enabled to follow the individual characteristics of sketches and the data were analysed with basic statistical methods afterwards. The findings show better quality of sketches of the objects prepared in microscope slides in comparison to the objects observed with stereomicroscope. There are many offences against rules and many mistakes in representation of observed reality.

Keywords: Science Education, Teacher Preparation, Training and Development

INTRODUCTION

Biological drawing is an important skill for biologists and biology teachers. Despite of almost excellent quality of the current imaging technologies and their increasing variety, the drawing is still important tool for the recording of outcomes the biological observation and documentation of specimens and objects (in several branches, for example in animal morphology and anatomy – for example Schneider, Kovac, Steck & Freidberg, 2018). Whilst biologists use the drawing in their research studies and labs or field research, from point of view of science education drawing is considered as very useful and important tool for visualization in scientific thinking and for conceptual understanding of the subject (Merkle, 2015; Bartoszeck &Tunniclife, 2017). Ainsworth, Prain & Tytler (2011) promote following five reasons why students' drawing should be considered alongside writing, reading, and talking as a key element in science education: (1) drawing enhances students' engagement, (2) drawing develops visual literacy and helps creating new and supporting current knowledge, (3) understanding is joined often with visual models and enables visual model-based reasoning (also Quilin & Thomas, 2015), (4) drawing can be effective learning strategy and helps organize students' knowledge or understanding and (5) it provides opportunities to exchange and clarify meanings between peers and science communication (also Watson & Lom, 2007). Therefore, drawing should be developed in teacher training, especially in science (biology) teacher education.

There are many definitions of drawing in the literature. Quilin &Thomas (2015, p. 2) formulated very important but quite extensive definition: *"By learner-generated external visual representation depicting any type of content, whether structure, relationship, or process, created in static two dimensions in any medium"*. We were focused on visual model of biological structures and specimens in our study. The biology drawing has specific parameters or principles in comparison with common drawings and cartoons. It is necessary to adhere respected principles of biological sketches, for example use sharp and no coloured pencil, draw continuous lines, sketch without shading, keep accuracy, enough size and correct labelling (OCR, 2015). The accuracy is very important for the record of specimens. The understanding and knowledge are necessary as well as for accuracy in drawing (drawing what is visible, not what author should see, elimination of disruptive artefacts etc.).

Biology and biology education contain typical specific subjects, which require drawing skills related with nature of science. Therefore, this research was aimed to the identify state of initial pre-service biology teachers' drawing skills at the beginning of their study at university. Outcomes can be useful for development and innovation of teacher educational programmes.

OBJECTIVES OF THE STUDY AND RESEARCH QUESTIONS:

(1) Are standard rules of biological drawing used by future teachers at start of their studies?

(2) Are students able to visualize typical attributes of specimens?

(3) Are there some typical and repeated mistakes in drawings or are some attributes preferred in drawing?

(4) Are there any misconceptions in biological knowledge recognizable from the sketches?

METHODS

Pre-service teachers (n = 57) were asked to make the sketches of selected biological specimens (feather, fish scale or arthropods such as tick, woodlouse, spider and dragonfly larva, all fixed using 70% ethanol) using the microscope and stereomicroscope (Olympus CX31, Olympus SZ51). Each pre-service teacher received the worksheets with adequate space for recording of observed objects without suggestions to biological drawing (to allow identifying the basic skills in drawing and basic knowledge of drawing rules from previous study of respondents at secondary school).

Sketches of the pre-service teachers were analysed with the coding tool with respect to the RQs (Table. 1.). The tool enabled to assess the individual characteristics of sketches and afterwards the data were analysed with basic statistical methods.

The assessment of sketches followed five basic characteristics: (1) quality of lines – purity and continuity; (2) drawing correctness – overlap, half-done lines, unclosed contours; (3) objective correctness – recording of essential characteristics of specimens, recording of artefacts; (4) large; (5) occurrence of misconceptions.

Table 1. Coding table for the assessment of sketches.

	1	2	3	4
quality of lines	very poor	poor	satisfactory	correct
drawing correctness	very poor	poor	satisfactory	correct
objective correctness	very poor	poor	satisfactory	correct
large	very poor (very small)	poor (small)	satisfactory	correct (adequate large)
occurrence of misconceptions	principal	considerable	petty	without

RESULTS

Results showed mistakes in all observed parameters. (Fig. 1)

(1) Quality of lines: On average about 31 % of respondents used very negligent drawing style and unsuitable lines characterized by interrupting, undulation and irregular thickness. There is unequal representation of mistakes at several specimens. The pictures of fish scales were the poorest sketches (very poor quality at 51 % examples). When draw this specimen it is necessary to use many small and thick lines and possibility of error is relative higher than in the case of uncomplicated specimens.

(2) Overlap and connected imperfections, as half-done or slack lines: There were found mistakes in up to 33 % of sketches, especially in case of drawing objects with many small and repeated structures (e.g. feather). The sketches of bigger objects and structures (e.g. whole body of arthropods) showed better quality, but there were found the same mistakes as mentioned above in details of these sketches.

(3) Objective correctness: This is the major parameter in relation to the demands on biology drawing. It is connected with visualisation of scientific thinking. In general, we can say that drawn objects were identifiable, but about 53 % of sketches corresponded with the reality only remotely (32 %) or not at all (21%). There is very small representation of correct sketches (about 7 % in all specimens). Usually sketches have average quality with larger or smaller mistakes and recognizable defects. Drawing of the arthropods specimens was shown as very difficult for respondents. (Figs. 2, 3, 4, 5, 6, 8)

(4) Size of the sketch: In this case the respondents' sketches were large enough with exception of few sketches. (Fig. 7)

(5) Misconceptions: Some observed structures were recorded with errors (mainly in the case of arthropods body). For example, there was absence of segmentation of body, legs or antennae or whole parts of body. The segmentation of body or legs absented relatively often. Crossing of contours and false visibility of body parts was frequent problem as well. Lack of experience with the use of stereomicroscope can be the reason for it. In the specimens and microscopy slides respondents identified some artefacts (bubbles, dust, rift, fibres) incorrectly and they identified them as common structures. They drew these structures without consideration of their origin. Described problems can show vague knowledge of some parts of curriculum and in this case biological drawing can provide valuable information about knowledge or competencies of students (pre-service teachers as well). (Fig. 2)

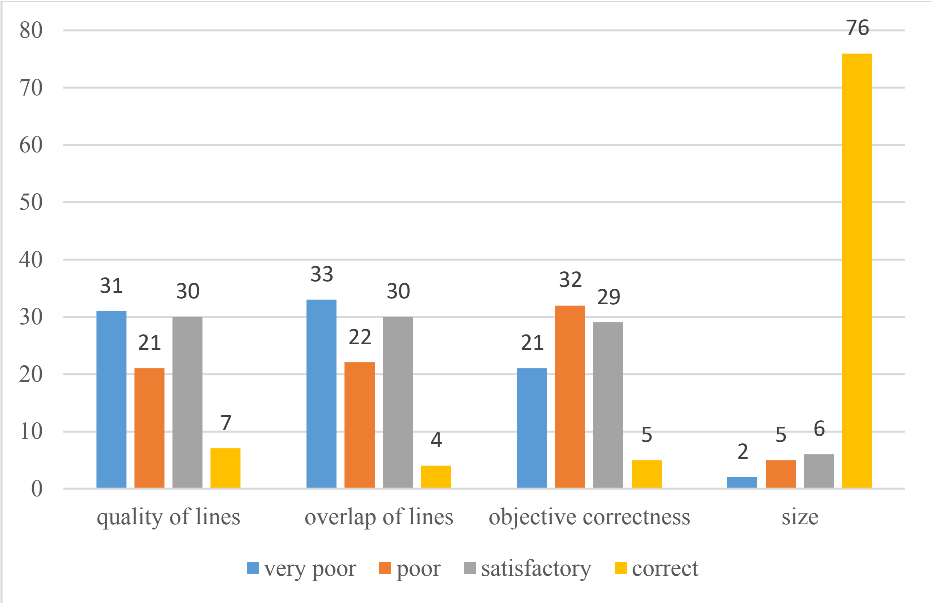

Figure 1. Quality of the sketches with regards to typical mistakes and offences against drawing rules (%).

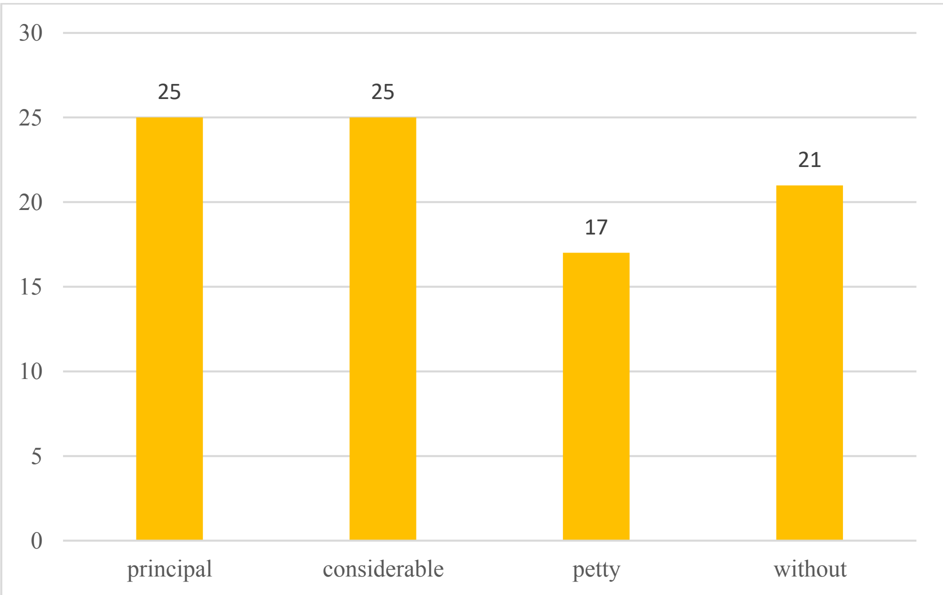

Figure 2. Frequency of misconceptions in the sketches (%). (Principal – e.g. missing segmentation in the pictures of arthropod body or legs; considerable – e.g. incorrect shape or position of details; petty – e.g. some artefacts considered as part of specimen, other objects were drew correctly; without – whole picture corresponds to the reality).

Figures 3. The microphotography made from microscopy slide of tick (*Ixodes ricinus*)**.** (Photo J. Petr);

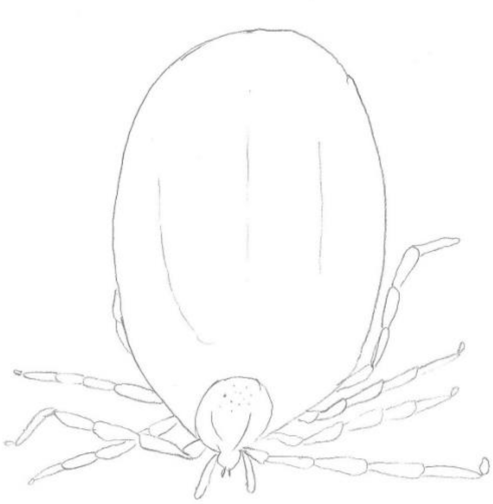

Figure 4. Relatively right sketch of the specimen. (Physical proportions of the body, segmentation of the legs and some structures on the surface of body are right captured; some minor mistakes in quality of lines are visible)

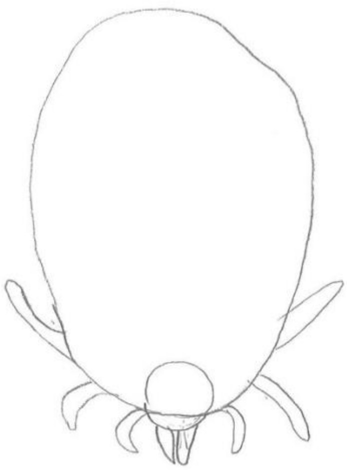

Figure 5. Wrong sketch with visible principal misconceptions. (Absent segmentation of the legs which are similar to undefined lobes, vague mouth apparatus, incorrect number of legs)

Figure 6. Evident effort to record all details of the ventral side of tick body. (There are technical mistakes in comparison with rules of biological drawing – overlapping and crossing of lines, poor quality of some lines – double or thick lines).

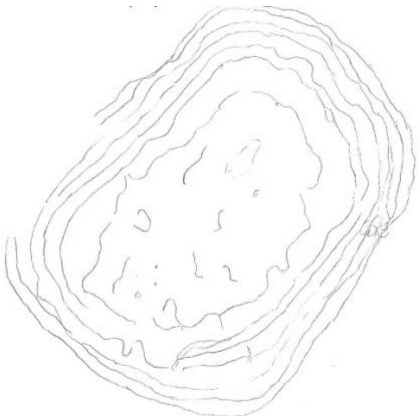

Figure 7. Sketch of fish scale. (There are technical mistakes in comparison with rules of biological drawing – repeated half-done lines, absented details like pigment cells).

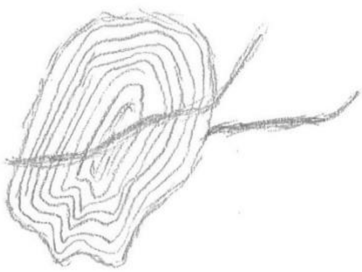

Figure 7. Sketch of fish scale. (Very small picture – original size about 3 cm, visible artefacts – cross lines – probably fibre from a cloth).

Figure 8. Sketches of two fish scales. (Unclear shape and position of some structures, crossing and double lines with their poor quality).

DISCUSSION AND CONCLUSIONS

Pre-service biology teachers had often poor skills connected to the biological drawing. The repeated mistakes were frequent in every domain characterized by each individual rule for appropriate biological drawing.

(RQ1) The pre-service teachers followed standard rules of biological drawing only particularly. It is challenge for next steps in teacher preparation not only in didactics but also in special/specific subjects and labs.

(RQ2) Pre-service teachers were not able to record all attributes of specimens correctly without deeper knowledge in appropriate subject or topic. All students or pre-service teachers do not have to draw pictures in artistic quality or quality created by experts in biology drawing but basic documentary skills are needed for future teacher practice.

(RQ3) Typical mistakes were found in the most of students' sketches.

(RQ4) It was possible to recognize some misconceptions in sketches. The question is whether it is caused by lack of knowledge or imperfection in drawing. If mistakes in biological drawing are caused by misconceptions, we can use drawing in evaluation of quality of education. For example this method was mentioned by Köse (2008).

The preparation of special course focused on the rules and principles of biology drawing could be very useful in pre-service biology teacher education. It is also necessary to develop their drawing skills during all labs courses in their study. Methodology described by Watson & Lom (2007) presents very useful tool for development of pre-service teachers' drawing skills within their professional training/preparation.

CELL BIOLOGY ANALOGIES IN BRAZILIAN BIOLOGY TEXTBOOKS: A TEACHER GUIDE BASED ON FAR MODEL

Iago Oliveira[1], Carla Y Araujo[1] and Zara Guimarães[1]

[1]University of Brasília, Brasília, Brasil

From a well-established model for the use of analogies in science teaching (Focus, Action, Reflection – FAR Guide) this research aimed to develop a teacher support resource (teacher guide) based on the four most frequent cell analogies in Brazilian biology textbooks which were: DNA as a spiral staircase, complex substrate enzyme as a key and lock, ATP as currency and mitochondria as a power plant. This teacher guide was evaluated by pre-service biology teachers from a Brazilian public university. Perceptions and recommendations were collected by questionnaires, participant speeches' recording and a field notebook. Students' responses were tabulated and analyzed, and these results were evaluated for a current version of the teacher guide. The comprehension of the content was perceptible by the majority of participants, however some of them showed doubts about analogies' limits. FAR Guide was considered a good way to plan use of analogies to a cell biology class and a viable didactic resource to be used in the Brazilian educational context.

Keywords: Classroom Discourse, Higher Education, Biology Education

INTRODUCTION

Analogies are used in different ways, contributing to science learning and teaching, teacher training, and even as research tools (Aubusson, Harrison, & Ritche, 2006). Analogies and metaphors are ways of comparing structures or processes from two different domains, from their similarities, with the intention of expressing something unknown or unfamiliar through something known or familiar (Duit, 1991; Aubusson et al., 2006). The familiar domain is called an analogy and the unfamiliar domain is called a target and, through analogical reasoning, the similarity relationships between these two domains are traced, giving rise to an analogical model (Duit, 1991).

Analogies can benefit the learning of new concepts allowing the student to build relationships between their previous knowledge (analogies) and scientific knowledge (targets) (Glynn, 1991). They also play an important role in the interpretation of scientific complex models by providing mental models from familiar analogies that, although limited, clarify natural phenomena until to learn more complex models (Glynn & Takahashi, 1998). The use of analogies allows an easier and more concrete perception of abstract concepts and structures that are not very tangible to students (Duit, 1991; Treagust, Harrison, & Venville, 1998), as is the case of content related to cell biology.

With regard to cell content, simple analogies are recurrent in Brazilian biology textbooks (Araujo & Guimarães, 2017) and teaching material to assist a systematic presentation of analogies is practically absent in these textbooks. In this way, we see an opportunity to produce support material for biology teacher. To this end, despite the popularity of Teaching With Analogies - TWA (Glynn, 1991) in Brazil, our research team chose Focus-Action-Reflection (FAR) Guide for Teaching with Analogies and Models (Treagust et al., 1998; Aubusson et al., 2006; Harrison and Treagust, 2006; Harrison and Coll, 2008) for being a pedagogical process that includes not only in-class actions, but also "two important aspects of effective teaching, namely, lesson planning and post-class reflection. A model was sought that would encourage teachers to think about and their presentation before, during, and following lessons in which analogies were used." (Treagust et al., 1998, p. 88).

In this article we report results of a qualitative research on perceptions of Brazilian pre-service biology teachers from a public university about a teacher guide developed according to Focus-Action-Reflection (FAR) Guide for Teaching with Analogies and Models (Treagust et al., 1998). This teacher guide was designed for the most frequent cell analogies in Brazilian biology textbooks. The research took place in a broader context (Oliveira, 2019) also involving biology textbooks analysis, selection and mapping of cell analogies, as well as the collect and analysis of students' prior knowledge about analogies. These results were not included in this article.

METHODS

From the well-established Focus-Action-Reflection (FAR) Guide for Teaching with Analogies and Models (Treagust et al., 1998), a teacher guide was developed for the four most frequent cell biology analogies in Brazilian biology textbooks according to Araujo & Guimarães (2017) and Oliveira (2019). The teacher guide was based on Duit (1991), Treagust et al. (1998), Aubusson et al. (2006), Harrison and Treagust (2006), Harrison and Coll (2008). Our major goal was to develop a teacher guide which could assist Brazilian in-service biology teachers when using biology textbooks in public high schools in their classes about cells.

In concern to teacher guide design, it was formatted in two parts. The first part was concerned to explain, in a general way, the role of analogies in science teaching and how they work in this context. For these purposes, a definition of the theme and an example of a cell analogy was presented: the comparison between the structure of a eukaryotic cell with a city, in a similar way to Venville (2008). Also included in the first part of this teacher guide are the positive and negative points from the use of analogy in science teaching, a historical example of the use of an analogy by a scientist, and a brief explanation of the FAR Guide phases. The second part of the teacher guide had as objective, based on the FAR Guide, to help biology teacher to use the four most frequent cell analogies in Brazilian biology textbooks which are regularly distributed by Brazilian government to public schools through the National Textbook Program. These most frequent analogies were: adenosine triphosphate (ATP) as currency, DNA structure as a spiral staircase, mitochondria as a power plant and the specificity between enzymes and substrates compared to a key and lock.

The structure of the FAR Guide was maintained with the "three stages for the systematic presentation of analogies and resembles the planning phases of expert teaching and the action research model" (Harrison & Treagust, 2006, p. 20). For each analogy, a text was prepared for the Focus and Reflection phase according to the contents of the target and analog domains adopted. In Focus phase, Concept, Students and Experience parts were inferences related to our team-teaching experience. The Action stage was presented through similarities and differences between each specific domain resulting in mappings. In addition to the steps of the FAR Guide, some parts of textbooks with the respective analogy were transcribed. Similar to what was done in FAR Guide publications (Treagust et al., 1998; Harrison & Coll, 2008), images of each target and analogy were also included in order to illustrate the two different domains.

The teacher guide was evaluated by 54 Brazilian pre-service biology teachers from the University of Brasília (Brasília, Federal District, Brazil). For its analysis, interventions were made during the 2018 second academic semester in different courses in which these students were enrolled. After oral presentations about general aspects of the use of analogies in teaching biology, carried out by our team, students organized themselves into small groups and received the teacher guide for analysis. Each small group has received a specific analogy to consider.

The results of this research are concerned about the second part of the teacher guide which was based on FAR Guide. Students' perceptions and recommendations were collected by questionnaires, participant speeches' recording and a field notebook in a qualitative research approach (Bogdan & Biklen, 1994). Each student answered, according to a specific analogy, five questions regarding the clarity and functionality of each phase of the FAR Guide being possible to make comments and suggestions. Data were tabulated and analyzed in Gibbs' perspective (2009), and results were considered for the current version of teacher guide.

RESULTS AND DISCUSSION

Overall, the teacher guide was evaluated positively by the 54 participants. The FAR Guide developed for the "ATP as currency" analogy was also positively evaluated in all aspects by 17 students. Despite this, some students commented that this analogy should be used with caution to avoid alternative conceptions of the target. One of the students pointed out that the domains are very different, maybe creating some difficulties in the learning process of the target. In face of this observation, it was clear that teacher guide did not allow the understanding of the analogy, which is even presented in Alberts et al. (2017), a reference for pre-service biology teachers during their cell biology courses. Probably, the participant's perception was due to the image chosen to illustrate this analog - a stack of coins - and may imply that the analogy - ATP as currency - would be structural, rather than functional. It is noteworthy that the inappropriate image selection also did not help the student to understand the analogy that is presented in textbooks as follows: "ATP is like energy currency" without any complementary explanation. In current version of teacher guide, a new image was chosen which illustrate a shopping transaction, which is the essence of the analogy in question.

In the other hand, another research participant argued that this analogy is only functional maybe being not efficient to the scientific concept's understanding. As pointed out by Duit (1991), all analogies, by definition, are limited. Venville (2008) stressed about some consideration to be taken in the first two steps, Focus and Action, of the FAR Guide to be sure to explain about analogy and target's attributes. Therefore, recognizing the limits of an analogy is a fundamental factor to stimulate the use of analogical reasoning properly. Because this discussion appeared in other occasions during this research, an additional information related to analogical relationship, as pointed by Curtis and Reigeluth (1984), was included in the current version of teacher guide.

The part of the teacher guide related to the "DNA/spiral staircase", in general, was well evaluated by 15 students. However, some students did not agree with certain parts of the teacher guide, reporting their dissatisfactions with the fact this analogy only serves to explain the structure and does not allow the explanation of the function of the DNA molecule. As in the ATP analogy as currency, these pre-service teachers had difficulties in recognizing the limits of the DNA/spiral staircase analogy that is, in fact, exclusively structural according to Curtis and Reigeluth (1984). A student stressed that she understood the analogical model but recommended the inclusion, in the teacher guide, a greater emphasis on the fact that this analogy is exclusively structural. Another student clearly questioned whether the analog (spiral staircase) is part of her daily life and proposed a school activity to explore the analogy more efficiently. It is emphasized that, in every analogical model, the analog needs to be recognized by the receptor, therefore, the participant's point of view is relevant in the school context (Venville, 2008). As the analogy was assessed using and instructional material prepared by our team and not by a classroom dynamics, as the FAR-Action step assumes to be (Treagust et al., 1998), research participants' familiarity with the analog was not checked and the above student soon realized the need for check receptor's familiarity when using any analogy in the classroom.

During the analysis of the teacher guide's FAR-Reflection phase, one of the students asked: "Would it be interesting to bring another analogy for students to explain the function of DNA, such as an analogy between DNA and the alphabet?", realizing that this analogy also needed for further explanation. The alphabet analogy was included in the teacher guide as inference elaborated by our team when developing the activities of the FAR Post-Lesson Reflection phase, specifically regarding to Improvements. This part was planned to encourage teacher to reflect on the following questions: "What changes are needed for the following lesson? "and "What changes are needed next time I use this analogy?" (Harrison & Treagust, 2006, p. 21). It was noticeable that the insertion of a new analogy in no way helped the FAR-Reflection phase and do not answer these questions. In the current version of teacher guide the alphabet analogy was removed from Improvements.

The students also emphasized that the image adopted to exemplify the spiral staircase could cause confusion for not illustrating a staircase with two handrails, which would be more suitable for comparison with the molecular structure of DNA model. With this perception and that one related to ATP analogy, a more careful image selection had to be done by our research team, also taking in account that in the Brazilian biology textbooks, with regard to the cell content, there are few pictorial-verbal analogies as emphasized by Araujo and Guimarães (2017).

In the teacher guide, the concept of mitochondria was explained in an analogous way by comparing organelle functions to that of a power plant. From the total of 13 student who analyzed this analogy, one of them suggested that in the FAR-Focus of teacher guide, the explanation of the analog should be close to that of the target concept and not interspersed with the projections of possible students' conceptions in relation to the target concept. Such change, in the participant's point of view, could facilitate the reader's understanding about the analogy. However, the FAR Guide is systematically presented with information from Pre-Lesson Focus in the following order: Concepts, Students and Analog (or Experience) (Treagust et al.1998; Harrison & Treagust, 2006; Venville, 2008). According to cited authors, first teacher reflects on the concept: “Is the concept difficult, single-family or abstract?” (Harrison & Treagust, 2006, p. 21). Then, the concept is analyzed from the students' perspective: “What ideas do the students already have about the concept?” (Harrison & Treagust, 2006, p. 21). Finally, teacher thinks about analogies “What familiar experiences do students have that I can use?” (Harrison & Treagust, 2006, p. 21). The teacher guide was modified following the student's recommendation. But, in future applications of the FAR Guide, we will return to the original sequence verifying, using data from further research, whether such a change is, in fact, really necessary over the logical sequence established in the FAR Guide.

Several students questioned the feasibility of using the mitochondria / power plant analogy considering that it is an analog difficult to understand: the operation of a power plant that produces energy. Such perception is related to a fundamental aspect in the use of analogy in the classroom: analogies facilitate learning when comparing something unknown with something known (Aubusson et al., 2006). According to Araujo and Guimarães (2017) and Oliveira (2019), the analogy in question is presented, in general, in biology textbooks as simple analogy (“mitochondria is a power plant”), usually without complementary explanations and leaving the responsibility for the textbook reader to understand it. In addition, the analogy refers to a specific aspect of mitochondria functioning explored in detail by Alberts et al. (2017), a reference used by Brazilian biology textbooks’ authors, and is related to the ATP synthase. In Brazilian biology textbooks, such an analogy is rarely put as follows: “At certain points in the membrane, however, protons can return to the mitochondrial matrix, and in doing so, similarly to what happens in a generator of hydroelectric plant, but in much smaller proportions, they literally spin a molecular rotor. This process, which generates ATP and is called chemiosmosis” (Bizzo, 2016, p. 143). As the main objective of the teacher guide is to assist the teacher who is faced with such an analogy in Brazilian biology textbooks, it will be up to the professional to decide whether or not to explore it in the classroom, ascertaining the student familiarity with the analog. However, it is considered that the most salutary in this research was the perception of participants of the need to establish student familiarity with the analog, as highlighted by Treagust et al. (1998, p. 85): “When using an analogy in science teaching, teachers should select an appropriate student world analog to assist in explaining the science concept.”

A student wrote the following: "In the textbook section, it was not clear to me whether it is considered a good or bad use of the analogy". This perception came from the Bizzo excerpt (2016, p. 143) shared above and which stands out, in relation to other biology textbooks, for being an enriched analogy according to Curtis & Reigetluth (1984). Therefore, we must still continue to test if insertion of excerpts from textbooks helps or not the teacher guide user, even if in current version the textbooks’ excerpts have been maintained.

The key and lock analogy had the least number of analysis (9), with participants evaluating it positively and being readily recognized as a familiar analogy. The main point highlighted by the participants was the presence of five marked differences between the domains, a higher number than that presented in the mapping of the other analogies. But it is also important to highlight that even in the face of the obsolescence of this analogy, this aspect was not accentuated by the students who analyzed it. Nelson and Cox (2014) reported that Emil Fischer in 1984, from his findings, postulated that the structures of enzymes would be complementary to their substrates, such as a key and lock. Subsequently, with advances and discoveries in the area, it is now understood that this analogy does not explain perfectly this molecular interaction. However, this analogy still remains in the Brazilian biology textbooks. This perpetuation is due to the fact that the National Textbook Program took into account, in the biology area, the understanding and recognition of the history of science as something beneficial for biology teaching, allowing the presence of this analogy in the biology textbooks with the purpose to stimulate discussions about how scientific knowledge is constructed (Ministério da Educação, 2017). However, none systematic presentation of this analogy is found in biology textbooks, leaving it up to the biology in-service teacher how to use and explore this analogy, not exactly in the perspective intended by the National Textbook Program.

In general, the second part of teacher guide that incorporated the FAR Guide for certain analogies of cell biology was positively evaluated by the participants. Even with the sharing of some criticisms and reservations, 52 students stated that they would use the teacher guide, making recommendations regarding its format and content. Only two students answered that they would not use the teacher guide, claiming that they did not like the analogy they received to carry out the analysis or because they did not feel comfortable using analogies as teaching resources. One of the questions in this research addressed whether the teacher guide would assist in conducting a cell biology class with analogies, and all responses were positive without any reservations. A total of 35 participants wrote that they would explain the contents about the cell with the teacher guide. Of this total, 24 participants would adopt the analogies to start explaining cellular concepts, as one of the students explained: “Just in the situation of explaining about this subject in biology, because I think it is much clearer and easier to learn if you compare something you have already know with something you would like to learn”. The other 11 participants, on the other hand, would also adopt analogies to explain scientific concepts, but as a second option and after a previous explanation of the target concept, a situation exemplified in the response of another student: “I would use it to consolidate the concept of DNA structure after an expository class on each of the elements”. It is noted in these considerations that the participants of this research would choose to use the analogy in the perspective of Glynn (1991) and Glynn and Takahashi (1998). And, mainly, these Brazilian pre-service biology teachers had the opportunity to analyze an instructional material based on the FAR Guide for Teaching and Learning With Analogies (Treagust et al., 1998; Harrison & Treagust, 2006; Harrison & Coll, 2008), a valuable systematic presentation of analogies still not well-known in Brazil.

CONCLUSIONS

To develop, by FAR Guide, and to test a teacher guide to help the use of cell analogies presented in the Brazilian biology textbooks allowed us to verify that Brazilian pre-service biology teachers are interested in an instructional resource which help to plan the use of analogies.

Most of the analogies related to the cell biology content were presented in the Brazilian biology textbooks without additional explanations (for example, their limits) when compared to the scientific concepts and the participants of this research demonstrated difficulties in realizing that any analogy, by its nature, has such limitations.

Brazilian pre-service biology teachers realized the need to be cautious in the use of analogies in the classroom to avoid alternative conceptions of scientific concepts by students and also the need to establish student familiarity with the analog.

The pre-service teachers' perceptions enabled us to verify that when choosing images to illustrate the analog and inserting it in an instructional material, a careful selection must be made, taking also into account that in the Brazilian biology textbooks, regarding the content of the cell, few analogies are pictorial-verbal.

FAR Guide can become an excellent instructional material complementary to biology textbooks distributed in the Brazilian territory, taking into account that, in the case of cell biology, scientific content is abstract, simple analogies are the most recurrent in these textbooks, with the absence of supplementary instructional material to assist teacher to present analogies in a systematic way.

MODELLING TEACHERS' CONTENT KNOWLEDGE IN PARTICLE PHYSICS

FINAL RESULTS FROM A DELPHI STUDY

Michaela Oettle[1], Silke Mikelskis-Seifert[1]
[1]University of Education, Freiburg, Germany

This project aimed at modelling the professional content knowledge teachers need to have in order to teach particle physics. We focussed on modelling subfacets of the knowledge dimension "content areas" by identifying relevant key concepts in particle physics and precisely describing them. The research design followed the Delphi method: During three consecutive survey rounds, a panel of experts from particle physics research, teaching and outreach were asked to name and characterise the key concepts in particle physics which are relevant for a secondary school physics teacher to know about. As result of the first two survey rounds, a content validated system of 10 knowledge categories and 35 subcategories could be established. In the third survey round, a definite consensus among the experts about the most relevant knowledge categories was reached. Additionally, the knowledge categories were also evaluated by teachers who have already taught particle physics in their classes. The common consensus of experts and teachers revealed the exceptional importance of 6 knowledge categories: Fundamental interactions, the structure of matter, particles in high energy physics, the role of particle physics in cosmology, types of experiments in high energy physics, and nuclear physics and radioactivity on particle level. Comparisons between the experts' and the teachers' opinions gave deeper insight into the way both groups argue when choosing the most important knowledge categories. The final results of the Delphi study – a well-structured and precisely described knowledge domain – can be regarded as normative target for teachers' content knowledge in particle physics and could function as a basis for the development of teacher training programmes.

Keywords: Teacher Content Knowledge, Particle Physics, Delphi Study

INTRODUCTION

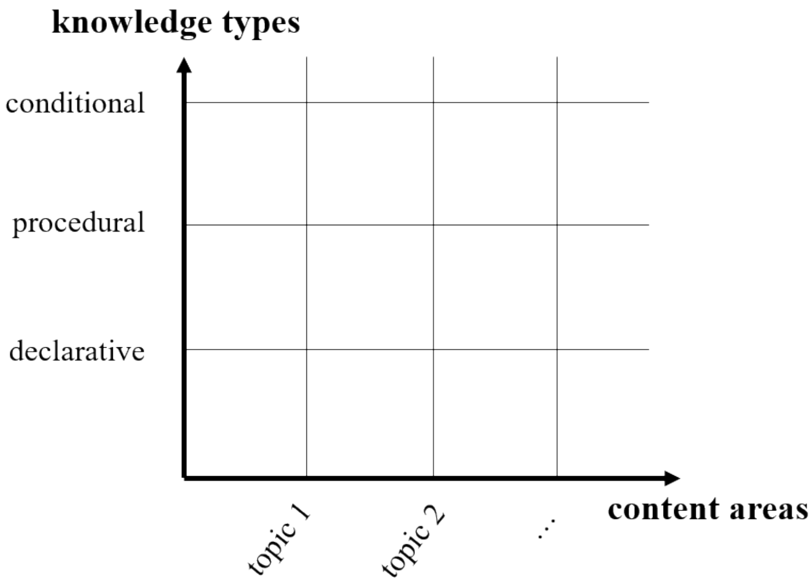
Motivation

Particle physics as a field of research addresses the investigation of subatomic structures such as the elementary constituents of matter and their interactions among each other. The rapidly evolving research in the field of modern particle physics along with the accompanying development of everyday applications and the media attention makes the topic intriguing for young people, i.e. school pupils. On the level of educational policies, the subject is in the progress of being included in scholar curricula. However, teaching particle physics can be challenging for teachers due to the complexity and the advanced level of the topic compared to other physical domains. Additionally, there is no consensus in science education research neither about the selection of particle physics issues to be taught in a secondary school physics class nor about the special knowledge that teachers need to have in order to teach this content. Here is where the project comes in: We aim at modelling teachers' content knowledge – as part of their professional knowledge - pertinent to the field of particle physics.

Theoretical Framework

Content knowledge is regarded as a central component of a teacher's professional knowledge (Shulman, 1986; Borko & Putnam, 1996). Modelling professional knowledge in general and in particular modelling content knowledge with the aim of working out a deeper knowledge structure is usually based on a conceptualization in different *knowledge dimensions,* each comprising in turn several *subfacets*. Research studies using the most elaborated and detailed model to structure the content knowledge especially in physics were mainly conducted in Germany: Following the findings from educational psychologists such as Paris et al. (1983), the project *ProwiN* (Tepner, et al., 2012), for example, focussed on the one hand on modelling the dimension of *knowledge types* (comprising the subfacets *declarative*, *procedural* and *conditional knowledge*). Simultaneously, *ProwiN* modelled the dimension of *content areas* (comprising different physical topics in mechanics). A schematic representation of a knowledge structure with two different dimensions, as for example modelled by *ProwiN,* can be found in Figure 1.

Figure 1. Schematic representation of a teacher's content knowledge as product of the dimensions content areas and knowledge types.



Comparing all such available models for teachers' content knowledge in physics reveals the importance of the dimension *content areas* which is used in all models as a frame of reference. The issue of modelling this important dimension especially for the domain of particle physics is addressed in the presented project.

METHOD

Research Questions

Modelling teachers' content knowledge in particle physics and focussing on the dimension of *content areas* needs to answer the following question: Which subfacets in terms of content can be identified and precisely described? In other words, we aim at gathering those key ideas in particle physics which are essential for a teacher to know about.

Research Design

The research design follows the Delphi method used in forecasting (Linstone & Turoff, 1975): A panel of experts from particle physics research, teaching, and outreach were asked to name and characterise the key ideas in particle physics relevant for a secondary school physics teacher to know about. The chosen Delphi design comprises three consecutive survey rounds and eventually strives for establishing a consensus among the participating experts about the most relevant key ideas. Each survey round was realized methodologically by means of an online survey containing open and closed questions. The survey rounds at a glance:

- *Round 1:* Open nomination of potentially relevant key ideas by the experts and development of a first model draft by assignment of the answers to a system of knowledge categories and subcategories
- *Round 2:* Content validation of the model draft using approvals, additions, and corrections to the draft given by the same panel of experts
- *Round 3:* Relevance rating of the remaining knowledge categories by the same experts as well as by experienced physics teachers to find a consensus about the most important topics for teachers' content knowledge.

ANALYSIS AND RESULTS

Survey Round 1

N=65 experts from 14 countries participated in the first survey round. The key ideas in particle physics named by the experts were assigned to 10 knowledge categories and 41 subcategories using a qualitative content analysis (Mayring, 2014). The overall interrater reliability between two raters assigning the answers to the categories was Cohen's $\kappa=.95$ showing excellent agreement. Additionally, the empirically established categories were triangulated with the literature by matching the categories to topics in standard text books for particle physics university courses. Besides the category titles, more detailed definitions in the form of a short summary for each subcategory could be derived from the experts' answers.

Survey Round 2

Proving the content validity of the categorical model from round 1 relies fundamentally on the question, if the derived system of categories covers the targeted content knowledge in all its facets - and only in that. For this purpose, in the second online survey, the experts were shown the system of categories derived from round 1 and were asked to evaluate it[1]. The following items were asked for each main category:

- 1 closed item: *How well do the shown subcategories cover the knowledge a teacher needs to have about the displayed main category?* (continuous rating with possible values between 0 and 100%)
- 2 open items: *Are any of the shown subcategories no part of the knowledge a teacher needs to have? Are there any fundamental aspects missing in the displayed list of subcategories?*

N=56 experts from 11 countries participated in the second survey round. Two thirds of the participants already contributed to survey round 1.

Concerning the closed rating item, the descriptive statistical parameters such as sample size *N*, mean, and standard deviation *SD* – rounded to integer numbers - are displayed for the ten main categories from round 1 in Table 1. The overall high values of the means show the experts' approval to the derived system of categories.

Table 1. Acceptance of the main categories derived from round 1 by the experts in round 2.

Main Category	N	MEAN [%]	SD [%]	D_{mn} (KS)	p (KS)
The Structure of Matter	12	92	9	0.72	< .001***
Particles in High Energy Physics	16	90	16	0.68	< .001***
Principles from SR and QM; QFT	10	80	24	0.49	.013*
Fundamental Interactions	15	85	21	0.59	< .001***
Symmetries & Conservations	13	93	11	0.69	< .001***
Particle Interactions & Decays	11	78	23	0.55	.003**
Higgs – Mechanism and Boson	15	91	16	0.62	< .001***
The Standard Model	14	85	13	0.62	< .001***
Cosmology	14	80	18	0.50	.002**
Open Questions	15	77	19	0.46	.003**

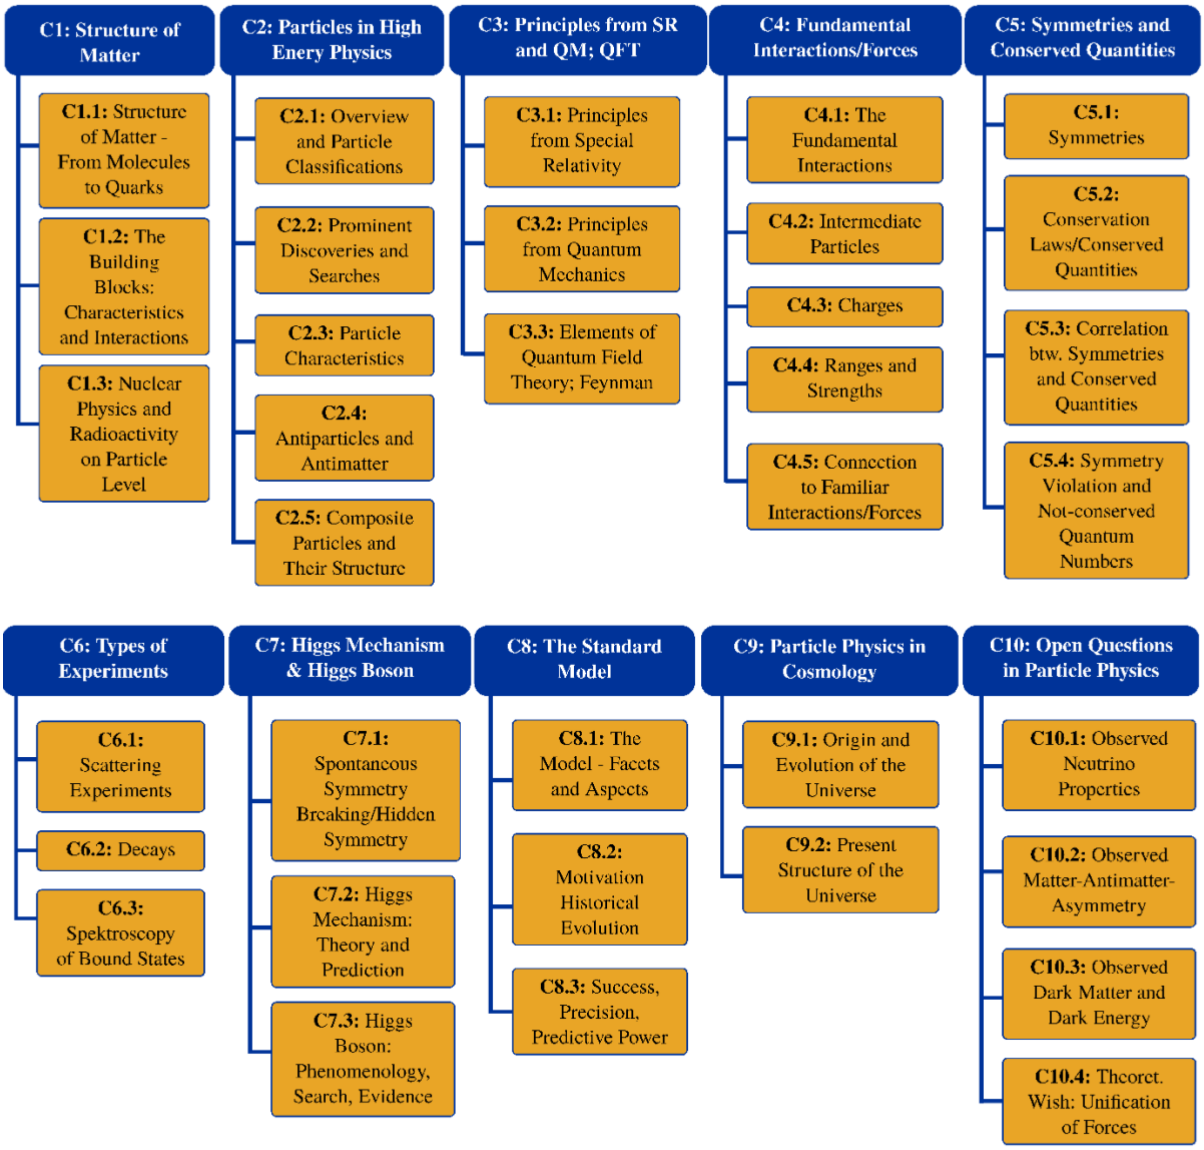
In order to assess the significance of the displayed results considering the small sample sizes for each category, we quantified how much the data deviates from a completely random rating behavior among the experts. For this purpose, the distribution of the measured data in each category was compared to the randomly expected uniform distribution using a *Kolmogorov-Smirnoff (KS) test* (see for example Daniel, 1990). The test statistic D_{mn} of the KS-test and the corresponding p-values are also listed in Table 1. These parameters show that the observed data deviates in each category significantly from a random rating by the experts.

The two open items in survey round 2 served to optimize the system of categories and subcategories derived from round 1. Using again a qualitative content analysis, we identified frequent proposals in the experts' open answers for removing or adding subcategories from or to the system. The interrater reliability for assigning the answers to an inductively derived system of proposals between two raters was Cohen's κ=.68 showing substantial agreement.

[1] Due to the large number of categories, each expert received for the evaluation only three out of the ten main categories as well as the corresponding subcategories and definitions.

The most frequently given proposals to change the system of categories were subsequently applied to the system. As result, the new system after round 2 comprised 10 knowledge categories with only 35 remaining subcategories. The content validated and optimized system resulting from survey round 2 is shown in Figure 2.

Figure 2. Content validated system of knowledge categories and subcategories as model of the content knowledge teachers need to possess in order to teach particle physics.



Survey Round 3

The following questions were central to the third and last survey round in the Delphi process:

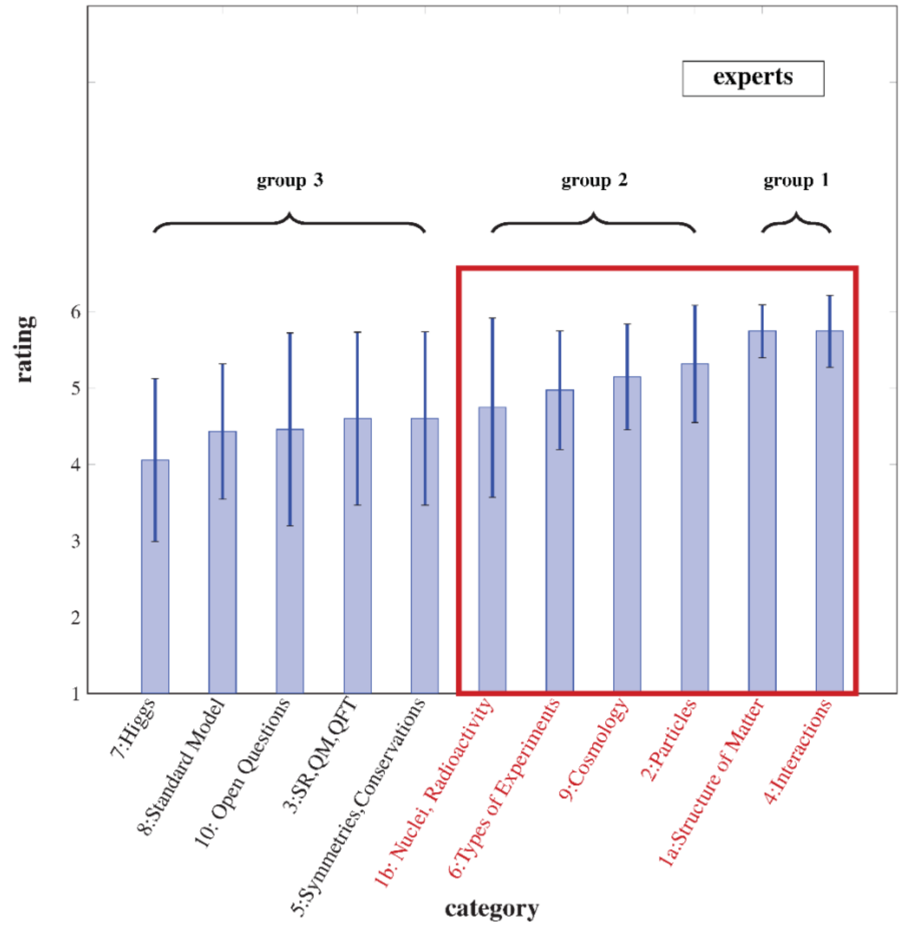
- Which of the knowledge categories determined in survey round 2 are particularly relevant for teachers' content knowledge?
- Which of the knowledge categories rated as particularly relevant by the experts can be validated from a practical point of view through similar ratings by teachers?

The first question aims to achieve a consensus among the participating experts about the fundamentally most important subject matter topics. Answering the second question involves a matching of the experts' ratings with the teachers' ratings who are regarded as practical experts.

The third survey round was again conducted by means of an online questionnaire. The participants were asked to rate all 35 knowledge subcategories from round 2 in terms of relevance for teachers' content knowledge. We used six-level Likert items with verbal anchors from "1=not at all relevant" until "6=very relevant". *N=35* experts from seven countries and *N=108* teachers from 32 countries participated in survey round 3. In order to facilitate the comparative analysis of the 35 rating items, we reduced the complexity by carrying out reliability analyses as well as exploratory factor analyses. Both types of statistical analyses showed that all subcategory ratings belonging to the same of the ten main categories are measuring the same underlying construct or factor. Therefore, the following analysis of the rating data can be conducted on the level of main categories instead of the subcategories. It should be noted that main category 1 forms an exception as there were the two factors "structure of matter" and "nuclear physics and radioactivity on particle level" that could be identified. Hence, the following analysis involves 11 new "main" categories instead of 10.

Analysing the rating data of the 11 categories solely for the panel of experts yields the bar chart in Figure 3 displaying the mean values and standard deviations of the categories sorted by mean values in ascending order.

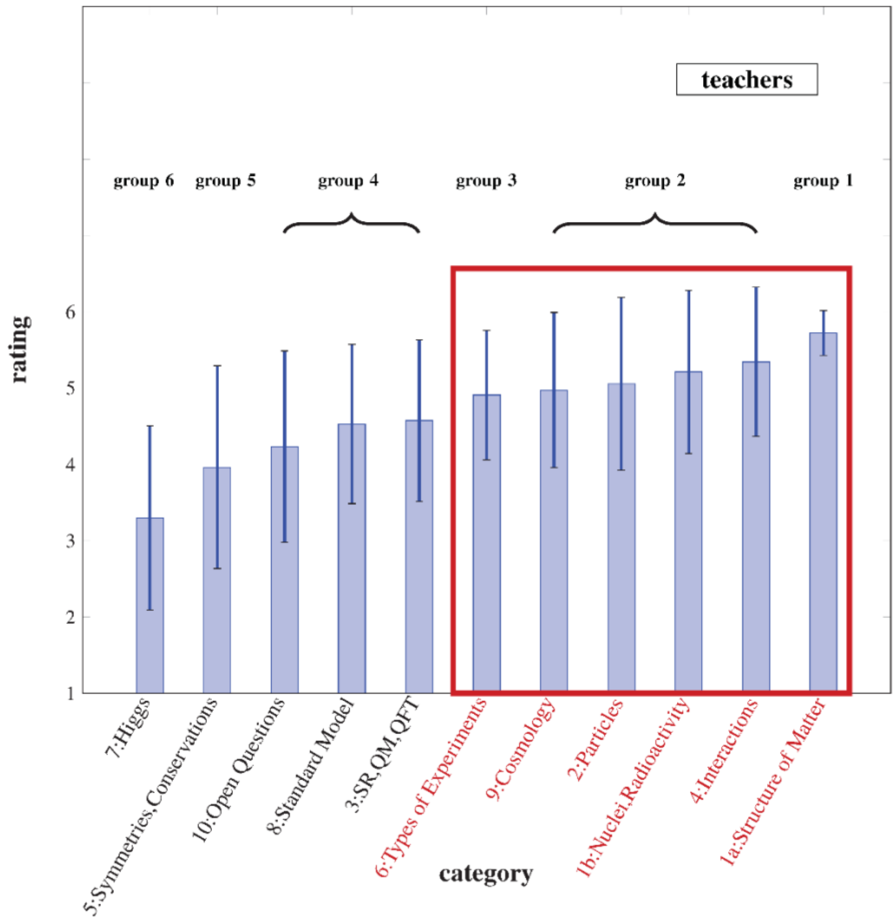
Figure 3. Mean values of the experts' relevance ratings for the 11 main knowledge categories.



Statistically significant differences in the mean values between categories were detected by means of a repeated measures ANOVA, whereby the parameters in the analysis of variance were estimated by linear mixed effect models. Adding the 11 categories as predictor to the model improved the fit to the data compared to the baseline model which only assumes the entity factor as predictor ($\chi^2(10)=135.17$, $p < .001$). Thus, the type of category affects the relevance ratings. Conducting suitable posthoc tests revealed where the differences are and which categories cannot be distinguished in term of relevance (see the three relevance groups in Figure 3). The groups of categories with highest and with second highest relevance constitute the answer to the question about the particularly important topics for a teachers' content knowledge. In the opinion of the experts, the categories about the structure of matter and about the fundamental interactions possess the greatest importance followed by the categories "particles in high energy physics", "particle physics in cosmology", "types of experiments in high energy physics" and "nuclear physics and radioactivity on particle level".

Establishing relevance groups among knowledge categories can be done in the same already described way for the rating data collected in the teacher sample. The groups of categories with non-distinguishable relevance are displayed in the bar chart in Figure 4.

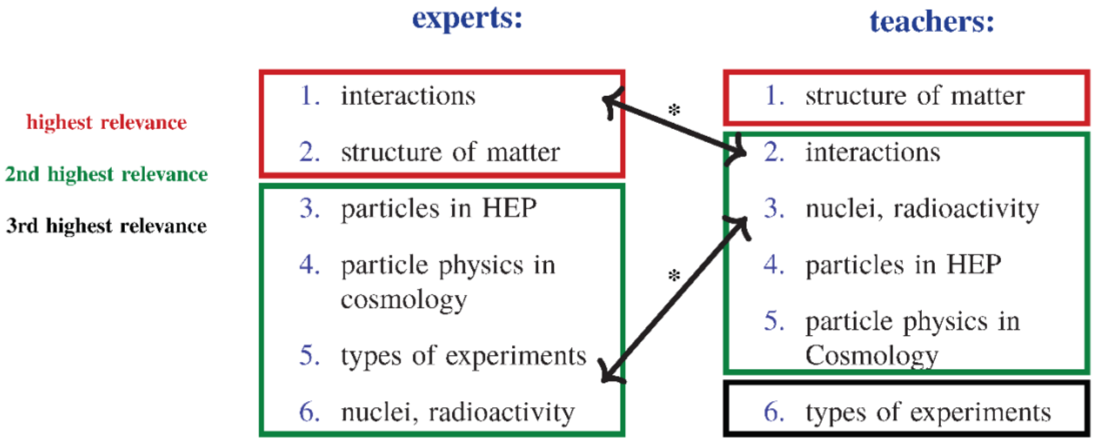
Figure 4. Mean values of the teachers' relevance ratings for the 11 main knowledge categories.



Comparing the results of the experts' and the teachers' sample in Figures 3 and 4, several differences can be detected as well as in the order of the categories as in the number of relevance groups. Nevertheless, both panels – experts and teachers – have rated the same six knowledge categories as being more relevant than the other five categories. The more relevant categories are highlighted in red in Figure 3 and 4. This answers the second questions asked in survey round 3 substantially. It can also be noted that the less relevant categories imply a higher level of mathematical modelling and abstractness (i.e. the standard model or quantum field theory) whereas the more relevant categories have a more conceptual and illustrative nature.

Directly contrasting the ranking of the six highest rated categories – as displayed in Figure 5 – yields further significant differences in the relevance ratings of the categories "interactions" and "nuclei, radioactivity" between the experts and the teachers. The significant differences were detected by conducting a factorial mixed ANOVA with appropriately chosen contrasts.

Figure 5. The most relevant content knowledge categories – TOP 6.



The differences give insight into the way experts and teachers reason. The experts rated the categories by taking into account the systematics of the subject matter domain which rely fundamentally on the standard model of particle physics and therefore to a great extent on the fundamental interactions. Teachers, on the other hand, assigned only "the structure of matter" the highest relevance and furthermore highlighted the role of "nuclei and radioactivity" compared to the experts. Thus, teachers argue from a curricular point of view since radioactivity and the structure of matter are already included in most curricula for high school level physics classes.

CONCLUSIONS AND RECOMMENDATIONS

This project aimed at modelling the dimension *content areas* of the content knowledge a secondary school physics teacher needs to have in order to teach particle physics. Conducting the Delphi study, 11 subject matter topics could be identified as being relevant for the teachers' content knowledge, six of which possess the highest relevance. The results could be used to fill the so far rather vague curricula with more details. Furthermore, the results can function as basis for the construction of future teacher training programmes in particle physics. We recommend a programme structure comprising 11 modules with an emphasis on the six most relevant topics. For the content of the modules, the definitions of the knowledge categories derived in survey round 2 should build the basis. If interested, all category definitions can be received from the authors.

APPLYING ARGUMENTATION IN PRIMARY PRE-SERVICE TEACHER EDUCATION. A TEACHING-LEARNING SEQUENCE USING COLLABORATIVE VIDEO ANNOTATIONS

Cristina García-Ruiz[1], *Jose Hierrezuelo-Osorio*[1] *and Teresa Lupión-Cobos*[1]
[1]Didáctica de las Ciencias Experimentales, Facultad de Ciencias de la Educación, Universidad de Málaga, Málaga, Spain

Argumentation process not only helps to promote the construction of new knowledge but also gives the students the possibility of participating in socio-scientific debates, approaching real Science to the scholar environment. As related argumentation competences are therefore fundamental for the professional profile of science educators, in this study, we would like to introduce a short sequence addressed to improve the argumentative competence in primary pre-service teachers through the use of collaborative video annotations. Using Climate Change Education (CCE) as a scientific context, we have designed a work sequence through examples and practical work about the argumentative process. The analysis of the preliminary results of a sample of 80 primary pre-service teachers, both at the level of preconceptions and the quality of the argumentative discourse indicates an opportunity to change the perception of this methodology regarding the advantages and improvements that the online video annotations may offer. In a subsequent study, comparisons of the pre/post-test profiles together with the productions of the students will provide a complete view of the degree of argumentation at this educational level and the improvements that should be implemented.

Keywords: Initial Teacher Education (Pre-service), Instructional Strategies, Video Analysis

INTRODUCTION

In recent years, argumentation has played an essential role in the curriculum for developing scientific thinking and critical citizens, with an increasing number of publications focused on the analysis of the argumentation discourse in science learning contexts (Jiménez-Aleixandre & Erduran, 2008). From a practical point of view, argumentation also aims to promote knowledge about the nature of Science, approaching socio-scientific contexts to students and connecting social concerns with their everyday life (Simonneaux, 2008).

As argumentation is used by scientist to relate evidence and claims thought use of warrants and backings (Toulmin, 2003), it represents a central role in the construction of explanations, models and theories (Siegel, 1995), and it is, therefore, necessary to promote it in the science classroom.

The teaching profile demands both valuable initial training and continuous professional development, updated and related to the necessities of society, which requires investing in innovative teacher preparation programs and establishing the professional competences needed for good teaching practice (Schleicher, 2011). Furthermore, it is essential to consider the design of proposals that contribute to the teacher's vision as a professional reflective of their practice (Korthagen, 2001; Mellado, 2010).

To Lupión-Cobos & Blanco-López (2016), this formation should include not only factors such as guidance and training but also other aspects related to Science Education, as its epistemological nature, the importance of scientific literacy, the development of STEM relationships and the use of relevant contexts for students learning. Thus, in initial teacher education, it is essential to promote the ability to establish relationships, argumentation and to question reality and define problems (Escudero, Vallejo, & Botías, 2008) as well as the digital competence, understood as the knowledge of the impact of technologies in the digital world and the promote collaboration to integrate them effectively (Prendes-Espinosa, Gutiérrez-Porlán, & Martínez-Sánchez, 2018), among others.

To this aim, a broad range of technologies has lately arisen to facilitate and support the learning of argumentation, with the video annotations emerging as a useful tool to identify problems and unexpected situations that can be analysed in the science classroom.

Hence, in the literature related to the development of professional skills, we can usually find proposals that employ video analysis as a strategy for teachers to learn to look professionally at their practice (Kersting, Givvin, Sotelo, & Stigler, 2010; Llinares, 2013), also developing the scientific argumentation skills necessary in the secondary classroom (Ruiz-Ortega, Márquez, Badillo, & Rodas-Rodríguez, 2018).

METHODOLOGY

With the purpose of promoting scientific argumentation skills in pre-service primary teachers at the University of Málaga (Daniel Cebrián-Robles, Franco-Mariscal, & Blanco-López, 2018) we propose a teaching-learning sequence based on the use of the digital tool CoAnnotation (https://coannotation.com) (Cebrián-Robles, Blanco-López, & Noguera-Valdemar, 2016), that helps to create online collaborative annotations. As scientific context for the design, we have chosen Climate Change Education (CCE), which affects all components of the education system (policy, legislation and curricula, among others) and promotes problem-solving skills in a collaborative way from a multidisciplinary perspective (United Nations Institute for Training and Research, 2013).

Design proposal

The complete sequence comprises six sessions, structured as indicated in Figure 1. The first session includes the pre-test, involving two main goals: to detect students' preconceptions about argumentation and to analyse the initial level of practice as well as the identification of the principal terms of arguments (forms, strategies or goals). During the second session, a teaching explanation of the different elements of the argumentation process, including Toulmin's model of argument and some practical examples are shown. Sessions third and fourth commit to the practice and auto-evaluation of argumentation through online collaborative video annotation and rubrics. After explaining the main features of CoAnnotation, students visualise a video about climate change and proceed to register their arguments in the online programme, together with an individual and collective reflexion, answering the critical question*: what is the foundation of a good argumentative essay?* Finally, each student completes the auto-evaluation process through CoRubric (http://corubric.com), an online tool that allows to create and register collaborative rubrics and analyse the results. In the fifth session, teachers provide students with their feedback about the practical activity and invite them to create an argumentation activity in the teacher role, following their recent knowledge on the topic. Students will select a video related to CCE and design the activity using CoAnnotation. Finally, the last session is devoted to the completion of the post-test and a final review of the evaluation.

SI	PRE-TEST	Students' preconceptions about argumentation	SV	FEEDBACK	Teaching feedback about the application of the argumentation process
SII	EXPLANATION	Elements of argumentation / Toulmin's model		APPLICATION	Selection of CCE video and design of activity (teacher role)
SIII	APPLICATION	Online collaborative video annotation with Coannotation© / Reflexions	SVI	POST-TEST	Students' postconceptions about argumentation
SIV	AUTO-EVALUATION	Online collaborative auto-evaluation with Corubric©		EVALUATION	Final outcomes about the evaluation of the sequence

Figure 1. Main schedule of the teaching-learning argumentation sequence

PRELIMINARY RESULTS

Here we would like to present a short insight into pre-service teachers' perceptions about argumentation as well as the level and quality of its practice prior to their instruction, outlining the difficulties they found and giving a general impression of the challenge to face in pre-service education. The preliminary results were collected from a semi-structured pre-test adapted from García-Romano (2017) and García-Romano, Condat, Occelli, & Valeiras (2016). The sample was composed of 80 pre-service teachers in their third year of undergraduate studies for primary school teachers.

First results about students' preconceptions show that 31% of pre-service teachers consider that subjects or contents to promote argumentation in science class (Figure 2) should be related to the student environment, focusing on the importance of contextualised situations for efficient learning, while only 10% regard socio-scientific issues as suitable topics.

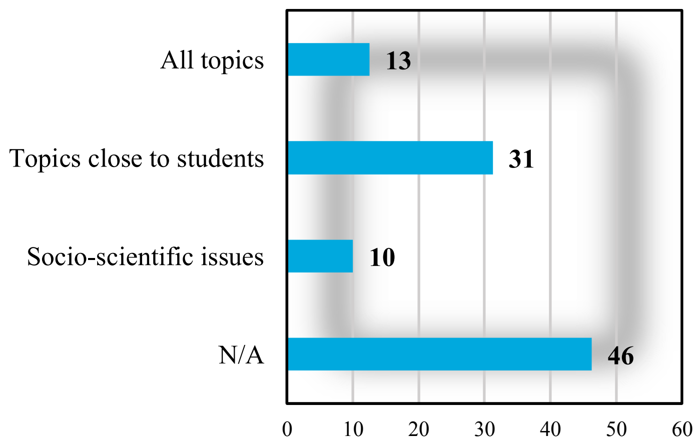

Figure 2. Subjects or contents to promote argumentation in science classroom (Data expressed in percentage of pre-service teachers)

Concerning the advantages of working argumentation (Figure 3), most pre-service teachers agree that it helps to promote critical thinking (53%), but also contributes to scientific literacy (13%). One of the main problems seems to be the low level of pre-service teachers to implement argumentation (55%), follow by other related problems such as the time required to practice it, the data management or the challenge for the teacher (Figure 3).

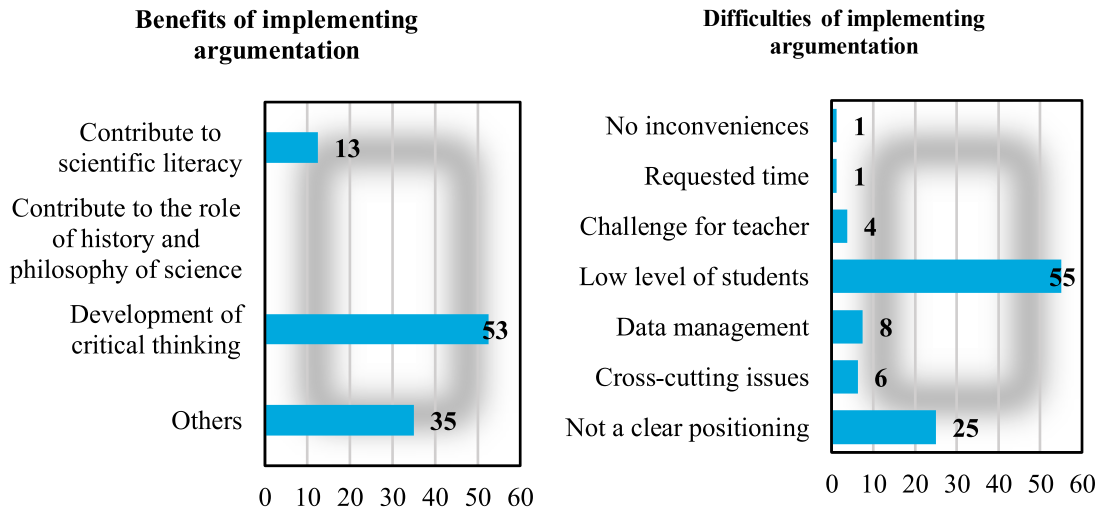

Figure 3. Preliminary results on pre-service teachers preconceptions about argumentation (Data expressed in percentage of pre-service teachers)

Moreover, up to 59% of future teachers indicated that defending a point of view in science is related to "presenting evidence to support it." To a lesser extent and in a similar proportion, the ideas of "justifying and trying to convince others that it is the right point of view" as well as "justifying without intentions to convince others" were chosen by 19% and 20% of the sample, respectively. Only 3% of students ran for the option of "justifying from what is known, without seeking information" (Figure 4).

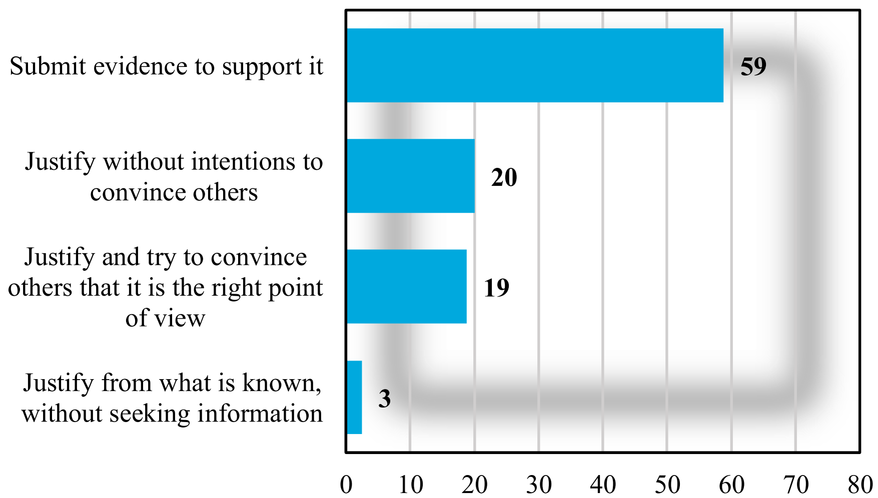

Figure 4. Notions linked to the idea of defending a point of view in science (Data expressed in percentage of pre-service teachers)

Regarding the future teaching practice and carrying out debate activities, about 99% of pre-service teachers considered as essential the participation of their students in debates where different points of view are discussed, while only 31% gave value to participation in debates in which a single argument is defended. About the use of materials for the search of information, up to 99% stressed the importance of using different sources of information. Additionally, 89% also consider the necessity to use the information that appears in books and notes (Figure 5).

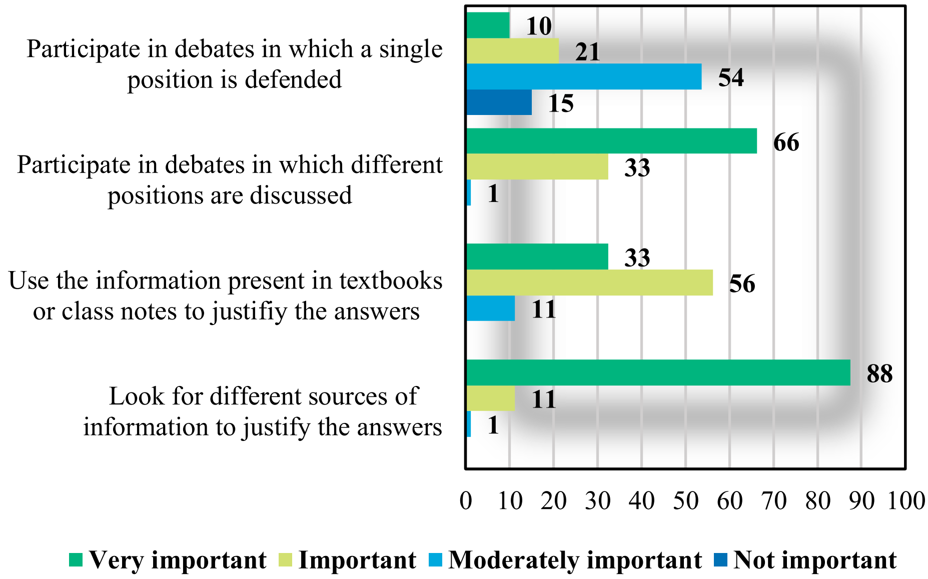

Figure 5. Importance granted by pre-service teachers to perform different tasks related to argumentation in science class (Data expressed in percentage of pre-service teachers)

Results about the quality of argumentative discourse (Figure 6) were evaluated through an environmental theme proposal based on energy sources, using the rubric published by Felton, García-Mila, & Gilabert (2009). While 68% of the students formulated a proposal for an energy source, establishing up to 50% the advantages of the selected source, only 25% listed the possible limitations of their choice. Although these results may be acceptable in a sample that has not yet worked on argumentative competence, the low percentages that have listed the advantages and limitations of the discarded energy sources (less than 5% in both cases) stand out negatively. More alarming may be the lack of coherence in the discourse, with only 6% making a reasoned conclusion. Regarding the contribution of relevant or additional information, the percentages are again low, with less than 10% of students in both cases.

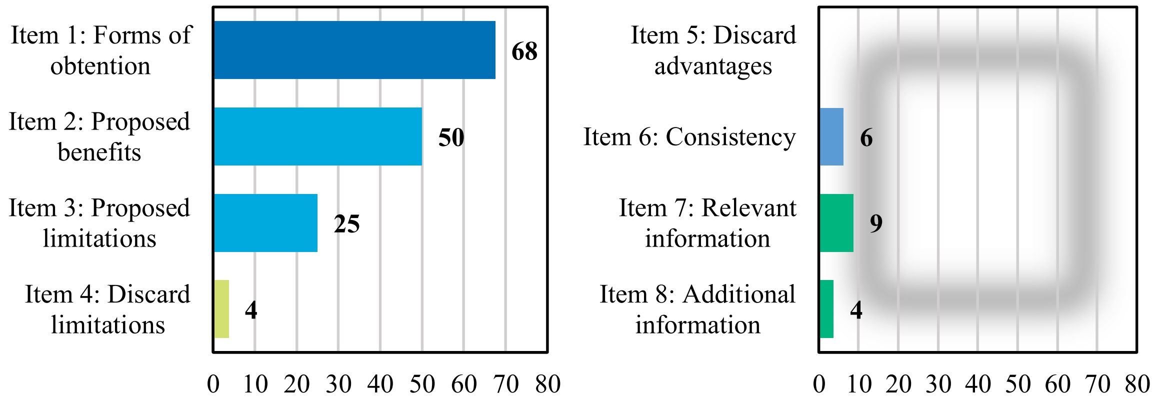

Figure 6. Preliminary results on the quality of pre-service teachers argumentative discourse (Data expressed in percentage of pre-service teachers)

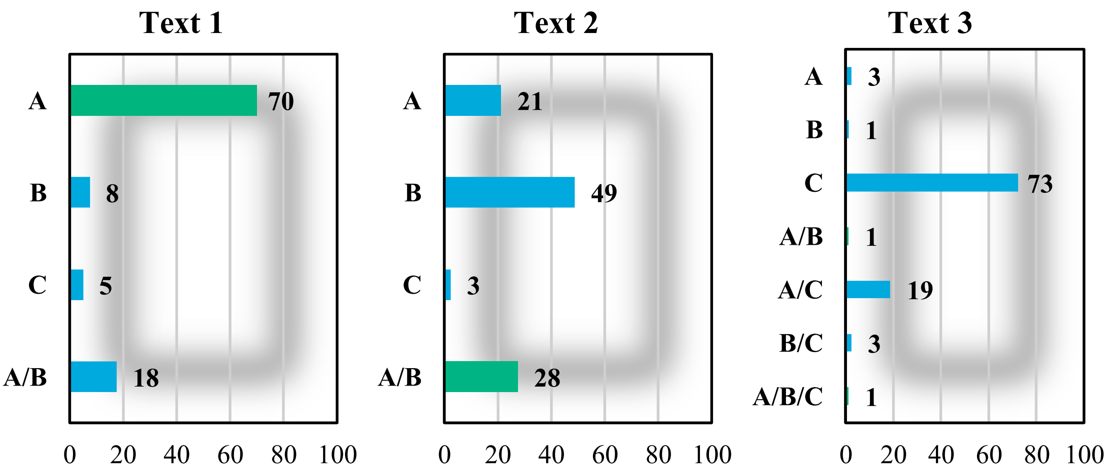
Finally, to know the degree of application of the argument, we adapted an activity related to CCE from the website http://leer.es,[1] a resource of the Spanish Ministry of Education. The objective of this activity was for pre-service teachers to critically analyse the information they receive, through an exhaustive analysis of the text and knowledge of the type of statements made in it. As climate change is a very new and current issue, it needs to be evident that this is a scientific problem where other political, economic and social issues are mixed. Likewise, since it remains unclear what the causes and consequences of warming are, therefore, it is still an open topic where many different opinions have a place. By doing so, we wanted pre-service teachers to recognize evidence and justifications within a text, to decide to what extent they accept or reject the information received and to become aware of their prejudices and their criteria of justification when they decide to believe or not a particular text. The closed-answers activity (Figure 7) consists of the correct classification of different texts (T1-T5) in facts (A), affirmations (B), hypotheses (C) or some combination of the three.

[1] Access to the activity: https://leer.es/documents/235507/242734/eso4_cn_cambioclimatico_prof_annagarrido.pdf/02a58087-46bb-429e-91e2-8004b633f974

T1	The hottest ten years ever recorded have all occurred since 1980 onwards.	Fact/Data	A
		Affirmation/Conclusion	B
		Hypothesis/Prediction	C
T2	During the last century, the level of carbon dioxide in the atmosphere has increased by 31%; the nitrous oxide level at 15%; and the level of methane at 100%. These are the three main gases causing global warming produced by the burning of fossil fuels.	Fact/Data	A
		Affirmation/Conclusion	B
		Hypothesis/Prediction	C
T3	Since 1900, the average temperature of the Earth's surface has risen between 0,3 and 0,6ºC. By the year 2100, it could have risen to 3,5°C, which constitutes a temperature change compared to what has occurred since the last ice age until today.	Fact/Data	A
		Affirmation/Conclusion	B
		Hypothesis/Prediction	C
T4	The melting of polar ice caps and glaciers could cause an increase in sea level of up to one meter by 2100. In this way, entire nations would be submerged, and the world map would be radically altered.	Fact/Data	A
		Affirmation/Conclusion	B
		Hypothesis/Prediction	C
T5	Scientists say that the world must reduce its emissions of global warming gases by 50% to 70% only to stabilize the current level of gases in the atmosphere. Nevertheless, projections indicate that the emissions of these gases will continue to increase in the coming decades.	Fact/Data	A
		Affirmation/Conclusion	B
		Hypothesis/Prediction	C

Figure 7. Translated texts and correct classification (in green)

Figure 8 shows the result set for each of the five texts presented, with the correct answer for each of them in green. While in sections 1 and 4 more than 70% of students choose the correct answer (fact and hypothesis, respectively), these success rates decrease considerably in sections 2 and 5, with less than 40% of successes in both cases. Finally, in section 3, a low 1% provided the correct answer (a combination of fact, statement and hypothesis), with the majority of pre-service teachers opting exclusively for the choice of hypotheses (73%).



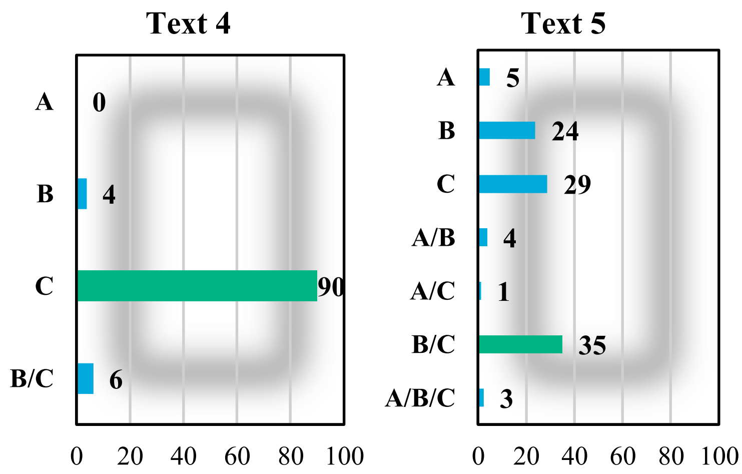


Figure 8. Results on application of the argumentative (correct answer in green) (Data expressed in percentage of pre-service teachers)

CONCLUSIONS

Preliminary results show a reasonable perception of the importance of contextualisation in the argumentative process, thus pointing out the relevance of using topics familiar to students. Nevertheless, socio-scientific issues were just taken into consideration for less than 10% of the sample, meaning that STEM relationships should be emphasised during this study.

As a major benefit of working with argumentation, the sample of pre-service teachers highlighted the development of critical thinking, one of the key milestones for scientific competence, which constitutes a solid starting point for this study. However, it should be noted that only a low percentage identifies the contribution of argumentation to scientific literacy (one of the fundamental objectives established by the OECD) or the contribution to the epistemology of science so that these aspects will be the goal of improvement in the teaching-learning programme proposed. More concerning are the decisions related to the higher difficulties to implement argumentation, with the focus set to the generally low level of students. This result will require the enhancing of learning environments to support students difficulties in argumentation, with the focus on work techniques such as the organisation of heterogeneous groups, the co-creation and sharing of intellectual artefacts or the acquisition of awareness tools, among others (Clark, Stegmann, Weinberger, Menekse, & Erkens, 2008).

The results regarding the quality of the argumentative discourse, both at the level of development and identification of the own elements, show that there is still a lack of coherence in it and a poor idea of the types of statements, being therefore necessary a more comprehensive formation in this regard to critically analyse the information received.

To sum up, the argumentative dimension analysed with the preliminary results of the pre-test points out the necessity of the application of learning opportunities in primary pre-service education in the context of argumentation, to improve the perception about the methodology and the quality itself. The next step in this research would be the implementation of the established innovation sequence, that we hope it will contribute to our purpose and will provide us with enough results to analyse and evaluate the relevance of the proposal regarding advantages and improvements of the online video annotations.

ACKNOWLEDGEMENT

ANALYSIS OF AN ARGUMENTATION ACTIVITY ON INVASIVE PLANTS IN PRE-SERVICE SCIENCE TEACHERS

José Manuel Hierrezuelo-Osorio[1], Pedro Juárez-González[1], Daniel Cebrián-Robles[1] and Antonio Joaquín Franco-Mariscal[1]

[1] Department of Science Education,
University of Málaga, Campus de Teatinos s/n, 29071 Málaga, Spain

Scientific argumentation is considered a relevant practice in science education in general, and biology in particular. This work focuses on the importance of knowing the difficulties of pre-service science teachers (PSTs) to build and assess arguments within the framework of the learning progression raised by Osborne et al. (2016) facing a socio-scientific problem in the field of biology. An argumentation activity, adapted from those authors, was administered to 132 Spanish Pre-service Early Childhood Teachers (PSECT) and Pre-service Primary School Teachers (PSPST) of the University of Malaga (Malaga, Spain). The task presented different evidences on the extension of the purple loosestrife plant in wetlands of the United States to build different arguments and counter-arguments. The responses were categorized based on a rubric that was associated with the cited learning progression. The results show a decreasing progression in the percentage of PSTs both Early Childhood as Primary Education degrees who gave appropriate responses to advance at different levels of the learning progression (constructing a claim, providing evidence, constructing a one-sided or two-sided comparative argument), suggesting the need to continue working with them in new tasks that exclusively address the highest levels of progression. Finally, the Mann-Whitney U test detected statistically significant differences in the sense that PSPSTs provide better evidence than PSECTs, while these can provide a two-sided comparative argument better than those of PSPSTs.

Keywords: Initial Teacher Education (pre-service), Socio-scientific Issues, learning progressions

INTRODUCTION

One of the most important scientific practices in science education is argumentation as it allows learning of science and its culture (Pinochet, 2015). Furthermore, argumentation is one of the three main activities of scientific practice in science education along with inquiry and modelling (Jiménez-Aleixandre & Crujeiras, 2017). Proof of this is their importance in, among others, the educational frameworks such as K-12 in the American system (National Research Council, 2012) or the PISA international assessment tests (OECD, 2016).

The literature shows an effort to present learning progressions to guide how the learning of sequenced argumentative skills occurs (Bravo-Torija & Jiménez-Aleixandre, 2018; Lee et al., 2014; Osborne et al., 2016). The Osborne et al. (2016) learning progression, taken into account in this work, distinguishes between the construction of an argument, and the critical or evaluative part of it, which includes the counter-argumentation and counter-critique. These last levels in the progression constitute the most complex elements in the argumentation capacity and tend to be carried out to practice with discussion activities (Iordanou, 2013).

In the field of biology, the scientific argumentation has been raised through socio-scientific issues that pose decision-making based on evidence such as the choice of whether new zoos should be opened or not (Simon, Erduran & Osborne , 2006), the management of marine food resources (Bravo-Torija & Jiménez-Aleixandre, 2018) or the problem of invasive species (Berland & Reiser, 2009). The present study revisits this last problem from the analysis of the argumentation based on the learning progression of Osborne et al. (2016).

For this purpose, this work presents an argumentation activity with different questions that allow us to know the level of argumentation of pre-service science teachers (PSTs) within progressive learning. It is also focused on analysing whether the PSTs of two degrees of education (Early Childhood and Primary Education) have difficulties in initial capacity to construct and assess arguments, in this case, putting as context a biological problem.

ARGUMENTATION ACTIVITY ON INVASIVE PLANTS

PSTs responded to an argumentation activity presented as part of a broader questionnaire that included other socio-scientific issues, focusing, in this case, on biology and specifically on invasive plants. This activity was taken by Stanford University group of scientific argumentation[2]. It is a clear example of the different levels of complexity of the elements that must be coordinated as levels of progress concerning the competence of the argumentation in the science since it provided four elements used to inquire about the different levels of learning progression (Osborne et al., 2016).

The activity exposes that purple loosestrife, a wetland plant, imported from Europe to North America, spread to many wetland ecosystems in the country, and provides two images (figure 1) showing a wetland before and after purple loosestrife was introduced (evidence E0).

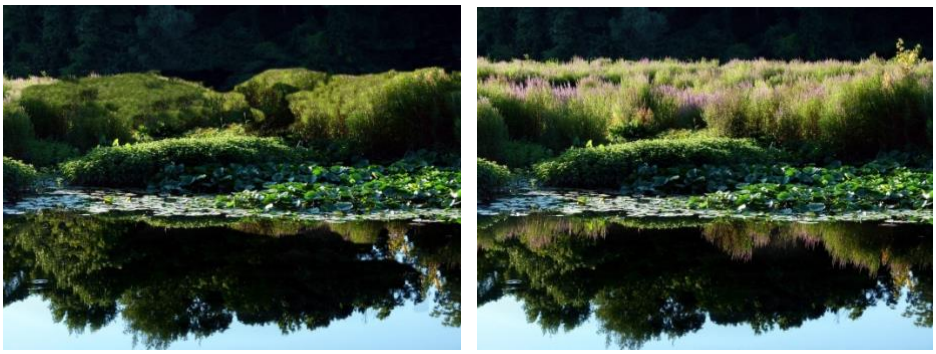

Figure 1. Images of the wetland before (left) and after (right) purple loosestrife.

[2] http://scientificargumentation.stanford.edu/assessments/loosestrife/

Three pieces of evidence are also provided by scientists who studied this specie in the United States:

(E1) The purple loosestrife grows twice as fast as the winged loosestrife (a native plant in these wetlands),

(E2) The winged loosestrife has ten different species of insects that eat its leaves,

(E3) The purple loosestrife has three different species of insects and two species of birds that eat its leaves.

The activity provides conclusions of two students (Sophie and Tina) following the election of if the invasive purple loosestrife is a successful invader and the evidence on which they are based:

(1) Sophie says: "I think the purple loosestrife is a successful invader because there are very few herbivores that eat it. Only five different species eat the purple loosestrife. Since it was so few things that eat it, it can just keep growing, and it can take over the ecosystem".

(2) Tina says: "I think the purple loosestrife is a successful invader because it grows much faster than other plants. The purple loosestrife grows twice as fast as a native plant. If the purple loosestrife grows faster than other species, then it can compete better for light, nutrients, and space".

This activity requires that PSTs rely on scientific data to elaborate and critique the relationships between arguments and scientific evidence. To help PSTs in the construction of the arguments, five questions were included in the task:

(A) Do you consider that the purple loosestrife is a successful invader in this ecosystem: yes or no?

(B) On what evidence do you base this assertion?

(C) On what argument are you in favour: Sophie or Tina?

(D) Why do you agree more with the argument selected in C?

(E) Why do not you agree with the other argument?

A, B, D and E are strictly questions linked to the levels of learning progression of Osborne et al. (2016) and question C is an opinion question, but related to D and E. Thus, in question A, PSTs must make a claim (level 0a); in B they must provide an evidence used to establish the conclusion in A (level 0c); in D they must construct a bilateral (level 2c) or unilateral (level 2b) comparative argument, and finally in E they must provide a counter-critique (level 2a).

METHOD

132 PSTs participated in this research: 56 Pre-service Early Childhood Teachers (PSECTs) and 76 Pre-service Primary School Teachers (PSPSTs) of the University of Malaga (Spain) during the course 2017-2018. They were all in a science education course in the third year of their

grade. 79.4% were women, and 20.6% were men, with an average age of 23. PSTs completed the online activity.

The answers of the PSTs were analysed through a rubric agreed by the researchers (Table 1) that relates the established categories with the different levels proposed by Osborne et al. (2016).

Table 1. Rubric to assess the argumentation activity on the purple loosestrife.

Rubric (established by researchers)			Levels (Osborne et al. 2016)
Question	Level and criteria		
A	No (inadequate)	0	
	Yes	0a	Constructing a claim
B	It does not provide any evidence or provides evidence E2, or provides E2 accompanied by other evidence (E0, E1 or E3) (inadequate).	0	--
	It contributes with 1, 2 or 3 different evidence of E2.	0c	Providing evidence
C	Opinion question	--	--
D & E	It does not construct any comparative argument (inadequate).	0	
	It agrees with one of the arguments of Tina or Sophie but does not justify or justify one.	2b	Constructing a one-sided comparative argument
	It elaborates a critique justifying the contributions of Tina and Sophie.	2c	Providing a two-sided comparative argument

An example of a response of a PST for the level 0 in question B was: "I guess the evidence is the changes that are being made in the ecosystem" (PSECT14) because he does not provide evidence in his argument. However, the following answer given for another PST “It grows faster than the winged loosestrife. Five different species eat loosestrife instead of ten” (PSECT22) was categorized in the level 0c since he can provide adequate evidence.

In the case of question D, an inadequate response (level 0) was “…because it grows faster.” (PSPST07). In this example of response, this PST does not provide a critique but repeats what was said. The PSPST11, for instance, had an adequate response in level 2b: “Because as it grows faster it can get more room to expand, better light, nutrients…”.

The possible statistically significant differences between groups were analysed with the SPSS 21.0 software using the Mann-Whitney U test.

RESULTS

Table 2 shows the results obtained from frequencies and percentages of PSTs for each level and question of the task, while figure 2 shows the evolution of the progression of the capacity of argumentation representing the most appropriate levels in each question of the task.

The results show a decrease in the performance of the PSTs in both degrees and their appropriate responses as progress is made in the levels of the learning progression (level 0a for question A, level 0c for question B and level 2c for questions D and E).

Table 2. Frequencies (f) and percentages (%) of PSTs for each level and question.

	f / %		f / %		f / %		f / %	
Question	PSECT	PSPST	PSECT	PSPST	PSECT	PSPST	PSECT	PSPST
	Level 0		Level 0a					
A	7 / 12.5	6 / 7.9	49 / 87.5	70 / 92.1				
	Level 0		Level 0c (1 evidence)		Level 0c (2 evidence)		Level 0c (3 evidence)	
B	4 / 14.3	4 / 10.6	3 / 42.9	0 / 25	1 / 41.0	4 / 55.3	24 / 1.8	19 / 9.2
	Level 0		Level 2b		Level 2c			
D	30 / 53.6	42 / 55.3	24 / 42.9	32 / 42.1	2 / 3.6	2 / 2.6		
E	23 / 41.0	47 / 61.8	32 / 57.1	27 / 35.5	1 / 1.8	0 / 0		

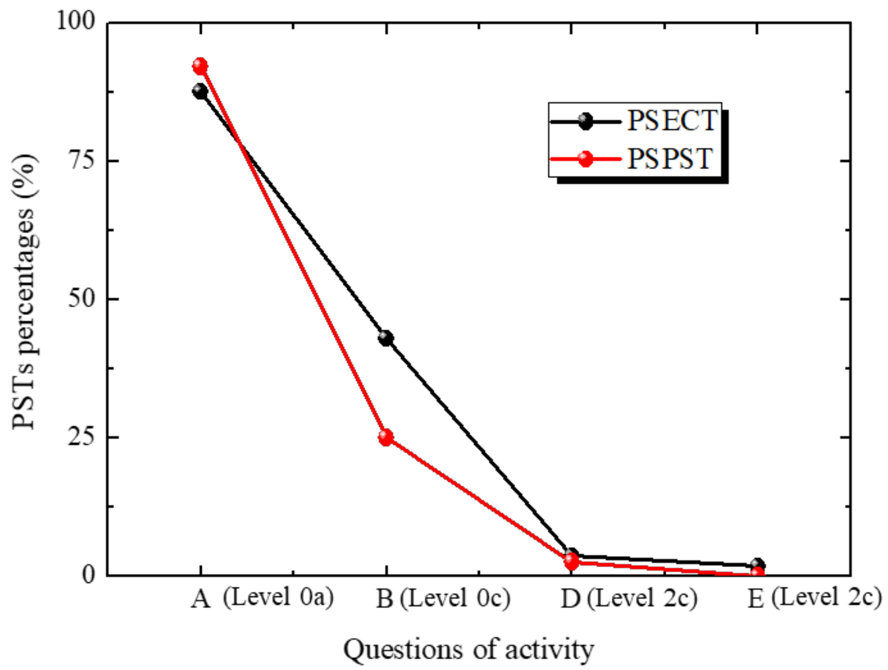

Figure 2. Evolution in the progress of the argumentative capacity of PSECTs and PSPSTs.

The Mann-Whitney U test (table 3) indicated that there were no significant differences between the two groups for questions A and D, showing that both PSECTs and PSPSTs presented similar results in their prior knowledge. In the case of questions B and E, statistically significant differences were detected being in question B in favour of the PSPSTs and question E in favour of the PSECTs.

Table 3. Results for the Mann-Whitney U test.

	Mean (median)		Mann-Whitney U test	
Question	**PSECT**	**PSPST**	**U**	**p**
A	1.9 (2.0)	1.9 (2.0)	2030.0	NS
B	4.1 (4.0)	4,5 (5.0)	1622.5	0.011*
D	1.5(1.0)	1.5 (1.0)	2084.0	NS
E	1.6 (2.0)	1.4 (1.0)	1671.5	0.015*

CONCLUSIONS

These results highlight the need to train the PSTs in constructing a one-sided and two-sided comparative arguments (levels 2b and 2c in the learning progression). For this purpose, we are developing a training programme for the PSTs to learn how to discuss about science.

We are also working on new biology contexts to try to justify the significant differences detected between PSPSTs and PSECTs in questions B and E.

ACKNOWLEDGEMENT

This work was supported by the Spanish government through its 2017 research calls [EDU2017-82197-P, R&D Project].

FUTURE CHEMISTRY TEACHERS' PERCEPTIONS OF VOCATIONALLY RELEVANT LEARNING METHODS

Johannes Pernaa and Maija Aksela
The Unit of Chemistry Teacher Education, Department of Chemistry,
University of Helsinki, Helsinki, Finland

The lack of relevance is a major challenge in chemistry education. In the last two decades, a lot of research and development projects for increasing the relevancy have been conducted in all educational levels, expect in chemistry teacher education. This research is filling this knowledge gap by investigating what kind of learning methods in pre-service chemistry teacher education have high and low vocational relevance. The relevance of different learning methods included in chemistry teacher education courses are analysed by studying future chemistry teachers' perceptions. Research was carried out as a case study utilising a mixed methods approach. Data was collected via an online questionnaire. The total number of respondents was 72. According to this research, laboratory activities, teaching exercises (e.g. teaching for peers or pupils in a non-formal learning environment study visit) and discussions (e.g. group discussions) were experienced the most vocationally relevant. Writing exercises were experienced the least relevant. All highly relevant learning methods stimulated high-order thinking skills and supported collaborative learning. The level of experienced relevance was mostly intrinsic (skills and knowledge for career) and it had both present and future focus. These results can be used for developing vocationally high relevance learning methods for pre-service chemistry teacher education.

Keywords: learning method, pre-service chemistry teacher education, relevance

INTRODUCTION

The term "relevance" is often mentioned as a goal for developing educational programs, courses and learning materials. It has interested scholars over many decades, because the lack of relevance is a major challenge in science education. For example, students don't experience science relevant for their everyday lives and therefore, they don't choose a science-related career (Osborne et al., 2003; Osborne & Dillon, 2008; Sjøberg & Schreiner, 2010).

Depending on the definition, relevance has been used e.g. as a synonym for interest, describing students' perception of meaningfulness or their learning needs or a mixture of all these. (Stuckey et al., 2013) One highly citated model for defining the concept of relevance has been published by Stuckey et al. in 2013. They made a broad literature review of how the term "relevance" has been used in education. Based on their review, they formed a multidimensional relevance model that summarises central ideas from earlier literature. In Stuckey et al.'s definition, the meaning of relevance is modelled through different dimensions (personal, societal and vocational) and the relevance may be experienced as internal or external in the present moment or in the future. (see Stuckey et al., 2013)

The lack of relevance has at least two dramatic effects – a lack of applicants and a great dropout number during university studies (Hailikari & Nevgi, 2010; Heublein & Schmelzer, 2018; Hill et al., 1990; Valto & Nuora, 2019). From the perspective of chemistry studies, this means that students don't experience chemistry as an interesting or an important subject and therefore don't choose it as their future study field. Also, from those who enrol for chemistry bachelor studies, about 30–40% of will drop out (Heublein & Schmelzer, 2018; Hill et al., 1990; Valto & Nuora, 2019). Many switch into more vocationally clearer fields like medical studies or drop out university studies altogether (Hailikari & Nevgi, 2010). The lack of relevance has led to a situation where too few young people enrol for chemistry studies and even fewer graduate, resulting a major lack of expertise. The situation is challenging because the need is massive. Chemistry is one of the world's biggest fields measured by any economical meter and provides jobs for over 15 million people (Oxford Economics, 2019).

In order to solve the relevance challenge and secure the talent pipeline from school to industry, the field is seeking answers from chemistry education research (Eilks & Hofstein, 2015). CER field has the key role in solving the relevance challenge of chemistry studies. Firstly, CER scholars develop new research-based solutions (e.g. learning materials, evaluation methods, curricula etc.) for supporting relevant chemistry education. This research area has been quite active in the recent years (see Eilks & Hofstein, 2015). Secondly, CER field educates a majority of future chemistry teachers who are introducing the field to countless children every day. According to research, teachers have a significant role in career decision making (Hill et al., 1990; Hugerat et al., 2015) and therefore, chemistry teachers are the most important group of professionals inspiring young people into the chemistry field. Even though chemistry teachers' role is crucial, there is a lack of relevance studies conducted in pre-service chemistry teacher education (see the next section for more details).

Through this research, we contribute to solving the relevance challenge by studying future chemistry teachers' perceptions of vocationally relevant learning methods (e.g. laboratory exercises, research tasks, writing assignments, learning discussions etc.). The study was directed through the following research questions: RQ1: What kinds of learning methods do future chemistry teachers consider most relevant or irrelevant for their learning and future career? RQ2: What kinds of arguments do they present for relevant and irrelevant methods? We propose that answering these questions is important for pre-service chemistry teacher education because:

1. Learning methods have a crucial role in engaging, inspiring and motivating students into chemistry learning. For example, carrying out laboratory experiments is experienced significantly more interesting than watching or planning experiments. (Bolte et al., 2013) If the most relevant and irrelevant methods can be identified, it enables developing pre-service chemistry teacher education into a more professionally relevant direction through a research-based approach.
2. Future chemistry teachers must be taught through versatile methods, because they learn how to teach and learn chemistry through those examples. Students build their professional identity around methods that they experience as supporting their own learning and use them in their future profession as chemistry teachers. (Aksela, 2010)

Our hypothesis is that methods that students find vocationally relevant, support building their chemistry knowledge, pedagogical content knowledge (PCK), professional confidence and self-efficacy. Self-confident chemistry teachers who trust their professional knowledge and skill set are one of the key solutions in solving the relevance challenge of chemistry studies.

VOCATIONAL RELEVANCE OF CHEMISTRY TEACHER EDUCATION

In Stuckey et al.'s (2013) relevance model, the vocational dimension refers to knowledge, skills and formal certificates that prepare or enable succeeding in the future profession (see Table 1). Analysed from the perspective of pre-service chemistry teacher education, the vocational dimension can be focused on many different skills or knowledge components. This is due to the diverse structure of the degree. The structure varies from country to country, but e.g. in Finland, training lasts five years including chemistry studies (1st teaching subject – two years), 2nd teaching subject (e.g. mathematics, physics, biology, computer sciences – one year), pedagogy (including teaching practice training – one year), chemistry education and its research (e.g. bachelor's and master's theses – one year). (Aksela, 2010) In this section, we don't address vocational relevance aspects related to chemistry subject studies, 2nd teaching subject or pedagogical studies, because our data is collected during chemistry education courses and targeted on learning methods included on those courses.

Table 1. Examples of vocational dimension in different levels and states (Stuckey et al., 2013).

Vocational Dimension	Intrinsic	Extrinsic
Present	Orientation about potential careers for chemistry teachers.	Passing exams for getting the degree.
Future	Knowledge, skills and networks that secure getting a satisfactory job.	Contributing to society's economic wellbeing.

We have viewed literature through the above limitations. Our review indicates that vocational relevance of teacher education in general has been studied extensively (see e.g. Sheridan, 2013), but there is a lack of studies conducted in chemistry teacher education. Fundamentally, the vocational perspective of teacher education is clear. Teacher training offers a clear pathway to a specific teaching profession. Therefore, also the vocational relevance of chemistry teacher education itself is clearer compared to e.g. the profession of a chemist. For example, Ogunde (2017) found that students mainly apply into chemistry BSc programs because they are interested in chemistry. Ogunde argues that undergraduate students see chemistry studies as a possibility for many kinds of careers, but only few have an accurate career objective.

CER field has been active in developing the relevance of chemistry education in all education levels except in chemistry teacher training (Eilks & Hofstein, 2015). Scholars have been developing e.g. authentic research-based learning environments for supporting the science career choice (e.g. Nuora & Välisaari, 2018; Veale et al., 2018) or approaching the relevance issue through a specific subject like e.g. sustainable development (Juntunen & Aksela, 2014) or tattoo colours (Stuckey & Eilks, 2014).

There are only few articles published that address the vocational relevance of chemistry teacher education. Early mentions have been made by Childs (2002) who reported a case study of different development actions made in the Irish chemistry education during 1999–2002. Childs described structures and processes that were developed for promoting career awareness in chemistry and physics but also in their teaching profession. Hugerat et al. (2015) argue that the vocational dimension is often neglected in pre-service chemistry teacher training. They propose that it can be strengthened by teaching future chemistry teachers in a similar way that they are taught to teach their future pupils – i.e. through inquiry-based collaborative learning in a highly relevant context.

The vocational possibilities of non-formal learning for chemistry teacher education is the most studied topic under this theme (Affeldt et al., 2015, 2017; Aksela, 2017; Garner et al., 2014, 2015; Garner & Eilks, 2015). These studies are carried out in non-formal chemistry laboratories located in universities or chemical industry (Tolppanen et al., 2015). According to these studies, non-formal learning offers two great possibilities. The first one is promoting in-service teachers' continuous professional development through learning in non-formal chemistry laboratories during study visits (e.g. Affeldt et al., 2017). The second one is using a non-formal chemistry laboratory as a learning environment in undergraduate chemistry education courses which seem to offer many possibilities for learning and developing teacher identity. Aksela (2017) studied pre-service chemistry teachers' perceptions of relevance when they engage in guiding study visits in a non-formal chemistry laboratory. According to her case study, analysed from the vocational perspective, it strengthened their knowledge of chemistry and PCK. In addition, it confirmed the right career selection and increased self-confidence.

METHODS

This research was carried out as a case study utilising a mixed methods approach (Cohen et al., 2007). Data was gathered via an online questionnaire between January 2017 and December 2019 in the end of every chemistry education course held in the Unit of Chemistry Teacher Education at the Department of Chemistry in the University of Helsinki, Finland. The unit organises eight courses every year. All learning methods (see Table 2) included in the courses are selected through latest CER recommendations and these are aligned with the objectives set by the Finnish curriculum. (see Aksela, 2010)

All together 72 future chemistry teachers participated in the research. 34 respondents were studying chemistry as their 1st teaching subject, 36 as their 2nd teaching subject and two respondents left teaching subjects unanswered.

The questionnaire included 14 items divided into five sections (1. Background information, 2. Writing, oral and lab exercises, 3. Teaching and presentations, 4. Chemistry education research and 5. Other feedback). For ensuring a mixed methods approach, the questionnaire included both closed and open items. Closed items were five-point Likert-scales (1 completely meaningless – 2 somewhat meaningless – 3 neutral option – 4 somewhat meaningful – 5 very meaningful) and they were used for gathering students' perceptions of the relevance of different learning methods (see full list from Table 2). Every closed item was followed by two open items where respondents were asked to write justifications for the most relevant and irrelevant methods.

The most relevant and irrelevant methods (RQ1) were analysed via descriptive statistics including frequency distributions, means and standard deviations. Statistical phase was used for identifying the most relevant and irrelevant methods. Data from open items triangulated statistical results. They were used for understanding the reasons why future chemistry teachers experience some methods more relevant or irrelevant than others (RQ2).

RESULTS

Future chemistry teachers experienced that laboratory related methods *(M_{design} = 4.6, SD = 0.65; $M_{inquiry\text{-}based}$ = 4.3, SD = 0.68; M_{short} = 4.2, SD = 0.84)*, teaching sessions for peers *(M = 4.5, SD = 0.62)*, working in a non-formal learning environment with real pupils *($M_{guiding}$ = 4.4, SD = 0.89; $M_{observing}$ = 4.3, SD = 0.78)*, discussions *(M = 4.4, SD = 0.71)* and group work exercises *(M = 4.3, SD = 0.83)* were highly relevant from the vocational perspective. Also, traditional chemistry exercises (e.g. calculations and reaction mechanisms) *(M = 4.3, SD = 1.00)* and lectures *(M = 4.2, SD = 0.76)* were reported important. Writing assignments like learning diaries *(M = 3.5, SD = 1.05)*, summaries and short texts *(M = 3.6, SD = 0.96)* and drama activities *(M = 3.5, SD = 0.90)* were experienced less relevant than hands on activities or teaching exercises. Writing a blog text about personal learning was experienced irrelevant *(M = 2.5, SD = 0.81)* (see Table 2).

Table 2. Learning methods organised from relevant to irrelevant.

Learning activity	**Activity Category**	**1**	**2**	**3**	**4**	**5**	**Mean**	**Std. Deviation**	**N**	**Response rate**

Justifications for vocationally relevant learning methods

Laboratory work was seen as vital in chemistry teacher education. An exercise where students designed new laboratory activities was experienced especially relevant. Respondents felt that this kind of expertise has a major role in chemistry teacher's daily work. It also enables thinking about pupils' learning needs and supports their own learning.

- *"Designing new laboratory activities has a major role in chemistry teacher's work. Even the new curriculum guides into this direction."* (R6)
- *"Designing laboratory activities enabled studying the content more carefully."* (R23)
- *"Designing laboratory activities enabled thinking about what pupils should think.*" (R24)

On the other hand, e.g. open inquiry-based laboratory activities were experienced difficult if the results are not clear. In addition, the relevance of laboratory work can be supported through interesting contexts.

- *"Inquiry-based laboratory activities don't always provide meaningful results."* (R1)
- *"Laboratory work was a bit like a separate section. It could have been integrated inside some other theme."* (R48)

All learning methods that increase teaching experience were experienced highly relevant. For example, teaching example lessons for peers helped learning content knowledge and getting familiar with teaching material development. Working in a non-formal chemistry laboratory with real pupils gave teaching experience and strengthened self-confidence.

- *"When we prepared the peer teaching session, we had to think about what is important for future chemistry teachers."* (R11)
- *"While we prepared materials for the peer teaching session, we had to learn the content profoundly and analyse our presentation critically."* (R13)
- *"Guiding a study visit for 7–9 grade pupils gave me experience on teaching chemistry through laboratory work. I found it useful."* (R54)

- *"Working in a non-formal learning environment helped me to understand what it is like to work with pupils. Experience of real teacher work."* (R51)

Future chemistry teachers experienced learning discussions (e.g. online/face-to-face discussions in pairs, small groups or within the whole class) as one of the most relevant learning methods. They felt that sharing own ideas, and hearing each other's thoughts forced to think and argument. Collaboration with peers enabled creating new ways to see things. Online discussions were reported challenging if instruction was experienced unclear.

- *"Discussions, if they stayed on topic, forced to think and argument."* (R3)
- *"Discussions with peers expanded my thoughts about teacher's vocation."* (R10)
- *"In discussions, I got feedback from my own thoughts and heard different opinions. I feel that discussions expanded my thinking."* (R13)
- *"Online discussions were poorly instructed, and I didn't get much out of them."* (R39)

Justifications for vocationally irrelevant learning methods

Writing assignments were experienced vocationally most irrelevant. Some respondents felt that writing did not support learning, or they felt that writing is not done to support their own learning.

- *"I can't evaluate my learning through writing assignments."* (R50)
- *"I feel that learning diaries are totally useless. They only add stress."* (34)
- *"Sometimes reflections are written for the teacher not for yourself. That's why they are not meaningful for supporting learning. Even though writing is a good way to learn."* (R11)

Some students responded that an assignment is irrelevant because they already know how to write that particular text type (e.g. summaries). Some felt learning diaries and blog texts unclear or not suitable for supporting learning or teaching.

- *"I am already familiar with writing summaries."* (R2)
- *"Learning diary is an unclear idea."* (R32)
- *"I don't see any use for blogs in teaching or learning."* (R12)
- *"Blog writing is a personal way to express oneself so it should be optional."* (R4)

Drama exercises divided opinions. Some students found them relevant and others disliked them. Responses show that sometimes the perception of irrelevancy may result from the unclear assignment description.

- *"Roleplay and drama exercises are a waste of efficient study time. I understand that others like them and it seems that they have some pedagogical value. However, many times the content suffers because of the entertainment perspective. These favour people that like to entertain by their nature. Teachers need to learn how to present a lesson in a classroom. It is not acting.* (R9)
- *"Drama exercise taught me to explore my boundaries, so I don't think that it was meaningless."* (R21)

DISCUSSION AND CONCLUSIONS

The most relevant learning methods experienced by future chemistry teachers were different kinds of laboratory activities, teaching exercises and discussions. Writing exercises were seen less relevant than other types of learning methods. When analyzing the results, one must keep in mind that these are preliminary findings. This case study is a starting point for learning method discussion in pre-service chemistry teacher education.

From the laboratory activities, especially designing new laboratory work was seen relevant in multiple ways, e.g. laboratory working has an essential role in chemistry teacher's work or an efficient method for supporting own and pupils' learning. Future chemistry teachers experienced designing new activities more relevant than just performing them, which differs from upper secondary school students' perceptions. Upper secondary school students found performing laboratory activities more relevant than planning them (see Bolte et al., 2013).

All kind of collaboration with peers (e.g. teaching example lessons for peers and learning discussions) was also experienced highly relevant. Our findings concerning the possibilities of non-formal learning are consistent with earlier research. Aksela (2017) reported that working with study visits strengthened students' chemistry knowledge, CPK, self-confidence and career choice. Our results showed that both engaging in non-formal learning environment and teaching example lessons for peers have the same kind of effects.

It was interesting that writing exercises were experienced the least relevant. After all, writing is one of the most important ways to express thoughts, especially for academically trained experts. According to our data, it seemed that the problem was in many cases an unclear assignment description. Students felt that they had to write for the teacher, and that it didn't support their own learning. For future research, we suggest that it would be important to develop writing task models that would be experienced more relevant.

Analysing these results through Stuckey et al.'s (2013) model, the vocational relevance related to learning methods was mainly internal (skills and knowledge for career) and focused partly in the present learning needs and partly in the future career orientation. Extrinsic perspectives were not present in this data.

For ensuring the high vocational relevance in chemistry teacher education, we encourage chemistry teacher training programs to increase engaging with non-formal learning environments and all kinds of teaching exercises. Designing learning materials, preparing and holding lessons, evaluating learning effects and re-designing lessons in a collaborative learning setting is an efficient model for supporting future chemistry teachers' professional development. We agree with Hugerat et al. (2015) and Aksela (2010), who argue that students need to be taught using versatile methods. An active learner will become an active teacher. Good practices learned during university years will transfer into their teaching. Enthusiastic and proficient chemistry teachers will be the key solution for increasing the relevance of chemistry studies, and that is why developing chemistry teacher education into a more relevant direction is important.

ACKNOWLEDGEMENT

We would like to thank our SECO research group members for participating in the development of the online questionnaire and in data collection. Together we are more!

THE TWO-SIDED COIN OF EFFECTIVE EVOLUTION EDUCATION: TEACHERS' COMPETENCIES AND STUDENTS' RECEPTIVITY

Elizabeth Marie Watts[1], Clemens Hoffmann[2]
[1]Friedrich-Schiller Universität Jena, Institute for Zoology and Evolutionary Research, Biology Education Research Group, Jena, Germany
[2]Friedrich-Schiller Universität Jena, Faculty for Chemistry and Earth Sciences, Chemistry Education Research Group, Jena, Germany

Despite the centrality of evolution within the biosciences, it remains a 'controversial' topic among the general public, meaning that it is not uncommon for students to enter the classroom with misconceptions about the validity of evolutionary theory. The complexity of evolution, coupled together with the perceived debate around it, makes teaching evolution that much more challenging for teachers. To support students' ability to understand the validity of evolution and the general nature of science a lesson plan was created that allows students to take on the role of the scientific investigator as they create and 'test' their own hypotheses regarding the existence and possible location of intermediary fossils. To test the applicability of this lesson plan, we conducted a trial run with a group of pre-service teachers at a German university. In addition to testing the usability and applicability of the lesson plan, we also asked the participants a series of questions before and after the lesson. Results from the questionnaire showed that the participants had an increased understanding of the validity of evolution following the lesson and also saw themselves as more capable of dealing with future anti-evolution challenges in the classroom. Post-lesson interviews also showed that the participants found the lesson material to be challenging but engaging and thus very applicable to the classroom.

Keywords: Nature of Science, Initial Teacher Education (Pre service), Misconceptions

INTRODUCTION

Teaching in general is emotionally laborious and this is especially true when teaching 'controversial' subjects such evolution or climate change. The emotional complexities and pressures that accompany the teaching of 'controversial' topics are often the reason why some teachers attempt to circumvent lessons on such polarizing topics, citing self-doubt about content knowledge and concerns about audiences' responses as motivations for this aversion (Swim & Fraser, 2013). This situation is exacerbated by the creation of materials such as "Ten Questions to Ask Your Biology Teacher about Evolution" by Jonathan Wells (2002) which aim to disrupt lessons on evolution and place teachers in the uncomfortable position of feeling personally responsible for upholding the validity of the theory of evolution (Watts, Levit, & Hossfeld, 2016).

Due the importance of the understanding of evolution for the general development of scientific literacy, this issue needs to be addressed both from the side of the student through the development of new engaging materials that act to counter materials such as the "Ten

Questions". At the same time, new training opportunities need to be developed that better prepare teachers to teach this complex topic in the face of continued 'controversy'.

To address this issue, a sample lesson plan was developed "Missing Links – Missing Evidence?" that focuses on the validity of the theory of evolution while also showing students how this theory can be tested. The lesson plan was originally published in the book *Neanderthals in the Classroom* (Watts, 2019) as a theoretical means of addressing misconceptions about evolution in the classroom. This lesson plan was then incorporated into a pre-service teacher training session that was taught together with Clemens Hoffmann in order to evaluate the lesson materials and gauge the participants' knowledge about evolution and their preparedness for the task of teaching evolution in the face of controversy.

The role of nature of science in evolution education

In addition to focusing on the facts of evolution, the lesson plan also seeks to inform students about the nature of science (NOS). In the sense of epistemological beliefs, ideas about NOS can influence the examination of other scientific content. Moreover, such beliefs about NOS can also serve as a filter (Fives & Buehl, 2012) and affect a person's experiences and perception. In other words, they influence how the environment, how objects and phenomena are perceived, how and which incoming stimuli are processed and how new experiences are linked with existing ones. In this way, they also have an impact on learning. This effect can be leveraged within a science class by combining subject content with the lessons of NOS (Kircher & Dittmer, 2004). Theoretical and historical elements of science thus represent an inadequately appreciated component of motivational and communicative learning in schools (Baumert, Bos, & Lehmann, 2000).

It is important that NOS is addressed directly in the classroom as ideas about NOS are often passed on to students subconsciously by teachers through their use of language and terminology (Miele, 2014). Teachers thus act as a multiplier system and it is thus imperative that teachers therefore develop appropriate ideas about how natural sciences work (Bruns, 2009). An additional advantage of incorporating components of NOS into the lesson is that it presents teachers with the opportunity to increase their students' general level of science literacy and socio-scientific decision making (Clough, 2017) as students have the opportunity to better understand the value of science as a central tool in explaining and understanding the natural world (McComas, 2017). In this way, they can better appreciate how scientists use observation, empirical data and other evidence to develop working theories that may change over time as new data is gathered. This newly gained knowledge, not only about evolution but also about scientific endeavour, may also enable students to better judge which sources are the most reliable with regard to statements about the validity of evolution and enable them to eventually distinguish between reliable and unreliable sources, which further increases their scientific literacy potential.

THE LESSON PLAN

The idea of missing links plays a central role in creationist argumentation. Creationists often claim that there is a lack of intermediate forms within the fossil record and that the theory of evolution must therefore be incorrect (Graf, 2011). Intelligent design proponents make similar arguments using different terminology such as ‘information problems’ (Watts, Hossfeld, Tolstikova, & Levit, 2016).

This lesson provides students with a great overview of macroevolution, which has been argued to be one of the most effective ways of teaching any student or adult about the validity of the theory of evolution (Padian, 2010), while also supporting students’ understanding of NOS as they take on the role of a scientist, creating and testing hypotheses.

Goals and expectations

The primary goal of this lesson is to support the development of scientific literacy and increase students’ interest in science. For a student to be considered “scientifically literate”, they need to be able to make scientific, evidence-based judgments for themselves and not simply memorize and repeat facts (DeBoer, 2000; Oulton, Dillon, & Grace, 2004). This lesson is thus designed to allow students to learn about evolution by taking on the role of the primary investigator as they reconstruct the historic discovery of *Tiktaalik* by learning to develop hypotheses regarding intermediary forms and then coming up with ways to test their hypotheses.

More specifically, this lesson familiarizes students with cladograms and geologic times scales and teaches them how to extract information from these visual aids in order to formulate a hypothesis. The lesson plan also integrates the use of new medias in the form of Macrostrat ® (Figure 1), which is a collaborative platform for geological data exploration.

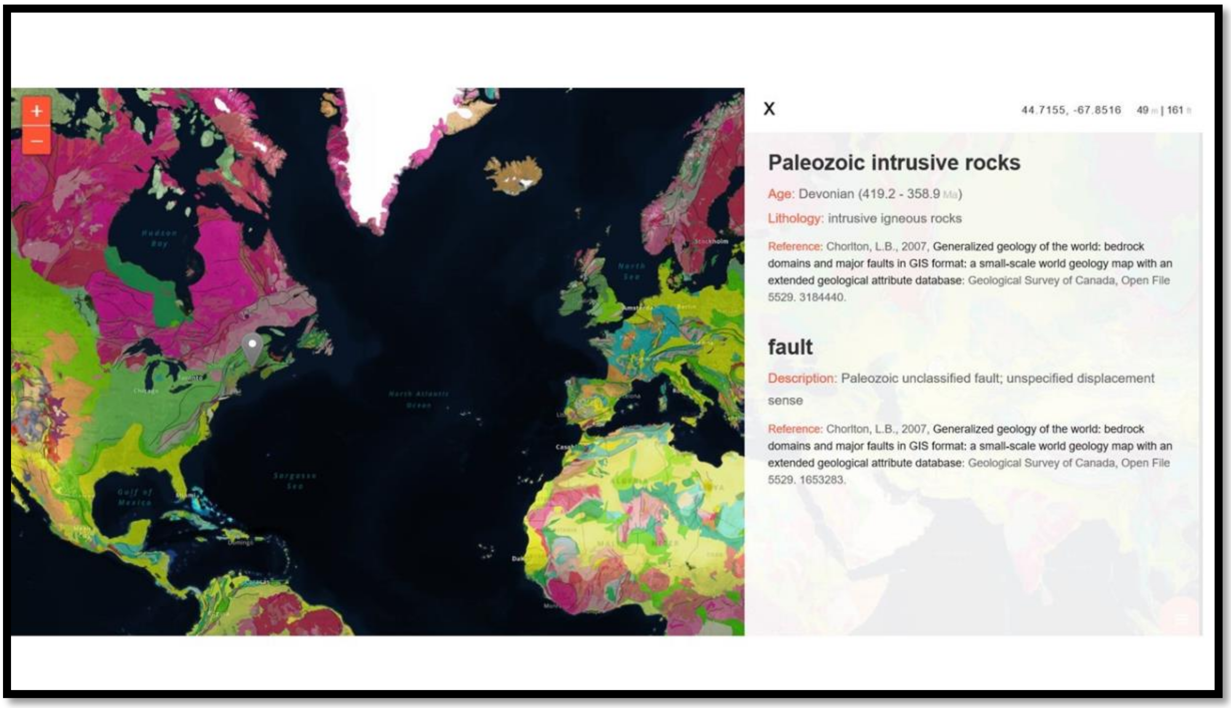

Figure 1. Example of Macrostrat, a collaborative platform for geological data exploration.

Various components of NOS are integrated into the different components of the lesson, which were designed to allow students to develop a better insight into the how scientific research is conducted as it has been shown that understanding this aspect of NOS is particularly useful for students (Markert, 2012). During the lesson, the students take on the role of researchers who are planning a hypothetical dig. This requires them to first develop a testable hypothesis and come up with a hypothetical location where they can test their hypothesis. As part of the preparation for this hypothetical dig, they must plan an excavation and defend their project location against the alternatives of the other groups. To do this, they must present their considerations comprehensibly and justify their processes according to budget restrictions and likelihood of success. In this way students not only practice their scientific argumentation, but also reflect that scientific endeavor is often embedded in a social context. In the end, only one group receives funding for their planned project.

Procedure

Working in groups, the students took on the role of researchers who are attempting to find the fossil remains of the 'missing link' between fish and amphibians. Students were provided a cladogram and a geological timescale so that they can make a prediction on how long ago this intermediary animal would have lived. Using the information sources provided to them the students were able to determine that this intermediary form should have existed during the Devonian period. Using Macrostrat®, the students then work in groups to choose a hypothetical dig site to test their hypotheses.

Once each group has chosen a hypothetical digging site, one member of the group should present their ideas to the 'committee'. In order to procure funding for their project, they needed to convince the committee that their chosen dig site would be the most suitable place to test their hypothesis. Each of the groups was able to create solid arguments based on both the age of the rocks as well as other arguments such as accessibility and costs.

Lesson conclusion

Once students had finished, we went over the story of *Tiktaalik* to discuss how scientists had actually conducted these same steps and were successful in finding the intermediary fossils (Daeschler, Shubin, & Jenkins, 2006). We concluded by watching a short 5-min video as Neil Shubin discussed how the group of scientists searched along the ancient Devonian shoreline in an attempt to find this then-hypothetical intermediary and how they ultimately discovered *Tiktaalik* (PBS, 2014).

PRE-SERVICE TEACHER EVALUATION OF THE LESSON PLAN

In order to test the effectiveness of this lesson plan, a group of twenty-five pre-service teachers were given the lesson plan to run through it in the role of a student and then the lesson plan was discussed as a potential lesson that they could later use in the classroom when confronted by anti-evolution arguments or as a means of teaching evolution and the nature of science. The goal of this intervention was to increase their understanding of evolution and to increase their confidence in their ability to teach their future students about evolution.

In that sense, the pre-service teachers took on the role of both a hypothetical student and a future teacher. In addition to trying out and evaluating the materials, they also participated in a questionnaire that examined their own views of evolution, their expectations regarding creationist beliefs in the classroom and their level of confidence in their ability to deal with classroom disputes over the validity of evolution. The participants answered an identical set of four questions before and after the lesson (Table 1). The pre-questionnaire was conducted using Mentimeter®, while the post-questionnaire was paper based.

Table 1. Pre- Post- question set for pre-service teachers.

Please rate the following statements about evolutionary theory: (strongly agree, agree, neither agree or disagree, disagree, strongly disagree)
1. Evolution cannot be considered a scientific theory because it cannot be tested, and thus cannot be confirmed or refuted. _____________
2. The theory of evolution cannot satisfactorily explain the origin of the species, since intermediary fossils have not yet been found. _____________
Please rate the following statements about your own approach to teaching evolutionary theory in the classroom: (The same scale)
3. As a teacher, I expect to have students in my classes who question the theory of evolution from a creationist perspective. _____________
4. Dealing with situations in which students critically question evolutionary theory will be easy for me. _____________

Evaluation of the lesson

During the lesson the pre-service teachers were highly engaged with the material. The general consensus based on a collection of written commentary was that the material was difficult/challenging but engaging and that they believed that they could and would implement it in the classroom. Most of the participants said that they believed that students would benefit from a pre-exercise to make sure that they were familiar with all of the concepts before beginning with the actual lesson.

Figure 2. Biology education students participating in analysis of lesson plan in Jena, Germany.

The results of the questionnaire showed a positive trend in their understanding of the theory of evolution, as there was an increase in the number of students who answered 'disagree' or 'strongly disagree' to items #1 and #2 (Table 1) on the post-questionnaire than on the pre-questionnaire. It also showed an increase in their levels of self-confidence regarding their ability to deal with future anti-evolution challenges which is marked by more pre-service teachers answering 'strongly agree' or 'agree' in item #4 (Table 1) on the post-questionnaire than on the pre-questionnaire. However, the pre-service teachers' expectations of being confronted with creationist argumentations remained steady (agree or strongly agree on item #3, Table 1) in both the pre- and post-questionnaire.

CONCLUSION

Improving the efficacy of evolution education requires a two-pronged approach: (1) creating engaging materials for students and (2) better preparing pre-service teachers to deal with the challenges that they will face from creationist students. The results of the lesson plan evaluation showed that the classroom materials were effective in that they were engaging and assisted to the students in their ability to better understand the validity of evolution through investigative, self-guided learning. The availability of these materials and the opportunity to try out the materials in a group setting increased not only the pre-service teachers' understanding of the validity of evolution but also increased their overall confidence in their teaching abilities with regard to evolution.

ACKNOWLEDGEMENT

We would like to thank all of the pre-service teachers who participated in this study.

THE IMPLEMENTATION OF TPACK AND SAMR MODELS IN SCIENCE TEACHER TRAINING PROGRAMS AT THE UNIVERSITY OF LJUBLJANA

Vesna Ferk Savec and Špela Hrast
University of Ljubljana, Faculty of Education, Ljubljana, Slovenia

Teachers need skills and knowledge to be effective in implementation of ICT enhanced teaching and learning in the informational age. The TPACK and SAMR models can be used to guide the planning, assessing, evaluating and use of technology in education. Thereby, the concept "TPACK + SAMR constructs" is used in order to address various combinations of TPACK and SAMR stages held by teachers. In order to support university teachers in using ICT in their teaching of prospective teachers the project "ICT in Teacher Training Study Programs at the University of Ljubljana" was launched from April 2017 to September 2018. The project involved 67 pilot-renewals, thereby 22 pilot-renewals in science teacher training programs, which are the focus of this article. The university teachers' reports about their pilot-renewals were analyzed with the focus on various kinds of ICT supported activities for prospective science teachers, that were imbedded in the implemented pilot-renewals. Pilot-renewals' reports were also examined about the levels of "TPACK + SAMR constructs" in ICT supported activities imbedded in the implemented pilot-renewals. The results indicate that most frequently used ICT supported activities were related to: (1) Presentations; (2) Laboratory experimental work; (3) Formative assessment and (4) Learning management system and materials. Additionally, it was found that university teachers most frequently planned their ICT supported activities on TCK-Augmentation level, which was included in more than half of analyzed pilot-renewals. The study provides inside into the state of art regarding the use of ICT in the teacher training study programs at the University of Ljubljana, Slovenia in science teaching area and points to the needs for further improvement and development possibilities in the future.

Keywords: ICT Enhanced Teaching and Learning, Initial Teacher Education, Science Education

THEORETICAL FRAMEWORK

Teachers need skills and knowledge to be effective in technology environments in order to design technology-rich learning experiences for students (Walser, 2008). The TPACK and SAMR models can be used to guide the planning, assessing, evaluating and use of technology in education (Jude, Kajura, & Birevu, 2014; Pamuk, 2012).

The TPACK encompasses the connections between teachers' Technological Knowledge (TK), Pedagogical Knowledge (PK) and Content Knowledge (CK) (Koehler & Mishra, 2009) and involves various interrelationships between its components (Chai, Koh, Tsai, et al., 2011) as presented in Figure 1.

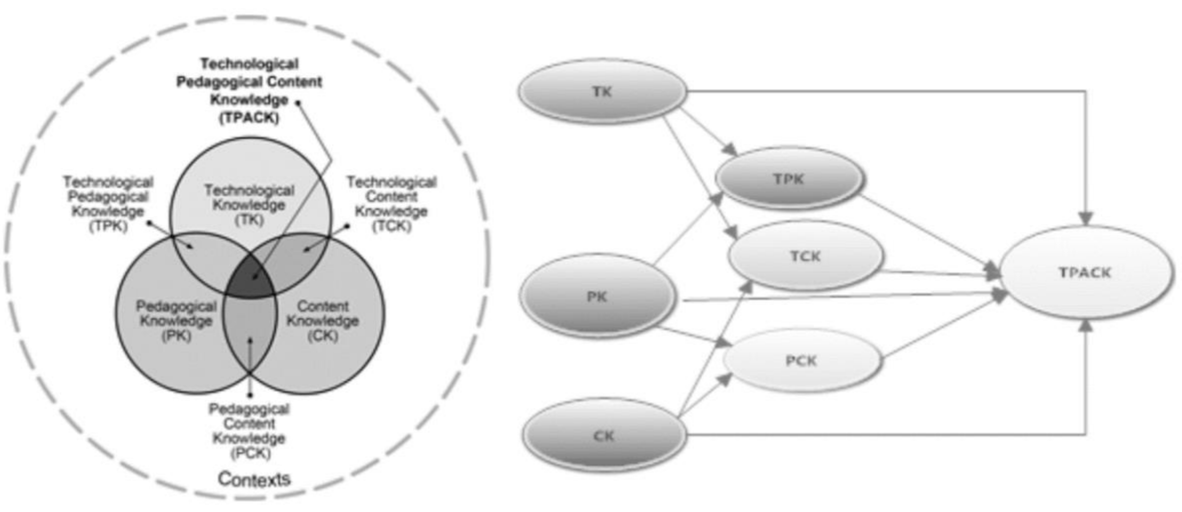

Figure 1. ***TPACK components and the structural model of interrelationships among TPACK components (Chai, Koh, Tsai, et al., 2011; Koehler & Mishra, 2009).***

On the other hand, the SAMR model is a tool for assessing and evaluating technology practices and their impacts in a classroom setting. It is divided into four different levels of classroom technology integration as seen from Figure 2: (1) Substitution (technology acts as a direct tool substitute, with no functional change); (2) Augmentation (Technology acts as a direct tool substitute, with functional improvement); (3) Modification (Technology allows for significant task redesign) and (4) Redefinition (Technology allows for the creation of new ideas) (Puentedura, 2013).

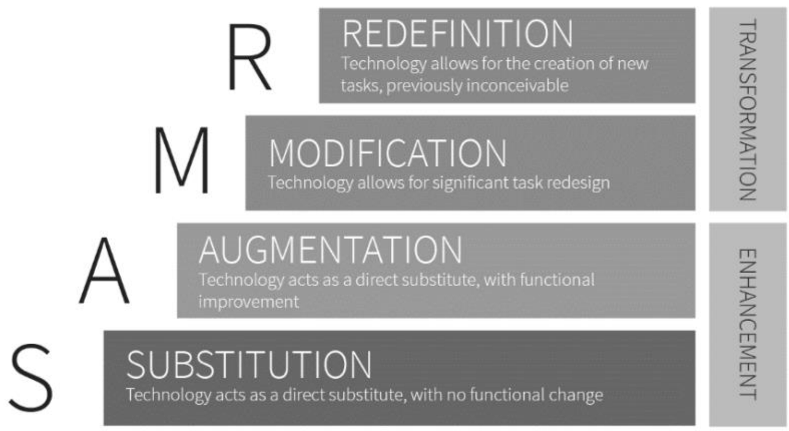

Figure 2. SAMR models levels as a tool for assessing and evaluating technology practices (Puentedura, 2013).

In order to facilitate the development of "TPACK and SAMR"- aware university teachers and assistants in science teaching, teacher training institutions must integrate relevant tools within the teacher training curriculum that considers a continuing change as a process (Thomas, Herring, Redmond, & Smaldino, 2013). Kihoza et al. (2016) introduced the concept "TPACK + SAMR constructs" in order to address various combinations of TPACK and SAMR constructs dealing with ICT implementations in the teaching process as planned by the teachers (Figure 3).

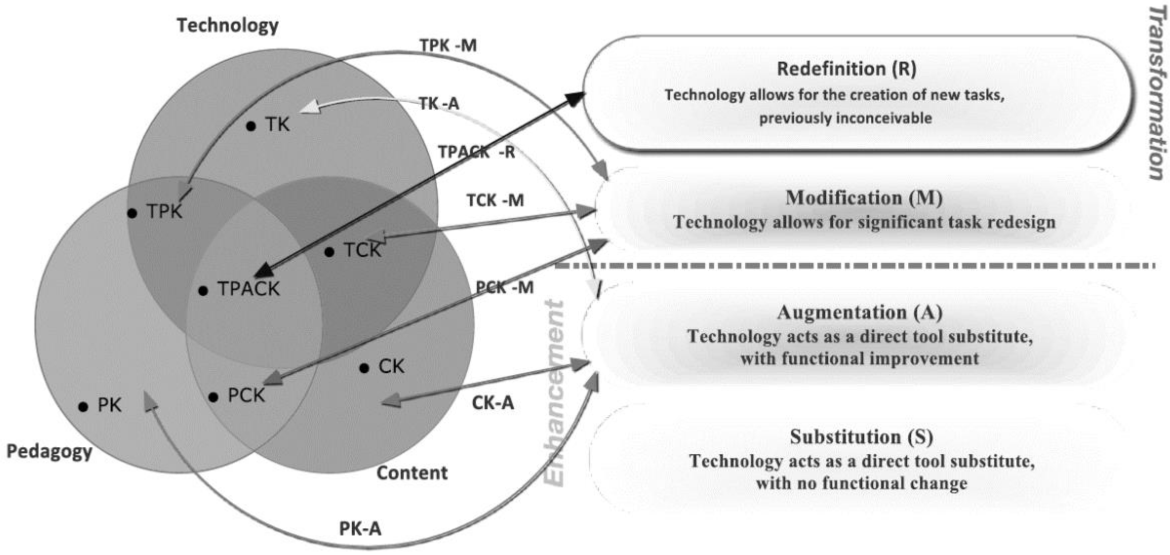

Figure 3. ***TPACK and SAMR models in correlation (*****Kihoza et al., 2016).**

The professional development of prospective teachers' related to the use of ICT during their study at the university is necessary for the successful implementation of the ICT-supported innovative approaches and effective teaching and learning in their prospective school practice.

To support the prospective teachers' development at University of Ljubljana, Slovenia, the project entitled "ICT in Teacher Training Study Programs at the University of Ljubljana" was launched from April 2017 to September 2018. The overall project included the renewal of 48 pedagogical study programs at the first and/or second Bologna levels at nine faculties of the University of Ljubljana. The involved pilot-renewals of the subjects/modules/programs based on the didactic implementations of ICT in the innovative teaching materials for students, the improvement of ICT-supported approaches to teaching and learning, and the development of pedagogical models.

AIM AND RESEARCH QUESTIONS

The main aim of this study was to investigate, which kinds of activities for prospective teachers the university teachers and assistants implemented in the pilot-renewals in science teaching area and on which level of "TPACK + SAMR constructs" were they.

With regard to this research aim, the following research questions (RQ) were defined:
(1st RQ) Which kinds of ICT supported activities for prospective science teachers were imbedded in the implemented pilot-renewals?

(2nd RQ) On which level of "TPACK + SAMR constructs" are the ICT supported activities for prospective science teachers imbedded in the implemented pilot-renewals?

RESEARCH METHOD AND DESIGN

Sample. The sample consisted of 25 university teachers and assistants in science teaching (12 female, 13 male) who participated in the developing pilot-renewals in the framework of the project entitled "ICT in Teacher Training Study Programs at the University of Ljubljana".

Pilot-renewals. 22 pilot-renewals in teacher training programs were implemented in the following subject-areas of the elementary and secondary prospective teachers´ education: Biology, Chemistry, Physics, and Science. All pilot-renewals took place in the study year 2017/18 at University of Ljubljana. The pilot-renewals included from 5 to 75 hours of upgraded activities, in each 10 to 87 prospective teachers (all together 673 prospective teachers) participated. Each of the pilot-renewals consisted of 1 to 7 new ICT-supported activities.

Data Collection. After the conclusion of the pilot-renewals, the university teachers and assistants filed out pilot-renewals reports. For the purpose of this paper, the following parts of the pilot-renewals reports are essential: descriptive data (course, study programme of prospective teachers, number of participating prospective teacher, range of upgraded activities) and content part of the report (purpose of the activities in pilot-renewal, description of the activities in pilot-renewal).

Data Analysis. In order to derive categorization of the implemented activities in the framework of pilot-renewals and “TPACK + SAMR constructs” of the implemented activities, pilot-renewals were analyzed based on Kihoza et al. (2016) categorization framework. The categorization was independently implemented by the two authors of the article with regard to the prevailing activity in particular parts of pilot-renewals. Each researcher independently grouped the characteristics into individual criteria. Finally, to reduce bias issues, through discussion, reconstruction and agreement, both researchers came to the final version of the rubric, which enabled a 95% inter-rater reliability about the categorisation of the analysed items.

FINDINGS

The analysis related to the ***1st research question*** (*Which kinds of ICT supported activities for prospective science teachers were imbedded in the implemented pilot-renewals?)* revealed that various kinds of ICT supported activities were included in implemented pilot-renewals by the university teachers and assistants in science teaching area, such as: Presentations; Laboratory experimental work; Formative assessment; Learning management systems and materials; Models, simulations and animations; Educational games; Data analysis; Project-based learning and Practical pedagogical training.

As can be seen from Table 1 most frequently used ICT supported activities for prospective teachers were related to: (1) Presentations (fa(%)=30.14, fa=22); (2) Laboratory experimental work (fa(%)=23.29, fa=17); (3) Formative assessment (fa(%)=17.81, fa=13) and (4) Learning management system and materials (fa(%)=13.70, fa=10).

Table 1. Description of prospective teacher's categories of activities related to the use of ICT.

Description of prospective teacher's activities related to the use of ICT	Activities	
	f_a	f_a [%]
PRESENTATIONS	22	30,14
LABORATORY EXPERIMENTAL WORK	17	23,29
FORMATIVE ASSESMENT	13	17,81
LEARNING MANAGEMENT SYSTEMS AND MATERIALS	10	13,70
MODELS, SIMULATIONS AND ANIMATIONS	6	8,22
EDUCATIONAL GAMES	2	2,74
DATA ANALYSIS	1	1,37
PROJECT-BASED LEARNING	1	1,37
PRACTICAL PEDAGOGICAL TRAINING	1	1,37

In activities related to ***Presentations***, the prospective teachers' observation of the use of presentational software (fa(%)=5.48, fa=4) and evaluation of various tools for preparation of concept maps (fa(%)=5.48, fa=4) prevailed as can be seen from Table 2.

Table 2. Description of students' activities in the category Presentations.

Description of students' activities	Activities		SAMR	TPACK + SAMR
	f_a	f_a [%]		
PRESENTATIONS	22	30,14		
Observation of the use of presentational software	4	5,48	A	TCK-A
Evaluation of tools for preparation of concept maps in specific topic	4	5,48	M	TCK-M
Use of presentational software	3	4,11	A	TCK-A
Development of meaningful implementation of specific software for representing partic. phenomena (e.g. animations)	2	2,74	R	TPACK-R
Development of meaningful impl. of QR-codes in specific topic	2	2,74	R	TPACK-R
Development of meaningful impl. of digital dichotomous identification keys	2	2,74	R	TPACK-R
Use of ICT in support of reporting about experimental work in specific topic	1	1,37	A	TCK-A
Evaluation of ICT in support of reporting about experimental work in specific topic	1	1,37	M	TCK-M
Observation of the use of videos for representing partic. phenomena	1	1,37	A	TCK-A
Evaluation of videos for representing partic. phenomena	1	1,37	M	TCK-M
Development of meaningful implementation of comic strips	1	1,37	R	TPACK-R

Most frequently implemented activities related to ***Laboratory experimental work*** was use of mobile application for capturing, presenting and analyzing experimental data (fa(%)=5.48, fa=4), further details are presented in Table 3.

Table 3. Description of students' activities in the category Laboratory experimental work.

Description of students' activities	Activities		SAMR	TPACK + SAMR
	f_a	f_a [%]		
LABORATORY EXPERIMENTAL WORK	17	23,29		
Use of mobile application for capturing, presenting and analysing experimental data	4	5,48	A	TCK-A
Use of sensors with software for capturing, presenting and analysing experimental data	3	4,11	A	TCK-A
Use of microscopy	2	2,74	A	TCK-A
Use of microscopy and presentation of results	2	2,74	A	TCK-A
Development of meaningful implementation of sensors with software for capturing, presenting and analysing experimental data	1	1,37	R	TPACK-R
Observation of the use of sensors with software for capturing, presenting and analysing experimental data	1	1,37	A	TCK-A
Evaluation of mobile applications for capturing, presenting and analysing experimental data	1	1,37	M	TCK-M
Evaluation of various sensors and mobile applications for capturing, presenting and analysing experimental data	1	1,37	M	TCK-M
Observation of the use of microscopy	1	1,37	A	TCK_A
Evaluation of sensors with software for capturing, presenting and analysing experimental data	1	1,37	M	TCK-M

As can be seen from Table 4, the the highest proportion of implemented activities related to ***Formative assessment*** achieved prospective teachers' observation of the use of response systems (fa(%)=13.70, fa=10). Within activities using Learning management system and materials, use of learning management system prevailed (fa(%)=8.22, fa=6).

Table 4. Description of students' activities in the category Formative assessment.

Description of students' activities	Activities		SAMR	TPACK + SAMR
	f_a	f_a [%]		
FORMATIVE ASSESMENT	13	17,81		
Observation of the use of response systems	10	13,7	A	TCK-A
Evaluation of response systems	1	1,37	M	TCK-M
Development of meaningful implementation of response systems	2	2,74	R	TPACK-R
LEARNING MANAGEMENT SYSTEM AND MATERIALS	10	13,7		
Use of learning management system	6	8,22	A	TCK-A
Observation of the use of collection of learning materials for representing particular phenomena	2	2,74	A	TCK-A
Observation of the use of ICT in support of active learning	1	1,37	A	TCK-A
Use of ICT in support of active learning	1	1,37	A	TCK-A
MODELS, SIMULATIONS AND ANIMATIONS	6	8,22		
Observation of the use of specific software for representing particular phenomena	5	6,85	A	TCK-A
Use of specific software for representing particular phenomena	1	1,37	A	TCK-A

From Table 4, it can also be seen that specific activities related to ***Models, simulations and animations***, were used, e.g. more specifically, prospective teachers' observation of the use of presentational software for represented particular phenomena (fa(%)=6.85, fa=5). Beside the mention activities, there are also several other activities that occurred in low frequencies.

The analysis related to the ***2nd research question*** (*On which level of "TPACK + SAMR constructs" are the ICT supported activities for prospective science teachers imbedded in the implemented pilot-renewals?*) revealed that different "TPACK + SAMR constructs" were included in implemented pilot-renewals by the university teachers and assistants in science teaching area, which is presented in Table 5.

Table 5. The proportion of different "TPACK + SAMR constructs" in science teaching pilot-renewals.

TPACK + SAMR constructs		Activities		Pilot-renewals	
TPACK	SAMR level	f_a	f_a [%]	f_{pr}	f_{pr} [%]
Technological knowledge (TK)	Substitution (S)	0	0	0	0
	Augmentation (A)	0	0	0	0
	Modification (M)	0	0	0	0
	Redefinition (R)	0	0	0	0
Technological content knowledge (TCK)	Substitution (S)	10	13,70	7	31,82
	Augmentation (A)	30	41,10	13	59,09
	Modification (M)	8	10,96	6	27,27
	Redefinition (R)	1	1,37	1	4,55
Technological pedagogical knowledge (TPK)	Substitution (S)	0	0	0	0
	Augmentation (A)	0	0	0	0
	Modification (M)	0	0	0	0
	Redefinition (R)	0	0	0	0
Technological Pedagogical content knowledge (TPACK)	Substitution (S)	0	0	0	0
	Augmentation (A)	0	0	0	0
	Modification (M)	12	16,44	9	40,91
	Redefinition (R)	12	16,44	8	36,36

Most frequently used ICT supported activities for prospective teachers were on TCK-A level (fa(%)=41.10, fa=30), which were included in more than half of pilot-renewals (fpr(%)=59.09, fpr=13). More advanced ICT supported activities for prospective teachers on TPACK – M level (fa(%)=16.44, fa=12) and TPACK – R level (fa(%)=16.44, fa=12) followed, and were implemented in more than one third of the pilot renewals (fpr(%)=40.91, fpr=9; fpr(%)=36.36, fpr=8), which is a good starting point to be encouraged.

About one third of the pilot renewals (fpr(%)=31.82, fpr=7; fpr(%)=27.27, fpr=6) implemented ICT supported activities for prospective teachers on TCK-S level (fa(%)=13.70, fa=10) and TCK-M level (fa(%)=10.96, fa=8), whereas it is interesting that was no activity in any pilot-renewal categorized as an activity on the TK–S/A/M/R levels, TPK–S/A/M/R levels and TPACK–S/A levels.

DISCUSSION OF FINDINGS AND IMPLICATIONS

ICT enhanced teaching and learning is crucial part of preservice science teachers' training in the informational age. The most frequently used models for guiding the planning, assessing, evaluating and use of technology in education are TPACK and SAMR models.

22 pilot-renewals in science teacher training programs at University of Ljubljana, Slovenia, where studied from two perspectives: (1) kinds of ICT supported activities, (2) levels of “TPACK + SAMR constructs” in ICT supported activities.

It was found that the most frequently used ICT supported activities were presentations, laboratory experimental work, formative assessment, learning management system and materials.

In Kihoza’s model targeting TPACK and SAMR correlation, only one construct has been proposed for each of the TPACK component (e.g. TK-A, CK-A, PK-A TPK-M, TCK-M, PCK-M, TPACK-R). Our research has indicated that several construct for some of the TPACK components are needed, namely more than half of analyzed pilot-renewals of the university teachers implemented ICT supported activities on TCK-Augmentation level, also about one third of the pilot renewals addressed TCK-S level and TCK-M levels. Similarly, TPACK-M and TPACK-R levels were present in more than one third of the pilot renewals.

We are glad to find out that TPACK-Modification and TPACK-redefinition levels were present in notable proportion of the pilot-renewals in the framework of the project entitled "ICT in Teacher Training Study Programs at the University of Ljubljana" were identified. The last can be used as examples of good practice for the further development in the teacher training study programs in science teaching and with other international projects point to development possibilities in the future.

TEACHER EDUCATION IN QUANTUM PHYSICS – A PROPOSAL FOR IMPROVING PEDAGOGICAL CONTENT KNOWLEDGE

Gesche Pospiech[1], Matthias Schöne[2]
[1]TU Dresden, Dresden, Germany
[2]Berthold Brecht Gymnasium, Dresden, Germany

Quantum physics is an important topic for physics courses at high school. In recent times big advances in the field of quantum information require corresponding modern approaches. Therefore preparation of teachers has to be adapted in developing systematically content (CK) and pedagogical content knowledge (PCK). Therefore, a seminar supplementing the quantum physics education of teacher students from an educational perspective has been developed along the model of educational reconstruction on university level. It was evaluated by a questionnaire with closed and open items and concept maps in a pre-post design with control group. The participating students showed a strong increase in CK and PCK where especially weak students profited strongly. The concept maps showed a clear shift in the desired direction and understanding of concepts. However, only a few students used the modern approach in their lesson plans.

Keywords: Quantum physics, teacher education, educational reconstruction

INTRODUCTION

In the 21st century physics education at high school is not complete without an insight into quantum physics. This includes nowadays also an introduction into the basics of quantum information as this area will influence future technologies and as corresponding reports find their way into the media. As future citizens all students should be able to value adequately media reports on advances in quantum technologies. In order to be able to do so a basic understanding of the principles of quantum physics and insight into quantum information is necessary. In addition differences between quantum physics and classical physics contribute to building a modern physics world view as part of general education.

Therefore, teaching topics of quantum physics in a way that promotes understanding of its basic concepts requires careful alignment of theoretical aspects and experiments as well as appropriate teaching methods. In the last years the two state-systems approach gained importance for teaching. There are hints that e. g. the concepts of a quantum state or uncertainty are better understood with this approach than with teaching along more traditional lines (Sadaghiani 2016, Zuccarini 2014). In order to reach a twofold goal – understanding the core concepts and insight into quantum information – teachers are needed who are able and willing to enter new ways of teaching on different levels. This requires a suitable preparation of future and in-service teachers which is not given in general. The prerequisites are that the teachers master the basics of quantum physics – including mathematical formalism – and that they feel prepared to transfer their knowledge into the classroom. Therefore they schould be able to explain quantum physics in an understandable way to school students including visual as well as formal means. This is the more important as the situation of teaching quantum physics is special in that there is a big gap between the complexity of the teaching level at university and the possibilities of teaching at school. Therefore the university teaching has to be adapted to the needs of future teachers, meaning that pedagogical content knowledge (PCK) in connection with content knowledge (CK) has to be developed systematically. Without explicit reflection on practice most teachers structure their lessons based on their own experience from school and their study at university. Hence, special attention has to be given to the goal that future teachers know different approaches and teaching-learning sequences such that they are able to develop appropriate teaching pathways according to modern view points. As they often rely on the obligatory school curriculum they should know how the different building blocks – the basic concepts, the traditional contents and modern contents – interplay and how they can combine different aspects.

EDUCATIONAL RECONSTRUCTION IN UNIVERSITY CONTEXT

In the following we will first shortly describe our use of the model of educational reconstruction in the context of university for this purpose.

Development of pedagogical content knowledge (PCK)

According to Shulman "PCK represents the blending of content and pedagogy into an understanding of how particular topics, problems, or issues are organized, represented, and adapted to the diverse interests and abilities of learners, and presented for instruction" (Shulman, 1987, S.8). Recently, Riese (2012) has shown that using a standard teaching procedure is correlated with a low level of expertise of teachers. Borowski et al (2011) hints that teachers develop school-relevant expertise mainly by actual responsible teaching in developing scripts for the topic at hand. Nevertheless, the earliest possible promotion of content knowledge (CK) and PCK is necessary, i. e. already during university studies. Reinhold (2004, p.134) cites as goals for the competence development "A curriculum for pedagogical content knowledge in the first phase of teacher training would then include basic, well-structured and connected knowledge at the levels of content knowledge/ reflection/ communication/ judgement and examplary knowledge at the levels of analysis and assessment/ planning/ testing/ evaluation". According to van Dijk and Kattmann (2007), PCK is individual and cannot be passed on directly from an expert to a novice, because teaching experience is essential for its development (Borowski et al 2011). However, own experiences as a teacher student at university are not enough, only the own teaching experience makes the difference. From this van Dijk and Kattmann (2007) conclude that PCK is acquired in an obligatory teacher training designed to enable novices and experienced teachers to learn from their experiences. One possibility of gaining such experiences is for example the theory-based independent development of a teaching-learning-sequence and its discussion. The teacher preparation at university should provide such learning environments.

Educational reconstruction for teacher education in quantum physics

To develop a learning environment at univeristy suitable for future teachers an extension of the model of educational reconstruction was developed, the so-called PCK-S (PCK in studies). It includes expertise in the design of learning environments, the associated analysis of student perceptions and the professional knowledge that teachers acquire during their individual teaching experience in the classroom. It is described as: „The educational ideas, [..] the field within educational research that focuses its research on the PCK that teachers possess, are different from teachers' PCK since they are extracted from their context: the knowledge, beliefs and experiences of the individual teacher."(van Dijk&Kattmann 2007, p.893). PCK-S represents a reconstruction and thus generalization of individual teaching practice and serves to develop new learning environments, which can be adapted for other teachers. van Dijk&Kattmann (2007, p.895) express: "PCK-S influence the design process if the teacher has acquired, during his or her teaching career, ways to present the subject knowledge in a for students understandable way. The results of this research process can then be used to improve teacher education.". This model has been adapted to quantum physics (see figure 1).

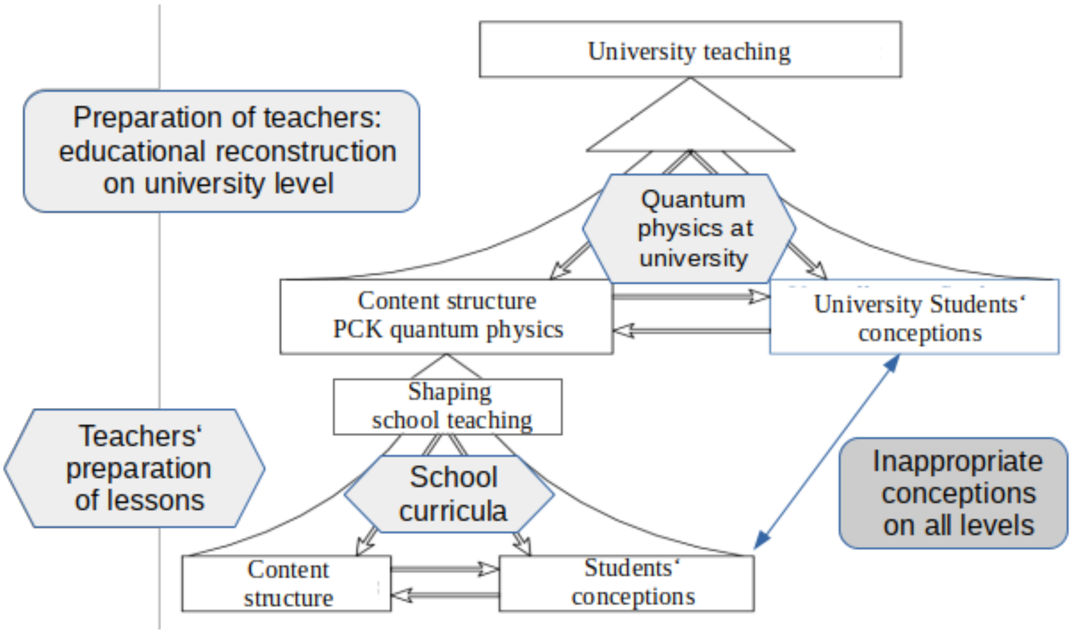

Figure 1. The model of educational reconstruction adapted for teacher education at university according to van Dijk and Kattmann, specified for teacher education in quantum physics

Quantum physics is a particularly demanding subject in teacher education with many problems on the way. First of all the abstract formalism of quantum physics together with the conceptual differences to classical physics requires a special preparation of the future teachers in order that they see possible elementarizations. Furthermore there is a nearly complete absence of real experiments suitable for school which may be a hindrance for many teachers who prefer teaching by visualizing with experiments. In addition there are strong teaching traditions (mainly the position first approach) with formal difficulties influencing teachers in their perception of the complexity of quantum physics. The new developments in quantum information and the two state systems approach are still often unknown to teacher students and have to be made explicit to them together with concrete teaching proposals. These should focus on central concepts: superposition, uncertainty, entanglement and the measuring process. An university course for teachers should therefore combine content knowledge, discussion of concepts to enhance PCK and the own development of teaching-learning sequences.

Analysis of content structure

The analysis of content as part of educational reconstruction serves to identify essential concepts with general educational value and high connectivity. Quantum physics is the only subject area at school still in flux. Today, there are many experimental implementations of earlier thought experiments and new areas of application are being opened up. In addition, the philosophical debate on the interpretation of quantum physics is still ongoing. Both aspects are reflected in the different approaches and proposals for teaching currently discussed. There are the milq-concept by Müller & Wiesner (2008), the Dirac-concept by Michelini et al. (2000) and the proposals by Pospiech (2000) with a focus on quantum information aspects. All these proposals focus in different ways on interference, state, uncertainty/ complementarity and information, on entanglemant and analysis of measuring process as core concepts. These abstract concepts and the complex formalism of quantum physics requiring a high mathematical effort make it difficult to elementarize. Nevertheless, a reduction of the learning material is possible by restricting it to essential phenomena, model experiments and guiding principles. The emphasis of the main principles of quantum physics such as superposition, interference and probability describes a pathway to an elementarisation. The characteristics of quantum information make it comparably easy to develop corresponding teaching sequences. This is reflected in the fact that recently quantum information approaches slowly find their way into the physics textbooks on different levels.

Analysis of students' conceptions

In order to enable the didactic structuring appropriate for school teaching the students' ideas have to be taken into account. There has been a large number of studies of student conceptions of quantum physics since the beginning of the 1970s, mainly on high school level, although significantly less than for classical physics. These concentrate mainly on atomic ideas, but also investigate the photo- and Compton effect, the Franck-Hertz experiment and double-slit experiments. There are also investigations on more abstract concepts like inexistence of permanent localization, uncertainty, for the interpretation of probability and the concept of state. A very comprehensive overview is given by Schorn (2014, p.26ff). We here refer mainly to the conceptions found e. g. according to Kalkanis et al. (2003) as well as Müller and Wiesner (1998). In summary, it can be seen that students' ideas about quantum physics are often based on the assimilation of new concepts into the construct of classical physics, e. g. the ontological nature of quantum physical uncertainty is not recognized. Often students' alternative conceptions correspond to the still prevailing traditional approaches to teaching quantum physics. It turns out that similar problems affect university students (Müller and Wiesner, 1998).

In order to overcome these traditional views and teaching methods a seminar for university for future teachers should be developed and evaluated that provides them with the necessary PCK and makes additions to their CK together with broad possibilities of reflection and discussion of view points.

RESEARCH METHOD AND DESIGN

It was the goal of the study presented here to elicit the needs of teacher students regarding their education and preparation for teaching on the field of quantum physics. Building on the revealed drawbacks and students' needs a seminar was developed and evaluated that focused on strengthening the PCK in quantum physics building on existing content knowledge and focusing on the two-states approach and giving insight into quantum information.

Research Questions

The following research questions were formulated:

Q1 What requirements do students have regarding quantum physics education of future teachers?

Q2 What is the students' content and pedagogical content knowledge at the end of the theoretical training in quantum theory?

Q3 Is a supplementary seminar constructed along the lines of the educational reconstruction effective in terms of content and educational competences? Is an expansion of the students' conceptual understanding observed?

Starting point of development of seminar

To answer research question Q1 teacher students were asked which quantum physics topics they think appropriate for teaching at school. The study was performed by an on-line questionnaire, after piloting sent to universities throughout Germany who offer study courses for future physics teachers. This questionnaire aimed at revealing the expectations of students as well as their experiences in learning quantum physics (Schöne, 2017). Therefore students from their third year at university on answered. Overall 110 students took part in this survey. The focus was if they felt prepared for teaching quantum physics at school and which topics they saw as adequate for school teaching. This was not a representative study but its results served as hints to the students' thinking and development of CK and PCK and their needs with respect to the development of a suitable seminar. The results showed that students mostly orient themselves towards the content they themselves learned at school. They proved to be more skeptical towards new contents or very mathematical aspects. Among the new contents quantum cryptography and quantum computer seemed to be especially attractive to the students (Schöne 2017). Therefore these topics in combination with the two state approach should play a role in the seminar to be developed.

Content and Structure of Seminar

It was supposed that all the participating students had attended the regular lecture on quantum theory before, thus having good content knowledge. Therefore the seminar relied on three intertwined threads: First of all it could not be supposed that students knew the two-state-systems approach. Therefore this was introduced in a way that could more or less be used as a pathway in school teaching. A second important thread were different variants of the double slit experiment with different objects (photons, electrons, molecules), which way information, quantum eraser, interaction free measurement and delayed choice. In this context the Mach-Zehnder-Interferometer was used as central experimental device and it was emphasized that the two arms of the interferometer are comparable to the double slit. A small Mach-Zehnder-Interferometer was available for model experiments. The third thread contained a formal description of the quantum physical processes. The Dirac notation was introduced and related to the physical interpretation of the mathematical structures of quantum physics. In order to give the students the means for treating these concepts in lessons also different representations and metaphors for superposition, uncertainty and entanglement were presented in order to promote understanding (Pospiech 2019). The concepts were anchored in concrete visual experiences by model experiments using calcite crystals. A strong emphasis was laid on discussion of the meaning of the basic concepts superposition, uncertainty, entanglement and the measuring process.

In order to deepen the insights aspects of quantum information were treated as this topic is being researched intensely and quantum technologies are being developed at an increasing pace and rapidly gaining significance. In addition quantum information can show the quantum principles at work as e. g. uncertainty is relevant for quantum cryptography, entanglement for quantum teleportation and the characteristics of the measuring process are used for proving the non-cloning theorem (also requiring the formal description).

All these threads were taken together by continous activities of students who had ample opportunity for discussion. As part of explicitly teaching PCK the students studied and compared different approaches to teaching quantum physics at school, the use of different types of visualization and they reflected on metaphors. In order to increase the practical aspects an important part of the seminar was that the teacher students developed in group work an own sequence of a teaching unit and the corresponding lesson plans.

Research method

Research questions Q2 and Q3 were answered in a pre-post design together with a comparison between intervention and control group. Whereas the intervention group attended the described seminar voluntarily, the control group attended an obligatory lecture combined with a seminar about history of physics with focus on teaching the nature of physics. Both courses comprised about the same amount of time.

The instruments were a combined questionnaire of content knowledge and pedagogical conent knowledge based on existing instruments (Müller 2003, Riese 2009). The content knowledge was evaluated with one open item and eleven closed items and the PCK was tested with 7 open items (including vignettes). The evaluation of the open items was controlled by interraters with a very good agreement (82%).

In addition the students of the intervention group made concept maps from given concepts and prepositions. The concept maps were evaluated with respect to their centrality and the frequency of the words were compared.

RESULTS

The intervention group (N=25) and control group (N=11) were students in the 4th to 5th year of study. As expected all students had attended lectures on quantum theory before.

Characterization of participants

The results of the pretest showed that there were no significant differences between the intervention and control groups (research question Q2). From all participants four groups of students could be identified (cluster analysis with the Ward method): There was an overall high performing group (16 %) and equally a low performing group (16%). These had either very good or very weak results in both parts of the questionnaire. Also a big group with focus on pedagogical content (52%) was identified and a small group with a strength on theoretical aspects and weaknesses in dealing with students' ideas (16%) (Schöne 2017). This is in line with other studies showing that teacher students have quite a clear vision of their future profession and prefer study contents related to what they will need in teaching at school (Gramzow et al 2011).

Evaluation of the seminar

The main goal was to evaluate in which way the students' CK and PCK developed during the seminar (research question Q3). Starting from the initial situation the teacher students profited highly concerning their content knowledge in quantum physics (CK) and their PCK. The overall picture showed that the development of content knowledge was increasing in the intervention group and decreasing in the control group. The PCK developed positively in the intervention group as expected but the control group showed constant results (see figure 2).

A closer look showed that the change of knowledge depends on initial knowledge in the sense that weaker students profited more in both areas of professional knowledge (see figure 3). A regression analysis showed that the changes of CK or PCK can be explained best alone from the initial CK or PCK respectively. A test for interaction with the preknowledge in the other domain did not show a better explanation of the results.

Concept maps and students' teaching proposals

In order to analyse in more depth the knowledge acquisition and conceptual change processes the students should also make concept maps before and after the seminar. Concept maps serve as a predominantly qualitative survey instrument, but also can be evaluated quantitatively according to various structural parameters (Krüger et al 2014, p.331). The most important concepts and prepositions were collected in a pilot study, generalised and then given as material (state, wave function, preparation, position, momentum, photo effect, Compton effect, Mach-Zehnder-Interferometer, photon, electron, quantum object, superposition, uncertainty, uncertainty relation, entanglement, non localization) in the main study. This reduces the difficulty for participants and results in a better comparability of the maps (Ruiz-Primo&Shavelson 1996). The structure of the map itself was not specified, so that the task was of a half-open type. The concept maps were drawn on paper by the students.

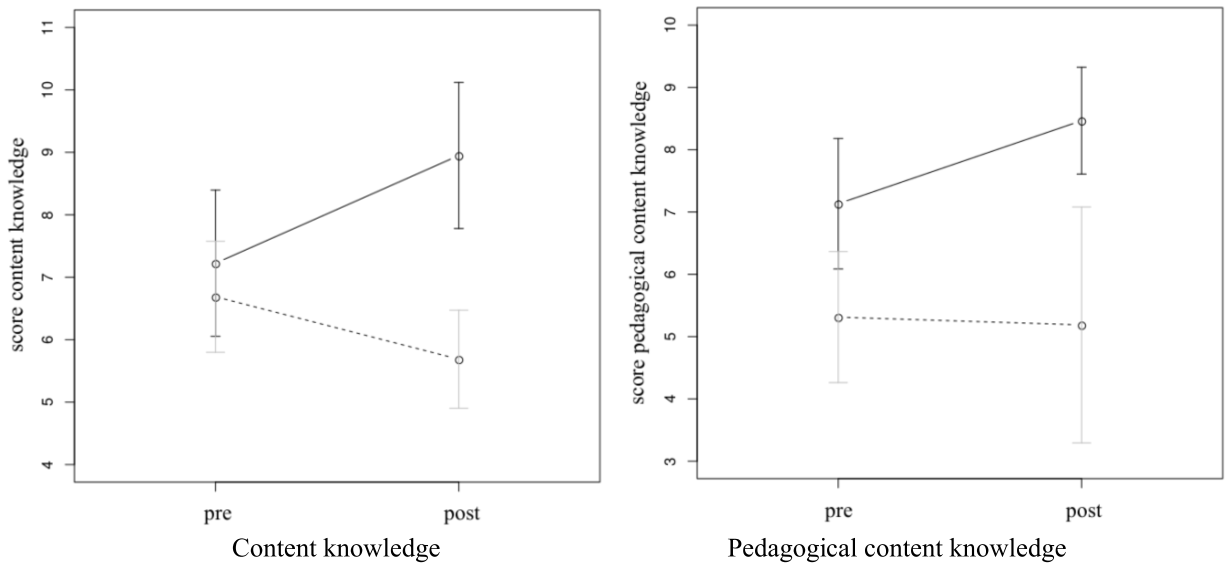

Figure 2. In the left part the development of the content knowledge from pretest to posttest of intervention and control groups is shown in an interaction plot; in the right plot similarly the development of the pedagogical content knowledge of both groups is shown. It is seen that the intervention group profits even in the content knowledge even if the main focus was on didactic aspects. In both graphs the solid line is the intervention group, the dotted line the control group (Schöne 2017).

An average map with weighted concepts and propositions was created from the individual maps. In the presentation we concentrate on the most central and frequent concepts. With several maps it can be observed that after the seminar quantum states are associated on shorter pathways with uncertainty and the newly appearing term "preparation". After the seminar the following observations are made: In some maps the terms uncertainty and uncertainty relation are distinguished. On average, in the intervention group new concepts, such as the experiment with the Mach-Zehnder interferometer were added. In some maps, the superposition and the wave function are included. Photons and electrons are used as examples of more generally perceived quantum objects. The concept of quantum object becomes much more central and thus more interconnected. Position and momentum as properties of quantum objects only appear in some maps. Similarly, the idea of particles in the Compton and photo electric effect disappears in some maps. But the concepts of uncertainty and entanglement increased in importance. Globally, the agreement of the propositions and concepts in the pre- and post concept maps of the control group is significantly greater than in the intervention group (centrality and frequency). As a form of forgetting, the density in the concept maps decreases clearly more in the control group than in the intervention group, although this effect is not significant due to the small sample size (not all students created two concept maps). These results show that the seminar is able to change the students' cognitive structure.

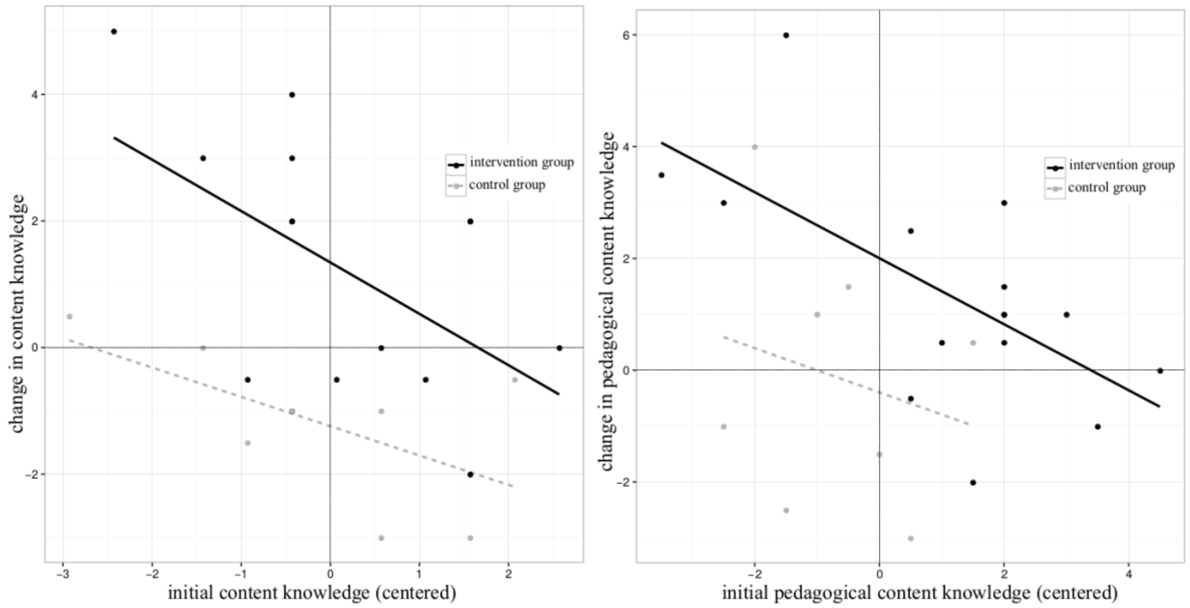

Figure 3. In the left graph the change of content knowledge in dependence on the pre knowledge for both groups is shown. It can be inferred that with lesser preknowledge the increase of CK is higher whereas with high preknowledge there is nearly no increase. A similar picture is seen in the PCK (right graph). This development is stronger visible with the intervention group. It is seen that in the intervention group especially the weaker students profited most from the seminar in both kinds of knowledge (Schöne 2017).

As a supplement, the frequency of concepts that stand out in the concept maps was analysed in the participants' lesson plans (intervention group). We only present the most obvious occurrences. The term "quantum object" appeared in almost all lesson plans. Also "preparation" is used by six participants, the wave function in five lesson plans and the differentiation of uncertainty and uncertainty relation is evident in seven teaching concepts. In these own lesson plans many students retreated to the "traditional" way of teaching. Only one teaching unit explicitly addressed quantum cryptography. This could be explained from several reasons: First the students felt at least partly obliged to follow the official curriculum of Saxony which up to now gives no explicit hint to quantum information. Secondly new material has to be internalized before it can be applied. Nevertheless, the students included partly newly learned material.

CONCLUSION

We might deduce from these findings that the approach of offering a seminar with focus on physics education aspects supplementing the lectures on quantum theory and stressing the connection of content and pedagogical content knowledge, enhances the students' content knowledge including quantum cryptography. Extended discussions of superposition, uncertainty and measuring process enables them to develop a deeper understanding of the concepts of quantum physics and to reduce misconceptions. However, the small number of participants requires careful interpretation of results. Nevertheless, such a seminar could contribute to the required special preparation: teacher students learn how to deal with the abstract formalism and to clarify the differences to classical physics.They are encouraged to overcome the strong teaching traditions in quantum physics and know possibilities of facilitating appropriate views by explicitly teaching the quantum perspective. Nevertheless, some of the developed lesson plans show that the future teachers may stay mixed between classical and quantum interpretation (Bailey&Finkelstein 2010). In this respect the seminar has to be optimized.

POST GRADUATE CERTIFICATE IN EDUCATION STUDENTS' TOPIC SPECIFIC PEDAGOGICAL KNOWLEDGE (TSPCK) ON PARTICULATE NATURE OF MATTER

Doras Sibanda[1] and Marissa Rollnick[2],

[1]School of Education, University of KwaZulu-Natal, Pietermaritzburg, South Africa

[2] Marang Centre, Wits School of Education, Wits University, Johannesburg, South Africa

The study investigates the development of Topic-Specific Pedagogical Content Knowledge (TSPCK) of 97 preservice teachers and how they transform their content knowledge (CK) of the particulate nature of matter into a teachable form, before and after engaging in teaching practice. TSPCK is PCK within a particular topic, is the result of integration of five well-defined interrelated constructs, namely the students' prior knowledge, curricular saliency, what makes a topic easy or difficult to understand, and representation and conceptual teaching strategies. These five components within a particular topic constitute TSPCK. Data was collected using validated instruments for TSPCK before and after teaching practice, as well as a determination of CK instrument after teaching. The findings show that pre-service teachers' TSPCK improved after teaching the topic on the particulate nature of matter during teaching practice. A significant improvement was observed on the following components of the TSPCK-identifying difficult topics and suggesting reasons why the topic was difficult to teach, curricular saliency and representation.

Keywords: particulate nature of matter, TSPCK, pre-service teachers

INTRODUCTION

Research shows that teachers' pedagogical content knowledge (PCK) and the ability to transform content knowledge for teaching, takes years of teaching experience to develop. Given the centrality of CK in PCK, it is self-evident that adequate science content knowledge (CK) is a prerequisite for PCK. The current study concerns a group of pre-service teachers training to teach natural sciences, a combination of four science disciplines, namely, physics, chemistry, earth sciences and life sciences. Most, if not all natural science teachers have insufficient CK in some or all of these disciplines (Davis, Petish, & Smithey, 2006). The pre-service teachers are in training to teach natural sciences but may not necessarily possess adequate prerequisite content knowledge. The requirements of the Post Graduate Certificate in Education (PGCE) programme assume that prospective teachers have acquired all necessary content knowledge to teach at lower grades in their undergraduate degrees. The students enrolled in the PGCE science programme need to have completed two first level courses in either physics, chemistry, life sciences or environmental sciences. As stated earlier, the natural sciences curriculum requires knowledge of several science disciplines, which is not necessarily the case for the pre-service teachers in this study. A particular challenge for the pre-service teachers in this study is their understanding of basic chemistry, in particular the particulate nature of matter, which is central to understanding topics that are more advanced. In this study, we investigate the ability of PGCE students to transform their CK of the particulate nature of matter to teaching practice.

Pedagogical Content Knowledge (PCK) formed the framework for the current study. According to Shulman (1986), PCK bridges the gap between the teachers' knowledge of the subject matter and the transformation of this knowledge into instructional form accessible to learners. It is thus an important component of teacher knowledge. According to Kind (2009), PCK has an elusive nature that is described as tacit and develops through practice. The tacit nature of PCK has led to debates on whether PCK is personal or canonical. Smith and Banilower (2015) claim that PCK exist both as personal and canonical and these feed into other forms in a cyclic manner. In this study, PCK is viewed as topic-specific. This study investigates the canonical PCK for the topic of the particulate nature of matter, known as Topic Specific PCK, or TSPCK, which is PCK within a particular topic (Mavhunga & Rollnick 2013). TSPCK constitutes of five well-defined components, namely students' prior knowledge, curricular saliency, perceptions about what makes a topic easy or difficult to understand, representations and conceptual teaching strategies, which work together when a topic is taught. The model in Figure 1 was chosen because it reflects all the Topic Specific PCK aspects.

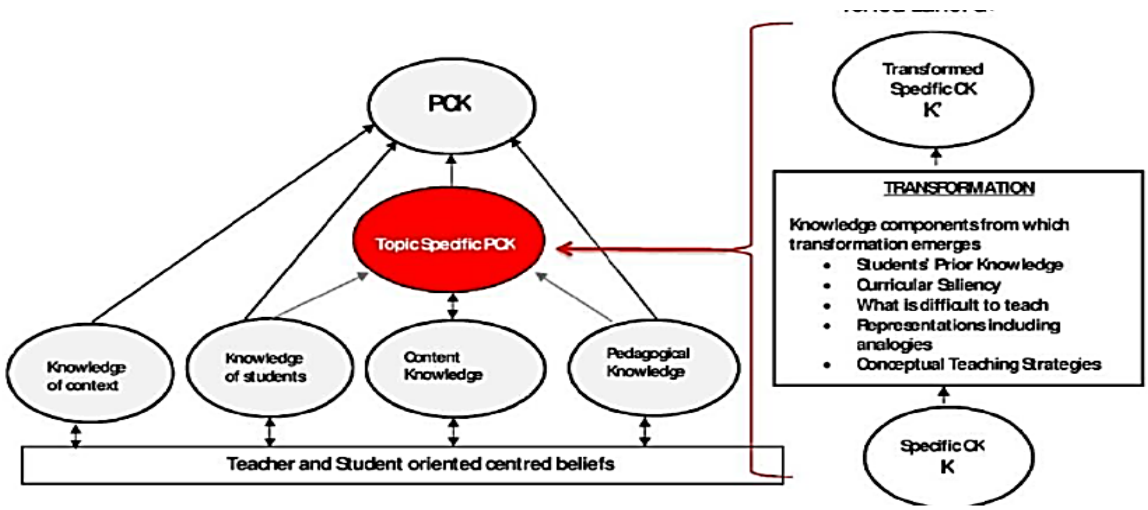

Figure 5: A model for Topic Specific PCK (Mavhunga & Rollnick 2013, p.115)

AIM OF THE STUDY

The aim of this study is to compare the change in TSPCK of PGCE students who taught the topic on the particulate nature of matter as part of their teaching experience with those who did not teach the topic. The paper answers the research question, how does the TSPCK of the particulate nature of matter differ between pre-service teachers who taught the topic to grade 8 and 9 students and those who did not?

METHOD

This paper reports on a mixed methods study located within a pragmatic paradigm (Creswell, 2014) with a group of PGCE students at a South African University. A mixed methods research, involves "mixing or combining quantitative and qualitative research techniques, methods, approaches, concepts or language into a single study" (Johnson & Onwuegbuzie, 2004, p. 17). In this study, priority of analysis was given to quantitative data (Benge, Onwuegbuzie, Burgess, & Mallette, 2010). The research strategy employed is a case study which targeted PGCE students. The PGCE is a one-year programme that consists of 16 weeks of direct teaching and additional 10 weeks in practice teaching.

The Sample

There were 97 PGCE students registered for the one-year PGCE programme at a South African university who completed both a TSPCK pretest and posttest on the topic of the particulate nature of matter. The study sample consisted of 38 male and 59 Female pre-service teachers.

Table 1. Shows the characteristics of participants

Characteristics	%
Grade 12 physics and chemistry	28
No University Chemistry	65
Taught particulate nature of matter in teaching practice	48

In Table 1, it evident that most of the participants did not study chemistry at the university, and only 28% of them had completed Grade 12 physics and chemistry.

DATA COLLECTION

Data was collected through validated instruments testing CK and TSPCK (Pitjeng-Mosabala & Rollnick, 2018). The CK instrument tested knowledge of content matter pertinent to the topic at grade 8 and 9 level while the TSPCK instrument was structured according to the five components of TSPCK, mentioned above. The TSPCK instrument used in this study was modified to suit the junior secondary level, relevant to the teaching of natural sciences. The instruments were administered to the pre-service teachers before and after teaching practice.
No specific instructions were given on the PCK course, but some students taught the topic during their teaching practice while others did not. The process by which they were assigned to teach the topic was determined by the schools where they were placed. Figure 2 below is an example of a TSPCK question, based on the Student Prior Knowledge component:

Water boiling in a kettle

2. When learners were asked to observe and describe what the bubbles are made of when the water in a kettle is boiling, Lwando gave the following written response:

There are large bubbles in the water and these bubbles were made of hydrogen and oxygen because water breaks when boiling to form hydrogen and oxygen.

What response would you write on her script?

Figure 3: Sample Question, Learner prior knowledge (LPK2)

DATA ANALYSIS

The responses to the TSPCK questionnaire were captured on an excel spreadsheet and coded using a validated TSPCK rubric as being limited, (1) basic, (2) developing (3) or exemplary (4). The coded data was analysed using Rasch analysis and the RUMM2030 programme (Andrich, Sheridan, & Luo, 2011).

A one-way analysis of variance available within the RUMM programme was used to establish if there was significant difference between the group of student teachers who taught aspects of the topic on the particulate nature of matter and those who did not. The responses were also analysed qualitatively in order to get an insight into the TSPCK development of PGCE student teachers on the particulate nature of matter.

RESULTS

The ratings determined by the rubric referred to above were checked using inter rater reliability. A posttest was administered to students when they returned from the school teaching experience to compare the performance of those who had taught the topic with those who had not. Racking of the pretest and posttest (labelling equivalent posttest items to their pretest items) was used in order to show the impact of the intervention (teaching experience). Item analysis for pretest and posttest results are shown in Figure 1.

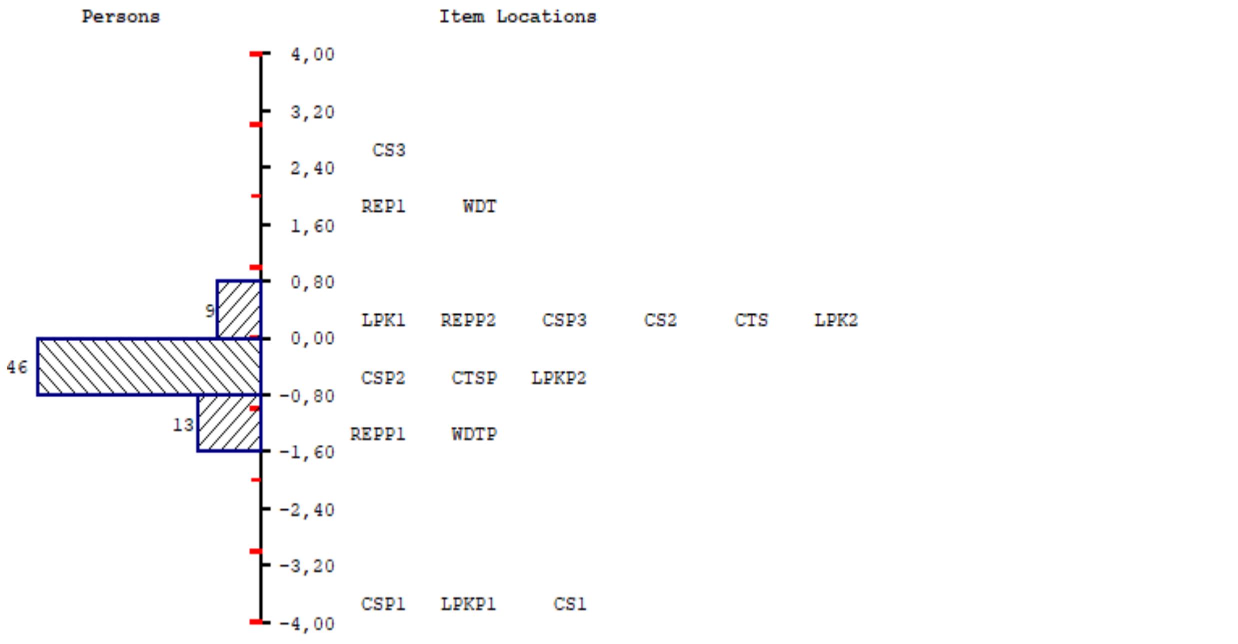

Figure 2: Item-person map of pretest and posttest TSPCK. TSPCK components are abbreviated as follows: CS1, CS2, CS3: curricular saliency, LPK1, LPK2: learners' prior knowledge, REP1, REP2: representations, WDT: What is difficult to teach and CTS: conceptual teaching strategies.

In Figure 1, the Rasch model provided an ordering of the TSPCK items from least to most difficult and this can provide an insight in how PGCE student teachers develop TSPCK in particulate nature of matter. The additional "P" on items identifies an item as a posttest item, for example, the posttest item corresponding to REP1 is REPP1. A comparison between pretest and posttest ranking of items show that CS3 was the most difficult item and three items, CSP1, LPKP1 and CS1 were equally ranked as the easiest items.

When looking at pretest items and their corresponding posttest items, it can be observed that several posttest items were ranked easier than their pretest counterparts (most notably CS3 to CSP3, REP1 to REPP1 and WDT to WTTP). In fact in no case was a posttest item ranked more difficult than a pretest item, demonstrating that the test as a whole was experienced by the PGCE students as easier than the pretest. This finding is confirmed in table 2.

Table 2. One-way Analysis of Variance comparison of those who taught Particulate Nature of Matter to those who did not

Source	Sum of square	df	Mean Square	F	Probability
Between Groups	34,1	1	34,1	90,60889	0,00001
Withon Groups	35,76	95	0,38		
Total	69,86	96			

The one-way ANOVA results show that there was a significant effect between TSPCK and teaching particulate nature of matter during teaching practice ($p < 0.05$) on the development of PCK of pre-service teachers.

There was no significantly link ($p > 0.05$) on completing physics and chemistry in matric, university chemistry course and the development of pre-service teachers PCK.

Qualitative analysis- Learner prior knowledge (LPK2)

Given below are extracts from written responses for both pretest and posttest of five participants.

Table 3.Selected Pre-service teachers' responses on learner prior knowledge question for pretest and post test

Student teacher	Coding Pretest	Responses LPK2 Pretest	Coding Post test	Responses LPK2 Posttest
1.	Limited[1]	It is the bond that joins hydrogen and oxygen that breaks not water. And the evaporation takes place as liquid water changes into gaseous state.	Basic [2]	As water is heated, it changes its form from liquid state to gaseous state. The molecules become loosely packed and bubbles are formed
2	Limited [1]	When the kettle is boiling the substance which is liquid will become gas	Basic[2]	Because the substance is heated the particles gain more kinetic energy, the bonds between particles has become more and more weaker and force of attraction between particles is not present, particle are moving freely from each other
4	Limited[1]	During boiling water is transformed to gas water. Hydrogen and oxygen break and escape as gas H_2.	Developing[3]	When the water molecule gain energy or when the heat is increased, the water molecule gain kinetic energy to overcome the intermolecular forces between them and the molecules move apart changing from liquid phase to gaseous phase
5	Limited[1]	As the water boils, it changes state from liquid to gas rather than a chemical change.	Limited[1]	I would mark her response as correct. However, I would encourage the learner to use scientific terms e.g. When water (H_2O) boils the hydrogen and oxygen covalent bond weakens as the molecules gets kinetic energy. When bonds have weakened, hydrogen and oxygen (no longer covalent bonded) escape to form the observed bubbles.
10	Limited[1]	When water boils, there is a change of state from a liquid to a gas bonds between H_2O breaks to release O_2 and H_2.	Developing[3]	The bubbles there are formed by the change of phase from liquid to gas through heating. There is kinetic energy among the particles and there is boiling which leads to evaporation which means the arrangement of particles move from liquid to gas. The bonds between particles have weakened.

These extracts display evidence of some level of PCK development in the responses of pre-service teachers' on learners' prior knowledge. Only participant 5 provides a response that is in line with the question provided in the instrument, "What response would you write on his script?" The explanation provided by Participant 5 does not illustrate an understanding of any aspects of TSPCK. Participant 10 does demonstrate an understanding of the representation of particles and the role played by kinetic energy.

DISCUSSION AND CONCLUSIONS

The TSPCK knowledge of PGCE natural science students show a level of improvement on TSPCK item on learner prior knowledge (LPK2, Curriculum salience (CS3), Representation (RP2) and conceptual teaching strategies (CST1). The findings also show that there was significant difference ($p < 0.05$) between TSPCK and teaching the particulate nature of matter during teaching practice. These findings which are similar to those of Pitjeng-Mosabala and Rollnick (2018) for a smaller sample of PGCE Teach SA candidates suggests that the experience of teaching a topic at grade 8 has a positive effect on TSPCK. However, the teachers in the above study did undergo a short intervention on a PCK course. The PGCE natural science teachers in the current study experience an intervention in the form of teaching the particulate nature of matter to grade 8 and 9 pupils in schools. There is thus reason to expect better scores in the teachers who have taught the topic (Kind, 2009).

This paper has demonstrated that teaching the topic particulate nature of matter at schools resulted in the improvement of pre-service teachers' TSPCK. The findings show that there was a significant link in the quality of TSPCK development in those who taught the particulate nature of matter in schools ($p = < 0.05$). The implication is that PGCE natural science programmes need to provide pre-service teachers with a platform to practice teaching different topics taught in grades 8 and 9.

DEVELOPMENT OF PRE-SERVICE CHEMISTRY TEACHERS' TECHNOLOGICAL PEDAGOGICAL CONTENT KNOWLEDGE

Ayla Cetin-Dindar[1] *and Yezdan Boz*[2]
[1]Bartin University, Bartin, Turkey
[2]Middle East Technical University, Ankara, Turkey

This study reports the empirical findings of a study that by collecting evidence on the pre-service chemistry teachers' Technological Pedagogical Content Knowledge (TPACK); and correspondingly the effectiveness of a course on the pre-service chemistry teachers' technological pedagogical content knowledge in terms of gender. The course consisted of 14 two class-hour weekly lectures and 13 two class-hour weekly laboratories with 17 pre-service chemistry teachers. The instructor taught explicitly using rich examples from the secondary school chemistry curriculum. During laboratories sections, the pre-service chemistry teachers discussed the pros and cons of the educational technologies in designing lessons in terms of chemistry, teaching strategies, prerequisite knowledge, and alternative conceptions. The instrument was used (in two periods: at the beginning and at the end of the semester) in the study to assess the pre-service teachers' TPACK domains and to measure their development of TPACK over the course of a semester. A mixed between-within subjects analysis of variance analysis was used and it was found that there was a significant main effect for TPACK. The findings of this study revealed that all components improved, indicating the pre-service chemistry teachers' technology content knowledge developed during the semester. Based on these findings, the development of pre-service and in-service chemistry teachers' TPACK is essential for teaching and learning chemistry and teachers should realize the potential of technology in the real-world classroom environment.

Keywords: Technological pedagogical content knowledge (TPACK); Pre-service teachers, Chemistry education
